Cisco Compliance Solution for HIPAA Security
Rule Design and Implementation Guide
A Cisco Validated Design
Solution Authors

Christian Janoff, Compliance Solutions Architect, STBU, Cisco Systems
Christian Janoff is a Solution Architect at Cisco Systems with over 15 years of solution architecture and design experience. Christian leads Cisco's participation on the Payment Card Industry Security Standards Council. He was elected to the PCI Council's Board of Advisors in May, 2009. Prior to Cisco, Christian worked as a network engineering manager at Safeway, Inc. Christian holds a bachelor's degree from University of California at Santa Cruz.

Bart McGlothin, Compliance Solutions Architect, STBU, Cisco Systems
Bart McGlothin is a Solution Architect in the Compliance Solutions group at Cisco Systems, Inc. Bart leads the technical aspect of Cisco's Security framework for Compliance and more specifically; Payment Card Industry (PCI) initiatives including Cisco's Validated Designs for PCI compliance. He has over sixteen years of solution architecture and design experience. Bart leads Cisco's involvement with the National Retail Federation's Association for Retail Technology Standards Committee (ARTS) as a member of the ARTS board and Executive Committee. Prior to Cisco, Bart worked as the Network Architect at Safeway, Inc.

Solution Overview

Introduction

Cisco customers have stated that the Health Insurance Portability and Accounting Act (HIPAA) is vague, and they are not sure how it directly applies to their enterprise networks. Many do not understand how HIPAA relates to technology and infrastructure. They have asked Cisco to provide guidance that shows this relationship. This Cisco Compliance Solution for HIPAA Security Rule provides a reference architecture designed to help covered entities and business associates simplify compliance with the HIPAA Security Rule. The guidance in this document maps architectures and products to the HIPAA Security Rule technical safeguards, standards, and implementation specifications.

Chapter 2, “HIPAA and the Solution Framework,” describes the elements that make up the solution framework. The solution framework organizes the scope of the Protected Health Information (PHI) data environment for contextual reference. Chapter 3, “Solution Architecture,” discusses what IT should consider when designing their network to best align with HIPAA Security Rule implementation specifications. For specific designs referencing these architectures, read Chapter 4, “Solution Implementation.” In Chapter 5, “Component Assessment,” each component is individually assessed for its capabilities, and configuration examples are given to demonstrate this utility. The complete assessment report authored by Verizon is located in Appendix C, “Reference Architecture Assessment Report—Cisco Healthcare Solution.”

The Cisco Compliance Solution for HIPAA Security Rule was built and tested using a holistic enterprise perspective including the following:

- Endpoint consideration—PHI systems and devices, including wireless devices
- Administrative concerns within scope of HIPAA
- Cisco, RSA, EMC, and Hytrust network infrastructure and architectures comprising data center, Internet edge, and healthcare facilities that simplify the process of meeting the HIPAA Security Rule implementation specifications.

Figure 1-1 shows an example of the enterprise architecture.
Solution Methodology

Cisco customers have asked for clarification on how HIPAA relates to Cisco architectures and individual components within the architecture. To address this challenge, Cisco contracted Verizon Business to “reassess” an existing compliance solution that protects credit card data; Cisco Compliance Solution for PCI DSS 2.0. The strategy is to use a common control structure that addresses multiple compliance standards using a “unified compliance” mindset. The intent is that regardless of the type of sensitive electronic data (payment or healthcare), a single security strategy should meet the needs of an organization to protect it from a compliance perspective.

Target Market/Audience

The audience for this solution includes compliance managers, as well as technical teams seeking guidance on how to design, configure, and maintain their IT architecture and components for HIPAA Security Rule compliance. Although the diagrams and references relate to healthcare institutions, the reference architecture also applies for other covered entities and business associate networks in relation to the HIPAA Security Rule.
Solution Benefits

The solution demonstrates how to design end-to-end enterprise systems that conform to the HIPAA Security Rule safeguards and provides the following benefits:

- Insight into the Cisco enterprise architecture and the controls used to address HIPAA Security Rule technical safeguards
- A detailed analysis and mapping of Cisco and partner components and their relationship with HIPAA Security Rule controls
- A scalable set of reference designs that can be used to establish the security controls necessary to achieve compliance with the HIPAA Security Rule
- A centralized management “tool kit” simplifying the operational challenges of an enterprise network
- The central focus of this design guide is the implementation of an architecture that meets the HIPAA safeguards; in addition, using the recommended segmentation strategies and additional quality of service (QoS) parameters can increase performance.

HIPAA Solution Summary Results

Table 1-1 lists the HIPAA citations that were addressed within the solution.

CHAPTER 2

HIPAA and the Solution Framework

The Health Insurance Portability and Accounting Act (HIPAA) was signed into law in 1996 (Public Law 104-191). The HIPAA Omnibus Final Rule was released January 2013, and included updates from the Health Information Technology for Economic and Clinical Health (HITECH) Act, breach notification, penalty tiers, and extended HIPAA compliance obligations to include both covered entities and business associates. Covered entities and business associates that create, receive, transmit, or maintain protected health information (PHI) in electronic form must make a good faith effort to protect the corporate computing environment from reasonably anticipated threats and vulnerabilities; and take reasonable and appropriate measures to protect the integrity, confidentiality, and security of such electronic data.

The HIPAA Omnibus Final Rule consists of three main parts (sections) that put in place security and privacy requirements for the protection of PHI:

- Part 160—General Administrative Requirements. Deals mostly with the legal, compliance, and penalty aspects of HIPAA
- Part 162—Administrative Requirements. Deals with unique identifiers for covered entities in healthcare, provisions for transactions, and many other administrative issues in healthcare
- Part 164—Security and Privacy. Deals with the safeguards for protecting PHI in electronic and paper media. Part 164 consists of the following:
  - Subpart A—General Provisions §164.1xx
  - Subpart B—Reserved
  - Subpart C—Security Standards for the Protection of Electronic Protected Health Information §164.3xx
  - Subpart D—Notification in Case of Breach of Unsecured Protected Health Information §164.4xx
  - Subpart E—Privacy of Individually Identifiable Health Information §164.5xx

The Cisco solution described in this document relates primarily to Part 164 Security and Privacy Subpart C.

The HIPAA Security Rule requires covered entities and business associates to perform an analysis of the potential risks to the electronic PHI for which they are responsible; and to then develop, implement, and maintain appropriate security measures to safeguard the integrity, confidentiality, and availability of that data. The HIPAA Security Rule incorporates recognized security objectives and protections, but is intentionally technology-neutral. It provides standards and, in some cases, implementation specifications with which covered entities and business associates must comply. The scope and nature
of HIPAA compliance activities for each covered entity or business associate vary according to the
specific environment and associated vulnerabilities as determined through risk assessment. Although
the standard is objective, a covered entity or business associate’s specific security controls may vary,
because the HIPAA Omnibus Final Rule permits flexibility in the approach to compliance.

Cisco and Verizon have provided clarity to the HIPAA Security Rule by providing a reference use case
common to an enterprise. This use case identifies specific risks as well as the appropriate technology and
configurations that can be used to satisfy the respective controls for these risks. Combining Cisco’s
technology portfolio, reference architectures, and Verizon’s HIPAA assessment expertise, Cisco
customers can benefit from using this document as an illustrative example of how to apply the same
technology, configurations, and architectures within their own organizations to satisfy the security
safeguards of HIPAA.

## Safeguard Applicability and Exclusions

HIPAA Part 164 Subpart C is made up of nine sections. Three of the sections are administrative and are
not part of this assessment. The remaining six sections (Security Standards: General Rules;
Administrative Safeguards; Physical Safeguards; Technical Safeguards; Organizational Requirements;
and Policies and Procedures and Documentation Requirements) consist of 52 security safeguards.

Verizon performed an initial assessment to determine whether the safeguards could be met by using
specific technology components provided by Cisco.

Of the 52 safeguards in the current healthcare requirements, Verizon identified 29 safeguards as not
applicable in the context of this assessment, because the safeguard was either explicit and demanding
direct (non-technology related) controls; or general, but not allowing for the reasonable use of
technology as a compensating control in the fulfillment of the safeguard. Table 2-1 lists the remaining
23 applicable safeguards.

Industry Standards

Although HIPAA is flexible and technology-neutral, industry standards are often used to meet the requirements. Among the standards often used are the NIST Special Publications, ISO 27002 and the HiTrust Common Security Framework (CSF). These standards provide more detail for the design and implementation of the infrastructure to meet the requirements.

The HiTrust alliance was formed by organizations in the healthcare industry to create a detailed framework to meet the vague HIPAA safeguards. Cisco’s Solution Framework is closely aligned with the HiTrust CSF and can be used to address many of the detailed security controls in the CSF.

This document addresses HIPAA safeguards directly.

Control Mapping to the Cisco Reference Architecture

Verizon found that Cisco’s solution architecture can directly address HIPAA safeguard requirements for technical controls to protect healthcare data. Any device that transmits or stores PHI data needs to be secured. An enterprise network can be conceptualized into several layers, creating a framework that ensures that these devices are properly handled.

HIPAA Solution Framework

Figure 2-1 shows how covered entities and business associates can be organized into a solution framework. By using this framework, healthcare security requirements and their associated control options can be simplified into three overarching layers that allow a simple way of discussing the complexity of the topic. The rest of this manual presents healthcare solution components within this context.
The HIPAA solution framework is used throughout this guide as a model for simplification.

Endpoints/Applications

The top layer of the solution framework takes into account applications or endpoints (workstations, clinical systems, medical devices, mobile carts, and doctors’ laptops/tablets/phones) that are involved in the presentation of ePHI for use by/with clinicians, patients, and other members of the workforce. This layer includes the individual applications that may store and process ePHI, including:

- Clinical management and electronic records management systems
- Billing and payment systems
- Image management subsystems
- Voice transcription subsystems
- Video conferencing subsystems

This layer also includes the individual applications that may otherwise provide technical controls that fulfill some element of the HIPAA Security Rule safeguards, including:

- Physical security subsystems
- Emergency voice and data systems
- Data backup subsystems
- Facilities management subsystems

Administration

The middle layer of the framework shows the services used to support administration of the other layers. Example controls include:
• Identity management, authorization, authentication, and access management controls
• Logging and log management controls
• Auditing capabilities
• Monitoring and event management controls
• Data encryption/decryption controls and key management controls
• Physical access, intrusion detection, and surveillance controls

HIPAA is highly focused on Administrative safeguards. 29 of the 52 HIPAA safeguards (9 standards and 20 implementation specifications) are Administrative. To create an environment that is aligned with HIPAA safeguards requires the capability to meet these safeguards. Cisco addresses 13 of the administrative controls.

Infrastructure

The bottom layer of the framework addresses infrastructure components such as routers, switches, firewalls, and security components that support the common and advanced security controls managed at the layers above. The HIPAA Solution framework leverages the inherent strengths of the Cisco network and systems building blocks to allow the customer to build and configure robust architectures that support and align with the HIPAA Security Rule safeguards. The Cisco solution is a set of architectures, strategic principles, and tactical designs meant to provide the reader with a clarifying understanding of how the safeguards (and associated security control implementation requirements) are identified in the HIPAA Security Rule, and how real-world implementations of today’s best-practice architecture can be efficiently deployed.

Services

The right-hand element that spans Endpoint, Administration, and Infrastructure layers includes services to plan, build, and manage the network to address the HIPAA Security Rule. These can be provided by Cisco, Cisco partners, and Verizon Business. Sample services can include the following:

• Strategy and analysis
• Assessments
• Design
• Validation
• Deployment
• Migration
• Product and solution support
• Optimization and operation services
Solution Architecture

Cisco’s Compliance Solution for HIPAA Security Rule is a set of architectures, strategic principles, and tactical designs that provide a clarifying understanding of how the network can be used to address HIPAA requirements. Cisco’s solution architecture is used as a baseline for demonstrating the range of places that typically exist within an enterprise healthcare provider. This chapter describes the solution architecture in detail so that the HIPAA Security Rule controls can be placed in context. The solution looks at an enterprise from an end-to-end perspective; from a clinic or hospital, where doctors use protected health information (PHI), to the back-end of the data center, where the PHI leaves the providers network to be handled by a business associate.

The Infrastructure layer of the framework shows enterprise locations such as the clinic, hospital, data center, and the Internet edge. The following sections in this chapter show the architectural design considerations of each of these locations. (See Figure 3-1.)

Figure 3-1  Solution Framework
Enterprise Architecture and HIPAA Design Considerations

Healthcare Security control requirements that are derived from the HIPAA Security Rule safeguards apply universally to all sizes of healthcare organization, payer or provider (for example, covered entity), healthcare information clearing houses, Healthcare plans, and Business Associates. The implementation of a secure architecture scales from a single remote clinic to the largest healthcare corporation, with headquarters, regional administrative offices, multiple data centers, points of presence on the Internet, dozens of hospitals, and hundreds of clinics. Cisco’s Compliance Solution for HIPAA Security Rule scales both vertically and horizontally to provide the building blocks to construct a compliant enterprise architecture.

Cisco’s solution does not guarantee compliance with HIPAA, the ownership of compliance always resides with the covered entity or business associate.

Figure 3-2 shows the enterprise-wide reference architecture and locations that commonly exist in enterprise domain.

Figure 3-2  Enterprise-wide Reference Architecture
Without this contextual reference, it is difficult to discuss specific controls. The following solution principles applied to this architecture reduce risk of losing control of PHI.

- **Segmentation**
  Within covered entities, the need to segment, separate, and isolate administrative and clinical functions and data is paramount to limiting the scope and depth of security controls that are applied to various forms of data. Generally, institutions that can effectively isolate PHI from other data are most effective at maintaining control over this information. By segmenting clinical information from administrative information, you are able to apply the appropriate controls to effectively protect the information based on its criticality. Enterprise addressing plans should take this into account by separating PHI onto its own address space. Whether in the data center, hospital, or clinic, segregating data leverages the power of the network to help support HIPAA Security Rule safeguards, and best manage risks to PHI and critical medical systems.

  There is an additional benefit beyond security that is a result of effective segmentation. Improved performance can be achieved by designing the architecture to restrict traffic within segments. With the large capacity files for imaging and streaming, this can have a large impact on the response time for healthcare professionals.

- **Identity and Access Management**
  Identity management, authentication, authorization, and access controls of users/systems to PHI is the central theme in the HIPAA Security Rule safeguards. A strong and manageable identity and access control solution is critical for warranting an assessment of low risk under a customer’s risk management program. Effective identity and access management is critical to an organization’s ability to meet the Accounting rule.

- **Logging, Auditing, and Monitoring**
  The need to log, audit, and monitor the access to PHI by users and systems is a critical requirement in the HIPAA Security rule. Centralized application/database/device access logging as well as support for auditing is critical to effectively supporting a covered entity or business associate’s breach management strategy. Real-time intrusion detection and protective response within very large and complex networks is critical to identifying compliance issues before they turn into breaches. Logging, auditing, and monitoring are critical to an organization’s ability to meet Accounting Rule 164.528, and can help identify whether a compromise has occurred that may lead to a breach notification.

- **Encryption**
  The ability to encrypt and decrypt PHI represents the most effective and organic control available to resist unwanted PHI data exposures. This applies to HIPAA Safeguard 164.312(a)(1)(2)(iv) Encryption and Decryption.

The following sections describe the major places affected by HIPAA compliance throughout the enterprise. Each section provides design considerations that are affected by HIPAA controls in more detail.
Hospital and Clinic Architectures

Hospitals and clinics provide in-patient and out-patient medical treatment and emergency medical treatment. Each involves creating, receiving transmitting, and maintaining PHI in the forms of electronic medical records, as well as patient treatment information in multiple formats (video, audio, converted photographic and x-ray images, and electronic imaging, and so on).

Design Considerations

The process of segmenting the wired or wireless networks into scopes (that is, devices containing PHI from other devices) is fundamental to demonstrating control and knowledge of the location and use of PHI, as required under HIPAA’s Risk Management requirement. The scope of the risk management program and cost of additive control for HIPAA is limited by controlling scope.

Clinics that do not collaborate or share patient data should be isolated from other clinics that do limit the unintentional flow of PHI between them. Consider the isolation of operating units from one another, and from non-required systems in the data center, and the grouping of like functions across segments (for example, LAN/WAN, Internet).

In addition to segmenting, separating, and isolating PHI from other data, VLAN capabilities establish device common “virtual rails” for medical devices, workstations, servers, mobile devices, physical security devices using IP transport, and so on, to simplify control policies between device types and devices.

Figure 3-3 shows the fundamental infrastructure components used within a healthcare location. These components are used in conjunction with each other to segment PHI data from other data.

Figure 3-3  Fundamental Infrastructure Components

Hospital or clinic component designs may scale or consolidate because of the relative size and complexity of the facility, but security functionality is maintained, and each device in the infrastructure is used for a different function.
• The router function can be used for the following:
  – Accessing the WAN
  – Routing between VLANs
  – Providing basic isolation via access control lists (ACLs)

Routing and access control lists provide segmentation between authorized and unauthorized access on the network. This applies to the HIPAA requirement for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i); and protecting ePHI from parts of an organization that are not authorized such as Isolating Healthcare Clearinghouse Functions 164.308(a)(4)(i). Segmentation also provides for protection against malicious software 164.308(a)(5)(ii)(B) and can modify the accessibility as described in Access Establishment and Modification 164.308(a)(4)(ii)(C).

• The firewall can be used for the following:
  – Filtering inappropriate network packets (data, service requests, service acknowledgements, and so on) via a stateful firewall and supporting security policy controls at the boundary edge; for example, limiting inappropriate clinic-to-clinic cross traffic.
  – Routing between VLANs

The firewall filtering and routing provide segmentation between authorized and unauthorized access on the network. This applies to the HIPAA requirement for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i); and protecting ePHI from parts of an organization that are not authorized such as Isolating Healthcare Clearinghouse Functions 164.308(a)(4)(i). Segmentation also provides for protection against malicious software 164.308(a)(5)(ii)(B).
  – Detecting and preventing intrusions; (IPS/IDS devices can also be separate appliances) based on the same security policy; for example, detecting and preventing access attempts from non-clinic personnel.

The IPS/IDS identifies and notifies appropriate individuals that suspicious activity is occurring. This applies to the HIPAA requirement for identifying and responding to suspected or known security incidents (164.308(a)(6)(ii)).

• Intrusion Prevention Systems (IPS)/Intrusion Detection Systems (IDS) monitor for anomalous behavior on the network and alerts administrators (for example, of issues or attacks that are across multiple servers in a hospital or multiple clinics).
  – The IPS/IDS identifies and notifies appropriate individuals that suspicious activity is occurring. This applies to the HIPAA requirement for identifying and responding to suspected or known security incidents (164.308(a)(6)(ii)).

• The switch can be used for the following:
  – Segmenting via VLANs

This applies to the HIPAA Safeguard for guarding against malicious software as described in 164.308(a)(5)(ii)(B).
  – Accessing wired devices

• The access point can be used for the following:
  – Filtering between authorized and unauthorized access on the network. This applies to the HIPAA requirement for preventing, detecting and containing security violations as listed in the Security Management Process 164.308(a)(i).
  – Supporting wireless segmentation to match the security policy being asserted in the wired network. Segmentation also provides for protection against malicious software 164.308(a)(5)(ii)(B).
- Accessing wireless devices

The function of each of these devices can be virtualized and consolidated for simplicity, depending on the space and management requirements of the facility footprint. For example, many clinics that occupy leased space are not in control of their IT closet, and may have several power, wiring closet, rack, and cabling restraints that benefit from virtualized devices that reduce the physical footprint of the infrastructure.

Identity and Access Management should be centralized, as is discussed in the data center section. However, when connectivity is lost to the centralized services, local identity and access management should be configured for emergency access.

Logging should be centralized and is discussed in the data center section. However, local device logging should be enabled if centralized connectivity fails. This ensures that auditing and monitoring can be used.

Encryption of PHI across networks is necessary as described in the HIPAA Security Series published by HHS: Covered entities must consider the use of encryption for transmitting ePHI, particularly over the Internet. As business practices and technology change, situations may arise where ePHI being transmitted from a covered entity would be at significant risk of being accessed by unauthorized entities. Where risk analysis shows such risk to be significant, a covered entity must encrypt those transmissions under the addressable implementation specification for encryption; there should be application layer encryption, but additional consideration should be given when PHI leaves the clinic over Internet service provider (VPN) or wireless networks (WPA2).

Conversely, in clinics that own their own space, are moderate size, or have a number of clinical subsystems and technology tools, each of these devices can be increased in number depending on the resiliency and redundancy requirements of the business. For example, if clinic connectivity is a business priority, using redundant routers for redundant WAN access might be a requirement to ensure that connectivity is maintained.

Clinics routinely have minimal space for the technology infrastructure. The ability to implement the technological components securely in minimal space is an advantage.

Regardless of how the IT infrastructure is designed from an ownership and scale perspective, the same types/locations of controls should be consistent and available across the various configurations.

From a control prospective, most health groups “home run” their Internet access from the remote clinics and connected hospitals into their central data center to more effectively manage Internet access, filter content, and enforce data loss prevention, control email connectivity and provide for email filtering in both directions.

This perimeter is typically secured as a demilitarized zone (DMZ) using firewalls and IDS/IPS.

When you introduce any type of untrusted network (wireless, Internet, microwave, satellite, cellular, and so on) into the healthcare environment, you have effectively created a new external perimeter that must now be secured with a firewall and intrusion detection/prevention system. Table 3-1 defines the types of factors that affect clinic controls and requirements.

The fundamental reference architecture assumes that a covered entity or business associate may eventually need to scale to these levels of services, but not necessarily immediately. From a facility perspective, Cisco’s Integrated Services Router (ISR) performs each of the functions listed in Table 3-1. This allows a provider to grow with its investment by purchasing a router that can scale by different license keys for different services without having to rip and replace. For example, a clinic can purchase an ISR for basic WAN connectivity. When the business wants to introduce wireless to the facility, the merchant can unlock the firewall/IPS/IDS feature set with a license.

The fundamental healthcare reference architecture in Figure 3-4 shows the solution framework endpoints/applications within the context of the fundamental healthcare component’s infrastructure.
In-scope devices can include the following:

- Medical devices and imaging subsystems
- Mobile video/audio carts and wireless tablets
- Physical access, ID, and surveillance subsystems for the facilities
- Clinical and administrative workstations
- Primary EMR servers

In general, an additional VLAN for management of infrastructure should be distinctly defined. The remaining devices at the facility level are considered out-of-scope and do not need to be audited, given that they are on their own network and segmented via firewall/IPS/IDS from the sensitive networks.

The HIPAA facility model and its controls were applied to multiple healthcare formats ranging from clinics to hospitals and are shown in Chapter 4, “Solution Implementation,” in detail. This section provides sample addressing plans used. Many designs can be extracted by understanding and using the Healthcare Reference Architecture shown above, but the overall functions are essentially the same.
Data Center

The data center provides a covered entity or business associate with the ability to centralize, aggregate, consolidate, share, maintain, and control their storage of PHI. (See Figure 3-5). The data center is also the place where management systems are deployed. The data center provides centralized control from an administrative perspective because administrative and management tools can span across the data center servers, hospital systems, and remote clinic systems. This minimizes operational overhead and enforces the security policy.

Figure 3-5  Data Center Architecture
Design Considerations

Data centers can house many types of functions and the term itself can encompass narrow and broad aspects. For the purposes of this guide, data centers include the following functions:

- WAN aggregation layer—Aggregates the clinic and hospital WAN connections to the core
- Core layer—Highly available, high-speed area that is the central point of connectivity to all data center areas
- Aggregation layer—Aggregates the services of one area and connects that area to the core
- Services layer—Data treatment and manipulation occurs between access layer and aggregation layer
- Access layer—Server-level access and connectivity between hosts/servers to the services and aggregation layers, depending on the nature of the application
- Host/server farm—Physical servers, virtualized servers, and appliances’ host applications
- Storage—Storage area networks (SANs)
- E-commerce/Health—Internet-based transactions for prescription renewals, payment of bills
- Internet/service provider edge demilitarized zone (DMZ)—Secure connectivity to the Internet
- Partner edge DMZ—Secure segmented connectivity to partners

Common data center security features include, but are not limited to, the following:

- Standardized equipment and software images that are deployed in a modular, layered approach simplify configuration management and increase the systems availability.
- The highly available data center design permits highly resilient access from clinics to core data and storage services.
- WAN aggregation alternatives allow flexible selection of service provider network offerings.
- The service aggregation design allows for a modular approach to adding new access layers and managing shared network services (for example, firewall, IDS, application networking, wireless management)
- Firewall, IDS, and application networking services are available at the service and aggregation layers of the data center.
- Scalability accommodates shifting requirements in data center compute and storage requirements.
- WAN access speeds are typically the limiting factor between the clinic network systems and the WAN aggregation layer.
- Backup network connections from remote facility networks to the data center are recommended when PHI is transported via the WAN.

Related to segmentation between clinical and other systems, clinical data should be, to the extent possible isolated to reduce the risk of copying PHI on to non-PHI data sets, databases, file, file shares, or system drives and backups. Isolation can be accomplished at both the system and network levels by organizing clinical systems in separate VLANs from other systems, and by enforcing access restrictions between dissimilar system/server functional groups. HIPAA 164.308(a)(4) Isolating Clearinghouse Functions requires that covered entities must create separation of PHI from the larger organization, which can be accomplished through router/switch segmentation functionality or through the use of firewalls to more effectively manage a uniform segmentation “policy” across multiple devices and interfaces. Consideration should be given to isolating PHI traffic between servers to a common and small (for example, controllable) set of VLANs, to the exclusion of other systems.
Related to segmentation between internal data center systems and Internet-exposed components, an organization must have policies and procedures in place for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i). Additionally, HIPAA §164.312(c)(1) Data Integrity mandates procedure (or technical controls) to protect PHI from improper alteration or destruction. The use of firewalls as a demarcation and access management point allows the customer to establish and manage a common security policy for data flows between data center and Internet-exposed devices/systems to support maintaining data integrity around PHI. Along with strong application and system controls, the use of network restrictions aligns with the defense-in-depth strategy. Obfuscate internal addressing schemes to the public, especially addresses of PHI storage devices and backups. Consider the use of enterprise-class firewalls to provide a unified security policy management framework to manage critical network boundaries between the covered entity/business associate and the rest of the Internet.

Identity management, authentication, and authorization of users and systems to PHI; and access controls between users/systems and PHI is critical to enforcing HIPAA safeguards. Having the ability to individually grant or deny access to a user or by system at the network (device) and/or system (server) levels provides the granularity of control necessary to support HIPAA safeguards. Consider leveraging centralized identity and access management functions across health groups, and within hospitals and clinics to best support restriction of users and systems to PHI. Ensure that the ability to control access during both routine and emergency access is supported. 164.312.(a)(1) Access Control requires that technical policies and procedures be implemented to allow access only to persons or software programs that are authorized.

An ability to seamlessly encrypt and decrypt PHI and to share encrypted files across the network provides opportunities for real-time PHI sharing and collaboration to improve patient care. The ability to seamlessly exchange PHI or various types, all in encrypted form, reduces the potential places where PHI can be breached. Encrypt PHI (and all operating data if possible) while in transit across the enterprise and when transiting the Internet or other public networks. Consider leveraging encryption management and engines to encrypt/decrypt all PHI when stored. Providing the capability to encrypt traffic sent over public networks helps an organization meet the HIPAA requirement for Transmission Security 164.312(e)(1), Integrity 164.312(e)(2)(i), and Encryption 164.312(e)(2)(ii).
WAN Aggregation

The WAN aggregation layer is a transit network that aggregates the connections from the healthcare locations, backstage locations, and offices, as shown in Figure 3-6.

Figure 3-6  WAN Aggregation Layer

Design Considerations

Segmentation is used at the WAN aggregation layer to minimize the PHI scope from sites that do not have PHI. The WAN aggregation layer needs Layer 3 filters to restrict PHI data from crossing into sites that do not have the need for PHI data.

Two options are possible at this layer for Layer 3 filters at the WAN aggregation layer:

- Firewall appliance—Interior to the WAN edge routers, a dedicated firewall appliance is used to secure incoming WAN traffic and to terminate remote facility VPN connections. This design provides the highest scalability. When managed centrally over several firewalls, a unified security policy can be exerted over the organization with the minimum of administrative overhead, and in a repeatable way that supports effective risk management. The firewall provides multiple safeguards to help a healthcare organization meet HIPAA safeguards. The firewall filtering and routing provide security between authorized and unauthorized traffic from an unsecured network. This is extremely important when connecting the organization to external networks such as the Internet or a business associate. This helps an organization meet the HIPAA requirement for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i).
- Cisco IOS Software firewall routers—Many Cisco routers also support the Cisco IOS security software option that includes a firewall feature. Cisco recommends the use of the Cisco IOS Security feature set in hospitals, branches, and teleworker deployments, because of a much lower number of users and connection rates than at the Clinic WAN aggregation head end location.

There are two typical WAN speed categories for a WAN aggregation network: less than and up to OC3 (155 Mbps), and OC12 (622 Mbps) and above. The choice of these two network speeds determines the platform set to select from Cisco. In addition, this design creates two profiles for each WAN speed. These profiles are designed to provide guidance when designing a WAN edge network, regardless of which enterprise WAN architecture is selected. The profiles for each WAN speed investigate integrated versus dedicated chassis for each functionality component, as highlighted in the previous section. Some customers prefer a highly integrated solution where most, if not all, of the WAN edge functions described in this document reside on a single or very few network devices. Other customers prefer the granularity and scalability of these same functions separated across multiple network devices.

The WAN aggregation architecture is based on the Infrastructure Protection and Security Service Integration Design for the Next Generation WAN Edge v2.0, which can be found at the following URL: http://www.cisco.com/en/US/docs/solutions/Enterprise/WAN_and_MAN/IPSNGWAN.html
Core Layer

The core layer provides the high-speed packet switching backplane for all flows going throughout the data center, as shown in Figure 3-7.

**Design Considerations**

Depending on the risk management strategy, high availability may be a requirement. The core is the fundamental layer of an enterprise architecture that provides high availability and connectivity between all other layers. The core layer provides connectivity to multiple aggregation layers and provides a resilient Layer 3 routed fabric with no single point of failure. The core layer runs an interior routing protocol, such as Open Shortest Path First (OSPF) or Enhanced Interior Gateway Routing Protocol (EIGRP), and load balances traffic between the core and aggregation layers using the Cisco Express Forwarding (CEF)-based hashing algorithms. The core is not a perimeter; no security filtration should be performed at this layer. The core layer support the efficient transport of clinical, imaging, and administrative data without throughout issues or bottlenecks, thereby ensuring the highest patient care through data availability to the care team.
The core, services aggregation, and server access tiers of the multi-tier data center architecture was based on the design documented in the *Cisco Data Center Infrastructure Design Guides*, which can be found at the following URL: http://www.cisco.com/en/US/solutions/ns340/ns414/ns742/ns743/ns994/landing_dc_infrastructure.htm

### Aggregation Block

An aggregation block is a combination of the aggregation, services, and access layer systems. It represents a repeatable, implementable template for scaling applications and services within the data center. (See Figure 3-8.)

**Figure 3-8  Aggregation Block**

**Design Considerations**

Segmentation can occur at this layer by separating entire aggregation blocks or within the block. These blocks can be zoned by function or compliance types. For example, an organization that has sensitive healthcare information may be zoned away from the payment card sensitive information. Zones are a best practice to isolate applications and services based on their individual policy requirements. You can
securely mix in-scope and out-of-scope applications and services within a single aggregation block but you may use entire aggregation blocks separately to ease administration as policies change over time. The aggregation layer uses Layer 3 filters to segregate and protect the edge of the scope of compliance.

In the services layer, server load balancing and wide-area application services (WAAS) are used at this layer to optimize applications. Using these devices to support HIPAA-relevant applications brings these devices into scope and susceptible to the same safeguards. For more information on understanding these safeguards and controls, consult [Chapter 5, “Component Assessment.”]

In the access layer, switches provide both Layer 2 and Layer 3 topologies to enable segmentation within the aggregation block. The solution management servers connect to the network in this layer. They are centralized, segmented from other business application servers, and protected by firewall services from the service aggregation layer above.

In the storage layer, a combination of disk encryption provided by the Cisco MDS encryption card, fibre-channel zoning, and logical unit (LUN) masking/zoning were used in the storage implementation of this solution. By deploying zoning within a Fibre Channel fabric, device access is limited to devices within the zone. This allows the user to segregate devices based on access to a particular storage device (disk array). This applies to HIPAA Safeguard 164.312(a)(1)(2)(iv) Encryption and Decryption. This is a requirement in a data center environment in which multiple file servers in the data center server farm are connected to the same SAN fabric, and access to PHI data must be restricted to a subset of servers. LUN masking takes zoning beyond the Fibre Channel switchport level by restricting access to specific LUNs on a given disk array. Only specific devices belonging to the LUN zone are able to access those sections of the disk. Applications can be grouped by PHI use/storage, with encryption support on some devices but not necessarily on all arrays. Encryption keys for storage are managed by Cisco Key Manager and RSA Data Protection Manager. This provides a uniform method to control encryption keys across the enterprise. Key management can be structured by organizational unit, so the multiple business units can be supported under the same key management scheme, and the potential to intermix or misroute PHI (when encrypted) can reduce the potential for breach. This measure can mean the difference between losing PHI when other security controls are intentionally compromised, and maintaining control over that data.

In the host layer, server virtualization technology can be used to further establish separation between applications containing PHI and other applications, and to organize process-intensive applications into demand-groups to ensure timely file retrieval and update. Individual blades within a blade server chassis can be used to segment sensitive and non-sensitive applications because they run independent hypervisors. Because hypervisors are considered insecure, when mixing sensitive applications with non-sensitive applications (mixed-mode) across the same hypervisor, the non-sensitive applications are now in scope.

While meeting the central focus of this design guide by recommending an architecture that meets the HIPAA Safeguards, additional QoS parameters can increase performance using the recommended segmentation strategies.

The host layer/server farm is where the centralized applications are deployed for managing and enforcing the segmentation policy, logging, auditing, monitoring, identity authentication and authorization.

E-commerce/Internet Edge/Service Provider Edge/Partner Edge

The solution uses a collapsed Internet edge and extranet network to support Internet connectivity and business partner connectivity, as shown in Figure 3-9.

**Figure 3-9  E-commerce/Internet Edge/Service Provider Edge**

**Design Considerations**

The primary segmentation of the perimeter of the enterprise occurs at the edge.

The design does the following:

- Provides an enterprise connection to the Internet.
- Secures the Internet edge design using Cisco firewall and intrusion detection systems.
- Provides a dual-threaded design for network resiliency.
Chapter 3  Solution Architecture

E-commerce/Internet Edge/Service Provider Edge/Partner Edge

- Provides a collapsed Internet edge and extranet network for a highly centralized and integrated edge network.
- Provides remote VPN access to enterprise users/telecommuters.

This design takes into account best practices from the Data Center Networking: Internet Edge Design Architecture Design Guide (http://www.cisco.com/go/designzone) and customizes these recommendations for Internet edge and extranet networks. The edges connect Internet services to the complete enterprise environment from hospitals to Internet service providers and clinic office connections that use a Cisco secure VPN to connect to data centers. The collapsed design provides highly centralized and integrated edge networks, and transports the aggregated traffic through various service modules (Cisco ACE, Cisco ASASM, and Cisco IDSM2) within a pair of Cisco Catalyst 6500 switch chassis. The Internet edge provides the following security functions:

- Secure configurations and management.
- IP anti-spoofing.
- Access control lists (ACLs) provide explicitly permitted and/or denied IP traffic that may traverse between inside, outside, and DMZ. Routing and access control lists provide segmentation between authorized and unauthorized access on the network. This applies to the HIPAA requirement for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i); and protecting ePHI from parts of an organization that are not authorized such as Isolating Healthcare Clearinghouse Functions 164.308(a)(4)(i). Segmentation also provides for protection against malicious software 164.308(a)(5)(ii)(B) and can modify the accessibility as described in Access Establishment and Modification 164.308(a)(4)(ii)(C).
- Stateful inspection provides the ability to establish and monitor session states of traffic permitted to flow across the Internet edge, and to deny traffic that fails to match the expected state of existing or allowed sessions. The firewall filtering and routing provide segmentation between authorized and unauthorized access on the network. This applies to the HIPAA requirement for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i); and protecting ePHI from parts of an organization that are not authorized such as Isolating Healthcare Clearinghouse functions 164.308(a)(4)(i). Segmentation also provides for protection against malicious software 164.308(a)(5)(ii)(B).
- Intrusion detection using Cisco IDSM2 provides the ability to promiscuously monitor traffic across discrete points within the Internet edge, and to alarm and/or take action after detecting suspect behavior that may threaten the enterprise network. The IPS/IDS identifies and notifies appropriate individuals that suspicious activity is occurring. This applies to the HIPAA requirement for identifying and responding to suspected or known security incidents (164.308(a)(6)(ii)).
- Applications servers that need to be directly accessed from the Internet are placed in a quasi-trusted secure area (DMZ) between the Internet and the internal enterprise network, which allows internal hosts and Internet hosts to communicate with servers in the DMZ.
- All public-facing web applications should be developed using the security best practices to prevent known attacks, and must be reviewed annually or after changes.

The Internet and Partner Edge provides multiple safeguards to help a healthcare organization meet HIPAA safeguards. The firewall filtering and routing provide security between authorized and unauthorized traffic from an unsecured network. This is extremely important when connecting the organization to external networks such as the Internet or a business associate. This helps an organization meet the HIPAA requirement for preventing, detecting, and containing security violations as listed in the Security Management Process 164.308(a)(i).

The firewall also provides encryption capability to encrypt traffic sent over public networks. This helps an organization meet the HIPAA requirement for Transmission Security 164.312(e)(1), Integrity 164.312(e)(2)(i), and Encryption 164.312(e)(2)(ii).
The IPS/IDS identifies and notifies appropriate individuals that suspicious activity is occurring. This helps an organization proactively address security incidents. This applies to the HIPAA requirement for identifying and responding to suspected or known security incidents (164.308(a)(6)(ii)).
Solution Implementation

Overview

Cisco customers have asked Cisco to provide insight on how Cisco products can be used to address their HIPAA compliance requirements. To fully accomplish this goal, Cisco hired an auditor and went through the same process as covered entities or business associates. To assess Cisco’s products for the capability and applicability to satisfy compliance safeguards and controls, they had to be installed and configured within a representative design.

This chapter demonstrates how the Cisco Compliance Solution for HIPAA Security Rule reference architecture provides a solution that was installed and configured to address commonly understood healthcare security controls. Cisco partnered with RSA, Hytrust, EMC, VCE, and Verizon to create a comprehensive design that reflected the framework and architectural principles discussed in earlier chapters.

Cisco’s solution was reviewed and validated in the Cisco lab in San Jose, California. Prototype hospital, clinic, data center, WAN, and Internet edge network infrastructures were built using Cisco’s best practice design guides, as represented by the Cisco designs and architectures (http://www.cisco.com/go/designzone). The individual components were installed and configured to best support HIPAA Security Rule control requirements and management of data protection. Verizon conducted an assessment of this design and advised on how Cisco security devices and features could provide direct and compensating controls in support of addressing the administrative, operational, physical, and technical Safeguards called in the HIPAA Security Rule. Verizon Business provided a detailed Healthcare Security Requirements Assessment, provided in Appendix C, “Reference Architecture Assessment Report—Cisco Healthcare Solution.”

Tip

An architecture is a strategic structure for the consistent design, construction, and operation of systems to achieve a desired set of outcomes.

A design is a tactical implementation of an architectural strategy, using specific configurations of products to satisfy business requirements.

Chapter 3, “Solution Architecture,” describes the enterprise architecture with regards to compliance. This chapter demonstrates a design or, in other words, a specific implementation of components to achieve these principles. Various designs can result from the solution architecture. The design that was
implemented is not intended to represent the only way that Cisco and partner products can be installed to protect PHI. It is intended to provide an example showing how and what was used to achieve the principles described in Chapter 3, “Solution Architecture.”

Although every company has specific considerations that vary from this implementation, these designs and the configurations of the components in Appendix E, “Detailed Full Running Configurations,” provide an instructive example of what is needed to secure PHI. Each component selected was assessed for its capabilities and applicability, and that assessment is covered in the next chapter.

In each section, a reference architecture is shown with the corresponding design that was implemented and validated within Cisco’s laboratories. The full configurations of each individual component are available in Appendix E, “Detailed Full Running Configurations.”

Infrastructure

The infrastructure layer of the solution framework addresses the components such as routers, switches, firewalls, and security components. These are used for reference architectures for a variety of locations such as hospitals or data centers as shown in Figure 4-1.

Figure 4-1  Infrastructure Layer of the Solution Framework

The following sections describe the designs that were implemented from the reference architecture.
Figure 4-2 shows the enterprise-wide reference architecture.

**Figure 4-2 ENTERPRISE-WIDE REFERENCE ARCHITECTURE**
Referencing an enterprise-wide architecture as shown in Figure 4-2, the design shown in Figure 4-3 was created in the Cisco lab.

**Figure 4-3  Cisco Lab Reference Architecture**

Note the following:

- Three clinic designs and one hospital design were elected to represent typical healthcare group IT needs.
- The data center consists of a single aggregation block based on the Data Center 3.0 architecture.
- The Internet edge is representative of both the e-commerce/health and partner edge for the purposes of validation.

The following sections describe this enterprise-wide design in more detail, and demonstrate what was implemented within the lab.
Healthcare Facilities—Clinics and Hospitals

Multiple healthcare facility footprints were implemented that address a variety of business objectives. Each footprint section contains designs that were extracted from the reference architecture. Each design contains the following:

- Reference architecture
- Healthcare facility design
  - Logical topology
  - Addressing plan
  - Components selected

For component compliance functionality, see Chapter 5, “Component Assessment.” For full device configurations, see Appendix E, “Detailed Full Running Configurations.”

**Note**

Each of these designs includes a variety of components that can be interchangeably used between them, depending on business requirements. For validation purposes, it was not necessary to implement all possible components in each design.
Small Clinic Architecture

Small clinics, such as a single physician or small physician practice, as shown in Figure 4-4, meet the following design requirements:

- Office size averages between 2000–6000 square feet; often the IT closet is outside of the control of the clinic in leased space, or is shared with other tenants. Often there is only one entry/exit and a fire door as an emergency escape, with remote or landlord-provided monitoring for fire and hazard controls.
- Fewer than 25 devices requiring network connectivity; many devices are standalone with widely variable networking and support requirements.
- Single router and integrated Ethernet switch.
- Preference for integrated services within fewer network components because of physical space requirements.
- Wireless connectivity for physician tablets and laptops to support physician mobility between treatment rooms.
- Treatment rooms and administrative offices designed to support specific clinical or administrative functions.
- Desire on the part of the physician to improve treatment options with advanced technology, but the need to control costs and make use of shared technology options such as video conferencing, remote audio dictation, and remote review of local medical instrumentation.

Figure 4-4 Small Clinic Architecture
The small clinic reference architecture is a powerful and modular platform for running multiple parallel and independent healthcare practices, all operating under a common operational and technical infrastructure. The small clinic module dictates simplicity and a compact form factor. This combination appeals to many clinical formats that can include the following:

- Traditional single doctor offices
- Small physician practices with 2–5 treatment rooms and basic functional organization
- Health specialty clinics and out-patient treatment facilities, designed specifically for one specialty—cancer treatment, OB/GYN, optical care, and out-patient surgical procedures, and so on
- Standardized clinic models running under a common “clinic” model—emergency care clinics, rehabilitation facilities, and so on

This network architecture is modular and consolidates many services into few infrastructure components. It supports a variety of clinic application models because an integrated Ethernet switch supports high-speed LAN services. Clinics routinely have minimal space for the technology infrastructure. The ability to implement the technological components securely in minimal space is an advantage.

Advantages include the following:

- Lower cost per site
- Fewer parts to spare, less complex remote maintenance required
- Less need to update software with fewer software images
- Lower equipment maintenance costs

Limitations include the following:

- Compromises in network resilience commensurate with the priority of treatment
- Some potential downtime because of single points of failure, demanding local replacement support
Small Clinic Design

Figure 4-5 shows the small clinic network design.

**Components Selected**

- Cisco 1941 Integrated Services Router (ISR)
- Cisco Catalyst 2960 Switch
- Cisco Aironet 3502e Access Point
Small Clinic—Managed Service Provider Design

The managed service provider office represents an alternate design for the small clinic architecture. Figure 4-7 shows the managed service provider network design.

**Figure 4-7 Managed Service Provider Office Network Design**

### Components Selected

- Cisco ASA 5515-x Firewall with vIPS
- Cisco Catalyst 2960S Switch
- Cisco Aironet 3502e Access Points
Medium Clinic Architecture

Medium clinics such as a physician practice or multi-practice, shown in Figure 4-8, meet the following design requirements:

- Facility space between 5000 and 30000 square feet with one or more floors of dedicated office and clinic spaces, waiting rooms, purpose-built treatment rooms, storage facilities of various types, and dedicated IT and utility spaces
- Number of devices connecting to the network averages 25–100 devices with most requiring IP network connectivity, and providing integrated telephone switching/call routing throughout the facility
- Redundant LAN and WAN infrastructures, and more purpose-specific devices for greater control and flexibility
- Wireless connectivity for mobile carts and wireless medical devices to support physician mobility between treatment rooms and review of patient data
- Treatment rooms and administrative offices designed to support specific clinical or administrative functions

Figure 4-8 Medium Clinic Architecture
The medium clinic architecture provides for flexibility to support a wide range of clinic operations under a common and cost-effective networking model. This model stresses the adaptability of the architecture to multiple functions and data types, all brought under a common control structure so the healthcare security requirements can be controlled either at the clinic or centrally across the larger organization. The medium clinic architecture is optimized for efficient business operation without sacrificing centralized controls and layered security control to best resist breach.

Owing to the flexibility of the architecture, the medium clinic model can be adapted to many configurations of out-patient clinics and today’s small hospitals.

The reference architecture is designed for clinical operations that require network resiliency and increased levels of application availability over the small clinic architecture and its single-threaded, simple approach. As more mission-critical applications and services converge onto the IP infrastructure, network uptime and application availability are more important. The dual-router and dual-LAN switch design of the medium clinic supports these requirements. Each of the ISR routers can run Cisco IOS security services and other clinic communication services simultaneously. Each of the Cisco ISR routers is connected to a dedicated WAN connection. Hot-Standby Routing Protocol (HSRP) is used to ensure network resilience in the event that the network connection fails.

The access layer of the network offers enhanced levels of flexibility and more access ports compared to the small clinic. Up to 12 wireless access points can be installed in the clinic, supported by the Cisco Wireless LAN Controller (WLC) as tested and without adding more controllers. The distributed Cisco Catalyst switches can support a combination of larger physical buildings or a larger number of endpoints than the small clinic.

Advantages include the following:

- More adaptive access layer with support for a greater number of endpoints and more diverse building requirements (multiple floors, sub-areas, and so on)
- Improved network resilience through parallel device design
- Improved network and application availability through parallel paths

Limitations include the following:

- No distribution layer between core layer (the ISR) and the access layer switches
- A single WLC controller decreases in-clinic resilience of the wireless network; the recommendation is to have clinic APs fallback to the central WLC controller if the local WLC controller fails, or to install dual-local WLC controllers.
Medium Clinic Design

Figure 4-9 shows the medium clinic design.

**Figure 4-9 Medium Clinic Design**

- Cisco Video Surveillance 2421 IP Dome Camera
- Cisco Video Surveillance 2500 Series IP Camera
- Cisco Operations Manager v4.1
- Cisco Physical Access Gateway
Hospital Architecture

The hospital reference architecture model shown in Figure 4-10 meets the following design requirements:

- Facility space between 3,000 to 3,000,000 square feet with one of more floors of dedicated office and clinic spaces, waiting rooms, purpose-built treatment rooms, storage facilities of various types, and dedicated IT and utility spaces
- Number of devices connecting to the network averages 250–1000 devices with most requiring IP network connectivity, and providing integrated telephone switching/call routing throughout the facility
- Redundant LAN and WAN infrastructures, and more purpose-specific devices for greater control and flexibility
- Large capacity network infrastructure to support high bandwidth demands for imaging, video conferencing, and telemedicine
- Wireless connectivity for mobile carts and wireless medical devices to support physician mobility between treatment rooms and review of patient data on laptops, tablets, and specialty devices
- Unified communications integration for current and future needs including VoIP, calling stations, IPTV, web conferencing, video conferencing, and telemedicine
- Treatment rooms and administrative offices designed to support specific clinical or administrative functions
The hospital reference architecture uses Cisco campus network architecture recommendations and adapts them to a healthcare environment. Network traffic can be better segmented (logically and physically) to meet business requirements. The distribution layer architecture can greatly improve LAN performance while offering enhanced physical media connections (that is, fiber and copper for connection to remote access layer switches and wireless access points). A larger number of endpoints can be added to the network to meet business requirements. Dual routers and distribution layer media flexibility greatly improve network serviceability because the network is highly available and scales to support the site requirements. Routine maintenance and upgrades can be scheduled and performed more frequently or during normal business hours because of parallel path design.

Advantages include the following:

- Highest network resilience based on highly available design
- Port density and fiber density for large locations
- Increase segmentation of traffic
- Scalable to accommodate shifting requirements

Limitations include the following:

- Higher cost because of network resilience based on highly available design
- These network designs are capable of helping an organization achieve compliance, and also serve as the scalable platform for new services and applications
Hospital Design

Figure 4-11 shows the hospital network design.

Cisco Compliance Solution for HIPAA Security Rule

OL-27664-01

4-17
Components Selected

- Cisco 3945 Integrated Services Router (ISR)
- Cisco Catalyst 3560X and 4500 switches
- Cisco Aironet 3502e and 3502i Access Points
- Cisco 5508 Wireless Controller
- Cisco 4500 Video Surveillance Camera
- Cisco Physical Access Gateway
Data Center

The data center is where centralized data communications occur and are stored (see Figure 4-12). The data center is also the place where management systems are deployed. The data center provides centralized control from an administrative perspective because it is typically where the tools that are used to monitor and enforce compliance are deployed.

![Figure 4-12 Data Center Architecture](image)

Design considerations are as follows:

- Centralized solution management supports all aspects of network, security, and systems management; and supports remote access from anywhere on the network.
- Standardized equipment and software images, deployed in a modular, layered approach, simplify configuration management and increase the systems availability.
- The highly available data center design permits highly resilient access from clinics to core data and storage services.
- WAN aggregation alternatives allow flexible selection of service provider network offerings.
- The service aggregation design allows for a modular approach to adding new access layers and managing shared network services (for example, firewall, IDS, application networking, wireless management).

- Firewall, IDS, and application networking services are available at the service and aggregation layers of the data center.

- Scalability to accommodate shifting requirements in data center compute and storage requirements.

- WAN access speeds are typically the limiting factor between the clinic network systems and the WAN aggregation layer.

- It is typical for implementers to over-subscribe the WAN circuits between the clinics and the WAN edge aggregation router. Over-subscription can cause inconsistent results and packet loss of PHI in the event that more traffic enters the WAN circuit simultaneously.

- Backup network connections from clinic networks to the data center are recommended when PHI is transported via the WAN.

Figure 4-13 shows the data center design.

**Figure 4-13  Data Center Design**

Data centers can house many types of functions, and the term itself can encompass narrow and broad aspects. For the purposes of this guide, data centers include the following functions:

- WAN aggregation layer—Aggregates the clinic and backstage WAN connections to the core
- Core layer—Highly available, high-speed area that is the central point of connectivity to all data center areas
- Aggregation block—Aggregates the services of one area and connects that area to the core, including Vblock1 design
- Internet edge—Secure connectivity to the Internet
WAN Aggregation Layer

Figure 4-14 shows the WAN aggregation layer design.

Components Selected

- Cisco ASR 1002-Fixed Router
- Cisco ASA 5555-X Adaptive Security Appliance
- Cisco Catalyst 3750X Switch
Core Layer Design

Figure 4-15 shows the core layer design.

Figure 4-15  Core Layer Design

Components Selected

- Cisco Catalyst 6500-E Switch

Note

In Chapter 3, “Solution Architecture,” the Cisco Nexus switch is recommended as the core layer component. At the time of this solution validation, the Cisco Catalyst was used in the core switching layer.
Aggregation Block Design

Figure 4-16 shows the aggregation block design.

Components Selected

- Cisco ASA 5585-X Adaptive Security Appliance
- Cisco Nexus 7010 Switch
- Cisco Catalyst 6500-E Switch
  - Cisco ACE 20
  - Cisco IDSM-2
- Cisco Nexus 5020 Switch
- Cisco Catalyst 3750-X Switch
Vblock Design

Figure 4-17 shows the Vblock design.

Components Selected

- Cisco UCS 5108 Blade Server Chassis
  - Cisco B200 Blade
- Cisco UCS 6120 Fabric Interconnect
- Cisco MDS 9506 Multilayer Director
- EMC CLARiion CX4 Model 240
Internet Edge Design

Figure 4-18 shows the Internet edge design.

Figure 4-18  Internet Edge Design

Components Selected

- Cisco ASR 1002 Series Router
- Cisco Catalyst 6500-E Switch
  - Cisco ASASM
  - Cisco ACE 30
  - Cisco IDSM-2
- Cisco Catalyst 3750X Switch
- Cisco MDS 9204i Switch
- Cisco IronPort C670
Administration

The administration layer of the solution framework addresses the components such as authentication, encryption, management, and monitoring, as shown in Figure 4-19.

### Authentication

**Components Selected**

- Cisco Secure Access Control Server (ACS)
- Cisco Identity Services Engine (ISE)
- RSA Authentication Manager
- Windows Active Directory

### PHI Encryption

**Components Selected**

- Cisco Security Manager
- Cisco Key Manager
- Cisco AnyConnect VPN
- RSA Data Protection Manager
Management

Components Selected

- Cisco Prime LAN Management Solution (LMS)
- Cisco Security Manager
- Cisco Wireless Control Server Manager
- EMC Unified Infrastructure Manager
- VMware vSphere vCenter
- Cisco Video Surveillance Manager
- Cisco Physical Access Manager
- RSA Archer

Monitoring

Components Selected

- RSA enVision
- HyTrust
Endpoints and Applications

The endpoints and applications layer of the solution framework addresses the components such as voice and physical security, as shown in Figure 4-20.

**Figure 4-20**  Endpoints and Applications Layer of the PHI Solution Framework

**Physical**

**Components Selected**

- Cisco Physical Access Gateway
- Cisco Video Surveillance Cameras (2421, 2500, 4500)

**Voice**

**Components Selected**

- Cisco Unified Communications Manager
- Cisco IP Phones (9971, 7975)
- Cisco Survivable Remote Site Telephony (SRST)
Services

The right-hand element that spans endpoint, administration, and infrastructure layers includes services to plan, build, and manage the network to address the HIPAA Security Rule. These can be provided by Cisco, Cisco partners, and Verizon Business. Sample services can include the following:

- Strategy and analysis
- Assessments
- Design
- Validation
- Deployment
- Migration
- Product and solution support
- Optimization and operation services

Note: For a complete Bill of Materials, see Appendix A, “Bill Of Material.” For assessment of components selected for PHI compliance, see Chapter 5, “Component Assessment.” For complete running configurations of components, see Appendix E, “Detailed Full Running Configurations.”
Cisco Compliance Solution for HIPAA Security Rule Result Summary

This solution combines components to create an end-to-end solution conforming to the security controls requirements as outlined in the HIPAA Security Rule Safeguards (see Table 4-1). The result is a set of recommended clinic, hospital, data center, and Internet-edge architectures and designs that can simplify the process of developing and maintaining healthcare security controls in support of a risk management program as required by HIPAA.

Component Assessment

This chapter discusses the function of each component and how it helps to address HIPAA compliance requirements. Each component was assessed by Verizon Business, and the full reference architecture report is available in Appendix C, “Reference Architecture Assessment Report—Cisco Healthcare Solution.” This assessment took place at a specific point in time using currently available versions of products and software.

Component Section Overview

Each component section includes the following:

- Description
- Assessment summary
- Primary function
- Design considerations
- Assessment detail

Description

A high level overview of the products, features, and capabilities with relevance to compliance.

Assessment Summary

For each component, the Assessment Summary table lists each of the HIPAA safeguards that were addressed or failed.

Table 5-1 shows an example.
Component Section Overview

Primary Function

A HIPAA-relevant description of how this device is useful in an enterprise for addressing HIPAA compliance.

Design Considerations

This section provides compliance principles as well as best practices for each technology deployed within a clinic or hospital environment.

Assessment Details

A comprehensive list of the HIPAA safeguard citations addressed including sample device configurations.

Endpoints

The endpoints layer of the solution framework addresses the components such as voice, e-mail, and physical security.

Voice

Cisco Unified Communications Manager and IP Phones

The Cisco Unified Communication Manager is a suite of voice applications, signaling control, and utilities that provide IP communications capabilities using devices such as the IP phones. It is configured as an appliance that is easy to deploy, flexible to manage, and allows robust security.

HIPAA Standards Failed  
No HIPAA standards were failed.

HIPAA Implementation Specifications Failed  
No HIPAA implementation specifications were failed.

Primary PHI Function

The primary function of the Cisco Unified Communications Manager in a healthcare network environment is to securely manage IP phones and communications flows, as well as securing publicly accessible network jacks in clinics and hospitals.
Design Considerations

The Cisco Unified Communication Manager is used to configure all of the communications infrastructure within the enterprise including IP phones, video endpoints, recording devices and conferencing bridges. Additionally it can also configure the flow of communications throughout the network.

The design features for improving security for the Cisco Unified Communications Manager appliance include:

- Deployment as a clustered redundancy model that includes a publisher server and several subscriber servers
- Downloading and installing security patches when vulnerabilities are announced by the Cisco Product Security Incident Response Team (PSIRT)
- Implementing Transport Layer Security (TLS) messaging for secure signaling and Secure RTP (SRTP) for encrypted media throughout the enterprise
- Enabling device authentication and communication encryption using X.509 certificates that are signed by the Certificate Authority Proxy Function (CAPF) feature on the server

Best practices for Cisco Unified Communications Manager phone security are as follows:

- Disable the gratuitous ARP setting on the Cisco Unified IP Phones.
- Disabling the web access setting prevents the phone from opening the HTTP port 80; this blocks access to the phone’s internal web pages.
- Disabling the PC Voice VLAN access setting in the phone configuration window prevents the devices connected to the PC port from using the voice VLAN functionality.
- Disabling the Setting Access option in the phone configuration window prevents users from viewing and changing the phone options, including the Network Configuration options, directly on the phone.
- Cisco Unified IP Phones can be configured for authentication and encryption by installing a CTL file on the phones that includes security tokens, trusted server and firewall information, and CAPF.

For more information on securing Unified Communications, see the Cisco Unified Communications System 8.x SRND at the following URL:

HIPAA Assessment Detail—HIPAA Safeguards Addressed

Here is a brief on communications from the HIPAA final rule:

Treatment sessions provided via video and audio conferencing software are not covered by the Security Rule. The HIPAA Final Rule specifically states “because ‘paper-to-paper’ faxes, person-to-person telephone calls, video teleconferencing, or messages left on voice-mail were not in electronic form before the transmission, those activities are not covered by this rule” (page 8342). If, however, the provider records the session and saves a copy, the saved version would be subject to Security Rule provisions for data at rest. Regardless, the treatment session and all related information and documentation from it are subject to the Privacy Rule provisions. To ensure the patient’s privacy during treatment sessions, clinicians should consider the use of private networks or encrypted videoconferencing software.

The HIPAA definition of electronic media is as follows:

Subpart A – General Provisions
§160-103
Electronic Media means:

(1) Electronic storage material on which data is or may be recorded electronically, including, for example, devices in computers (hard drives) and any removable/transportable digital memory medium, such as magnetic tape or disk, optical disk, or digital memory card;

(2) Transmission media used to exchange information already in electronic storage media. Transmission media include, for example, the Internet, extranet or intranet, leased lines, dial-up lines, private networks, and the physical movement of removable/transportable electronic storage media. Certain transmissions, including of paper, via facsimile, and of voice, via telephone, are not considered to be transmissions via electronic media if the information being exchanged did not exist in electronic form immediately before the transmission.

This solution validation did not include storage or recording of voice or video communications, therefore no implementation steps are shown on how to secure recorded ePHI.

All of the sample configurations shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(i) Security Incident Procedures. Implement policies and procedures to address security incidents.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- **Integrity**—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.
– §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

Sample Configuration

Cisco Unified Communication Manager is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. They were met using the Cisco Unified Communication Manager’s internal user database, because it has extensive features for administering users. Cisco Unified Communication Manager also supports linking to a centralized user database such as Active Directory using LDAP. Within Cisco Unified Communication Manager, individual user IDs are assigned and roles are based on group membership.

End users and administrators are added to the system by creating user IDs and passwords in the User Management section of the Cisco Unified Communication manager web interface, as shown in Figure 5-1.

Figure 5-1  End User Configuration

The role configuration menu in the Cisco Unified Communication Manager server allows specifying the assignment of privileges based on the role description. No systems access is permitted without an account. (See Figure 5-2.)
Cisco Unified Communication Manager supports configuring a credential policy for user management and applying that policy to a designated group. **Figure 5-3** shows a modified default credential policy.

The system provides trivial credential checks to disallow credentials that are easily hacked. You enable trivial credential checks by checking the Check for Trivial Passwords check box in the Credential Policy Configuration window.
Endpoints

Passwords can contain any alphanumeric ASCII character and all ASCII special characters. A non-trivial password meets the following criteria:

- Must contain three of the four allowable characteristics: uppercase character, lowercase character, number, and symbol.
- Must not use a character or number more than three times consecutively.
- Must not repeat or include the alias, username, or extension.
- Cannot consist of consecutive characters or numbers (for example, passwords such as 654321 or ABCDEFG)

The Cisco Unified Communication Manager uses various role definitions for permitting access to various application components on the server. (See Figure 5-4.)

**Figure 5-4** Find and List Roles

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco Unified Communications Manager enforces this as part of the default system behavior. The system locks the user’s session if the session has been idle for fifteen minutes, requiring the user to login again.
To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco Unified Communication Manager can be configured to send the logs to an external syslog server where it cannot be altered by the appliance users. Figure 5-5 and Figure 5-6 show the configurations necessary for log forwarding.

Figure 5-5 Enterprise Parameters Configuration

![Enterprise Parameters Configuration](image)

Figure 5-6 shows the necessary configuration under Cisco Unified Serviceability.
Within the Cisco Unified Communications Manager appliance operating system, root access to the OS is disabled and this prevents any unwanted services from being implemented. To secure authentication information and management of the server, addressing safeguard 164.308(a)(1)(i) Security Management, Telnet and HTTP access to the server for administration is disabled. The communication between phones and server over HTTP can be secured using SSL. (See Figure 5-7.)
The Cisco Unified Communication Manager appliance does not allow changes to the operating system, or to the database or installation of unsupported hardware or of unsupported third-party software.

As a best practice, it is recommended to restrict physical and or logical access to publicly accessible network jacks. For example, areas accessible to visitors should not have network ports enabled unless network access is explicitly authorized. As Cisco IP phones include a pass-through port on them allowing a device to be connected to the network on which an IP phone resides, it is recommended to disable these ports or have them connect to a guest network segment when not intended for use on the ePHI network. Disabling the PC port can be accomplished in the phone configuration window for ports that are not in use, as shown in Figure 5-8.

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the
data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco Unified Communications Manager uses NTP by configuring the NTP server, as shown in Figure 5-9.

**Figure 5-9 NTP Server List**

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Physical Security**

Cisco Physical Security solutions provide broad capabilities in video surveillance, IP cameras, electronic access control, and groundbreaking technology that converges voice, data, and physical security in one modular platform. Cisco Physical Security solutions enable customers to use the IP network as an open platform to build more collaborative and integrated physical security systems while preserving their existing investments in analog-based technology. As customers converge physical security infrastructures and operations and begin using the IP network as the platform, they can gain significant value through rapid access to relevant information and interoperability between systems. This creates a higher level of situational awareness and allows intelligent decisions to be made more quickly.

**Cisco Video Surveillance**

Video surveillance technology provides security monitoring capabilities within a clinic, hospital, and data center environment. Video surveillance for loss prevention can now be extended into the area of protecting the ePHI data environment.
As the core component of Cisco’s video surveillance software portfolio, the Cisco Video Surveillance Media Server offers the power and flexibility to meet a diverse range of video surveillance requirements. The media server:

- Uses IP technology to provide outstanding scalability in terms of sites, cameras, viewers, and storage
- Delivers low-latency, high-quality, event-tagged video
- Supports a broad range of cameras, codecs (such as JPEG, and MPEG-4, and H.264), viewing platforms, and network topologies
- Archives at various frame rates, durations, and locations

Quickly and effectively configure and manage video throughout your enterprise with the Cisco Video Surveillance Operations Manager (VSOM). Working in conjunction with the Cisco Video Surveillance Media Server and Cisco Video Surveillance Virtual Matrix, the Operations Manager meets the diverse needs of administrators, systems integrators, and operators by providing:

- A web-based toolkit for configuration, management, display, and control of video from a wide variety of both Cisco and third-party surveillance endpoints
- Management of a large number of Cisco Video Surveillance Media Servers, Virtual Matrixes, cameras, and users
- Flexible video recording options including motion-based, scheduled, and event-based
- Comprehensive control of users and user roles including scheduling of operator shifts, event filters, and user-specific video views
- Detailed activity reports and system audit

Primary PHI Function

The primary function of video surveillance is to monitor physical access to sensitive areas within the ePHI data environment.

Design Considerations

- Ensure that cameras are positioned to monitor servers or systems within the ePHI data environment.
- Cameras should be appropriately positioned to identify personnel accessing these systems.
- Ensure adequate storage of video for three months or as specified by company policy.

For more information, see the Cisco IP Video Surveillance Guide at the following URL:

A best practices guide is available for Securing Cisco Video Surveillance Manager at the following URL:

HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of Cisco Video Surveillance shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict Access to ePHI Data as required by HIPAA Administrative and Technical Safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.310(a)(1) Facility Access Control: Implement policies and procedures to limit physical access to its electronic information systems and the facility or facilities in which they are housed, while ensuring that properly authorized access is allowed.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.
§164.308(a)(1)(i) Security Management Process. Implement policies and procedures to prevent, detect, contain, and correct security violations. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.

§164.308(a)(6)(i) Response and Reporting. Implement policies and procedures to address security incidents. Requirements addressed include: Incident Response and Auditing.

§164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

Cisco VSOM is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership. The role configuration menu in the VSOM server allows specifying the assignment of privileges based on the role description. No systems access is permitted without an account.

Individual users and roles are created locally and authentication directed to LDAP, as shown in Figure 5-10.

Figure 5-10 VSOM Users Authenticate to LDAP Service
Using the Video Surveillance Management Console, configure LDAP as specified in the installation guide. Figure 5-11 shows the LDAP configuration implemented for validation.

**Figure 5-11  VSOM LDAP Configuration**

![Image of VSOM LDAP Configuration](image)

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco VSOM can be configured to enable session timeout and has a minimum session timeout of 30 minutes in the configuration for the version validated. To configure session timeouts navigate to Settings in the Administrator pages and select the Settings Tab.

To secure the authentication information and management of the server, addressing Safeguard 164.308(a)(1)(i) Security Management, the Cisco Video Surveillance Manager uses SSL for web-based administration and operator access, and uses SSH for remote terminal access. Use the Cisco Video Surveillance Operations Manager Secure Login feature, found within the Administrative Settings, to enable and force secure HTTPS application login. SSH access should be used to securely login to the VSM host.

To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco VSOM can be configured to send its log data to the RSA enVision log management platform. The following configuration script was implemented to send the local log files to the RSA enVision server to be secured and the integrity established:

```
#!/bin/sh
FTP_USER=anonymous
FTP_PASS='vsom@cisco.com'
localDIR="/usr/BWhttpd/bas/db/backups"
serverDIR="/vsom_backup/"
```

Directory: `/etc/cron.daily`
Filename: `ftp-backup-files.cron`
cd $localDIR
ftp -n -i 192.168.42.124 <<EOF
user $FTP_USER $FTP_PASS
binary
cd $serverDIR
mput VSOM_MSP-DC-1_backup_20$(date +%y%m%d)*.tar.gz
quit
EOF
exit 0

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Network Time Protocol (NTP) is supported and must be enabled within both the IP cameras and Video Surveillance Manager.

**Step 1** In the YaST Control Center window, click **Network Services**, then click **NTP Configuration** in the right panel, as shown in Figure 5-12.

*Figure 5-12  Accessing NTP Options*

The Advanced NTP Configuration area appears, as shown in Figure 5-13.
Step 2  Make sure that the During Boot radio button is selected, as shown in Figure 5-14.

Step 3  Uncheck the Configure NTP Daemon via DHCP check box, as shown in Figure 5-15.

Step 4  Then click the Add button. The New Synchronization area appears, as shown in Figure 5-16.
Step 5  In the New Synchronization area, make sure that the Server radio button is selected, and click Next. The NTP Server panel appears, as shown in Figure 5-17.

Step 6  In the NTP Server area, take these actions:
   a. In the Address field, enter the IP address or host name of your NTP server.
   b. (Optional) Click Test to make sure that the Multi Services Platform can access the NTP server.
   c. Check the Use for Initial Synchronization check box.
   d. Click OK.
   e. When complete, in the Advanced NTP Configuration screen, click Finish.

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.
HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Cisco Physical Access Control

Cisco Physical Access Control allows organizations to secure their physical doors and locations. Cisco Physical Access Control addresses specific HIPAA safeguards by providing:

- Secure access to the server by supporting secure protocols such as HTTPS and also securing the accounts using strong passwords
- Role-based access to the system by making use of profiles that can restrict access to the modules, depending on the roles
- Automated backup of events to a centralized server
- Ability to archive audit reports on a centralized server

Cisco Physical Access Control is a comprehensive IP-based solution that uses the IP network as a platform for integrated security operations (see Figure 5-18). It works with existing card readers, locks, and biometric devices and is integrated with Cisco Video Surveillance Manager (VSM) and with Cisco IP Interoperability and Collaboration System (IPICS).

Figure 5-18  Scalable, Modular Architecture

Cisco Physical Access Control has two components:

- The hardware component, Cisco Physical Access Gateway, provides a modular and scalable platform to connect readers, inputs, and outputs to the system. The gateway scales from a single door to thousands of doors at a fixed cost per door.
- The software component, Cisco Physical Access Manager, manages the hardware, monitors activity, enrolls users, and integrates with IT applications and data stores.

Table 5-4  PHI HIPAA Assessment Summary—Cisco Physical Access Control

<table>
<thead>
<tr>
<th>Models Assessed</th>

<tbody>
<tr>
<td>Cisco Physical Access Manager version 1.2.0</td>
</tr>
</tbody>
</table>

| HIPAA Safeguards Addressed |
Primary PHI Function

The primary function of the CPAM appliance is to configure, manage, monitor, and report on the physical doors and door hardware, protecting sensitive areas within the healthcare ePHI data environment.

Design Considerations

Best practices are as follows:

- Use high availability for Cisco Physical Access Manager (PAM) servers.
- Map each branch location and identify the following:
  - Actual doors and modules
  - Door devices and module ports
- Use backup power supply for servers, modules, and devices.
- Cisco PAM was implemented following the Cisco Physical Access Manager Appliance User Guide, Release 1.2.0: http://www.cisco.com/en/US/docs/security/physical_security/access_control/cpam/1_2_0/english/user_guide/cpam_1_2_0.html

HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the CPAM shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
Endpoints

- §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.310(a)(1) Facility Access Control: Implement policies and procedures to limit physical access to its electronic information systems and the facility or facilities in which they are housed, while ensuring that properly authorized access is allowed.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

- §164.308(a)(6)(i) Response and Reporting. Implement policies and procedures to address security incidents. Requirements addressed include: Incident Response and Auditing.

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

Sample Configuration

Cisco PAM is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

Role-based access can be configured on Cisco PAM by making use of profiles. Profiles are pre-defined sets of access privileges that define the Cisco PAM modules and commands available to a user. For example, users that should have all privileges can be assigned to the Administrators profile.
To create profiles, do the following:

**Step 1** Select **Profiles** from the Users menu.

**Step 2** To add a profile, choose **Add**. (See **Figure 5-19**.)

**Figure 5-19   Profiles Module Main Window**

![Profiles Module Main Window](image)

**Step 3** Select a Profile template that most closely matches the desired level of user access, as shown in **Figure 5-20**:
- Default—A basic set of privileges is set.
- Most Restrictive—No privileges are set.
- Least Restrictive—All privileges are set.

**Figure 5-20   Profile Templates**

![Profile Templates](image)

**Step 4** Enter the basic profile settings, as shown in **Figure 5-21**.
Figure 5-21  Profile—General Tab

- Profile name—Enter a descriptive name for the profile.
- Enabled—Select the check box to enable the profile, or deselect the box to disable the profile.
- Partition—Select the partition from the drop-down menu.

Step 5  Click the General tab to define the basic profile properties. Click the checkbox next to each field to enable or disable the privilege, as described in Table 5-5.

Table 5-5  General Settings—Profile Module

</tr>
</tbody>
</table>

Step 6  

Click the Modules tab to define the modules accessible to the profile, as shown in Figure 5-22.

a. Select a Cisco PAM module.

b. Select Allow access to module to enable access to the module.

c. (Optional) Use the Default Filter with modules such as Event, Badge, and Personnel to define the filter applied when a user opens the module.
For example, to create a profile with access to the Events module that displays events for a specific door by default, complete the following sample steps:

1. Create a profile with access to the Events module, as described in the previous steps.
2. Click **Default Filter**, as shown in Figure 5-22.
3. Select the **Device** tab, as shown in Figure 5-23.
4. Click **Choose**.

   In the Choose Devices window, expand the Logical Driver device tree and select a door (Figure 5-23).

5. Click **OK** to save the changes and close the windows.

---

**Figure 5-23  Default Filter: Device Settings**

Step 7  Click the **Device Commands** tab to define the hardware configuration commands available to the user (see Figure 5-24).
a. Expand or collapse the list of commands for a device.

b. Highlight a command.

c. Select the following options:
   • Allow command to be issued:
     – Default—If user has access to issue device commands, the command access is enabled by default.
     – No—Denies access to the command.
     – Yes—Allows access to the command.
   • Filter—Apply a filter to limit the devices for the command.

**Step 8** Click the **Data Types** tab to define the data available to the profile, as shown in Figure 5-25.
Figure 5-25  Profile—Data Types Tab

a. Select a module and the type of data in the list.

b. To restrict the data, click the check boxes for the properties listed in Table 5-6.

Table 5-6  Profile—Data Types

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>View</td>

</tr>
<tr>
<td>Delete</td>
<td>Allows the user to delete data.</td>
</tr>
<tr>
<td>Default Filter...</td>
<td>Allows the user to apply a default filter to limit objects from view.</td>
</tr>
</tbody>
</table>

Step 9  Click **Save and Close** to save the profile settings.

Step 10 Assign the profile to one or more Cisco PAM operators using the Logins module. (See the following section).

Creating User Login Accounts and Assigning Profiles

To give users access to Cisco PAM functionality, create a login account and assign one or more access profiles to the username.

Step 1  Select **Logins** from the Users menu. The main window (Figure 5-26) lists all the usernames in the system.
Figure 5-26 Logins Module Main Window

Step 2 To add a login, choose Add.
- To modify an existing login, select the entry and choose Edit.
- To remove a login, select the entry and choose Delete.

Note Most properties of the cpamadmin login are read-only.

Step 3 Complete fields in the General tab, as shown in Figure 5-27. Table 5-7 describes the field properties.

Figure 5-27 Logins Module—General Tab

Note The Username, Password, and Confirm password fields are required.

Table 5-7 General Tab Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username</td>
<td>Required—The username of the login.</td>
</tr>
<tr>
<td>Password</td>
<td>Required—Password to access the system.</td>

<td>Required—The value must be entered exactly as it was in the Password field.</td>
</tr>
</tbody>
</table>
Step 4 Assign access privileges for the login:

a. Select the Profiles tab, as shown in Figure 5-28.

b. Select the checkbox next to each profile to enable or disable access rights as defined by the access profile. For more information, see Defining User Profiles for Desktop Application Access.

c. Click Save and Close to save the changes and close the window.

Tip To create a new access profile, click the New button to open the Profiles module and refer to Defining User Profiles for Desktop Application Access.

Figure 5-28 Assigning One or More Profiles

Step 5 To verify the changes, log off and then log in with the new username and password. Verify that you can access the modules and functions specified by the assigned profiles.

Table 5-7 General Tab Fields

<tr>
<td>Site</td>
<td>Read-only—A site is a single instance of a Cisco PAM database.</td>
</tr>
<tr>
<td>Comments</td>
<td>Comments or notes about the login.</td>
</tr>
</tbody>
</table>
Cisco PAM has a default policy of “Deny-all”. If a specific badge has to get access to certain set of doors, an access policy must be created.

Cisco PAM supports authentication through LDAP. Because LDAP supports this feature, Cisco supports the methods listed above.

**Configuring LDAP User Authentication on Cisco PAM**

To authenticate users using a Lightweight Directory Access Protocol (LDAP) server, do the following:

1. Configure the LDAP Server
2. Create the LDAP User Account in Cisco PAM

**Configure the LDAP Server**

Enter the LDAP server settings to configure the LDAP server connection and user authentication, as described in the following steps.

---

**Step 1**

Select **System Configuration** from the Admin menu, and then select the **LDAP** tab.

**Step 2**

Enter the LDAP user authentication settings. The LDAP configuration depends on the authentication mode:

- **User principal name (recommended method)**—The user principal name is unique in the organization.
- **sAMAccountName**—The sAMAccount username is unique only in the search domain.

LDAP uses a principle to authenticate. The principle is formed from the username: prefix + username + suffix. The exact format of the principle varies based on the type of LDAP server, and the domain.

For OpenLDAP, the prefix should be: **uid=**

The suffix should be changed to reflect the actual domain.

So for my-domain.com, this would be: ,dc=my-domain, dc=com

For more information, see the following:

- **LDAP Example: User Principal Name**
- **LDAP Example: sAMAccountName**

**Step 3**

Enter the other LDAP server settings, as listed in **Table 5-8**.

**Table 5-8  LDAP System Configuration Settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable LDAP</td>
<td>Click the checkbox to enable or disable LDAP support.</td>
</tr>
<tr>
<td>LDAP server URL</td>
<td>URL of LDAP server, must begin with ldap://</td>
</tr>
<tr>
<td></td>
<td>Example: ldap://192.168.1.1:389</td>
</tr>
<tr>
<td>Note</td>
<td>389 is the port number.</td>
</tr>
<tr>
<td>Principle suffix</td>
<td>Appended to the username for authentication. See above.</td>
</tr>
<tr>
<td>Principle prefix</td>
<td>Prepended to the username for authentication. See above.</td>
</tr>
</tbody>
</table>
Step 4 Log out and log back in to the Cisco PAM application to enable the changes (select Logout from the Options menu).

LDAP Example—User Principal Name
In the example shown in Figure 5-29, the user principal name is cpsm.user@ad1.cpamlab. The Cisco PAM user login must be the same (cpsm.user).

LDAP Example—sAMAccountName
In the example shown in Figure 5-30, the user login is the same as the samaccount name (cpsmuser).
Creating the LDAP User Account in Cisco PAM

Create the user account to be authenticated using an LDAP server with the following steps.

**Step 1** Select Logins from the Users menu. (See Figure 5-31.)

**Step 2** Click Add, or select an existing login and click Edit.
Step 3  Select the Login type LDAP. The Login type field appears only if LDAP was enabled and the Cisco PAM application was restarted (see Configure the LDAP Server).

Step 4  Enter the username, password, and other settings for the LDAP login. See Creating User Login Accounts and Assigning Profiles.

Note  Although a password must be entered for all user Login records, it is not used for LDAP authentication. LDAP servers use the password entered when the user logs in to Cisco PAM.

Step 5  Click Profiles and select the user's Cisco PAM profiles. See Defining User Profiles for Desktop Application Access for more information.

Note  Cisco PAM does not synchronize the LDAP profiles.

Step 6  Click Save and Close.

To secure authentication information and management of the server, addressing Safeguard 164.308(a)(1)(i) Security Management, SSL is enabled by default on the Cisco PAM appliance. All the communication between the Cisco PAM client and the gateway is encrypted using the 128-bit AES encryption. Console access to Cisco PAM is through SSH. The Cisco PAM appliance should also be configured to disable unsecure protocols. To disable unsecure protocols, you must edit one of the configuration files on the Cisco PAM appliance. The step-by-step instructions are as follows:

1. SSH into the Cisco PAM server
2. sudo su
3. Enter the cpamadmin password
4. Stop the service: /etc/init.d/cpamadmin stop
5. Comment out a configuration from the file /opt/cisco/cpam/apache-tomcat/conf/server.xml. Remove or comment the snippet below.

```xml
<Connector executor="tomcatThreadPool" port="8080" protocol="HTTP/1.1" connectionTimeout="20000" redirectPort="8443" />
```

6. Re-start the service: /etc/init.d/cpamadmin start

When you try to launch the web UI using HTTP, you see “Page cannot be displayed”.

To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco PAM allows for the creation of global I/O rules to trigger sending audit reports to a centralized server. Following are the instructions to create a global I/O with audit reports.

Step 1  In the Cisco PAM client, click Events & Alarms -> Global I/O > Add.

Step 2  Enter a name and click New in the Trigger field. (See Figure 5-32.)
Step 3 Select **Periodic** and click **OK**. (See Figure 5-33.)

**Figure 5-33 Selecting Periodic**

Step 4 Choose the Interval and enter the Time of Day. Click **OK**. (See Figure 5-34.)
Step 5  Under Actions, Click Add…

Step 6  Select Report. (See Figure 5-35.)

Step 7  Choose Audit Records–All and click OK. (See Figure 5-36.)

Step 8  Click Save and Close. (See Figure 5-37.)

Step 9  Under Notification section of the Global I/O, click New and Choose FTP. Click OK. (See Figure 5-38.)
Figure 5-38  Select Notification Type

Step 10 Enter the FTP Host, Username, Password, and Path. Click OK. (See Figure 5-39.)

Figure 5-39  FTP Notification

Step 11 Click Save and Close. You should see a new entry created. You can create similar global I/O rules for every hour.

The audit report is read into RSA enVision server, which then maintains and protects the integrity of the file.

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco PAM has a hard-coded session timeout of 30 minutes in the configuration for the version validated.

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. All the events in the Access Control system have a time stamp associated to them. Cisco PAM and the gateway are configured to use NTP, as shown in Figure 5-40.
HIPAA Standards Failed

No HIPAA standards were failed.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Cisco Unified Computing System

The Cisco Unified Computing System (UCS) is designed to securely deploy sensitive and compliance-related applications. Provisioning options, including virtualization technology, allow the mixing of sensitive and non-sensitive applications without compromising scope boundaries.

Improve IT responsiveness to rapidly changing business demands with this next-generation data center platform. Cisco UCS accelerates the delivery of new services simply, reliably, and securely through end-to-end provisioning and migration support.

Benefits include the following:

• Streamlines data center resources to reduce total cost of ownership
• Scales service delivery to increase business agility
• Radically reduces the number of devices requiring setup, management, power, cooling, and cabling

<table>

</tr>
<tr>
<td><strong>HIPAA Safeguards Addressed</strong></td>
</tr>
</tbody>
</table>
Primary PHI Function

The primary function of Cisco UCS is to securely host one primary compliance-related function per physical or virtual server.

It provides segmentation of sensitive applications from out-of-scope applications via physical and virtualization technology. Cisco UCS extends Layer 3 boundaries to virtual network and storage adapters within the chassis. Using VLANs and VSANs, Cisco UCS allows an organization to separate its ePHI systems (in-scope) from other non-sensitive data (out-of-scope).

Design Considerations

- Cisco UCS allows for the provisioning of individual servers on blades. Each blade can host a native operating system such as Windows 2008 server, or a virtualization hypervisor system such as VMware ESX/ESXi. These provisioning options represent a primary function for the server blade. In the lab validation, VMware ESX was installed on each of the Cisco UCS blades, and several VM hosts were then configured, each with one primary function. Each server blade is provisioned via a profile. Profiles can be created locally in Cisco UCS Manager or centrally using the Vblock provisioning utility, Unified Infrastructure Manager (UIM), which provides simplified Vblock management by combining provisioning with configuration, change, and compliance management.
- EMC SAN is a primary component of the VCE architecture for Vblock Infrastructure Platforms. Vblock 1 is designed for medium to high numbers of virtual machines, and is ideally suited to a broad range of usage scenarios, including shared services, e-mail, file and print, virtual desktops, and collaboration.
- Cisco UCS allows for the provisioning of individual servers on blades. Each blade can host a native operating system such as Windows 2008 server, or a virtualization hypervisor system such as VMware ESX/ESXi.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

Table 5-9 PHI HIPAA Assessment Summary—Cisco UCS (continued)
• Each Cisco UCS server blade is provisioned via a profile. Profiles can be created locally in Cisco UCS Manager or centrally using the Vblock provisioning utility, EMC Unified Infrastructure Manager (UIM), which provides simplified Vblock management by combining provisioning with configuration, change, and compliance management.

• The hypervisor of an individual blade is considered insecure for segmenting scopes of compliance. Therefore, when putting non-sensitive VM servers with sensitive VM servers on the same physical blade, the non-sensitive would be included in the scope of the audit.

• The UCS system securely segments network and storage to each blade, which allows mixing of sensitive and non-sensitive applications across different physical blades of the chassis.

• Cisco UCS does not feature an explicit session timeout. Administration time limits would need to be enabled systemically through active directory policy to the admin workstation desktops, locking them when there is no activity.

Cisco UCS was implemented using the Cisco UCS installation guides: http://www.cisco.com/en/US/products/ps10276/prod_installation_guides_list.html

HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the Cisco UCS shown below were used to meet the following list of satisfied controls:

• Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  – §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  – §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response and Auditing.
  – §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  – §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

• Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  – §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(i) Response and Reporting. Implement policies and procedures to address security incidents. Requirements addressed include: Incident Response and Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.
  - §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

Sample Configuration

Cisco UCS servers are able to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership. Cisco UCS includes extensive controls for defining user privileges and by default denies access to all individuals without a system user ID.

Add the Cisco Secure ACS server under the TACACS+ protocol option, as shown in Figure 5-41.
Select tacacs from the Console and Default dropdown menus on the Authorization page, as shown in Figure 5-42.

On the TACACS+ server, create custom attributes defining the desired role for the user or group accessing the Cisco UCS Manager (see Figure 5-43):

- TACACS+ custom attributes for UCS Manager:
  ```
cisco-av-pair*shell:roles="admin aaa"
```
- If combined with other systems roles, such as for the Nexus:
  `cisco-av-pair*shell:roles="network-admin admin aaa"`

**Figure 5-43** Group Configuration Page on TACACS+ Server

Local individual user accounts can be configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords.

To secure authentication information and management of the UCS Manager, addressing Safeguard 164.308(a)(1)(i) Security Management, the Cisco UCS allows for the disabling of non-secure administrative interfaces. **Figure 5-44** shows that the secure management protocols of SSH and HTTPS for administration. Telnet, HTTP, and other unused protocols are disabled.
Cisco UCS uses strong encryption for SSH and HTTPS connections. Encryption keys are created and managed under the Key Management feature. (See Figure 5-45.)
To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco UCS can be configured to send its data to the RSA enVision log management platform using the syslog function and/or SNMP traps. In the solution, only syslog was used. (See Figure 5-46).

Figure 5-46  Using Syslog
As a best practice, NTP is used to synchronize clocks among network devices (see Figure 5-47). This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers.

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.
HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Cisco UCS Express on Services Ready Engine

The Cisco Unified Computing System (UCS) Express and Services Ready Engine (SRE) is designed to allow organizations to securely deploy sensitive applications directly within the routing platform. By using the UCS E-series, organizations can remove legacy compute resources in the branch, saving space, energy, and operational costs.

Cisco UCS E-series is a converged networking, computing, and virtualization platform for hosting essential business applications in the clinic location. The SRE modules are router blades for the second generation of Cisco Integrated Services Routers (ISR G2) that provide the capability to host Cisco, third-party, and custom applications. A service-ready deployment model enables clinic applications to be provisioned remotely on the modules at any time. Cisco SRE modules have their own processors, storage, network interfaces, and memory, which operate independently of the host router resources and help ensure maximum concurrent routing and application performance.

Primary PHI Function

The primary function of the Cisco UCS Express is to securely host one primary compliance-related function per physical or virtual server.
It provides segmentation of sensitive applications from out-of-scope applications via physical and virtualization technology. UCS extends Layer 3 boundaries to virtual NIC and storage adapters within the chassis. Using VLANs and VSANs, Cisco UCS allows an organization to separate its sensitive ePHI (in-scope) from other non-sensitive data (out-of-scope).

Design Considerations

The major consideration when using Cisco UCS Express with sensitive applications is the security of the hypervisor. Verizon considers all hypervisors to be insecure because of vulnerabilities that may exist resulting in data leakage between VMs. Therefore, use separate Cisco UCS Express implementations when scoping. Although it is acceptable to mix non-sensitive applications onto a Cisco UCS Express deployment with sensitive applications, doing so brings those applications into scope and audit. (See Figure 5-48.)

Figure 5-48 Using UCS Express with Cisco SRE

Note Newer versions of UCS Express (version 1.5 +) enable central management of the VMware ESXi on Cisco UCS Express through vCenter (upgrade license required) as well as eliminate the Cisco console VM and local user management/VMware ESXi management restrictions. With the new release, Cisco UCS can manage users on VMware ESXi exactly as it would on a standalone VMware ESXi 4.1 server.

Note The Cisco UCS Express module comes installed with VMware ESXi. This is the primary function for the server module. Each module can host several independent operating systems as virtual servers. Each virtual server should have only one primary function.

• Cisco UCS Express requires the use of VLANs in the router. Depending on the deployment within the clinic, this may require the use of bridged virtual interfaces.
• Cisco UCS Express is based on VMware’s ESXi and uses vSphere client for management.

HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the UCS Express shown below were used to meet the following list of satisfied controls:

• Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards

- §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response and Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

- §164.308(a)(6)(i) Response and Reporting. Implement policies and procedures to address security incidents. Requirements addressed include: Incident Response and Auditing.

- §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response and Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4). Requirements addressed include: Access Control and Auditing.

- §164.308(a)(6)(i) Response and Reporting. Implement policies and procedures to address security incidents. Requirements addressed include: Incident Response and Auditing.
Endpoints

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

- §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

Sample Configuration
Cisco UCS servers are able to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership. Cisco UCS Express includes extensive controls for defining user privileges and by default denies access to all individuals without a system user ID. On the UCS server configuration of the ESX hypervisor is part of the vSphere and vCenter infrastructure.

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords.

To secure authentication information and management of the UCS server, addressing Safeguard 164.308(a)(1)(i) Security Management, the UCS management console supports only HTTPS and SSH access.

Cisco UCS Express is designed to track and monitor all administrative user access, events such as profile creation, interface up/down, and device authentications. All of these events are sent to the vSphere and vCenter infrastructure.

NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers, as shown in Figure 5-49.

Administration

Authentication

Cisco Secure Access Control Server

Cisco Secure Access Control Server (ACS) was used as a central authentication system for the majority of products validated in this solution. It links user authentication to Windows Active Directory using group mapping that segments users based on their role and function.

Cisco Secure ACS is an access policy control platform that helps you comply with growing regulatory and corporate requirements. By using a single authentication method for all system devices, insight into who made changes is simplified for internal administration, assessors, and post-breach audits. It supports multiple scenarios simultaneously, including the following:

- Device administration—Authenticates administrators, authorizes commands, and provides an audit trail
- Remote access—Works with VPN and other remote network access devices to enforce access policies
- Wireless—Authenticates and authorizes wireless users and hosts and enforces wireless-specific policies
- Network admission control—Communicates with posture and audit servers to enforce admission control policies

Cisco Secure ACS lets you centrally manage access to network resources for a growing variety of access types, devices, and user groups. These key features address the current complexities of network access control:

- Support for a range of protocols including Extensible Authentication Protocol (EAP) and non-EAP protocols provides the flexibility to meet all your authentication requirements
- Integration with Cisco products for device administration access control allows for centralized control and auditing of administrative actions
- Support for external databases, posture brokers, and audit servers centralizes access policy control and lets you integrate identity and access control systems

<table>

<th>Models Assessed</th>
<th>HIPAA Safeguards Addressed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco Secure Access Control Server</td>
<td>Release 4.2(1) Build 15 Patch 3</td>
</tr>
</tbody>
</table>
The primary function of Cisco Secure ACS is to securely authenticate users to the systems within the ePHI environment. The ACS allows for management of user access (authorization) to systems containing ePHI. Additionally, the ACS can prevent unauthorized devices from accessing systems containing ePHI and protect access from unauthorized locations. Users can be assigned to groups and, based on privilege levels, have access to only the information they require for their job function.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

HIPAA safeguards are spread across multiple categories. ACS allows healthcare-covered entities and business associates to meet access control safeguards in the Administrative and Technical categories. The access control can be applied to both internal and external users that access ePHI data.

All of the sample configurations of the ACS shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations it might be accessed. Requirements addressed include: Access Control and Auditing.

Requirements addressed include: Access Control and Auditing.

- §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate’s access authorization policies, establish, document, review, and modify a user’s right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.

- §164.312(a)(2)(ii) Automatic logoff. Implement electronic procedures that terminate an electronic session after a predetermined time of inactivity. Requirements addressed include: Access Control.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- §164.312(a)(2)(i) Unique User Identification. Assign a unique name and/or number for identifying and tracking user identity. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(2)(ii) Emergency Access Procedures. Establish (and implement as necessary) procedures for obtaining necessary ePHI during an emergency. Requirements addressed include: Access Control.

- §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical Safeguards.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

**Design Considerations**

- Cisco Secure ACS has been configured to authenticate individual users using Active Directory (AD). This is accomplished by creating user groups in AD and mapping them to role-based groups in Cisco Secure ACS. This provides the granularity of secure authentication needed to address the HIPAA specification.

- The solution used the windows versions of Cisco Secure ACS. The CSA client was installed to protect and alert on unauthorized access of the log and audit trail.

- Remove the default accounts for administration.

- Enable HTTPS and disable HTTP.
User authentication services for Cisco Secure ACS are linked to a centralized Active Directory user database. When personnel are added or removed from Active Directory, their access to infrastructure is similarly affected addressing Safeguard 164.308(a)(3)(ii)(C) Termination Procedures.

Sample Configuration
Cisco ACS is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through Cisco ACS and ISE via LDAP, RADIUS, and TACACS+ services enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

Cisco Secure ACS supports the creation of local administrative users. Each user must be assigned a unique ID. Cisco Secure ACS password policy enables setting of an inactivity option where an administrator is locked out after a specified period of inactivity determined by company policies. Local administrator user accounts in Cisco Secure ACS require the setting of a password according to the password requirements, as shown in Figure 5-50. By default, Cisco Secure ACS requires another administrator to re-enable locked out accounts.

Figure 5-50 Administrator Password Requirements
HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco Secure ACS supports session policies under the Administration Control/Session tab. The default session timeout is 60 minutes. It is a best practice to change the session timeout to 15 minutes, as shown in Figure 5-51.

![Figure 5-51 Session Timeout](image)

To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco Secure ACS can be configured to send its log data to the RSA enVision log management platform. The configuration procedure is documented in the RSA enVision Event Source Configuration Guide for Cisco Secure ACS, which can be found at RSA Secure Care Online (https://knowledge.rsasecurity.com/).

RSA enVision requires that specific attributes for each reporting function to be specified and configured in a particular order. Figure 5-52 shows the required items for generating Syslog Passed Authentications. Settings for other event types are available in the RSA enVision Event Source Configuration Guide for Cisco Secure ACS.
To secure authentication information and management of the ACS server, addressing Safeguard 164.308(a)(1)(i) Security Management, the ACS management console was configured to support HTTPS access, with HTTP access disabled. Cisco Secure ACS is configured to use SSL as a highly secure management portal technology (see Figure 5-53). Cisco Secure ACS employs port hopping to a random high port for secured communication transport.
As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. Time synchronization for Windows servers is specified through the domain policy. Servers synchronize their clocks with the domain controller, which in turn is synchronized using NTP. This implementation of Cisco ACS was Windows-based.

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**RSA Authentication Manager**

RSA Authentication Manager is the management component of the RSA SecurID®, a two-factor authentication solution, which provides a much more reliable level of user authentication than reusable passwords. SecurID authentication is based on something you know (a password or PIN) and something you have (an authenticator). As the management component, RSA Authentication Manager is used to verify authentication requests and centrally administer authentication policies for enterprise networks.

Primary PHI Function

The primary function of RSA Authentication Manager is to securely authenticate remote users using two-factor authentication.

Design Considerations

RSA Authentication Manager stores and processes highly sensitive authentication information and should be deployed and operated in a secure manner. Detailed recommendations are found in the RSA Authentication Manager Security Best Practices Guide, which can be downloaded from RSA Secure Care Online (https://knowledge.rsasecurity.com/).

HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the RSA Authentication Manager shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).
- **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(i) Security Incident Procedures. Implement policies and procedures to address security incidents.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.
- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.
- **Integrity**—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.
§164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

Sample Configuration

RSA Authentication Manager has powerful access control capabilities to limit, track, and monitor all user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. RSA Authentication Manager protects ePHI data based on user role or group membership. Users and groups are created under the Identity tab of the Security console, as shown in Figure 5-54.

Figure 5-54 Users and Groups

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached, and support advanced policies regarding password rotation and expiration as can be configured as necessary. Local user accounts in RSA Authentication Manager require setting of a password according to the assigned password policy as shown in Figure 5-55.
Additional authentication tokens can also be assigned to each user, as shown in Figure 5-56.
HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. RSA Authentication Manager supports session policies under the Access tab. Change the Session Time-out for the Console/Command API to 15 minutes from the default, as shown in Figure 5-57.
To secure authentication information and management of the server, addressing Safeguard 164.308(a)(1)(i) Security Management, the management console supports only HTTPS access by default.

To address the Incident Response and Auditing HIPAA Safeguards identified above, RSA Authentication Manager can be configured to send its log data to the RSA enVision log management. The configuration procedure is documented in the enVision Event Source Configuration Guide for RSA Authentication Manager, which can be found at RSA Secure Care Online (https://knowledge.rsasecurity.com/). One step is editing the IMS.Properties file, as shown in Figure 5-58.

**Figure 5-58 IMS Properties File**

```plaintext
[ims.properties - Notepad]

# RSA Authentication Manager IMS properties
#
# __AM_VERSION__
# ims.plugin.dir=C:/PROGRA-1/RSASEC-1/RSAAUT-1/utils/plugins

ts.ims.logging.audit.adm.syslog_host = 102.168.42.124
ts.ims.logging.audit.adm.syslog_layout = %d, %c{clientIP}, %m, %n
ts.ims.logging.audit.adm.syslog_facility = 8
ts.ims.logging.audit.adm.use_os_logger = true
nts.ims.logging.audit.RUNTIME.syslog_host = 102.168.42.124
ts.ims.logging.audit.RUNTIME.syslog_layout = %d, %c{clientIP}, %m, %n
nts.ims.logging.audit.RUNTIME.syslog_facility = 8
ts.ims.logging.audit.RUNTIME.use_os_logger = true
nts.ims.logging.system.syslog_host = 102.168.42.124
ts.ims.logging.system.syslog_layout = %d, %c{clientIP}, %m, %n
nts.ims.logging.system.syslog_facility = 8
ts.ims.logging.system.use_os_logger = true
```

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. Time synchronization for Windows servers is specified through the domain policy. Servers synchronize their clocks with the domain controller, which in turn is synchronized using NTP. This implementation was Windows-based.

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Cisco Identity Services Engine**

The Cisco Identity Services Engine (ISE) allows for management of user access (authorization) to systems containing PHI. Additionally, the Access Control Server is designed to prevent unauthorized devices from accessing systems containing PHI and protect access from unauthorized locations. ISE is a security component that provides visibility and control into who and what is connected to the network. Cisco ISE allows organizations to embrace the rapidly changing business environment of mobility.
virtualization, and collaboration while enforcing compliance, maintaining data integrity and confidentiality, and establishing a consistent global access policy. Cisco ISE allows businesses to gain complete control over the access points into their networks. This includes all wired, wireless, and VPN network entry points.

Cisco ISE allow you to see what devices and users are on your network, and that those devices and users comply with your security policies via the following components:

- **Cisco Identity Services Engine**—A next-generation policy manager that delivers authentication, authorization, and accounting (AAA); posture; profiling; and guest management services on a single platform. The Cisco ISE automatically discovers and classifies endpoints, provides the right level of access based on identity, and provides the ability to enforce endpoint compliance by checking a device’s posture. The Cisco ISE also provides advanced authorization and enforcement capabilities, including Security Group Access (SGA) through the use of security group tags (SGTs) and security group access control lists (ACLs). Administrators can centrally create and manage access control policies for users and endpoints in a consistent fashion, and gain end-to-end visibility into everything that is connected to the network.

- **Cisco ISE Identity on Cisco Networking Infrastructure**—Identity-based networking services on the Cisco routing, switching, and wireless infrastructure provides the ability to authenticate users and devices via features such as 802.1x, MAC authentication bypass, and web authentication. In addition, this same infrastructure is what enforces the appropriate access into parts of the network via VLANs, downloadable or named ACLs and security group ACLs.

- **Client**—Cisco AnyConnect is a software client that enables you to deploy a single 802.1x authentication framework to access wired and wireless networks while the Cisco NAC agent delivers endpoint posture information. The Cisco ISE architecture also supports native O/S supplicants.

The Cisco Identity Services Engine solution offers the following benefits:

- Allows enterprises to authenticate and authorize users and endpoints via wired, wireless, and VPN with consistent policy throughout the enterprise
- Prevents unauthorized network access to protect corporate assets
- Provides complete guest lifecycle management by empowering sponsors to on-board guests, thus reducing IT workload
- Discovers, classifies, and controls endpoints connecting to the network to enable the appropriate services per endpoint type
- Enforces security policies by blocking, isolating, and repairing noncompliant machines in a quarantine area without needing administrator attention
- Offers a built-in monitoring, reporting, and troubleshooting console to assist helpdesk operators and administrators streamline operations.

Figure 5-59 shows an example of a Cisco ISE-based LAN deployment.
Figure 5-59  Cisco ISE-Based LAN Deployment

HIPAA Standards Failed
No HIPAA standards were failed.

HIPAA Implementation Specifications Failed
No HIPAA implementation specifications were failed.

Primary PHI Function
Cisco ISE identity features are designed to detect and prevent rogue wireless devices from connecting to in-scope PHI networks; in addition, Cisco ISE locks down publicly accessible network ports to only authorized devices and users.
The Identity Services Engine allows for management of user access (authorization) to systems containing PHI. Additionally, the Access Control Server can prevent unauthorized devices from accessing systems containing PHI and protect access from unauthorized locations.

Identity Services Engine logs can be used to identify unauthorized attempts to connect to systems containing PHI to help meet the supervision requirements.

Design Considerations

For the purposes of this guide, Cisco ISE is configured to authenticate individual users and ISE Admin users using Active Directory (AD). Cisco ISE is also used to profile and assess the posture of individual wired and wireless devices to ensure that they comply with the HIPAA standard. Cisco ISE relies on TrustSec wired and wireless identity features such as 802.1x, MAB, and web portal authentication on Cisco infrastructure to collect user identity information. It relies on the Cisco ISE NAC agent and the Cisco ISE profiler engine to collect posture and profiling information from devices.

Note the following ISE configuration best practices for HIPAA compliance:

- The solution tested used the virtual machine appliance version of Cisco ISE running on an ESX platform.
- The default accounts for administration are removed.
- ISE only supports HTTPS and SSH access.
- Cisco ISE communicates with the Cisco switches and wireless controllers using RADIUS.
- Cisco ISE can use dynamic VLAN and port or VLAN access control rules to provide HIPAA segmentation of a network. For example, members of the HIPAA active directory group are automatically moved to the HIPAA VLAN when they connect to the network. Cisco ISE can then apply strong access lists to this VLAN or directly to the user switch port to accomplish segmentation.
- Access control rule sets must adhere to a “least amount of access necessary” policy. Rules must be defined by specific source/destination addressing and TCP/UDP ports required for the PHI data environment.
- Configure appropriate banner messages on login, incoming, and exec modes of the router. The login banner warning should not reveal the identity of the company that owns or manages the router. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.
- The Cisco ISE system is configured to be compliance with all of the access controls, logging controls, and other general system controls required by HIPAA.

HIPAA Assessment Detail—HIPAA Safeguards Passed

All of the sample configurations of the Cisco ISE shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
- §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity's or the business associate's access authorization policies, establish, document, review, and modify a user's right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

**Sample Configuration**

Cisco ISE is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via
LDAP and RADIUS services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

Figure 5-60 shows admin authentication configured to use Active Directory.

**Figure 5-60  Admin Access Using Active Directory for Authentication**

Cisco ISE controls access so that only privileged users can access the ePHI environment. This is done using the authentication credentials supplied by the wired and wireless infrastructure, along with the AD attributes of a user connecting to the network. Based on a Cisco ISE authorization profile match, that user is put onto the proper VLAN and given a group-specific port access control list to control where they can go on the network. Additionally, a Cisco SmartPort macro can be run on the switchport for proper configuration.

Figure 5-61 shows the Authorization Profiles screen.

**Figure 5-61  Authorization Profiles**

If Cisco ISE does not explicitly match an authorization policy as shown in Figure 5-62, network access is denied.
Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords. The passwords used for these accounts can be tailored by editing of the Password Policy to match corporate requirements as shown in Figure 5-63.

![Figure 5-62 Authorization Policy](image)

![Figure 5-63 ISE Admin Password Policy Settings](image)
HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco ISE supports session idle timeout under the Administration Access/Session tab. It is a best practice to change the session timeout to 15 minutes, as shown in Figure 5-64, which will re-authenticate both admin users and RADIUS users.

Figure 5-64 Admin Access

To secure authentication information and management of the ISE server, addressing Safeguard 164.308(a)(1)(i) Security Management, the ISE management console supports only HTTPS access.

Additionally, Cisco ISE NAC capabilities can be configured on the clinic and hospital switches to automate the verification of approved devices being attached to the network. In addition to configuring the ISE authentication services in the data center, adding the following configurations to all switch and switch interface ports where ISE network access control is required. In most cases, every access switch port in your network should be protected using ISE. However, as a minimum, any switch port that could potentially let a host find its way to the ePHI security domain should be protected by Cisco ISE.

Pre-requirements for ISE NAC (domain name, name server, time settings, crypto keys):

```
    ip domain-name cisco-irn.com
    ip name-server 192.168.42.130
    Crypto key generate rsa 1024
    ntp server 192.168.62.161 prefer
    ntp server 192.168.62.162
    clock timezone PST -8
    clock summer-time PDT recurring
    
    ! ----Configurations to add for NAC ----
    !
    aaa new-model
    
    aaa authentication dot1x default group radius local
    aaa authorization network default group radius
    aaa authorization auth-proxy default group radius
    aaa accounting dot1x default start-stop group radius
    
    aaa server radius dynamic-author
    client 192.168.42.111
    server-key 7 <removed>
    
    radius-server attribute 6 on-for-login-auth
    radius-server attribute 6 support-multiple
    radius-server attribute 8 include-in-access-req
    radius-server dead-criteria time 5 tries 3
```
Methods that may be used in the process include, but are not limited to, wireless network scans, physical site inspections, Network Access Control (NAC), or wireless IDS/IPS.

Cisco ISE Identity features were enabled on the wired infrastructure to authenticate users and devices. The Cisco ISE Policy Manager was configured to not allow an unauthorized device to connect to the wired network. Cisco ISE was configured to alert and mitigate this threat.

Cisco ISE was configured to profile all devices connected to the network. Any devices detected were allowed only if they were in the approved list. All wired ports were set up to authenticate and posture-assess users and devices connecting to the network switches. The device posture assessment included checks for the setup of peer-to-peer wireless network and the setup of a wireless card as an access point on the device. If either of these were true, the device would be denied network access.

To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco ISE can be configured to send its log data to the RSA enVision log management platform. Figure 5-65 shows the configuration of logging servers.
As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco ISE uses NTP to meet these requirements by implementing the following configuration statement:

```
ntp server 192.168.62.161 192.168.62.162
```

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.
Management

Cisco Prime LAN Management Solution (LMS)

Cisco Prime LAN Management Solution (LMS), a part of Cisco Prime Infrastructure, delivers powerful network lifecycle management by simplifying the configuration, compliance, monitoring, troubleshooting, and administration of Cisco networks. Cisco Prime LMS offers end-to-end management for Cisco’s latest business-critical technologies and services such as Mediant, Cisco ISE, and Cisco EnergyWise while complying with corporate and regulatory requirements.

Table 5-14 PHI HIPAA Assessment Summary—Cisco LMS

**HIPAA Standards Failed**
No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**
No HIPAA implementation specifications were failed.

Primary PHI Function

LMS simplifies compliance by ensuring that all of the devices across the network adhere to the security policy of the company. In addition, it will verify that device configurations; match templates, are synchronized, and includes a customized compliance dashboard to simplify the ongoing management for administrators.

Design Considerations

- Provide sufficient licenses to cover all devices in your network.
- Provide proper host system sizing including CPUs, memory, and storage for the selected operating system.
- Restrict access behind a firewall or access list to only those administrative clients that need access.
- Activate the NMC capability license for compliance audits.
Licensed/Unlicensed Compliance and Audit Reports

The following compliance and audit reports require a regulatory compliance management license:
- HIPAA Compliance Reports
- SOX (COBIT) Compliance Reports
- ISO/IEC 27002 Compliance Reports
- NSA Compliance Reports
- PCI DSS Compliance Reports
- DHS Checklist Reports
- DISA Checklists Report
- CIS Benchmarks

The following compliance and audit reports are supported by the LMS license alone and do not require a regulatory compliance management license:
- Service Reports
- Lifecycle Management Reports
- Vendor Advisory Reports
- Change Audit Reports

For compliance and audit license information, see the topic “Regulatory Compliance Management License in Administration with Cisco Prime LAN Management Solution 4.2.2”.

The Compliance and Audit Report module uses the stored configurations within the LMS database and evaluates them against specifically defined criteria of the selected devices.

HIPAA Assessment Detail—HIPAA Safeguards Passed

All of the sample configurations of the LMS shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).
• Incident response—Implement security incident response as required by HIPAA Administrative safeguards.
  – §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

• Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  – §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

Sample Configuration
A centralized user database (Active Directory) is accessed by Cisco Secure ACS using TACACS+ services. Individual user IDs are assigned. Roles are defined within LMS and based on group membership. This configuration was used to address all of the safeguards listed under Access Control above.

Cisco Prime LMS supports role-based user access. Users can be assigned to role groups and, based on privilege levels, have access to only the tasks they require for their job function. By default in Cisco Prime LMS, authenticated users are allowed help desk level access unless specifically configured and assigned to appropriate roles. To restrict access to only configured users, clear the default role option under Admin > System > User Management > Role Management Setup (see Figure 5-66).

**Figure 5-66  Role Management Setup**

Local user accounts are configured to authorize role privileges and can also be used as fallback if the central authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration. (See Figure 5-67.)
Several AAA services are available to externally authenticate users assigned to administer the system. Roles for these individuals are created and managed within the LMS system (see Figure 5-68). As of version 4, LMS no longer supports external authorization.
In the TACACS server configuration, either all accounts or only specified accounts can be allowed for authentication in the event that the ACS server cannot be reached. (See Figure 5-69.)

**Figure 5-69 Login Module Options**

![Login Module Options](image)

The majority of LMS system activities on the server are accomplished through jobs. Each of these jobs tracks the requestor, the success or failure, the type of event, and the systems against which they are executed. The Job Browser shows status of scheduled, current and past jobs. The jobs browser is located at Admin > Jobs > Browser.

To address the Incident Response and Auditing HIPAA Safeguards identified above, additional audit trail information for system configuration changes (for example, changing the authentication mode of the LMS Server from local to TACACS and back to local) require enabling debug mode logging for the Tomcat service. With debug mode enabled, the server is able to capture sufficient information for logging this configuration change and other similar system changes.

To enable debug mode for the Tomcat console, navigate to Admin > System > Debug Settings > Common Services Log Configurations (see Figure 5-70). Select “Console logs from Tomcat” in the component dropdown. Click the Enable radio button and then click Apply.
Enabling debugging may have a significant performance impact on the LMS system, depending on the number of users who are simultaneously accessing and managing the system. All web front end activity is logged in detail.

The “accesslogfilter.log” captures source IP address, date, time, and username for logged-in users as well as failed logins. Failed logins in this log have a “null” username. The attempted usernames of the failed logins appear in the Audit-Log-{date}.CSV report. These reports do not include the user’s source IP address, so some manual correlation must be done between the two logs. These reports are generated at Reports > System Audit Reports > System, or available in \CSCOpx\MDC\log\audit. Information about currently logged-in users is available in Reports > System > Users > Who is logged On.

The “stdout.log” and “accesslogfilter.log” files should be added to the Log Rotation under Admin > System > Log Rotation.

To add these logs to the rotation, click Add at the bottom of the page. (See Figure 5-71.)

In the popup window, set the max file size needed to capture about a day’s worth of information for your environment and usage. Set the number of backups to the maximum of 99. (See Figure 5-72.)
Click **Browse** and navigate to the file location as appropriate for the operating system; for example, C:/PROGRA~2/CSCOpx/MDC/tomcat/logs/stdout.log. (See Figure 5-8.)

Click **OK** to complete the file section, and then **Apply** to complete the addition of the log rotation file.

The Cisco Prime LMS GUI and console scripts support periodic log rotation based on file size and can be configured for the maximum size of the file and number of files to maintain. A script must be created to copy these log files off the system to an external secure repository (for example, a directory on the RSA enVision server) because LMS is not natively capable of sending system events to a centralized repository or ensuring the integrity of the logs to the standards required. This script file should be automated and scheduled to run periodically at least daily (for example, every 1, 2, or 24 hours) via the operating system (Linux, Solaris, Windows) based on the deployment OS. Logs stored locally are buffered and require operator level privileges on the system to be viewed.

Logging enabled by implementing the following configuration statements in the CLI is only for system events such as software updates via the cars application utility:

```
logging 192.168.42.124
logging loglevel 6
```

RSA enVision supports the periodic collection of log files from Cisco LMS versions 3.2 and 4.0. The old method required the daily running of a .VBS script on the server (Windows only) where a file is created in the directory/files/rme/archive directory. It then required the installation of an RSA enVision NIC SFTP Agent, which is used to transfer the log files to the RSA enVision appliance. RSA recently added support for ODBC collection of change audit information from Cisco LMS. It is highly recommended to update to the latest RSA enVision ESU and move to this ODBC method as log collection occurs more frequently. ODBC importing was not validated for LMS at the time of this publication.
To secure authentication information and management of the LMS server and the devices that it manages, addressing Safeguard 164.308(a)(1)(i) Security Management, the LMS system was configured to support only encrypted protocols, as shown in Figure 5-74. Device management preferences are configured in Admin > Collection Settings > Config > Config Transport Settings. Add secure protocols to the list in order of preference and remove insecure protocols for each Application Named function.

Figure 5-74  Device Management Transport Settings

Cisco Prime LMS supports encrypted administrative access via SSH and HTTPS. SSH is enabled by default after installation. HTTPS can be enabled with a self-signed certificate or public certificate. To enforce the use of only SSL for the web interface of LMS, perform the following configurations, as shown in Figure 5-75. These configuration steps can also be found in the LMS 4.2 Administration Guide, page 53.
To enable browser-server security, complete the following steps.

**Procedure**

**Step 1** Select Admin > Trust Management (4.2.2 patch) > Local Server > Browser-Server Security Mode Setup.

The Browser-Server Security Mode Setup dialog box appears.

**Step 2** Select the **Enable** option to enable SSL.

**Step 3** Click **Apply**.

**Step 4** Log out from your Cisco Prime session and close all browser sessions.

**Step 5** Restart the Daemon Manager from the LMS Server CLI.

On Windows:

a. Enter `net stop crmdmgtd`

b. Enter `net start crmdmgtd`

On Solaris/Soft Appliance:

a. Enter `/etc/init.d/dmgtd stop`

b. Enter `/etc/init.d/dmgtd start`

**Step 6** Restart the browser and the Cisco Prime session.

When accessing the LMS CLI, you need to enter the SHELL by using the `shell` command. Then you can execute the stop/start commands for the soft appliance.

If you have issues logging in to LMS (such as long delays), try disabling the launch of the LMS Getting Started page by default (as the first page after log in) by completing the following steps:

a. Open the properties file name “gs.properties” under the following path:

Windows:

`\<<NMS-ROOT>>/MDC/tomcat/webapps/cwlms/WEB-INF/classes/com/Cisco/nm/gs/ui/gs.properties`

Soft appliance:

`./opt/CSCOpx/MDC/tomcat/webapps/cwlms/WEB-INF/classes/com/cisco/nm/gs/ui/gs.properties`

b. Update the field IS_DEFAULT_PAGE as “false”.
c. Clear the browser cache and login-in (Daemon restart not required).

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco LMS supports session policies under the Admin > System > System Preferences tab. It is a best practice to change the session time-out to 15 minutes, as shown in Figure 5-76.

**Figure 5-76   LMS System Preferences for Idle Timeout**

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. The Cisco Prime LMS appliance uses NTP to meet these requirements by implementing the following configuration statements:

```
ntp server 192.168.62.161 192.168.62.162
```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.
HIPAA Standards Failed

No HIPAA standards were failed.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Cisco Security Manager

The Cisco Security Manager is a powerful yet easy-to-use solution for configuring firewall, VPN, and IPS policies on Cisco security appliances, firewalls, routers, and switch modules.

Cisco Security Manager helps enable enterprises to manage and scale security operations efficiently and accurately. Its end-to-end tools provide consistent policy enforcement, quick troubleshooting of security events, and summarized reports from across the security deployment.

Cisco Security Manager enables you to centrally manage security policies over 250 types and models of Cisco security devices. Cisco Security Manager supports integrated provisioning of firewall, IPS, and VPN (most site-to-site, remote access, and SSL) services across the following:

- Cisco IOS/ISR/ASR routers
- Cisco Catalyst switches
- Cisco ASA and PIX security appliances
- Cisco Catalyst Service Modules related to firewall, VPN, and IPS
- Cisco IPS appliances and various service modules for routers and ASA devices

For a complete list of devices and OS versions supported by Cisco Security Manager, see Supported Devices and Software Versions for Cisco Security Manager at the following URL:

The high-performance and easy-to-use integrated event viewer allows you to centrally monitor events from IPS, ASA, and FWSM devices and correlate them to the related configuration policies. This helps identify problems and troubleshoot configurations. Then, using Configuration Manager, you can make adjustments to the configurations and deploy them. Event Viewer supports event management for Cisco ASA, IPS, and FWSM devices.

In addition to the Primary Event Data Store, events can be copied and stored in the Extended Event Data Store. The Extended Event Data Store can be used to back up and archive a larger number of events. This is useful for historical review and analysis of events where Event Viewer can gather event data from both the Primary Event Data Store and the Extended Event Data Store. The Extended Event Data Store can be enabled in Event Management in Security Manager's Administration settings.

For supported platforms and more information, see the “Monitoring and Diagnostics” section of the User Guide for Cisco Security Manager 4.1 at the following URL:

The new integrated report management allows you to generate and schedule ASA, IPS, and remote access VPN reports. Reports for ASA and IPS devices are created by aggregating and summarizing events collected by the Event Viewer. Security reports can be used to efficiently monitor, track, and audit network use and security problems reported by managed devices. Report Manager helps in developing and customizing reports for Cisco ASA and IPS devices.

For supported platforms and more information, see the “Monitoring and Diagnostics” part of the User Guide for Cisco Security Manager 4.1 at the following URL:
Primary PHI Function

The primary function of Cisco Security Manager is to implement security configuration in firewalls, routers, and intrusion detection devices based on policy templates to secure the ePHI data. The Cisco Security Manager allows for the secure configuration of network devices to enforce user access (authorization) to systems containing PHI. Additionally the Cisco Security Manager can run reports on access attempts and can help troubleshoot security events across the infrastructure allowing the organization to monitor access to systems and devices that contain ePHI.

Design Considerations

- Use descriptive notes for each rule set. These are displayed as remarks in the running configuration.
- Virtualize firewall rule set deployment by using a consistent interface naming standard.
- Apply the anti-spoofing feature to all interfaces using FlexConfig.

HIPAA Assessment Detail—HIPAA Safeguards Addressed

HIPAA safeguards are spread across multiple categories. The CSM allows healthcare-covered entities and business associates to meet access control safeguards in the Administrative and Technical categories. The access control can be applied to both internal and external users that access ePHI data.

All of the sample configurations of the CSM shown below were used to meet the following list of satisfied controls:

*Table 5-15 PHI HIPAA Assessment Summary—Cisco Security Manager*

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.
• Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations it might be accessed. Requirements addressed include: Access Control and Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity's or the business associate's access authorization policies, establish, document, review, and modify a user's right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.
• Incident response—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.
  - §164.312(a)(2)(i) Unique User Identification. Assign a unique name and/or number for identifying and tracking user identity. Requirements addressed include: Access Control and Auditing.
• Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.
  - §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

Sample Configuration
Cisco CSM is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.
To secure authentication information and management of the CSM server, addressing Safeguard 164.308(a)(1)(i) Security Management, the CSM management console was configured to support HTTPS access only. Figure 5-77 shows that Cisco Security Manager is configured in Common Services so that only encrypted communications for administration are used, and AAA role setup type was implemented as Cisco Secure ACS and identified the appropriate Cisco Secure ACS servers.

**Figure 5-77 CSM Secure Administration and AAA Policy**

Sample Configuration
Cisco Security Manager is designed to track and monitor all administrative user access and events. To address the Incident Response and Auditing HIPAA safeguards identified above, Cisco Secure CSM can be configured to send its log data to the RSA enVision log management platform.

**Figure 5-78, Figure 5-79, and Figure 5-80 show the Logs, Audit Report, and View Settings screens.**

**Figure 5-78 Logs**
HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of Automatic logoff options. Cisco CSM supports session idle timeout under the Administration Custom Desktop Settings tab. It is a best practice to change the session timeout to 15 minutes, as shown in Figure 5-81.
As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. Time synchronization for Windows servers is specified through the domain policy. Servers synchronize their clocks with the domain controller, which in turn is synchronized using NTP. This implementation of Cisco CSM was Windows-based.

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Encryption**

**RSA Data Protection Manager**

RSA Data Protection Manager (formerly RSA Key Manager) provides encryption, tokenization, and key management capabilities. It can be used to achieve HIPAA requirements for protecting stored ePHI data, regardless of where the information resides.

RSA Data Protection Manager is an easy-to-use management tool for encrypting keys at the database, file server, and storage layers. It is designed to lower the total cost of ownership and simplify the deployment of encryption throughout the enterprise. It also helps properly secure information and enables its accessibility when needed at any point in its lifecycle through a powerful management console and built-in high availability features. RSA Data Protection Manager provides a comprehensive platform for enforcing and managing the security of sensitive data.

**Table 5-16  PHI HIPAA Assessment Summary—Cisco RSA Data Protection Manager**

<table>
<thead>
<tr>
<th>Models Assessed</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSA Data Protection Manager version KM-3.1 / AM-6.1.SP3</td>
</tr>
</tbody>
</table>

**HIPAA Safeguards Addressed**
The primary function of RSA Data Protection Manager is to securely manage the keys that protect ePHI data.

This safeguard was met using the RSA Data Protection Manager to encrypt data in the database, file server, and storage. All ePHI data is encrypted to prevent unauthorized access or modification to the data. Unauthorized access attempts are logged and automatic notification can be sent to authorized personnel. With automated event notification, the RSA Data Protection Manager’s detection capabilities can help an organization quickly identify and contain security violations.

Design Considerations

RSA Data Protection Manager’s encryption and key management capabilities can be used to store the data in a compliant manner. RSA Data Protection Manager provides application development libraries that support a wide range of development languages and enables developers to easily integrate encryption into point-of-sale, payment, CRM, ERP, and other business applications that create or process sensitive information. RSA Data Protection Manager can also be used to encrypt data as it flows to both disk and tape by providing key management services to Cisco MDS or EMC storage systems. Because there were no PHI applications in the simulated lab environment, RSA Data Protection Manager was integrated with Cisco MDS to encrypt all data in the environment regardless of whether it was ePHI data or not.

In an RSA Data Protection Manager deployment, a PKI needs to be set up to enable secure communication between the RSA Data Protection server and its clients. (See Figure 5-82.)
The certificates and credentials that need to be prepared include:

- Client PKCS#12 certificate and key pair—Used to authenticate RSA Data Protection Manager clients to the RSA Data Protection Server
- Server SSL certificate and key pair—Used by RSA Data Protection Manager Clients to authenticate the server
- Trusted CA certificate—Installed on both clients and the server to verify the signature of certificates sent by a peer. For example, a RSA Key Manager Client has a trusted CA certificate to verify the signature of the server certificate.
- Middle CA certificate (optional)—If a certificate is not signed directly by a trusted CA certificate, a middle CA certificate should be installed and sent during SSL connection to verify the certificate chain.

Because of vulnerabilities with RSA signatures with a small public exponent, especially 3, RSA recommends that an exponent of F4 (216+1) be used.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

All of the sample configurations of RSA Data Protection Manager shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical Safeguards.
  - §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

**Sample Configuration**

RSA Data Protection Manager embeds and is protected by RSA Access Manager, which has very powerful and flexible capabilities to define password and account lockout policies and is designed to meet all of the Access Control safeguards above. The included RSA Access Manager Internal Database is used. Within RSA Data Protection Manager (and the included Access Manager), individual user IDs are assigned. Roles are defined and based on group membership.

RSA Data Protection Manager embeds and is protected by RSA Access Manager, which has very powerful and flexible capabilities to define password and account lockout policies that can meet all of the above criteria.

Configuration of user policies is performed via the administration console that can be accessed at the following URL: https://<server address>/admingui/Login.jsp.

*Figure 5-83* shows an appropriate password policy for compliance.
Figure 5-83 Password Policy Settings

RSA Access Manager is designed to track and monitor all administrative user access and events. RSA Access Manager can be configured to send its log data to the RSA enVision log management platform to address the Incident Response and Auditing HIPAA Safeguards identified above. The configuration procedure is documented in the enVision Event Source Configuration Guide for RSA Access Manager, which can be found at RSA Secure Care Online (https://knowledge.rsasecurity.com/).

RSA Data Protection Manager is designed to track and monitor all administrative user access and events. RSA Data Protection Manager can be configured to send its log data to the RSA enVision log management platform to address the Incident Response and Auditing HIPAA Safeguards identified above. The configuration procedure is documented in the enVision Event Source Configuration Guide for RSA Data Protection Manager, which can be found at RSA Secure Care Online (https://knowledge.rsasecurity.com/).
NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. The appliance uses NTP to meet these requirements by specifying the appropriate NTP servers during the installation steps. If NTP servers need to be modified, use the following steps:

1. Open the `/etc/ntp.conf` file.
2. Under the List Servers section, provide the ntp server ip address or host name to the server parameter.
3. Save the `/etc/ntp.conf` file.
4. Execute the following commands (as root) to forcibly synchronize the clock of the appliance to the NTP server:
   a. Stop the NTPD daemon by typing the following:
      ```
      service ntpd stop
      ```
   b. Execute the following command at least three times (to minimize the offset):
      ```
      ntpdate -u <ntpserver>
      ```
   c. Start the NTPD daemon by typing the following:
      ```
      service ntpd start
      ```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Storage**

**EMC SAN Disk Array**

The EMC SAN disk array is used to securely store sensitive compliance data within the data center. Using virtual storage technology, organizations are able to safely combine (in-scope) sensitive data with (out-of-scope) data while maintaining the compliance boundary.

EMC technology combines midrange networked storage with innovative technology and robust software capabilities to manage and consolidate your data.
Chapter 5  Component Assessment

The primary function of the EMC SAN disk array is to store ePHI data. There is no direct PHI requirement for this storage function. This control was met using the EMC SAN Disk Array granular access control to minimize the access to the ePHI data in storage. Additionally the EMC SAN Disk Array can work with application security controls to minimize access privileges to ePHI data. This helps meet the requirement for minimal use by allowing the individual to only access what is needed to perform the job function. Users can be assigned to groups and, based on privilege levels, have access to only the information they require for their job function.

Design Considerations

The EMC SAN disk array is a primary component of VCE Vblock architecture. Vblock 1 is designed for medium-to-high numbers of virtual machines, and is ideally suited to a broad range of usage scenarios, including shared services, e-mail, file and print, virtual desktops, and collaboration.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

HIPAA safeguards are spread across multiple categories. The EMC SAN allows healthcare covered entities and business associates to meet access control safeguards in the Administrative and Technical categories. The access control can be applied to both internal and external users that access ePHI data.

All of the sample configurations of the EMC SAN Disk Array shown below were used to meet the following list of satisfied controls:

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.
Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards

- §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations it might be accessed. Requirements addressed include: Access Control and Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(2)(i) Unique User Identification. Assign a unique name and/or number for identifying and tracking user identity. Requirements addressed include: Access Control and Auditing.

Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

- §164.312(c)(1) Data Integrity. Implement policies and procedures to protect ePHI from improper alteration or destruction. Requirements addressed include: Encryption, Integrity, and Auditing.

Sample Configuration

EMC SAN Disk Array is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. A centralized user database (Active Directory) is accessed by the EMC SAN Disk Array using LDAP services. Individual user IDs are assigned. Roles are defined and based on group membership.

When you start a session, Unisphere prompts you for a username, password, and scope (local, global, or LDAP). These credentials are encrypted and sent to the storage management server. The storage management server then attempts to find a match within the user account information. If a match is found, you are identified as an authenticated user.

Step 1 To configure LDAP authentication, go to the Domains tab, then select Configure LDAP for CLARiiON Systems from the Users menu on the left.

Step 2 Add a new LDAP service by clicking Add and then OK, as shown in Figure 5-84.
Step 3 Configure the LDAP server for Active Directory, as shown in Figure 5-85.

Figure 5-85 Configuring the LDAP Server for Active Directory

Step 4 After communications are established with the LDAP service, specific LDAP users or groups must be given access to Unisphere by mapping them to Unisphere roles. The LDAP service merely performs the authentication. Once authenticated, user authorization is determined by the assigned Unisphere role. The most flexible configuration is to create LDAP groups that correspond to Unisphere roles. This allows you to control access to Unisphere by managing the members of the LDAP groups. Roles were configured as shown in Figure 5-86.
**Step 5**  The Advanced features were left at their default settings, as shown in Figure 5-87.

**Figure 5-87  Advanced Settings**

**Step 6**  You can then log out, and log back in, selecting the **Use LDAP** option for centralized authentication, as shown in Figure 5-88.
EMC CLARiiON is designed to track and monitor all administrative user access and events. To address the Incident Response and Auditing HIPAA safeguards identified above, SP event logs on CLARiiON storage systems can store only a fixed number of events, and wrap if that limit is exceeded. This may take days, weeks, months, or years depending on the logging activity. To keep all logs for a set period of time, you need to archive the logs from the CLARiiON storage system on a regular basis. You can do this with the CLI `getlog` command, but a much more integrated method is to use the “log to system log” option of the Event Monitor template to log events to the Windows system log. You can then archive these logs as required.

Additional SNMP Traps are configured to send event notifications directly and immediately to RSA enVision. (See Figure 5-89.)
To secure authentication and management of the EMC Array, addressing Safeguard 164.308(a)(1)(i) Security Management, when you connect to Unisphere through http://<clariion_ip> (port 80), a Java applet is delivered to the browser on your computer. The applet establishes a secure connection over SSL/TLS (port 443) with the storage management server on the CLARiiON storage system. Therefore, even though “https://” is not displayed in the browser, the connection is secure.

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. EMC CLARiiON uses Network Time Protocol (NTP) to update and synchronize local clock facilities. CLARiion uses the NTP configuration statements shown in Figure 5-90.
Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Monitoring**

**RSA enVision**

RSA enVision is a security information and event management (SIEM) platform that addresses HIPAA safeguards to track and monitor all access to systems and network resources containing ePHI data. RSA enVision does this by collecting, permanently archiving, and processing all the log and event data generated by devices and applications within your network, and generating alerts when it observes suspicious patterns of behavior. Administrators can interrogate the full volume of stored data through an intuitive dashboard, and can use advanced analytical software to gain visibility and understanding of how their network is used and the threats and risks to the infrastructure and applications.

The RSA enVision platform can draw logs from tens of thousands of devices at once, including Cisco network devices, the VCE Vblock infrastructure, the VMware virtual environment, Cisco ASA firewalls, Cisco IPS devices, Cisco IronPort E-mail Appliance, other RSA products, and the HyTrust appliance. Out of the box, RSA enVision can produce compliance reports and alerts based on the log and event data it collects. RSA enVision also offers powerful tools to create custom reports and alerts specific to your environment.
Primary PHI Function

The primary function of RSA enVision is to securely store and correlate the system logs that it receives.

Design Considerations

Depending on the size of your network, RSA enVision may be deployed as a standalone, self-contained, security-hardened appliance or in a distributed deployment to cope with the demands of the largest enterprise networks. When deployed in a distributed architecture, multiple dedicated appliances are deployed where required to perform key roles. Local and remote collectors perform data collection. Data servers manage the data. Application servers perform analysis and reporting. Data itself can be stored using direct attached, online, near-line or offline storage from the full EMC storage portfolio.

RSA enVision does not require any client-side agents to pull log or event data from your infrastructure or applications. RSA enVision can integrate with event sources through standard protocols such as syslog or SNMP by configuring the event source to send data to enVision. For richer event data, enVision integrates with some event sources through their APIs or directly with their database backends. Specific event source device configuration procedures can be found at RSA Secure Care Online (https://knowledge.rsasecurity.com/)

RSA enVision is sold as a standalone appliance. It is available in a variety of hardware options based on the requirements of the enterprise design. The system comes pre-installed on an already hardened operation system.

HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the RSA enVision shown below were used to meet the following list of satisfied controls:

No HIPAA standards were failed.

No HIPAA implementation specifications were failed.
• **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(1)(ii)(D) Information System Activity Review. Implement procedures to regularly review records of information system activity, such as audit logs, access reports and security incident tracking.
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.

• **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed

• **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

**Sample Configuration**
The RSA enVision Internal Database is used (as part of its local Windows Active Directory). For validation, RSA enVision was linked to the centralized user database (Active Directory) using LDAP. Within RSA enVision, individual user IDs are assigned. Roles are defined and based on group membership.

RSA enVision management interfaces implement role-based access control that can be used to restrict access to privileged user IDs, as shown in Figure 5-91.
RSA enVision’s access control system defaults to deny access.

RSA enVision is configurable to use its local Active Directory database, or an external database via LDAP, as shown in Figure 5-92.
RSA enVision is designed to track and monitor all administrative user access and events. To address the Incident Response and Auditing HIPAA safeguards identified above, it performs the role of a central logging repository. RSA enVision collects syslog and SNMP information from all devices to ensure the integrity and correlation of events.

RSA enVision delivers mirrored, unfiltered data to its Internet Protocol Database, which provides the ability to retain data in its original format. Further, “write once, read many” capabilities help ensure that the mirrored copy remains intact, even if the original data is compromised. RSA enVision-captured event logs are stored on a hardened operating system and protected using an integrity check mechanism.

To secure authentication information and management of the RSA enVision server, addressing Safeguard 164.308(a)(1)(i) Security Management, the management console is accessible only via HTTPS.

As a best practice, NTP is used to synchronize clocks among network devices. Time synchronization for this windows server is specified through the Domain Policy because the RSA enVision appliance is itself a Domain Controller. The server synchronizes its clock to know time sources using NTP as specified in the initial appliance setup. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers.

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.
HIPAA Standards Failed

No HIPAA standards were failed.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

HyTrust Appliance

Vblock Infrastructure Platforms from VCE allow organizations to take advantage of the architectural, operational, and financial benefits of virtualization in their PHI infrastructure. HyTrust Appliance (HTA) complements Vblock capabilities by providing:

- Access control for virtual infrastructure including least privilege, separation of duties, and two-factor authentication
- Granular and exhaustive logging and auditing
- Segmentation of infrastructure to support virtualized applications

Virtualized technologies create additional security requirements to ensure that the virtualized environment security controls are appropriate for the data sensitivity. This requirement is consistent with additional risks introduced by mobility and the fast-paced change rate of virtualized assets that can now be reconfigured, relocated, and duplicated by remote administrators. These capabilities combined with poor access control create a significant risk. Hypervisor logs geared toward software maintenance and troubleshooting are obviously useful, but not in the context of a compliance audit.

HyTrust Appliance systematically addresses the three broad areas of IT control objectives (access and user administration, change and configuration, and operations), by proactively enforcing policies for all administrative access, regardless of access method: Secure Shell (SSH) to host, VMware vSphere client to host, or VMware vCenter or any of the programmatic access. HyTrust Appliance provides two-factor authentication and role-based access control, logical segmentation of shared infrastructure, root password vaulting, and audit-quality logs of every attempted access.

Table 5-19 PHI HIPAA Assessment Summary—HyTrust Appliance

No HIPAA standards were failed.
Primary PHI Function

The primary function of HyTrust Appliance is to provide an automated control and audit facility for the virtual infrastructure and cloud stack.

Design Considerations

Define rules and deploy policy to activate protection for the virtual infrastructure.

Administrators can define custom rules that restrict entitlement based on specific virtual infrastructure objects that users need to access and manage. Rules that define entitlement can be based on pre-defined roles or administrators can use custom user-defined roles.

The HyTrust appliance provides complete logging of administrator actions by proxying VMware vCenter client connections to the vSphere management server, and clients that try to connect directly to ESX/ESXi hosts. This logging includes the source IP address of the clients, permitted actions and actions that are blocked because the client may not have sufficient privileges.

HIPAA Assessment Detail—HIPAA Safeguards Passed

The HyTrust Appliance allows for management of user access (authorization) to systems containing ePHI. Additionally, the HyTrust Appliance can prevent unauthorized devices from accessing systems containing ePHI and protect access from unauthorized locations.

The HyTrust Appliance logs can be used to identify unauthorized attempts to connect to systems containing PHI to help meet the supervision requirements.

All of the sample configurations of the HyTrust Appliance shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.
§164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.

§164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

Sample Configuration

The Hytrust Appliance is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. By integrating HyTrust Appliance authentication with Microsoft Active Directory, user accounts and passwords are not managed on the HyTrust Appliance; instead, when authentication is requested by the user, the HyTrust Appliance performs the actual authentication request against Active Directory. Complex AD environments with multiple domains are supported for authentication. Individual user IDs and roles are based on group membership.

The HyTrust Appliance implements a sophisticated policy-driven access control system that makes an authorization decision for every attempted operation in the Vblock environment. The authorization decision is based on the user ID as obtained from the vSphere session, the user function as derived from the user’s assigned role in Active Directory, logical infrastructure segmentation, least privilege role defined for this activity, and object-level policy active for that user.

In the reference implementation, a policy was created that restricted virtual systems to operating only on the PHI portion of the infrastructure and enforced separation of duties between the network administrators and application owners. (See Figure 5-93.)

Figure 5-93  Edit Rule Screen

Policy and privilege definition was performed by a separate group of authorized users, typically security professionals.
The HyTrust Appliance implements default “deny all” access policy. Many of the users that gain access to Vblock infrastructure by the means of HyTrust Appliance proxying their operations do not have privileges to log into the HyTrust Appliance management console.

RSA two-factor authentication is supported, where the user enters the AD password (something they know) in conjunction with an RSA physical token (something they have).

The HyTrust Appliance enables RSA two-factor authentication to work with any methods of access to VMware vSphere or Cisco Nexus 1000V Vblock infrastructure.

The HyTrust Appliance enforces the use of one-time root passwords for all VMware ESX hosts in the environment. Unique random machine-generated passwords of 12 characters in length are set up for each host and rotated every five days (see Figure 5-94). If requested by a privileged user, a different one-time use password was generated and remained valid for a fixed time duration not to exceed 24 hours.

**Figure 5-94 Using Root Passwords**

To secure authentication information and management of the HyTrust and VMware vSphere hosts, addressing Safeguard 164.308(a)(1)(i) Security Management, the HyTrust Appliance configures the virtualization platform (VMware ESX server) to disable unsecure protocols. In addition, the HyTrust Appliance proxies non-console management access and redirects attempts to connect via the HTTP management protocol to HTTPS-based connections. In the reference implementation, the configuration of VMware ESX 4.0 servers was performed in accordance with the HyTrust default configuration template. Specifically, the following controls are set:

```bash
ssh_config: Protocol = 2
sshd_config:
  Protocol = 2
  X11Forwarding = yes
  IgnoreRhosts = yes
  RhostsAuthentication = no
  RhostsRSAAuthentication = no
  HostbasedAuthentication = no
  PermitRootLogin = no
  PermitEmptyPasswords = no
  Banner = /etc/issue.net if not set
```
As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. The HyTrust Appliance uses NTP by specifying the NTP server in the IP settings. (See Figure 5-95.)

Figure 5-95 Specifying the NTP Server

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.
Infrastructure

Routing

Router—Clinic

The primary HIPAA function of the Cisco Integrated Services Router (ISR) is the segmentation of ePHI scope and enforcement of that new scope boundary. The ISR is the component that is used as the main routing and security platform of the clinic. It can securely scale to the requirements of the business because it has integrated firewall, VPN, and IPS/IDS capabilities. WAN options include traditional terrestrial paths using T1, T3, Ethernet, and so on; wireless options include 3G/4G/Wi-Fi modules connecting clinics over public paths for higher availability.

The Cisco ISR consolidates voice, data, and security into a single platform with local and centralized management services. It delivers scalable rich media, service virtualization, and energy efficiency ideal for deployments requiring business continuity, WAN flexibility, and superior collaboration capabilities. The Cisco ISR uses field-upgradeable motherboards, with services such as security, mobility, WAN optimization, unified communications, video, and customized applications.

</table>
Primary PHI Function

The primary function of the Cisco ISR is the segmentation of HIPAA scope and enforcement of that new scope boundary.

It has five primary functions/capabilities in relation to HIPAA.

1. As a router, directing traffic between networks

A router in its simplest form routes between networks. By segmenting a network into sub-networks, an organization can isolate sensitive information from non-sensitive information. The Cisco ISR can segment and route sensitive traffic separately from non-sensitive traffic to reduce the overall scope of a company’s ePHI data environment. Depending on risk vectors within the clinic, different levels of enforcement might be required at the segmented scope boundary level. (See items 2, 3 and 4 following.)

2. As a router with ACLs, restricting traffic between the ePHI data environment and other areas of the network

A router with ACLs can be used to enforce segmented traffic only if the ACLs are used to filter and segment private networks of the organization. They may not be used to filter untrusted networks. For example, many organizations have a central chokepoint in their data center that is the connection to the Internet (an untrusted network). As long as the organization has only untrusted network connections outside of the clinic, (the data center, in this case), then an organization may use router access lists to protect its scope from its own private internal networks. As soon as the clinic connects to untrusted networks directly, items 3 and 4 below become relevant. (See Figure 5-96.)

3. As a stateful firewall, restricting traffic between the ePHI data environment and other areas of the network

As soon as any untrusted network is introduced at the clinic level, stateful firewalling needs to be implemented. The following are examples of untrusted networks:

- The Internet
- Wireless
- Satellite
- 3G/4G cellular backup

Step 8 As an intrusion prevention system, inspecting all traffic going to and from the ePHI data environment.
HIPAA Safeguard 164.308(a)(1)(i) requires policies and procedures to detect security violations. IDS is used to address wherever ePHI is present in the organization to detect for anomalous behavior of the sensitive area. (See Figure 5-97.)

**Figure 5-97 Using Firewall and IDS/IPS**

The Cisco ISR can be used to address segmentation challenges and enforce scope boundaries depending on the levels required by the organization. Each of these features can be enabled by using a license key. This feature is particularly useful for organizations because it does not require a visit to every clinic to enable the firewall/IPS/IDS capability. If these capabilities are not used within the Cisco ISR, an external component(s) can be used to address this level of scope enforcement.

4. As a VPN system, encrypting all traffic going to and from the clinic across open and public networks.

The Cisco ISR can be used to address the need to encrypt the transmission of ePHI data across open, public networks such as 3G/4G/Wi-fi, and satellite technologies using SSL and IPSec technologies.

**Design Considerations**

- The security features of the Cisco ISR routers in the clinic designs are configured using Cisco Security Manager. When adopting this as the primary method of router configuration, Cisco does not recommend making changes directly to the command-line interface (CLI) of the router. Unpredictable results can occur when central and local management are used concurrently.
- The general configuration of the Cisco ISR routers in the clinic designs are maintained with Cisco Prime LMS.
- Firewall rule sets must adhere to a “least amount of access necessary” policy. Rules must be defined by specific source/destination addressing and TCP/UDP ports required for the ePHI data environment (for example, hospitals) networks.
- Enable inspection rules and/or zones on the Cisco ISR router so that the firewall maintains state (none are enabled by default).
- Redundant Cisco IOS firewalls do not have the capability to maintain state between the routers. During a failure, client communication sessions need to be re-established through the alternate router. If high availability with statefulness is a requirement, Cisco ASA firewalls should be used.
• Access into a clinic router from the WAN needs to be protected by a clinic-located firewall filter if the WAN technology is considered untrusted/public (for example, Internet DSL or cable network, public 3G or 4G, satellite). In the Cisco Solution lab, a private MPLS WAN is simulated, and filtering of the clinic traffic occurs on the WAN link of all in-scope locations.

• Disable the HTTP server service on the router and enable the HTTP secure server.

• Disable use of Telnet and enable use of only SSH version 2.

• Configure the session-timeout and exec-timeout commands to 15 minutes or less on the console, VTY, and line interfaces on the router. Disable the AUX interface.

• Configure appropriate banner messages on login, incoming, and exec modes of the router. The login banner warning should not reveal the identity of the company that owns or manages the router. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.

• Configure the primary login authentication of the router to be directed to the Cisco Secure ACS. Individual user account profiles need to be created. Configure secondary or tertiary authentication local to the router itself in the event of a WAN or Cisco Secure ACS failure.

• Use the no service password-recovery command in conjunction with the service password encryption command to prevent password theft by physical compromise of the router.

• Change default passwords and community strings to appropriate complexity.

• Configure logs to be sent to a centralized syslog server, such as RSA enVision.

• Configure NTP to coordinate all logging.

• Disable un-necessary services (for example, Bootp, Pad, ipv6).

• Shutdown unused interfaces.

Each of the clinic designs was implemented using guidance from the following:

• Cisco Enterprise Branch Security Design Guide—

• Branch/WAN Design Zone—

Additional information for router hardening can be found at the following URLs:

• Cisco Guide to Harden Cisco IOS Devices—

• Cisco IOS Security Configuration Guide, Release 12.4—

• Cisco Enterprise Branch Security Design Guide—

• Branch/WAN Design Zone—

• Additional information for router hardening can be found at the following URLs:

• Cisco Guide to Harden Cisco IOS Devices—

• Cisco IOS Security Configuration Guide, Release 12.4—
HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the ISR shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing
  - §164.308(a)(5)(ii)(C) Log-in Monitoring. Procedures for monitoring log-in attempts and reporting discrepancies. Requirements addressed include: Access Control and Auditing
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).
  - §164.312(e)(2)(ii) Encryption. Implement a mechanism to encrypt electronic protected health information whenever deemed appropriate.

- **Incident response**—Implement security incident response as required by HIPAA Administrative Safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

**Sample Configuration**

Cisco ISR routers are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership. The following configurations enable central Authentication, Accounting and Authorization:

```plaintext
aaa new-model
aaa authentication login CiscoACS group tacacs+ local
aaa authentication enable default group tacacs+ enable
aaa authorization exec default group tacacs+ if-authenticated
aaa accounting update newinfo
aaa accounting exec default
```
Local user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration.

```
username bart privilege 15 secret 5 <removed>
username emc-ncm privilege 15 secret 5 <removed>
username bmcgloth privilege 15 secret 5 <removed>
username csmadmin privilege 15 secret 5 <removed>
```

These AAA authentication groups are assigned to the administrative interfaces where users connect:

```
ip http authentication aaa login-authentication CiscoACS
line con 0
  login authentication CiscoACS
line vty 0 4
  login authentication CiscoACS
line vty 5 15
  login authentication CiscoACS
```

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco ISR routers support session timeout. It is a best practice to set the session timeout to 15 minutes, as shown below.

```
ip http timeout-policy idle 900
line con 0
  session-timeout 15 output
  exec-timeout 15 0
line vty 0 4
  session-timeout 15 output
  exec-timeout 15 0
line vty 5 15
  session-timeout 15 output
  exec-timeout 15 0
```

If only the session timeout command is specified, the session timeout interval is based solely on detected input from the user. If the session timeout command is specified with the output keyword, the interval is based on both input and output traffic. You can specify a session timeout on each port. The session-timeout command behaves slightly differently on virtual (vty) terminals than on physical console, auxiliary (aux), and terminal (tty) lines. When a timeout occurs on a vty, the user session returns to the EXEC prompt. When a timeout occurs on physical lines, the user session is logged out and the line returned to the idle state. You can use a combination of the exec-timeout and session-timeout line
configuration commands, set to approximately the same values, to get the same behavior from virtual lines that the session-timeout command causes on physical lines.

To secure authentication information and management of the ISR router, addressing Safeguard 164.308(a)(1)(i) Security Management, the ISR management interfaces were configured to support HTTPS access, and SSH. Before crypto keys can be generated, hostname and domain name must be entered:

```
hostname R-A2-Small-1
ip domain name cisco-irn.com
```

Generate keys with 1024 or larger bit key generation, not the default 512:

```
Crypto key generate rsa 1024
```

Configure the SSH server to use the more secure protocol version SSHv2:

```
ip ssh version 2
```

Configure the HTTP server to use HTTPS, and only more secure ciphers:

```
no ip http server
ip http secure-server
ip http secure-ciphersuite 3des-ede-cbc-sha
```

Cisco ISR routers use firewalling and intrusion detection capabilities to address Safeguard 164.308(a)(1)(i) Security Management by segmenting ePHI networks from other networks and monitoring activity across these networks.

To segment ePHI information, Cisco zone-based firewalls are configured with source and destination zones to control traffic passing from one zone to another. Each of these zone pairs receives a service policy, which is the mechanism that identifies permitted traffic, while all other traffic is dropped and logged.

```
zone-pair security CSM_S_POS-W-S_POS_1 source S_POS-W destination S_POS
    service-policy type inspect CSM_ZBF_POLICY_MAP_18
```

Cisco zone-based firewalls are configurable to perform stateful inspection by use of the inspect statement in the associated class map, policy map, and zone pair service policy statements.

```
class-map type inspect match-all CSM_ZBF_CLASS_MAP_9
    match access-group name CSM_ZBF_CMAP_ACL_9
    match protocol tcp

policy-map type inspect CSM_ZBF_POLICY_MAP_7
    class type inspect CSM_ZBF_CLASS_MAP_9
        inspect Inspect-1
    class type inspect CSM_ZBF_CLASS_MAP_10

    class type inspect CSM_ZBF_CLASS_MAP_11
        inspect Inspect-1
    class class-default
        drop log
```

In the clinic, VLANs are used to segment traffic based on function and security requirements. Each of these VLANs are assigned to an appropriate security zone using the zone-based firewall feature of the router.

```
interface GigabitEthernet0/0.11
    description POS
    zone-member security S_POS

interface GigabitEthernet0/0.13
    description VOICE
```
Cisco routers are capable of performing intrusion detection. Each of the reference designs includes networks where intrusion detection capabilities are required. IPS signature updates and configurations are managed centrally through Cisco Security Manager, which implements the following configuration statements to enable the IPS inspection capability in the routers:

```bash
ip ips config location flash0: retries 1 timeout 1
ip ips notify SDEE
ip ips name CISCO-IPS
!
ip ips signature-category
category all
   retired true
category ios_ips default
   retired false
!
interface GigabitEthernet0/0
description WAN
ip ips CISCO-IPS in
ip ips Store-IPS out
interface GigabitEthernet0/1.11
description POS
ip ips CISCO-IPS in
ip ips CISCO-IPS out
interface GigabitEthernet0/1.15
description WIRELESS-POS
ip ips CISCO-IPS in
ip ips CISCO-IPS out
```

To address the Incident Response and Auditing HIPAA safeguards identified above, Cisco ISR routers can be configured to send log data to the RSA enVision log management platform. Cisco routers track individual administrator actions through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

```bash
logging trap debugging
logging 192.168.42.124
logging buffered 50000

login on-failure log
login on-success log

archive
log config
logging enable
notify syslog contenttype plaintext
hidekeys

And SNMP:

```bash
snmp-server user remoteuser remoteuser remote user 192.168.42.124 v3 access 88
snmp-server user remoteuser remoteuser v3
snmp-server group remoteuser v3 noauth
snmp-server trap-source Loopback0
snmp-server enable traps snmp authentication linkdown linkup coldstart warmstart
snmp-server enable traps envmon fan shutdown supply temperature status
snmp-server enable traps flash insertion removal
snmp-server enable traps energywise
snmp-server enable traps config-copy
snmp-server enable traps config
snmp-server enable traps config-ctid
snmp-server enable traps entity
snmp-server enable traps harp
```
Public WAN link connections include technologies such as DSL, cable, satellite, Wi-Fi, and 3G/4G networks. These are public networks and Safeguard §164.312(e)(2)(ii) Encryption specifies that electronic protected health information is to be encrypted. A VPN is required to securely tunnel traffic between the clinic and the enterprise network across these mediums.

The following example describes equipment located at the clinic and the data center headend router. The clinic router is referred to as the spoke router, and the data center router as the hub. Figure 5-98 shows a simplified Cisco VPN topology.

Cisco VPN technology connects the clinics to the data center over the Internet. As a result, a secure, encrypted tunnel is used to secure sensitive information such as ePHI data. Cisco VPN technologies offer a choice to protect the data in transit and provide a secure access to the clinics’ networks, including Easy VPN and Dynamic Multipoint VPN (DMVPN).

This example shows DMVPN as the VPN technology. DMVPN uses IPSec-encrypted GRE tunnels, with dynamic routing. Two simultaneously active DMVPN tunnels are built from each clinic to different hub routers, providing instant failover. If the primary tunnel fails, routing converges to use the secondary tunnel, and all sessions are kept alive. In addition, with DMVPN, clinic routers can dynamically build spoke-to-spoke tunnels between each other to exchange data, without having to tunnel the traffic back to the hub, thus alleviating the load on the headend.

Following are sample DMVPN spoke and hub configurations. Enhanced Interior Gateway Routing Protocol (EIGRP) is used as the routing protocol inside the DMVPN network. Split-tunneling is used and only traffic on the POS and employee VLANs going to the servers on the 10.0.0.0 network at the headquarters is sent through the DMVPN tunnel, while any other traffic is sent straight to the Internet. Note that, if split-tunneling is not required, a default route (to 0.0.0.0) can be advertised from the hubs to the spokes, instead of specific subnets.

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the
The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco routers use NTP to meet these requirements by implementing the following configuration statements:

```
ntp server 192.168.62.161 prefer
ntp server 192.168.62.162

clock timezone PST -8 0
clock summer-time PDT recurring

service timestamps debug datetime localtime show-timezone
service timestamps log datetime msec localtime show-timezone
```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Routers—Data Center**

The primary function of data center routers from a HIPAA perspective is routing between ePHI networks and out-of-scope networks and enforcing that boundary with firewall services. Data center routers function as WAN aggregation routers or connecting to larger networks such as the Internet. Therefore, performance and scalability are equally important as securely passing data. For this reason, and unlike the routers in the clinic, security functions are typically separated physically into distinct appliances. The Cisco ASR routers were used for the Internet edge and clinic WAN edge portions of the network within the solution testing.

**HIPAA Standards Failed**
Primary ePHI Function

The primary function of the data center routers is the segmentation of ePHI scope and enforcement of that new scope boundary. The data center router has four primary functions/capabilities in relation to HIPAA:

1. As a router, directing traffic between networks
   A router in its simplest form routes between networks. By segmenting a network into sub-networks, an organization can isolate sensitive information from non-sensitive information. Data center routers can segment and route sensitive traffic separately from non-sensitive traffic to reduce the overall scope of a company’s HIPAA ePHI environment. Depending on risk vectors, different levels of enforcement might be required at the segmented scope boundary level. (See items 2, 3, and 4 following.)

2. As a router with ACLs, restricting traffic between the ePHI networks and other areas of the network
   A router with ACLs can be used to enforce segmented traffic only if the ACLs are used to filter and segment private networks of the organization. They may not be used to filter untrusted networks. For example, if a data center router is used to segment sensitive ePHI networks from other internal networks, an organization may use router access lists to protect its scope. As soon as this segment connects to untrusted networks directly, item number 3 becomes relevant.

3. As a stateful firewall, restricting traffic between the ePHI environment and other untrusted areas.
   As soon as any untrusted network is introduced to the connections of the data center router, firewallsing must be deployed. The following are examples of untrusted networks:
   - Internet
   - Wireless
   - Satellite
   - Cellular backup

4. As an intrusion prevention system, inspecting all traffic going to and from the ePHI environment.
   HIPAA Safeguard 164.308(a)(1)(i) requires policies and procedures to detect security violations. IDS is used to address wherever ePHI is present in the organization to detect for anomalous behavior of the sensitive area.

Design Considerations

- Configuration was done manually on the router CLI, and backup of configuration and monitoring of configuration for changes and non-compliance were done through Cisco Prime LMS (alternatively, CiscoWorks Resource Manager Essentials, a component of Cisco LMS, can be used as well).
- Disable the HTTP server service on the router and enable the HTTP secure server.
- Configure the `session-timeout` and `exec-timeout` commands to 15 minutes or less on the console, VTY, and line interfaces on the router. Disable the AUX interface.
- Configure appropriate banner messages on login, incoming, and exec modes of the router. The login banner warning should not reveal the identity of the company that owns or manages the router. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.

- Configure the primary login authentication of the router to be directed to the Cisco Secure ACS. Individual user account profiles need to be created. Configure secondary or tertiary authentication local to the router itself in the event of a WAN or Cisco Secure ACS failure.

- Use the `no service password-recovery` command in conjunction with the `service password encryption` command to prevent password theft by physical compromise of the router.

- Enable anti-spoofing on all interfaces.

- Routers in the data center were implemented using guidance from the following:

  - Enterprise Data Center Design guide based on a Data Center 3.0 Architecture—

  - Enterprise Internet Edge Design Guide—

- For the Internet edge routers, use the access list below on the interface that is facing the Internet. This access list explicitly filters traffic destined for the infrastructure address space. Deployment of edge infrastructure access lists requires that you clearly define your infrastructure space and the required/authorized protocols that access this space. The access list is applied at the ingress to your network on all externally facing connections, such as peering connections, customer connections, and so forth.

```plaintext
!  ip access-list extended COARSE-FILTER-INTERNET-IN
  remark --------------------------------------
  remark ---Block Private Networks---
  deny   ip 10.0.0.0  0.255.255.255 any log
  deny   ip 172.16.0.0 0.15.255.255 any log
  deny   ip 192.168.0.0 0.0.255.255 any log
  remark -
  remark ---Block Autoconfiguration Networks---
  deny   ip 169.254.0.0 0.0.255.255 any log
  remark -
  remark ---Block Loopback Networks---
  deny   ip 127.0.0.0 0.0.255.255 any log
  remark -
  remark ---Block Multicast Networks---
  deny   ip 224.0.0.0 15.255.255.255 any log
  remark -
  remark ---Block Your assigned IP’s at edge---
  deny   ip <YOUR_CIDR_BLOCK> any log
  remark -
  remark ---Allow remaining public internet traffic---
  permit ip any any
!
```

**Note** The `log` keyword can be used to provide additional details about source and destinations for a given protocol. Although this keyword provides valuable insight into the details of access list hits, excessive hits to an access list entry that uses the `log` keyword increase CPU utilization. The performance impact associated with logging varies by platform.
HIPAA Assessment Detail—HIPAA Safeguards Addressed

All of the sample configurations of the Cisco ASR shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

**Sample Configuration**

Cisco ASR routers are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership. The following configurations enable central Authentication, Accounting and Authorization:

```bash
aaa new-model
aaa authentication login CiscoACS group tacacs+ local
aaa authentication enable default group tacacs+ enable
aaa authorization exec default group tacacs+ if-authenticated
aaa accounting update newinfo
aaa accounting exec default start-stop group tacacs+
aaa accounting commands 15 default start-stop group tacacs+
aaa accounting system default start-stop group tacacs+
aaa session-id common
```
Local user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration.

username bart privilege 15 secret 5 <removed>
username bmcgloth privilege 15 secret 4 <removed>
username csmadmin privilege 15 secret 4 <removed>

These AAA authentication groups are assigned to the administrative interfaces where users connect:

ip http authentication aaa login-authentication CiscoACS
line con 0
  login authentication CiscoACS
line vty 0 4
  login authentication CiscoACS
line vty 5 15
  login authentication CiscoACS

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco ASR Routers support session timeout. It is a best practice to set the session timeout to 15 minutes, as shown below.

ip http timeout-policy idle 60 life 86400 requests 10000
line con 0
  session-timeout 15 output
  exec-timeout 15 0
line vty 0 4
  session-timeout 15 output
  exec-timeout 15 0
line vty 5 15
  session-timeout 15 output
  exec-timeout 15 0

If only the session timeout command is specified, the session timeout interval is based solely on detected input from the user. If the session timeout command is specified with the output keyword, the interval is based on both input and output traffic. You can specify a session timeout on each port. The session-timeout command behaves slightly differently on virtual (vty) terminals than on physical console, auxiliary (aux), and terminal (tty) lines. When a timeout occurs on a vty, the user session returns to the EXEC prompt. When a timeout occurs on physical lines, the user session is logged out and the line returned to the idle state. You can use a combination of the exec-timeout and session-timeout line configuration commands, set to approximately the same values, to get the same behavior from virtual lines that the session-timeout command causes on physical lines.

To secure authentication information and management of the ASR router, addressing Safeguard 164.308(a)(1)(i) Security Management, the ASR management interfaces were configured to support HTTPS access, and SSH. Before crypto keys can be generated hostname and domain name must be entered:

hostname RWAN-1
ip domain name cisco-irn.com
Generate keys with 1024 or larger bit key generation, *not* the default 512.

\[
\text{Crypto key generate rsa 1024}
\]

Configure the SSH server to use the more secure protocol version SSHv2.

\[
ip ssh version 2
\]

Configure the HTTP server to use HTTPS, and only more secure ciphers:

\[
\text{no ip http server}
\]
\[
ip http secure-server
\]
\[
ip http secure-ciphersuite 3des-ede-cbc-sha
\]

Configure the use of Secure Copy in place of TFTP:

\[
ip scp server enable
\]

To address the Incident Response and Auditing HIPAA safeguards identified above, Cisco ASR Routers can be configured to send log data to the RSA enVision log management platform. Cisco routers track individual administrator actions through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

\[
\text{logging trap debugging}
\]
\[
\text{logging 192.168.42.124}
\]
\[
\text{logging buffered 50000}
\]
\[
\text{login on-failure log}
\]
\[
\text{login on-success log}
\]
\[
\text{archive log config}
\]
\[
\text{logging enable}
\]
\[
\text{notify syslog contenttype plaintext hidekeys}
\]

And SNMP:

\[
\text{snmp-server engineID remote 192.168.42.124 0000000000}
\]
\[
\text{snmp-server user remoteuser remoteuser remote 192.168.42.124 v3 access 88}
\]
\[
\text{snmp-server user remoteuser remoteuser v3}
\]
\[
\text{snmp-server group remoteuser v3 noauth}
\]
\[
\text{snmp-server trap-source Loopback0snmp-server enable traps snmp authentication linkdown}
\]
\[
\text{linkup coldstart warmstart}
\]
\[
\text{snmp-server enable traps envmon fan shutdown supply temperature status}
\]
\[
\text{snmp-server enable traps flash insertion removal}
\]
\[
\text{snmp-server enable traps energywise}
\]
\[
\text{snmp-server enable traps config-copy}
\]
\[
\text{snmp-server enable traps config}
\]
\[
\text{snmp-server enable traps config-ctid}
\]
\[
\text{snmp-server enable traps entry}
\]
\[
\text{snmp-server enable traps hsrp}
\]
\[
\text{snmp-server enable traps cpu threshold}
\]
\[
\text{snmp-server enable traps rsrp}
\]
\[
\text{snmp-server enable traps syslog}
\]
\[
\text{snmp-server enable traps vtp}
\]
\[
\text{snmp-server enable traps ipsla}
\]
\[
\text{snmp-server host 192.168.42.124 remoteuser}
\]

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the
data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco routers use NTP to meet these requirements by implementing the following configuration statements:

```
ntp server 192.168.62.161 prefer
ntp server 192.168.62.162

clock timezone PST -8 0
clock summer-time PSTDST recurring

service timestamps debug datetime localtime show-timezone
service timestamps log datetime msec localtime show-timezone
```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Switching**

**Switches—Clinic**

Cisco branch switches provide connectivity for wired endpoints and the ability to segment them onto their own sensitive scope networks. Virtual local area networks (VLANs) are used to put sensitive ePHI applications and devices onto their own network and segregate them from devices that are on non-sensitive networks.

- Cisco branch switches are stackable, expandable switches that can be used for wired device port density in branch wiring closets. Access switches offer a variety of modular and fixed configuration options, and feature operational efficiency with StackPower, FlexStack, and NetFlow to increase visibility and control.
- Core/distribution—Highly redundant, powerful core switches allow for the most demanding business requirements of the healthcare organization. Modular functionality provides the ability to insert security technology as the needs of the business expand into new areas.

**Primary PHI Function**

The primary HIPAA compliance feature of clinic switches is to provide secure wired port access.

Clinic switches also provide compliance via segmentation of sensitive networks from out-of-scope networks. Switches extend that Layer 3 boundary to Layer 2. Using VLANs, Cisco clinic switches allow organizations to put their networks into separate VLANs (scopes) from other non-sensitive data (out-of-scope).

Figure 5-99 shows an example of switch segmentation.
Although the enforcement of these boundaries would be handled by either a router or firewall, the switch provides the port density and access required to connect the devices from the clinic floor.

**Design Considerations**

- The configurations of the Cisco Catalyst switches in the clinic architectures are maintained within Cisco Prime LMS (alternatively CiscoWorks Resource Manager Essentials, a component of C-LMS, can be used as well).
- The use of VLANs on the Cisco Catalyst switch enables the organization to provide same-box wired access to its devices while maintaining segregated addressing schemes.
- Disable the HTTP server on the switch and enable the HTTP secure server.
- Using the stacking capability of Cisco Catalyst switches improves high availability designs while simplifying configuration and support.
- Cisco SmartPorts simplifies connecting the right device to the right VLAN.
- Network Admission Control (NAC) protects the network from rogue devices being connected.
- Cisco compact switches can easily add more securely managed ports where needed (for example, Cash Wrap and customer service desk), and some models can use PoE.
- Set the `session` and `exec timeout` commands to 15 minutes or less.
- Configure appropriate banner messages on login, incoming, and exec modes of the switch. The login banner warning should not reveal the identity of the company that owns or manages the switch. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.
- Configure the primary login authentication of the switch to be directed to the Cisco Secure ACS. Individual user account profiles need to be created. Configure secondary or tertiary authentication local to the switch itself in the event of a WAN or Cisco Secure ACS failure.
- Use the `no service password-recovery` command in conjunction with the `service password encryption` command to prevent password theft by physical compromise of the switch.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

All of the sample configurations of the Cisco clinic switches shown below were used to meet the following list of satisfied controls:
• **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

• **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

• **Integrity**—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.
  - §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.
  - §164.312(e)(1) Transmission Security. Implement technical security measures to guard against unauthorized access to ePHI that is being transmitted over an electronic communications network. Requirements addressed include: Encryption and Integrity.
  - §164.312(e)(2)(i) Integrity Controls. Implement security measures to ensure that ePHI is not improperly modified without detection until disposed of. Requirements addressed include: Integrity.
  - §164.312(e)(2)(ii) Encryption. Implement a mechanism to encrypt ePHI whenever deemed appropriate. Requirements addressed include: Encryption.

• **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(i) Security Incident Procedures. Implement policies and procedures to address security incidents.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

**Sample Configuration**
Cisco switches are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.
aaa new-model
aaa authentication login CiscoACS group tacacs+ local
aaa authentication enable default group tacacs+ enable
aaa authorization exec default group tacacs+ if-authenticated
aaa accounting update newinfo
aaa accounting exec default start-stop group tacacs+
aaa accounting commands 15 default start-stop group tacacs+
aaa accounting system default start-stop group tacacs+
aaa session-id common
tacacs-server host 192.168.42.131
tacacs-server directed-request
tacacs-server domain-stripping
tacacs-server key 7 <removed>

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration.

username bart privilege 15 secret 5 <removed>
username emc-ncm privilege 15 secret 5 <removed>
username bmcgloth privilege 15 secret 5 <removed>
username csadmin privilege 15 secret 5 <removed>

These AAA authentication groups are assigned to the administrative interfaces where users connect.

ip http authentication aaa login-authentication CiscoACS
line con 0
login authentication CiscoACS
line vty 0 4
login authentication CiscoACS
line vty 5 15
login authentication CiscoACS

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco Clinic switches supports session timeout. It is a best practice to set the session timeout to 15 minutes, as shown below.

ip http timeout-policy idle 900
line con 0
  session-timeout 15 output
  exec-timeout 15 0
line vty 0 4
  session-timeout 15 output
  exec-timeout 15 0
line vty 5 15
  session-timeout 15 output
  exec-timeout 15 0

To secure authentication information and management of the clinic switch, addressing Safeguard 164.308(a)(1)(i) Security Management, the clinic switch management interfaces were configured to support HTTPS access, and SSH. Before crypto keys can be generated hostname and domain name must be entered:

hostname S-A2-MED-1/2
ip domain name cisco-irn.com

Generate keys with 1024 or larger bit key generation, not the default 512.

Crypto key generate rsa 1024
Configure the SSH server to use the more secure protocol version SSHv2:

```plaintext
ip ssh version 2
```

Configure the HTTP server to use HTTPS, and only more secure ciphers:

```plaintext
no ip http server
ip http secure-server
ip http secure-ciphersuite 3des-ede-cbc-sha
```

Configure the use of Secure Copy in place of TFTP:

```plaintext
ip scp server enable
```

Cisco switches are able to track and monitor all administrative user access, events such as port up/down, as well as device authentication events when using 802.1x. See Cisco ISE for more information regarding port authentication.

To address the Incident Response and Auditing HIPAA safeguards identified above, Cisco Switches can be configured to send log data to the RSA enVision log management platform. Cisco switches track individual administrator actions through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

```plaintext
logging trap debugging
logging 192.168.42.124
logging buffered 50000

login on-failure log
login on-success log

archive
log config
logging enable
notify syslog contenttype plaintext
hidekeys

And SNMP:

```plaintext
snmp-server user remoteuser remoteuser remoteuser remoteuser 192.168.42.124 v3 access 88
snmp-server user remoteuser remoteuser remoteuser v3
snmp-server group remoteuser v3 noauth
snmp-server trap-source Loopback0
snmp-server enable traps snmp authentication linkdown linkup coldstart warmstart
snmp-server enable traps config-copy
snmp-server enable traps config

snmp-server enable traps envm-on fan shutdown supply temperature status
```
snmp-server enable traps errdisable
snmp-server enable traps mac-notification change move threshold
snmp-server enable traps vlan-membership
snmp-server host 192.168.42.124 remoteuser

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco switches use NTP to meet these requirements by implementing the following configuration statements:

ntp server 192.168.62.161 prefer
ntp server 192.168.62.162
clock timezone PST -8 0
clock summer-time PSTDST recurring

service timestamps debug datetime localtime show-timezone
service timestamps log datetime msec localtime show-timezone

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Cisco Catalyst Switches—Data Center**

The Cisco Catalyst family of data center switches are designed to securely switch data from servers to high speed trunks, maintaining the integrity of segmented scopes of compliance. They provide scalable inter-switch connectivity, high port density for wired endpoints, and the ability to segment them into sensitive scope networks. VLANs are used to put sensitive ePHI applications and devices onto their own network and segregate them from devices that are on non-sensitive networks. Data center Cisco Catalyst switches are highly redundant, capable of delivering high performance switching, with feature options depending on the needs of the business.

Modular functionality provides the ability to insert security technology to enforce compliance needs.

- Security services include access control, firewall, and intrusion prevention.
- Wireless services can be aggregated into these switches for central policy control of unified wireless access points.
- Application services include quality of service (QoS), content filtering, and load balancing.

HIPAA Standards Failed
No HIPAA standards were failed.

HIPAA Implementation Specifications Failed
No HIPAA implementation specifications were failed.

Figure 5-100  Cisco Catalyst Data Center Switches

- Catalyst Switches with Services Modules
- VLAN Routing
- Firewall Segmentation
- Load Balancing
- Content Inspection and Filtering
- Intrusion Detection and Prevention
- Wireless Services Control
The primary function of the Cisco Catalyst data center switches is segmentation of scope and enforcement of that new scope boundary. These switches have five primary functions/capabilities in relation to HIPAA:

- Using VLANs, Cisco Catalyst switches allow an organization to put its ePHI networks into separate VLANs (scopes) from other non-sensitive data (out of scope).
- The Layer 3 Cisco Catalyst switch acts as a router, directing traffic between networks. By segmenting a network into sub-networks, an organization can isolate sensitive information from non-sensitive information. The Cisco Catalyst switch can perform the ability to segment and route sensitive traffic from non-sensitive and reduce the overall scope of a company’s ePHI data environment. Depending on risk vectors, different levels of enforcement are required at the segmented scope boundary level. See the following bullets for details.
- The Layer 3 Cisco Catalyst switch acts as a router with ACLs, restricting traffic between the ePHI data environment and other areas of the network. A Cisco Catalyst switch with ACLs can be used to enforce segmented traffic if the ACLs are used only to filter and segment private networks of the organization. ACLs may not be used to segment untrusted networks.
- The Cisco Catalyst switch with a firewall service module restricts traffic between the ePHI data environment and other areas of the network. As soon as any untrusted network is introduced, firewallsing must be deployed.
- The Layer 3 Cisco Catalyst switch with an intrusion prevention module inspects all traffic going to and from the ePHI data environment. HIPAA Safeguard 164.308(a)(1)(i) requires policies and procedures to detect security violations. IDS is used to address wherever ePHI is present in the organization to detect for anomalous behavior of the sensitive area.

**Design Considerations**

- The configurations of the Cisco Catalyst switches in the data center and Internet edge architectures are maintained within Cisco Prime LMS (alternatively CiscoWorks Resource Manager Essentials, a component of C-LMS, can be used as well).
- The use of VLANs on the Cisco Catalyst switch enables the organization to provide same-box wired access to its devices while maintaining segregated addressing schemes.
- Using the stacking capability of Cisco Catalyst switches improves high availability designs while simplifying configuration and support.
- Disable the HTTP server on the switch and enable the HTTP secure server.
- Set the **session** and **exec timeout** commands to 15 minutes or less.
- Configure appropriate banner messages on login, incoming, and exec modes of the switch. The login banner warning should not reveal the identity of the company that owns or manages the switch. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.
- Configure the primary login authentication of the switch to be directed to the Cisco Secure ACS. Individual user account profiles need to be created. Configure secondary or tertiary authentication local to the switch itself in the event of a WAN or Cisco Secure ACS failure.
- Use the **no service password-recovery** command in conjunction with the **service password encryption** command to prevent password theft by physical compromise of the switch.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

All of the sample configurations of the Cisco Catalyst data center switches shown below were used to meet the following list of satisfied controls:
Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards

- §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

- §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

- §164.312(e)(1) Transmission Security. Implement technical security measures to guard against unauthorized access to ePHI that is being transmitted over an electronic communications network. Requirements addressed include: Encryption and Integrity.

- §164.312(e)(2)(i) Integrity Controls. Implement security measures to ensure that ePHI is not improperly modified without detection until disposed of. Requirements addressed include: Integrity.

- §164.312(e)(2)(ii) Encryption. Implement a mechanism to encrypt ePHI whenever deemed appropriate. Requirements addressed include: Encryption.

Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

- §164.308(a)(6)(i) Security Incident Procedures. Implement policies and procedures to address security incidents.

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

Sample Configuration
Cisco switches are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

username csmadmin privilege 15 secret 5 <removed>

These AAA authentication groups are assigned to the administrative interfaces where users connect.

ip http authentication aaa login-authentication CiscoACS
line con 0
  login authentication CiscoACS
line vty 0 4
  login authentication CiscoACS
line vty 5 15
  login authentication CiscoACS

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco data center switches support session timeout. It is a best practice to set the session timeout to 15 minutes, as shown below.

ip http timeout-policy idle 900
line con 0
  session-timeout 15 output
  exec-timeout 15 0
line vty 0 4
  session-timeout 15 output
  exec-timeout 15 0
line vty 5 15
  session-timeout 15 output
  exec-timeout 15 0

To secure authentication information and management of the Cisco data center switches, addressing Safeguard 164.308(a)(1)(i) Security Management, the Cisco data center switches management interfaces were configured to support HTTPS access, and SSH. Before crypto keys can be generated hostname and domain name must be entered:

hostname S-A2-MED-1/2
ip domain name cisco-irn.com

Generate keys with 1024 or larger bit key generation, not the default 512.

Crypto key generate rsa 1024
Configure the SSH server to use the more secure protocol version SSHv2:

```
ip ssh version 2
```

Configure the HTTP server to use HTTPS, and only more secure ciphers:

```
no ip http server
ip http secure-server
ip http secure-ciphersuite 3des-ede-cbc-sha
```

Configure the use of Secure Copy in place of TFTP

```
ip scp server enable
```

Cisco switches are able to track and monitor all administrative user access, events such as port up/down, as well as device authentication events when using 802.1x. See Cisco ISE for more information regarding port authentication.

To address the Incident Response and Auditing HIPAA safeguards identified above, Cisco Switches can be configured to send log data to the RSA enVision log management platform. Cisco switches track individual administrator actions through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

```
logging trap debugging
logging 192.168.42.124
logging buffered 50000

login on-failure log
login on-success log

archive
log config
logging enable
notify syslog contenttype plaintext
hidekeys
```

And SNMP:

```
snmp-server user remoteuser remoteuser remote 192.168.42.124 v3 access 88
snmp-server user remoteuser remoteuser v3 noauth
snmp-server group remoteuser v3 noauth
snmp-server trap-source Loopback0
snmp-server enable traps snmp authentication linkdown linkup coldstart warmstart
snmp-server enable traps config-copy
snmp-server enable traps config
snmp-server enable traps config-ctid
snmp-server enable traps dot1x auth-fail-vlan guest-vlan no-auth-fail-vlan no-guest-vlan
snmp-server enable traps energwise
snmp-server enable traps entity
snmp-server enable traps hsrp
snmp-server enable traps power-ethernet group 1-4
snmp-server enable traps power-ethernet police
snmp-server enable traps cpu threshold
snmp-server enable traps rtr
snmp-server enable traps bridge newroot topologychange
snmp-server enable traps syslog
snmp-server enable traps vtp
snmp-server enable traps vlancreate
snmp-server enable traps vlancedelete
snmp-server enable traps flash insertion removal
snmp-server enable traps port-security
snmp-server enable traps envmon fan shutdown supply temperature status
snmp-server enable traps errdisable
```
snmp-server enable traps mac-notification change move threshold
snmp-server enable traps vlan-membership
snmp-server host 192.168.42.124 remoteuser

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco switches use NTP to meet these requirements by implementing the following configuration statements:

ntp server 192.168.62.161 prefer
ntp server 192.168.62.162

clock timezone PST -8 0
clock summer-time PSTDST recurring

service timestamps debug datetime localtime show-timezone
service timestamps log datetime msec localtime show-timezone

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

HIPAA Standards Failed

No HIPAA standards were failed.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Cisco Nexus 1000V Switch—Data Center

The Cisco Nexus 1000V Series Switch provides connectivity for virtual servers with the ability to segment them on their own sensitive scope networks. VLANs are used to put sensitive PHI applications and devices on their own network and segregate them from devices that are on non-sensitive networks.

The Cisco Nexus 1000V Series Switch provides advanced networking functions and a common network management model in a virtualized server environment. The Cisco Nexus 1000V Series Switch replaces the virtual switching functionality of the VMware vCenter data center container of servers. Each server in the data center container is represented as a line card in the Cisco Nexus 1000V Series Virtual Supervisor Module (VSM) and is managed as if it were a line card in a physical Cisco switch.

Key benefits of the Nexus 1000V include the following:

- Policy-based virtual machine (VM) connectivity
- Mobile VM security and network policy
- Non-disruptive operational model for your server virtualization, and networking teams

Table 5-24 PHI HIPAA Assessment Summary—Cisco Nexus 1000V Switch

<table>
<thead>
<tr>
<th>Models Assessed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco Nexus 1000V version 4.2(1)SV1(4)</td>
</tr>
</tbody>
</table>
The primary HIPAA compliance feature of Cisco Nexus switches is secure aggregation and access layer connectivity.

- Using VLANs, Cisco Nexus switches allow an organization to put its ePHI network into separate VLANs (scopes) from other non-sensitive data (out of scope).
- The Layer 3 Cisco Nexus switch acts as a router, directing traffic between networks. By segmenting a network into sub-networks, an organization can isolate sensitive information from non-sensitive information. The Cisco Nexus switch can segment and route sensitive traffic separately from non-sensitive traffic to reduce the overall scope of a company’s ePHI data environment. Depending on risk vectors, various levels of enforcement are required at the segmented scope boundary level.
- The Layer 3 Cisco Nexus switch acts as a router with ACLs, restricting traffic between the ePHI data environment and other areas of the network. A Cisco Nexus switch with ACLs can be used to enforce segmented traffic if the ACLs are used only to filter and segment private networks of the organization. ACLs may not be used to segment untrusted networks.
- The Cisco Nexus switch uses virtualization contexts, which are essentially virtualized switches. Each virtualized context has its own configuration and management interfaces that can be used to segregate not only data but administration as well.

### Design Considerations

The Cisco Nexus 1000V Series Switch includes the Cisco Integrated Security features that are found on Cisco physical switches to prevent a variety of attack scenarios. For example, a rogue virtual machine can spoof its MAC and IP addresses so that it appears to be an existing production virtual machine, send a rogue Address Resolution Protocol (ARP) transaction mimicking the way that VMware vMotion announces the location of a migrated virtual machine, and divert traffic from the production virtual machine to the rogue virtual machine. With Cisco Integrated Security features, this type of attack can...
easily be prevented with simple networking policy. Because server virtualization is being used for
desktop and server workloads, it is critical that this type of security feature be deployed for the proper
operation of a virtualized environment.

The Cisco Nexus 1000V Series implementation has two primary components:

- Virtual Supervisor Module (VSM)
- Virtual Ethernet module (VEM)

The Cisco Nexus 1000V VSM is installed as an appliance server on either a standalone Cisco UCS server
(Cisco Nexus 1010) or as a virtual appliance on VMware ESXi server running on a blade of the
Cisco UCS system.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

All of the sample configurations of the Cisco Nexus 1000V Series Switch shown below were used to
meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical
  safeguards

- §164.308(a)(1)(i) Security Management Process. Implement policies and procedures to prevent,
detect, contain, and correct security violations. Requirements addressed include: Access Control,
  Integrity, Incident Response, and Auditing.

- §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization
  and/or supervision of workforce members who work with ePHI or in locations where it might be
  accessed. Requirements addressed include: Auditing.

- §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is
  part of a larger organization, the clearinghouse must implement policies and procedures that protect
  the electronic protected health information of the clearinghouse from unauthorized access by the
  larger organization. Requirements addressed include: Access Control, Integrity, Incident Response,
  and Auditing.

  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting
    access to electronic protected health information, for example, through access to a workstation,
    transaction, program, process, or other mechanism. Requirements addressed include: Access
    Control and Auditing.

  - §164.308(a)(5)(ii)(C) Log-in Monitoring. Procedures for monitoring log-in attempts and
    reporting discrepancies. Requirements addressed include: Access Control and Auditing.

  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic
    information systems that maintain ePHI to allow access only to those persons or software
    programs that have been granted access rights as specified in §164.308(a)(4).

- **Incident response**—Implement security incident response as required by HIPAA Administrative
  safeguards.

  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known
    security incidents; mitigate, to the extent practicable, harmful effects of security incidents that
    are known to the covered entity or business associate; and document security incidents and their
    outcomes. Requirements addressed include: Incident Response and Auditing.

- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use
  ePHI as required by HIPAA Technical Safeguards.

  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that
    record and examine activity in information systems that contain or use electronic protected
    health information. Requirements addressed include: Auditing.
Sample Configuration
Cisco Nexus 1000V is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

To enable central authentication, you first have to enable the TACACS+ feature on the Cisco Nexus 1000V:

```
config t
feature tacacs+
```

The following commands show how to configure the TACACS+ server:

```
tacacs-server key 7 password
```
```
tacacs-server host 192.168.42.131
```
```
aaa group server tacacs+ CiscoACS
```
```
server 192.168.42.131
```
```
use-vrf management
```
```
source-interface mgmt0
```
```
aaa group server tacacs+ tacacs
```
```
aaa authentication login default group CiscoACS
```
```
aaa authentication login console group CiscoACS
```

Number 7 in the key command specifies an encrypted string (key) to follow.

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords. Configure the local user with encrypted passwords for fallback authentication:

```
username janoff password 5 <removed>  role network-admin
```
```
username bart password 5 <removed>  role network-operator
```

Both roles used in the `username` commands are pre-defined roles in the Cisco Nexus 1000V. The network admin role has access to all commands on the switch, whereas the network operator role has access to all read commands on the switch.

To address the Incident Response and Auditing HIPAA safeguards identified above, Cisco Nexus 1000V can be configured to send its log data to the RSA enVision log management platform. Cisco Nexus switches track individual administrator actions through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

```
logging server 192.178.42.124 6 facility syslog
```
```
aaa accounting default group CiscoACS
```

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco Nexus 1000V supports session timeout, it is a best practice to set session timeout to 15 minutes, as shown below.

```
line vty
exec-timeout 15
```
```
line console
exec-timeout 15
```

NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The
Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco Nexus switches use NTP to meet these requirements by implementing the following configuration statements.

```plaintext
enable NTP
ntp server 192.168.62.161 use-vrf management
ntp server 192.168.62.162 use-vrf management
clock timezone PST -8 0
clock summer-time PST 1 Sun Apr 02:00 5 Sun Oct 02:00 60
```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Cisco Nexus Switches—Data Center**

The Cisco Nexus family of data center switches is designed to securely switch data from healthcare application servers to high speed trunks of the core, maintaining the integrity of segmented scopes of compliance. They provide scalable inter-switch connectivity and high port density for wired endpoints. VLANs are used to put sensitive applications and devices onto their own network and segregate them from devices on non-sensitive networks.

Cisco Nexus switches are ideal for enterprise-class server and aggregation layer deployments. These multipurpose, multilayer switches can be deployed across a diverse set of traditional, virtualized, unified, and high-performance computing environments. They enable diverse transports over Ethernet (including Layer 2, Layer 3, and storage traffic) on one common platform. Nexus switches help transform your data center, with a standards-based, multipurpose, multiprotocol, Ethernet-based fabric.

Primary PHI Function

The primary HIPAA compliance feature of Cisco Nexus data center switches is secure aggregation and access layer connectivity.

- Using VLANs, Cisco Nexus switches allow an organization to put its ePHI network into separate VLANs (scopes) from other non-sensitive data (out of scope).
- The Layer 3 Cisco Nexus switch acts as a router, directing traffic between networks. By segmenting a network into sub-networks, an organization can isolate sensitive information from non-sensitive information. The Cisco Nexus switch can segment and route sensitive traffic separately from non-sensitive traffic to reduce the overall scope of a company’s ePHI data environment. Depending on risk vectors, various levels of enforcement are required at the segmented scope boundary level.
- The Layer 3 Cisco Nexus switch acts as a router with ACLs, restricting traffic between the ePHI data environment and other areas of the network. A Cisco Nexus switch with ACLs can be used to enforce segmented traffic if the ACLs are used only to filter and segment private networks of the organization. ACLs may not be used to segment untrusted networks.
- The Cisco Nexus switch uses virtualization contexts, which are essentially virtualized switches. Each virtualized context has its own configuration and management interfaces that can be used to segregate not only data but administration as well.

Design Considerations

- Configuration was done manually on the router CLI, and backup of configuration and monitoring of configuration for changes and non-compliance were done through the Cisco Prime LMS (alternatively CiscoWorks Resource Manager Essentials, a component of C-LMS, can be used as well).
- Configure appropriate banner messages on login, incoming, and EXEC modes of the router. The login banner warning should not reveal the identity of the company that owns or manages the router. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.
- Configure the primary login authentication of the router to be directed to the Cisco Secure ACS. Individual user account profiles need to be created. Configure secondary or tertiary authentication local to the router itself in the event of a WAN or Cisco Secure ACS failure.
- Nexus switches in the data center were implemented using guidance from the Enterprise Data Center Design guide based on a Data Center 3.0 Architecture:
  Enterprise Internet Edge Design Guide:
The Cisco Nexus 7010 and the Cisco Nexus 5000 were used for the aggregation block portions of the lab validation network.

**HIPAA Assessment Detail—HIPAA Safeguards Addressed.**

All of the sample configurations of the Cisco Nexus data center switches shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a health care clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

**Sample Configuration**

Cisco Nexus switches are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.
To enable central authentication, you first have to enable the TACACS+ feature on the Cisco Nexus 1000V:

```
config t
  feature tacacs+
```

The following commands show how to configure the TACACS+ server:

```
tacacs-server key 7 "<removed>
  tacacs-server host 192.168.42.131
  aaa group server tacacs+ CiscoACS
    server 192.168.42.131
    use-vrf management
    source-interface mgmt0
  aaa group server tacacs+ tacacs
  aaa authentication login default group CiscoACS
  aaa authentication login console group CiscoACS

Number 7 in the key command specifies an encrypted string (key) to follow.

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords. Configure the local user with encrypted passwords for fallback authentication:

```
username janoff password 5 <removed>  role network-admin
username bart password 5 <removed>  role network-operator
```

Both roles used in the `username` commands are pre-defined roles in the Cisco Nexus 1000V. The network admin role has access to all commands on the switch, whereas the network operator role has access to all read commands on the switch.

To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco Nexus 1000v can be configured to send its log data to the RSA enVision log management platform. Cisco Nexus switches track individual administrator actions through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

```
logging server 192.178.42.124 6 facility syslog
!
! --- for implementations using VRF's ----
!
logging server 192.168.42.124 6 use-vrf servers1

aaa accounting default group CiscoACS
```

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco Nexus 1000V supports session timeout, it is a best practice to set session time-out to 15 minutes, as shown below.

```
line vty
  exec-timeout 15
line console
  exec-timeout 15
```

NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco Nexus switches use NTP to meet these requirements by implementing the following configuration statements.

```
! NTP can only be configured in the default VDC
```
enable NTP
tp server 192.168.62.161 use-vrf management
ntp server 192.168.62.162 use-vrf management
clock timezone PST -8 0
clock summer-time PST 1 Sun April 02:00 5 Sun Oct 02:00 60

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Wireless**

Cisco Wireless technologies provide connectivity for mobile clients within the clinic. They are designed to securely connect traditional business functions such as guest access, without increasing risk. In addition to expanding business functionality, Cisco wireless technology seamlessly provides the capability to detect rogues.

Cisco Aironet access points are designed to provide industry-leading performance to enable highly secure and reliable wireless connections for both indoor and outdoor environments. Cisco offers a broad portfolio of access points targeted to specific business needs and topologies.

Cisco wireless controllers help reduce the overall operational expenses of Cisco Unified Wireless Networks by simplifying network deployment, operations, and management. They extend policy and security from the wired network to the wireless edge.

Cisco Wireless Control System (WCS) delivers full visibility and control of Cisco Aironet access points, Cisco Wireless LAN Controllers (WLC) and the Cisco Mobility Services Engine (MSE) with built-in support for Cisco adaptive wireless intrusion prevention systems (wIPS) and Cisco context-aware services. This robust platform helps you reduce total cost of ownership and maintain a business-ready wireless network.

Primary PHI Function

The primary ePHI function of Cisco Unified Wireless is secure connectivity and authentication of wireless clients as well as rogue device detection.

Design Considerations

Wireless technology in the PHI environment is a growing concern for organizations in the healthcare field. Implementing wireless requires that appropriate security controls are in place to prevent, detect and respond to security violations. A hacker might infiltrate a PHI environment and install a rogue wireless device (for example, access point, wireless-enabled printer, or radio-enabled USB stick). This would allow a hacker remote access into the PHI environment (from the parking lot, for example) that is hard to detect. There are several methods for detecting rogue devices. Cisco Unified Wireless offers the benefit of continuous rogue detection while simultaneously passing normal wireless traffic.

Wireless technology is an untrusted network connection. Appropriate security must be in place for wireless technology in the ePHI environment. Organizations must ensure that controls are in place to prevent unauthorized access. Appropriate controls include a firewall to segment and protect the PHI data environment and intrusion detection services to identify potential intrusion attempts to the secured network. Stateful firewalls must be configured to limit traffic to and from the wireless environment (all enabled services, protocols, and ports must have documented justification for business purposes). All other access should be denied.
When implementing wireless in an ePHI environment, encryption must be configured to adequately protect ePHI transmitted over the wireless medium. Today the minimum level of encryption deemed acceptable by auditors is WPA2.

Cisco recommends using the Unified Wireless (controller-based) architecture for enterprise wireless deployments because of the Cisco ongoing wireless strategy. The autonomous Cisco IOS access points are not being enhanced. Future security and user enhancements will be developed on the controller-based architecture.

For WCS servers running software versions prior to 4.1, Cisco recommends a combination of documented password policies, manual audit procedures, and firewall segmentation for WCS servers within the data center:

- Configure unique SSIDs
- Disable broadcast of the SSIDs

**HIPAA Assessment Detail—HIPAA Safeguards Addressed**

All of the sample configurations of the Cisco Wireless technologies shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate's access authorization policies, establish, document, review, and modify a user’s right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).
  - §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.
Chapter 5 Component Assessment

Infrastructure

- §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

- §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate’s access authorization policies, establish, document, review, and modify a user’s right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.

- §164.312(a)(2)(ii) Emergency Access Procedure. Establish (and implement as needed) procedures for obtaining necessary ePHI during an emergency.

- §164.312(e)(1) Transmission Security. Implement technical security measures to guard against unauthorized access to ePHI that is being transmitted over an electronic communications network. Requirements addressed include: Encryption and Integrity.

- §164.308(e)(2)(i) Integrity Controls. Implement security measures to ensure that ePHI is not improperly modified without detection until disposed of. Requirements addressed include: Integrity.

- §164.308(e)(2)(ii) Encryption. Implement a mechanism to encrypt ePHI whenever deemed appropriate. Requirements addressed include: Encryption.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- §164.312(a)(2)(i) Unique User Identification. Assign a unique name and/or number for identifying and tracking user identity. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(2)(ii) Automatic logoff. Implement electronic procedures that terminate an electronic session after a predetermined time of inactivity. Requirements addressed include: Access Control and Auditing.

- Encryption—Implement mechanisms to encrypt and decrypt ePHI.

- §164.312(a)(ii)(iv) Encryption and Decryption. Implement a mechanism to encrypt and decrypt electronic protected health information. Requirements addressed include: Encryption and Integrity.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.
Sample Configuration

Cisco WCS is designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

Cisco Unified Wireless allows the network administrator to set user IDs that can be monitored and restricted with respect to access and other privileges when necessary.

For network security, the Cisco solution uses profiles for appropriate access where a user is assigned to the profile, and user access can be restricted as shown in Figure 5-101 and Figure 5-102.

**Figure 5-101   Local Management Users Screen**

![Local Management Users Screen](image)

**Figure 5-102   Management Via Wireless Screen**

![Management Via Wireless Screen](image)

Cisco WCS is configured to use TACACS+ for authentication of administrators, as shown in Figure 5-103.
The authentication servers for TACACS+ in WCS Manager are configured as shown in Figure 5-104.

The citations in this section were addressed with the sample configuration at the end of this section.
Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords. Local user accounts on Cisco WCS Manager and controllers require a password.

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of Automatic logoff options. Cisco WCS supports session policies under the management tab. It is a best practice to change the session timeout to 15 minutes, as shown in Figure 5-105.

**Figure 5-105  Controller Secure Management for SSH**

The Cisco WLAN performs 24-hour scanning to immediately detect and contain unauthorized and rogue wireless devices addressing safeguard 164.308(a)(1)(i) Security Management. Threats to network security can occur in between regularly scheduled scans, creating the need to continuously scan and to use automatic alerts and containment mechanisms. Similarly, physical and/or port scanning on the wired network is not enough. Cisco Wireless LAN Controllers include wIPS and wIDS that find and stop rogue wireless devices and attacks. WCS is a single point of management for WLAN devices, the mobility services engine, and mobility services. Cisco context-aware location services in the Cisco 3300 Series Mobility Services Engine (MSE) can locate multiple rogue devices. Cisco enhanced local mode (ELM) access points offer monitor mode wIPS on local mode access points for additional protection without a separate overlay network. Cisco CleanAir technology allows the detection and location of rogue devices on nonstandard Wi-Fi channels. (See Figure 5-106 and Figure 5-107.)
Cisco WCS has the ability to forward alerts to e-mail addresses. The system can forward all or selected alerts to multiple receivers. (See Figure 5-108.)
Cisco offers Control and Provisioning of Wireless Access Points (CAPWAP)-compliant DTLS encryption to provide full-line-rate encryption between access points and controllers across remote WAN/LAN links (see Figure 5-109). The Cisco Unified Wireless Network defaults to the highest CipherSuite available on the network. Furthermore, fallback on less secure SSL versions (that is, SSLv2 and SSLv1) can also be disabled, thus always forcing use of SSLv3. The Cisco Unified Wireless Network provides 256-bit encryption and provides automated vulnerability scanning in the WCS to identify WLANs using suboptimal encryption/authentication configurations.

Cisco supports both WPA and WPA2 and provides automated vulnerability scanning in the WCS to identify WLANs using suboptimal encryption. Cisco does not advertise the organization’s name in the Service Set ID (SSID) broadcast. Cisco also disables SSID broadcast by default for non-guest networks. Cisco supports WPA2 Personal mode with a minimum 13-character random pass-phrase and Advanced Encryption Standard (AES) encryption, and provides automated vulnerability scanning in the WCS to identify WLANs using suboptimal encryption/authentication configurations. (See Figure 5-110.)
The citations in this section were addressed with the sample configuration at the end of this section.

To address the Incident Response and Auditing HIPAA Safeguards identified above, the Cisco Unified Wireless system is designed to track and monitor all administrative user access and events. Cisco Unified Wireless tracks individual administrator actions through several mechanisms including AAA, logging, and system events.

Figure 5-111 shows the configuration of local logging settings, and Figure 5-112 shows the syslog server configuration used to send logs to RSA enVision.

Figure 5-111  WLAN Information

The citations in this section were addressed with the sample configuration at the end of this section.
As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers.

A Network Time Protocol server can be configured within the Cisco WCS and Controllers to meet this requirement for all wireless devices, as shown in Figure 5-113.
HIPAA Standards Failed

No HIPAA standards were failed.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Storage

Cisco MDS Storage Switches

Cisco MDS storage switches provide the central switching infrastructure connecting servers to storage. They provide the added capability to encrypt all information “on the fly” between these systems for specified targets; specifically, the EMC storage array and Cisco UCS servers in the solution.

The Cisco MDS 9000 Series Multilayer SAN Switches can help lower the total cost of ownership of the most demanding storage environments. By combining robust and flexible hardware architecture with multiple layers of network and storage management intelligence, the Cisco MDS 9000 Series helps you build highly available, scalable storage networks with advanced security and unified management.
Primary PHI Function

The primary function of Cisco MDS storage switches is to securely encrypt ePHI data at rest as it passes from server to storage. This safeguard was met using the MDS configuration to implement encryption for ePHI data in storage to prevent unauthorized access and prevent unauthorized modification to the ePHI data. Logs can be used to monitor access attempts to ePHI data in storage.

Design Considerations

Cisco MDS 9000 Family security features such as VSANs, advanced zoning, fabric binding, port security, Fiber Channel Security Protocol (FC-SP) authentication, and role-based access control (RBAC) with SNMPv3 and SSH make the Cisco MDS 9000 Family an excellent platform for enforcing this requirement. SSH RBAC in particular, if used in conjunction with VSANs, is especially designed to support tight partitioning of the physical infrastructure.

The MDS 9500s were configured for zoning and LUN masking to secure the logical partitioning of disk used for storing ePHI data. Only host machines in the data center that require access to that logical disk partition were allowed access. Configuration of the VSANs, host UUIDs, and mappings was partially performed using EMC Unified Infrastructure Manager as directed by the Vblock architecture by VCE. Vblock requires specific software versions and pre-configurations to be completed as specified in the Vblock preparation guide.

More information of Vblock designs can be found at the following URL: http://www.vceportal.com/solutions/68580567.html#

Information in installing and configuring Cisco MDS can be found at the following URL: http://www.cisco.com/en/US/products/hw/ps4159/ps4358/tsd_products_support_series_home.html

HIPAA Assessment Detail—HIPAA Safeguards Passed

All of the sample configurations of the Cisco MDS storage switches shown below were used to meet the following list of satisfied controls:

- **Access Control**—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- **Incident response**—Implement security incident response as required by HIPAA Administrative safeguards.
  - §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- **Auditing**—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

- **Integrity**—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.
  - §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

**Sample Configuration**

Cisco MDS storage switches are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

The following configurations demonstrate how to configure the Cisco MDS for TACACS+ authentication to a central server.

```
Feature tacacs+
tacacs-server key 7 "<removed>"
tacacs-server host 192.168.42.131
aaa group server tacacs+ CiscoACS
```
To configure LDAP authentication in NX-OS version 5.0 or higher, enable LDAP (feature ldap) and follow configuration steps in the Cisco MDS 9000 Family NX-OS Security Configuration Guide.

Assignment of privileges to individuals based on job classification and function is accomplished with the following configuration:

Feature privilege
change admin user ID:
username admin password <password> role network-admin (password will be encrypted when displayed)
create network operator type user ID:
username <assigned name> password <password> role network-operator (password will be encrypted when displayed)
create default user ID:
role name default-role
description This is a system defined role and applies to all users.
rule 5 permit show feature environment
rule 4 permit show feature hardware
rule 3 permit show feature module
rule 2 permit show feature snmp
rule 1 permit show feature system
username <assigned name> password <password> role default-role (password will be encrypted when displayed)
create custom user ID:
role name <name>
description User defined permissions define here:
rule 1 permit show interface
    ...
    ...
    Rule 256 permit show module
username <assigned name> password <password> role <name> (password will be encrypted when displayed)

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords.

username bmcgloth password 5 <removed> role network-admin
username bart password 5 <removed> role network-admin

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco MDS supports session timeout configuration in the CLI. It is a best practice to set the session timeout to 15 minutes, as shown below.

line vty
exec-timeout 15
line console
exec-timeout 15

To secure authentication information and management of the Cisco MDS Switch, addressing Safeguard 164.308(a)(1)(i) Security Management, the management intercedes are configured to support only encrypted access using the following configurations:

server 192.168.42.131
aaa authentication login default group CiscoACS
aaa authentication login console group CiscoACS
aaa authorization ssh-certificate default group CiscoACS
aaa accounting default group CiscoACS
aaa authentication login error-enable

Note
To configure LDAP authentication in NX-OS version 5.0 or higher, enable LDAP (feature ldap) and follow configuration steps in the Cisco MDS 9000 Family NX-OS Security Configuration Guide.
Configure terminal
feature ssh
ssh key dsa or ssh key rsa <768-2048>
no feature telnet
no feature http-server

And access to the management interface is restricted with an access list.

Secure access to the management port as follows:

- ip access-list 23 permit ip 127.0.0.1 0.0.0.0 <mgmt port ip address> 0.0.0.0
- ip access-list 23 permit ip <ip address of mgmt workstation> 0.0.0.0 <mgmt port ip address> 0.0.0.0
- ip access-list 23 permit ip <ip address of snmp workstation> 0.0.0.0 <mgmt port ip address> 0.0.0.0
- ip access-list 23 permit ip <ip address of AAA server> 0.0.0.0 <mgmt port ip address> 0.0.0.0
- ip access-list 23 permit ip <ip address of NTP workstation> 0.0.0.0 <mgmt port ip address> 0.0.0.0
- ip access-list 23 deny ip any any log-deny
- interface mgmt0
  ip address <ip address> <mask>
- ip access-group 23 in

To address the Incident Response and Auditing HIPAA safeguards identified above, the Cisco MDS 9000 Family implements the Cisco Data Center Network Manager (DCNM), which continuously monitors the SAN and allows you to establish criteria and thresholds to generate real-time alarms and call-home functions. Syslog and SNMP traps offers detailed entries and can be redirected to the RSA enVision log server to consolidate IT infrastructure monitoring information. Note that the log never contains application data. Cisco MDS is designed to track and monitor all administrative user access and events.

Logs stored locally are buffered and require operator level privileges to be viewed. External logging and SNMP traps are enabled by implementing the following configuration statements:

- logging server 192.168.42.124 6
- snmp-server host 192.168.41.101 traps version 2c public udp-port 2162
- snmp-server host 192.168.42.121 traps version 3 auth public

A central logging repository, RSA enVision, collects syslog and SNMP information from all devices to ensure the integrity and correlation of events.

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers. Cisco MDS use NTP to meet these requirements by implementing the following configuration statements:

- clock timezone PST -8 0
- clock summer-time PST 1 Sun April 02:00 5 Sun Oct 02:00 60
- ntp server 192.168.62.161
- ntp server 192.168.62.162

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

- No HIPAA standards were failed.
HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.

Security

Cisco ASA Firewalls

The Cisco Adaptive Security Appliance (ASA) is designed to provide secure segmentation within a network. The stateful firewall and modular intrusion detection modules enable the healthcare entity to securely connect public networks to the PHI environment. The ASA also enables secure connectivity from remote locations via encrypted tunnels using its VPN technology.

The Cisco ASA delivers superior scalability, a broad span of technology and solutions, and effective, always-on security designed to meet the needs of a wide array of deployments. By integrating the world's most proven firewall; a comprehensive, highly effective intrusion prevention system (IPS) with Cisco Global Correlation and guaranteed coverage; high-performance VPN and always-on remote access, the Cisco ASA helps organizations provide secure, high performance connectivity and protects critical assets for maximum productivity.

The Cisco ASA 5500 Series includes the Cisco ASA 5505, 5510, 5512-X, 5515-X, 5520, 5525-X, 5540, 5545-X, 5550, 5555-X, 5580, and 5585-X Adaptive Security Appliances-purpose-built, high-performance security solutions that take advantage of Cisco expertise in developing industry-leading, award-winning security and VPN solutions. Through Cisco Multi-Processor Forwarding (MPF), the Cisco ASA 5500 Series brings a new level of security and policy control to applications and networks. MPF enables highly customizable, flow-specific security policies that have been tailored to application requirements. The performance and extensibility of the Cisco ASA 5500 Series is enhanced through user-installable security service modules (SSMs) and virtual modules. This adaptable architecture enables businesses to rapidly deploy security services when and where they are needed, such as tailoring inspection techniques to specific application and user needs or adding additional intrusion prevention and content security services such as those delivered by the Adaptive Inspection and Prevention (AIP) and Content Security and Control (CSC) SSMs. Furthermore, the modular hardware architecture of the Cisco ASA 5500 Series, along with the powerful MPF, provides the flexibility to meet future network and security requirements, extending the investment protection provided by the Cisco ASA 5500 Series and allowing businesses to adapt their network defenses to new threats as they arise.

The Cisco ASA Services Module (ASASM) is an integrated module installed inside a Cisco Catalyst 6500 Series Switch or Cisco 7600 Internet Router. The Cisco ASASM allows any port on the Cisco Catalyst switch to operate as a firewall port and integrates firewall security inside the network infrastructure.

All Cisco ASA offer both IPsec and SSL/DTLS VPN solutions; Clientless and AnyConnect VPN features are licensed at various price points, on a per-seat and per-feature basis. By converging SSL and IPsec VPN services with comprehensive threat defense technologies, the Cisco ASA provides highly customizable, granular network access tailored to meet the requirements of diverse deployment environments, while providing advanced endpoint and network-level security.
The primary function of the Cisco ASA firewall in a healthcare network environment is to securely segment PHI data environments to prevent unauthorized access from public and business associate networks at clinics, hospitals, clearinghouses and to provide intrusion detection capabilities. Additionally, the firewall can provide the isolation necessary for organizations with clearing house functions to protect against unauthorized access to the clearing house from the larger organization.

Design Considerations

- Select the appropriate Cisco ASA model/SSM module for the traffic needs in the healthcare entity.
- Configure security policies, objects, and rules centrally with Cisco Security Manager to support segmentation of the LAN from Internet exposure, implement restrictions based on identity and authorization to access ePHI, and set up logging and monitoring alerts for central capture and auditing.
- Firewall rule sets must adhere to a “least amount of access necessary” policy. Rules must be defined by specific source/destination addressing and TCP/UDP ports.
- Allow only SSHv2 (and not Telnet or SSHv1) connection from network management station to Cisco ASA.
- Configure appropriate banner messages on login, incoming, and exec modes of the Cisco ASA. The login banner warning should not reveal the identity of the company that owns or manages the Cisco ASA. The incoming and executive banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.
- Configure the primary login authentication of the Cisco ASA to be directed to the Cisco Secure ACS. Individual user account profiles need to be created. Configure secondary or tertiary authentication local to the Cisco ASA itself in the event of connectivity or Cisco Secure ACS failure.
- Change default passwords and community strings to appropriate complexity.
- Configure the `ip verify reverse path` command on all interfaces to provide anti-spoofing functionality.
- Configure the console timeout commands to 15 minutes or less on the console of the Cisco ASA.
- For Internet edge, disable `icmp permit` on the outside interface of Cisco ASA. If users need to access servers in the DMZ segment, make sure that external users can reach the servers using very specific protocol and ports.

HIPAA Assessment Detail—HIPAA Safeguards Addressed

HIPAA safeguards are spread across multiple categories. The ASA firewall helps healthcare-covered entities and business associates meet access control safeguards in the Administrative and Technical categories. The access control can be applied to both internal and external users that access ePHI data. Additionally, controls to protect the administrator accounts on the firewall have been implemented to protect the firewall from unauthorized modification if the authentication server fails. These local accounts represent only a subset of select individuals that would need access in the event central authentications services are unavailable.

All of the sample configurations of the ASA shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - 164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a health care clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.
Chapter 5 Component Assessment

- 164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.

- 164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate’s access authorization policies, establish, document, review, and modify a user's right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.

- 164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in 164.308(a)(4).

- 164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

  - 164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

  - 164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate’s access authorization policies, establish, document, review, and modify a user's right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.

  - 164.312(a)(2)(ii) Emergency Access Procedure. Establish (and implement as needed) procedures for obtaining necessary ePHI during an emergency.

  - 164.312(e)(1) Transmission Security. Implement technical security measures to guard against unauthorized access to ePHI that is being transmitted over an electronic communications network. Requirements addressed include: Encryption and Integrity.

  - 164.308(e)(2)(i) Integrity Controls. Implement security measures to ensure that ePHI is not improperly modified without detection until disposed of. Requirements addressed include: Integrity.

  - 164.308(e)(2)(ii) Encryption. Implement a mechanism to encrypt ePHI whenever deemed appropriate. Requirements addressed include: Encryption.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

  - 164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

  - 164.312(a)(2)(i) Unique User Identification. Assign a unique name and/or number for identifying and tracking user identity. Requirements addressed include: Access Control and Auditing.
164.312(a)(2)(ii) Automatic logoff. Implement electronic procedures that terminate an electronic session after a predetermined time of inactivity. Requirements addressed include: Access Control and Auditing.

- Encryption—Implement mechanisms to encrypt and decrypt ePHI.
  - 164.312(a)(ii)(iv) Encryption and Decryption. Implement a mechanism to encrypt and decrypt electronic protected health information. Requirements addressed include: Encryption and Integrity.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  - 164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.
  - 164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

Sample Configuration
Cisco ASA firewalls are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

Cisco ASA firewalls are configured to use a AAA model for user-based access. Users can be assigned to groups and based on privilege levels, have access to only the information they require for their job function. By default in Cisco ASA firewalls, no users are allowed access unless specifically configured and assigned appropriate passwords. The following configuration statements create an authentication group called Oncology, which is assigned to various interfaces. This group uses the TACACS+ protocol to communicate with the Cisco ACS server where individual user groups and roles are configured, limiting and logging access as appropriate.

```
aaa-server CiscoACS protocol tacacs+
aaa-server CiscoACS (inside) host 192.168.42.131
    key *****
user-identity default-domain LOCAL

aaa accounting ssh console CiscoACS
aaa accounting enable console CiscoACS
aaa accounting command privilege 15 CiscoACS
aaa authentication secure-http-client
aaa local authentication attempts max-fail 6
aaa authorization exec authentication-server
```

Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords.

```
username csmadmin password <removed> encrypted privilege 15
username janoff password <removed> encrypted privilege 15
username bart password <removed> encrypted privilege 15
```
It is a best practice that these local accounts represent only a subset of key network or security device administrators that would need administrative access in the event central authentications services are unavailable. This should not be the complete list of users that require access to ePHI.

These AAA authentication groups are assigned to the administrative interfaces where users connect.

```
aaa authentication ssh console CiscoACS LOCAL
aaa authentication enable console CiscoACS LOCAL
aaa authentication http console CiscoACS LOCAL
```

Cisco ASA firewalls are configurable to restrict traffic through the use of object and service-based access lists, thereby addressing Safeguard 164.308(a)(4)(ii)(A), which requires isolating healthcare information. By default, the firewall does not forward any traffic unless explicitly permitted.

The following configuration example shows how objects identify hosts and services within the network and their use in an access list to permit approved traffic:

```
object-group network EMC-NCM
description EMC Network Configuration Manager
network-object 192.168.42.122 255.255.255.255
object-group network CSMManager
description Cisco Security Manager
network-object 192.168.42.133 255.255.255.255
object-group network RSA-enVision
description RSA EnVision Syslog collector and SIM
network-object 192.168.42.124 255.255.255.255
object-group network AdminStation3
network-object 192.168.42.138 255.255.255.255
object-group network Admin-Systems
group-object EMC-NCM
group-object AdminStation
group-object AdminStation2
group-object CSMManager
group-object RSA-enVision
group-object AdminStation3
group-object AdminStation4-bart
object-group service CSM_INLINE_svc_rule_77309411635
description Generated by CS-Manager from service of FirewallRule# 3
(ASA-DC-1-vdc1_v1/mandatory)
service-object tcp destination eq ssh
service-object tcp destination eq https
object-group HTTPS-8443
object-group network CSM_INLINE_dst_rule_77309411635
description Generated by CS-Manager from dst of FirewallRule# 3
(ASA-DC-1-vdc1_v1/mandatory)
group-object DC-ALL
group-object Stores-ALL
group-object DC-DMZ
```
Administration access to the firewall is further restricted through the use of network permit statements applied to the web and terminal interfaces. Isolating administrative access to this device enforces the perimeter of the ePHI scope of the infrastructure.

The following configuration shows the authorized management hosts for SSH and HTTPS administration, and none for Telnet.

```
http server enable
http 192.168.41.101 255.255.255.255 south
http 192.168.41.102 255.255.255.255 south
http 192.168.42.122 255.255.255.255 south
http 192.168.42.124 255.255.255.255 south
http 192.168.42.133 255.255.255.255 south
http 192.168.42.138 255.255.255.255 south
telnet timeout 5
ssh 192.168.41.101 255.255.255.255 south
ssh 192.168.41.102 255.255.255.255 south
ssh 192.168.42.122 255.255.255.255 south
ssh 192.168.42.124 255.255.255.255 south
ssh 192.168.42.133 255.255.255.255 south
ssh 192.168.42.138 255.255.255.255 south
```

It is a recommended practice to enable only management interface protocols that use strong encryption, to best protect the ePHI information and the identities and passwords of those who must have access. Cisco ASA firewalls support strong encryption for SSH and HTTPS. The following configurations are used to configure strong cryptography:

```
! ---Specify only Strong algorithms for SSL connections---
ssl encryption 3des-sha1 aes128-sha1 aes256-sha1
!
! ---Specify strong encryption version of SSH---
ssh version 2
!
```

SNMP versions 1 and 2(c) transmit data between the SNMP server and the SNMP agent in the clear. This makes your infrastructure and corresponding infrastructure devices vulnerable to attack and/or misuse. SNMP v3 adds authentication and privacy options to secure its communication between SNMP servers and SNMP agents.

Cisco ASA firewalls allow secure administration using SNMP version 3 with encryption and authentication using the priv security model.

SNMP groups provide an access control policy to which users are added. The user inherits the security model of the group.

SNMP users are assigned a username, a group to which they belong, authentication password, encryption password, and associated algorithms to use. Authentication algorithms are MD5 and SHA. Encryption algorithms are DES, 3DES, and AES (128,192,256).

```
snmp-server enable
snmp-server group V3Group v3 priv
snmp-server user ciscolms V3Group v3 auth sha <AUTHENTICATION-PASSWORD> priv aes 256 <ENCRYPTION-KEY>
```
VPNs enable secure communication between locations by encrypting and decrypting traffic addressing Safeguard 164.312(a)(ii)(iv).

The following configurations show the setup of the additional AAA RADIUS server and authentication group for SSL VPN access from external sources.

```
aaa-server partnerauth protocol radius
aaa-server partnerauth (inside) host 192.168.42.137
timeout 5
key *****
radius-common-pw *****
webvpn
enable outside
internal-password enable
smart-tunnel list AllExternalApplications All-Applications * platform windows
group-policy DfltGrpPolicy attributes
webvpn
url-list value page1
smart-tunnel enable AllExternalApplications
group-policy HEALTH-HIPAA internal
group-policy HEALTH-HIPAA attributes
vpn-tunnel-protocol ssl-clientless

! tunnel-group DefaultRAGroup general-attributes
  authentication-server-group partnerauth
  tunnel-group DefaultWEBVPMGroup general-attributes
  authentication-server-group partnerauth
  tunnel-group ComplianceLab type remote-access
  tunnel-group ComplianceLab general-attributes
  authentication-server-group partnerauth LOCAL
  default-group-policy HEALTH-HIPAA

Cisco ASA firewalls track individual administrator actions, which address all of the HIPAA Auditing safeguards summarized above, through several mechanisms including AAA, logging, and system events by implementing the following configuration statements:

```
logging enable
logging timestamp
logging trap informational
logging adm informational
logging host south 192.168.42.124
```

An SNMP host is the server to which SNMP notifications and traps are sent. SNMP v3 hosts require the SNMP server IP address and SNMP username. Each SNMP host can have only one username associated with it. The user credentials on the NMS (CiscoPrime, EMC NCM, and so on) must match the SNMP username credentials.

```
snmp-server host south 192.168.42.134 version 3 ciscolms
snmp-server host south 192.168.42.139 version 3 ciscolms
snmp-server host south 192.168.42.133 version 3 csmadmin
```

Enable the SNMP traps (this will change depending on environment and business requirements). The following example enables all, but this could be limited to a subset of traps.

```
snmp-server enable traps all
snmp-server location Building SJC-17-1 Aisle 1 Rack 3
snmp-server contact EmployeeA
```
In addition to being able to set timeout limits for remote access VPNs, Safeguard 164.312(a)(2)(ii) Automatic Logoff, requires that the administrative sessions to the Cisco ASA firewalls be limited with the following configurations:

```
http server idle-timeout 15
ssh timeout 15
cron timeout 15
```

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. Cisco ASA firewalls use NTP by implementing the following configuration statements:

```
ntp server 192.168.62.162 source south
ntp server 192.168.62.161 source south prefer
clock timezone PST -8
clock summer-time PDT recurring
```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002 and NIST Security Publications.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.

**Cisco Virtual Security Gateway**

The Cisco Virtual Security Gateway (VSG) for Cisco Nexus 1000V Series Switches was used in the data center for setting a boundary between the sensitive scope of the organization’s ePHI data environment and out-of-scope networks. It is a virtual firewall for Cisco Nexus 1000V Series Switches that delivers security and compliance for virtual computing environments. Cisco VSG uses virtual service data path (vPath) technology embedded in the Cisco Nexus 1000V Series Virtual Ethernet Module (VEM), offering transparent firewall insertion and efficient deployment. All the policy management for VSG is done via Virtual Network Management Center (VNMC). Cisco VSG provides the following:

- Zone-based security controls based on network as well as virtual machine attributes. This flexibility simplifies security policies, which are easy to troubleshoot and audit.
- Secure multi-tenant deployment, protecting tenant workloads on a shared compute infrastructure.
- Leverages vPath intelligence for efficient network-wide deployment and accelerated performance through fast-path off-load.
- IT security, network, and server teams collaborate while enabling administrative segregation to meet regulatory and audit requirements and reduce administrative errors.

Cisco Compliance Solution for HIPAA Security Rule

OL-27664-01
Primary PHI Function

The primary function of the Cisco VSG is segmentation of PHI scope and enforcement of that new scope boundary. The Cisco VSG serves as a stateful firewall, restricting traffic between the cardholder data environment and other areas of the network.

Design Considerations

Cisco VSG integrates with Cisco Nexus 1000V Series Switches to enforce security policies for your virtualized environment. VNMC provides policy management for a multitenant environment. One or more VSGs are required per tenant. VSG uses the vPath intelligence in the Virtual Ethernet Module (VEM) of the Cisco Nexus 1000V Series to provide the security policy enforcement.

Cisco VSG is deployed as a virtual appliance in vCenter. The primary function of Cisco VSG is to protect against unauthorized access to the cardholder environment. (See Figure 5-114.)
HIPAA Assessment Detail—HIPAA Safeguards Addressed

HIPAA safeguards are spread across multiple categories. The VSG firewall helps healthcare covered entities and business associates meet access control safeguards in the Administrative and Technical categories. The access control can be applied to both internal and external users that access ePHI data. Additionally, controls to protect the administrator accounts on the firewall have been implemented to protect the firewall from unauthorized modification if the authentication server fails. These local accounts represent only a subset of select individuals that would need access in the event central authentications services are unavailable.

All of the sample configurations of the VSG shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
- §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate’s access authorization policies, establish, document, review, and modify a user’s right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response and Auditing.

- §164.312(a)(1) Access Control. Implement technical policies and procedures for electronic information systems that maintain ePHI to allow access only to those persons or software programs that have been granted access rights as specified in §164.308(a)(4).

- §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

- Integrity—Protect electronic protected health information from improper alteration or destruction as required by HIPAA Technical safeguards.

- §164.312(c)(1) Data Integrity. Implement policies and procedures to protect health information from improper alteration or destruction.

- §164.308(a)(4)(ii)(C) Access Establishment and Modification. Implement policies and procedures that, based upon the covered entity’s or the business associate’s access authorization policies, establish, document, review, and modify a user’s right of access to a workstation, transaction, program, or process. Requirements addressed include: Access Control, Incident Response, and Auditing.

- §164.312(a)(2)(ii) Emergency Access Procedure. Establish (and implement as needed) procedures for obtaining necessary ePHI during an emergency.

- §164.312(e)(1) Transmission Security. Implement technical security measures to guard against unauthorized access to ePHI that is being transmitted over an electronic communications network. Requirements addressed include: Encryption and Integrity.

- §164.308(e)(2)(i) Integrity Controls. Implement security measures to ensure that ePHI is not improperly modified without detection until disposed of. Requirements addressed include: Integrity.

- §164.308(e)(2)(ii) Encryption. Implement a mechanism to encrypt ePHI whenever deemed appropriate. Requirements addressed include: Encryption.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards.

- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- §164.312(a)(2)(i) Unique User Identification. Assign a unique name and/or number for identifying and tracking user identity. Requirements addressed include: Access Control and Auditing.

- §164.312(a)(2)(ii) Automatic logoff. Implement electronic procedures that terminate an electronic session after a predetermined time of inactivity. Requirements addressed include: Access Control and Auditing.
• Encryption—Implement mechanisms to encrypt and decrypt ePHI.
  – §164.312(a)(ii)(iv) Encryption and Decryption. Implement a mechanism to encrypt and decrypt electronic protected health information. Requirements addressed include: Encryption and Integrity.

• Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.
  – §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.
  – §164.312(d) Person or entity authentication. Implement procedures to verify that a person or entity seeking access to electronic protected health information is the one claimed. Requirements addressed include: Access Control and Auditing.

**Sample Configuration**
Cisco VSG firewalls are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

User roles in VNMC contain one or more privileges that define the operations allowed for the user who is assigned the role. A user can be assigned one or more roles. A user assigned multiple roles has the combined privileges of all assigned roles. For example, if Role1 has policy-related privileges, and Role2 has tenant-related privileges, users who are assigned to both Role1 and Role2 have policy and tenant related privileges.

The system contains the following default user roles:
- aaa—User has read and write access to users, roles, and AAA configuration. Read access to the rest of the system.
- admin—User has complete read-and-write access to the entire system and has all privileges. The default admin account is assigned this role by default, and it cannot be changed.
- network—User creates organizations, security policies, and device profiles.
- operations—User acknowledges faults and performs some basic operations such as logging configuration.
- read-only—User has read-only access to system configuration and operational status with no privileges to perform any operations.

Roles can be created, modified to add new or remove existing privileges, or deleted. When a role is modified, the new privileges are applied to all users assigned to that role. Privilege assignment is not restricted to the privileges defined for the default roles. That is, you can use a custom set of privileges to create a unique role. For example, the default Network and Operations roles have different sets of privileges, but a new Network and Operations role can be created that combines the privileges of both roles.

To configure roles in VNMC, do the following:
1. Click the Administration tab, then click the Access Control sub-tab.
2. In the Navigation pane, select the **Roles** node. In the Work pane, click **Create Roles** (see Figure 5-115.)

**Figure 5-115   Configuring Roles**

In addition to roles, the user is also provided another dimension of privilege, which limits the user to tenant level visibility, called **locale**. Each locale defines one or more organizations (domains) to which the user is allowed access, and access would be limited to the organizations specified in the locale. To configure locales in VNMC, do the following:

1. Click the Administration tab, then click the Access Control sub-tab.
2. In the Navigation pane, select the Locales node.
3. In the Work pane, click the Create Locale link. (See Figure 5-116.)
CLI configuration of AAA services is as follows:

```
tacacs-server key 7 "<removed>"
tacacs-server host 192.168.42.131
aaa group server tacacs+ CiscoACS
    server 192.168.42.131
    use-vrf management
    source-interface mgmt0
aaa group server tacacs+ tacacs
!
aaa authentication login default group CiscoACS
aaa authentication login console group CiscoACS
```

HIPAA Safeguard 164.312(a)(2)(ii) requires the enabling of automatic logoff options. Cisco VSG supports session timeout. It is a best practice to set session time-out to 15 minutes,

```
line vty
    exec-timeout 15
line console
    exec-timeout 15
```

It is a recommended practice to only enable management interface protocols which use strong encryption in order to best protect the ePHI information and the identities and passwords of those who must have access. Cisco VSG firewalls support strong encryption for SSH and HTTPS. Only SSH access is allowed for firewall console access over the network. The communication between Cisco VSG and Management Platform (VNMC) is all encrypted over SSL (443).

Cisco Nexus VSG can be configured to use secure protocols for all system functions. This includes SSH for remote management, SCP, and SFTP for file transfers. Insecure services can be disable or blocked using configuration statements and access lists.

```
no feature telnet
no telnet server enable
feature ssh
```
Cisco Nexus VSG support administrative protocols with strong cryptography such as SSH version 2.
Cisco ASA firewalls track individual administrator actions, which address all of the HIPAA Auditing Safeguards summarized above, through several mechanisms including AAA, logging, and system events by implementing the following syslog server configurations for Cisco VSG to send all the logging information to a standard syslog server. This setting is available as part of the device profile.

1. Navigate to Policy Management > Device Policies > Tenant> Policies > Syslog Policies. Add a syslog policy, as shown in Figure 5-117.

![Figure 5-117 Configuring Syslog](image)

2. The severity of the logging should be at level 6 to capture the firewall policy hit in the VSG. (See Figure 5-118).

![Figure 5-118 Configuring Logging Severity](image)

3. The syslog policy is attached to the Device Profile to enable the settings in the VSG. CLI configuration of logging services is as follows:
logging logfile messages 2
logging server 192.168.42.124 6 facility local0
logging monitor 2

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP servers were hosted at the data center site. The Cisco Lab uses two NTP servers that are synchronized to external reference sources. All systems and devices in the lab are pointed to these two servers.

NTP is configured in the Firewall Device Profile for the Cisco VSG VNMC. The setting is published via the device policy to Cisco VSG.

1. In the navigation pane, click the Policy Management tab, then the Device Policies sub-tab, and expand the Device Profile for a tenant.

2. Click a Profiles node to add a firewall device profile, and you see the option to add NTP server, as shown in Figure 5-119.

Figure 5-119 Configuring NTP

HIPAA Standards Failed

No HIPAA standards were failed.

HIPAA Implementation Specifications Failed

No HIPAA implementation specifications were failed.
Intrusion Detection

Cisco Catalyst 6500 Series Intrusion Detection System Services Module 2

The Cisco Catalyst 6500 Series Intrusion Detection System Services Module 2 (IDSM2) is an important intrusion prevention system (IPS) solution that protects switched environments by integrating full-featured IPS functions directly into the network infrastructure through the widely deployed Cisco Catalyst chassis. This integration allows the user to monitor traffic directly off the switch backplane.

The Cisco IDSM2 with Cisco IPS Sensor Software v6.0 helps users stop more threats through the use of the following elements:

- Multivector threat identification—Detailed inspection of Layer 2–7 traffic protects your network from policy violations, vulnerability exploitations, and anomalous activity.
- Accurate prevention technologies—The innovative Cisco Risk Rating feature and Meta Event Generator provide the ability to take preventive actions on a broader range of threats without the risk of dropping legitimate traffic.

When combined, these elements provide a comprehensive inline prevention solution, providing the ability to detect and stop the broadest range of malicious traffic before it affects business continuity.

Primary PHI Function

The primary function of the Cisco IDSM2 is to monitor all traffic at the perimeter of the ePHI data environment as well as at critical points inside of the ePHI data environment, and alert personnel to suspected compromises.

Design Considerations

- Configure the Cisco IDSM2 to lock accounts so that users cannot keep trying to login after a certain number of failed attempts.
- Allow secure management of the Cisco IDSM2 only from specific host/hosts.
- Configure appropriate banner messages on login. The login banner warning should not reveal the identity of the company that owns or manages the Cisco IDSM2. The banners should state that these areas are considered private and that unauthorized access will result in prosecution to the full extent of the law.
- Change default passwords and community strings to appropriate complexity.

For more information, see the Installation Guide at the following URL:

HIPAA Assessment Detail—HIPAA Safeguards Passed

All of the sample configurations of the IDSM shown below were used to meet the following list of satisfied controls:

- Access Control—Restrict access to ePHI data as required by HIPAA Administrative and Technical safeguards
  - §164.308(a)(3)(ii)(A) Authorization/Supervision. Implement procedures for the authorization and/or supervision of workforce members who work with ePHI or in locations where it might be accessed. Requirements addressed include: Auditing.
  - §164.308(a)(4)(ii)(B) Access authorization. Implement policies and procedures for granting access to electronic protected health information, for example, through access to a workstation, transaction, program, process, or other mechanism. Requirements addressed include: Access Control and Auditing.
  - §164.308(a)(5)(ii)(B) Protection from malicious software. Procedures for guarding against, detecting, and reporting malicious software. Requirements addressed include: Incident Response and Auditing.

- Incident response—Implement security incident response as required by HIPAA Administrative safeguards
  - §164.308(a)(6)(i) Security Incident Procedures. Implement policies and procedures to address security incidents. Requirements addressed include: Incident Response and Auditing.
- §164.308(a)(6)(ii) Response and Reporting. Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity or business associate; and document security incidents and their outcomes. Requirements addressed include: Incident Response and Auditing.

- Auditing—Implement mechanisms to record and examine activity in systems that contain or use ePHI as required by HIPAA Technical safeguards.

- §164.312(b) Audit controls. Implement hardware, software, and/or procedural mechanisms that record and examine activity in information systems that contain or use electronic protected health information. Requirements addressed include: Auditing.

Sample Configuration
Cisco IDSM modules are designed to track and monitor all administrative user access and events, thereby addressing all of the safeguards listed under Access Control above. User access throughout the solution uses a centralized user database in the Active Directory, which is linked through authentication servers via LDAP, RADIUS, and TACACS+ services, enabling verification of users and administrators of devices and endpoints. These services are located in the data center. Individual user IDs are assigned, and roles are based on group membership.

Cisco IDSM2 modules are configured to use a AAA model for user-based access. Users can be assigned to groups and based on privilege levels and have access to only the information they require for their job function. By default, no users are allowed access unless specifically configured and assigned appropriate passwords. The following configuration statements use the RADIUS protocol to communicate with the Cisco ACS server where individual user groups and roles are configured, limiting and logging access as appropriate.

```
! ------------------------------
service aaa
aaa radius
primary-server
server-address 192.168.42.131
shared-secret <removed>
exit
nas-id DMZ-IDS1
local-fallback enabled
console-authentication radius-and-local
default-user-role administrator
exit
exit
! ------------------------------
```

Cisco IDSM2 modules allow only administrative connections from authorized hosts/networks as specified in the device configuration. The following configuration shows the authorized management hosts for SSH and HTTPS administration, and disabling of Telnet.

```
! ------------------------------
service host
network-settings
host-ip 192.168.21.94/24,192.168.21.1
host-name DMZ-IDS2
telnet-option disabled
access-list 192.168.41.101/32
access-list 192.168.41.102/32
access-list 192.168.42.122/32
access-list 192.168.42.124/32
access-list 192.168.42.133/32
access-list 192.168.42.138/32
```
Local individual user accounts are configured in the event that the centralized authentication server cannot be reached. These accounts must be manually updated to maintain compliance requirements regarding password rotation and expiration as specified in established policies for passwords.

Cisco IDSM2 modules support the ability to specify a minimum password length for local accounts.

```plaintext
! -----------------------------------------------
service authentication
password-strength
size 7-64
! -----------------------------------------------
```

Cisco IDSM2 modules support the ability to specify alphanumeric passwords for local accounts.

```plaintext
! -----------------------------------------------
service authentication
password-strength
digits-min 1
lowercase-min 1
other-min 1
! -----------------------------------------------
```

Cisco IDSM2 modules support the ability to specify that old passwords should not be re-used for local accounts.

```plaintext
! -----------------------------------------------
service authentication
password-strength
number-old-passwords 4
! -----------------------------------------------
```

Cisco IDSM2 modules support the ability to specify that only a limited number of attempts can be made when authenticating for local accounts.

```plaintext
! -----------------------------------------------
service authentication
attemptLimit 6
! -----------------------------------------------
```

Cisco IDSM2 modules support the ability to lockout local accounts after the specified number of failed attempts, requiring an administrator to re-enable them. Locked accounts are indicated by parentheses when using the show users command:

```
sensor# show users all
CLI ID User       Privilege
* 1349 bart       administrator
  5824 (pauljones) viewer
  9802 christian  operator
```

Cisco IDSM2 modules are capable of performing intrusion detection and prevention through the use of VLAN interfaces from the host Cisco Catalyst service chassis addressing safeguard 164.308(a)(1)(i) Security Management. IPS signature updates and configurations are managed centrally through Cisco Security Manager. The following configuration statements are necessary in the Cisco Catalyst service chassis to forward traffic via VLANs and enable the IDS inspection capability:

```plaintext
! 
! intrusion-detection module 2 management-port access-vlan 21
intrusion-detection module 2 data-port 1 trunk allowed-vlan 83,84
! 
```

Cisco IDSM2 module interfaces are configured as follows to receive, inspect, and forward traffic across the assigned VLANs:
To address the Incident Response and Auditing HIPAA Safeguards identified above, Cisco IDSM can be configured to send its log data to the RSA enVision log management platform. RSA enVision collects information from all devices to ensure the integrity and correlation of events.

Cisco IDSM2 modules are capable of sending system events to a centralized repository using SNMP traps. Logs stored locally are buffered and require operator level privileges on the device to be viewed. External logging is enabled by implementing the following configuration statements to send them to the RSA enVision server:

```
! ------------------------------
service notification
trap-destinations 192.168.42.124
trap-community-name RSAenVision
exit
enable-notifications true
trap-community-name RSAenVision
exit
! ------------------------------
```

As a best practice, NTP is used to synchronize clocks among network devices. This synchronization allows events to be correlated when system logs are created and when other time-specific events occur. All devices in the network used NTP to synchronize their clocks. The NTP server was hosted at the data center site. Cisco IDSM2 uses NTP to meet these requirements by implementing the following configuration statements:

```
time-zone-settings
offset -8
standard-time-zone-name PST
exit
ntp-option enabled-ntp-unauthenticated
ntp-server 192.168.62.161
exit
summertime-option recurring
summertime-zone-name PDT
```

Clock synchronization is a requirement for common industry security frameworks such as the HiTrust Common Security Framework (CSF), ISO 27002, and NIST Security Publications, as well as other industry-based standards.

**HIPAA Standards Failed**

No HIPAA standards were failed.

**HIPAA Implementation Specifications Failed**

No HIPAA implementation specifications were failed.
Summary

HIPAA is flexible and open to interpretation based on the type of healthcare entity. Cisco customers have asked for clarification in relation to the common architectures and security products that might be utilized. In response, Cisco contracted Verizon Business to assess Cisco’s enterprise reference architectures and components. Verizon provides design guidance and explains the rationale that they used for assessing healthcare entities in the context of Cisco’s enterprise solution set.

This Cisco Compliance Solution for HIPAA Security Rule provides a reference architecture designed to help covered entities and business associates clarify compliance with the HIPAA Security Rule by mapping architectures and products to the HIPAA Security Rule Technical Safeguards, standards, and implementation specifications.

Compliance is a journey, not a destination. It requires continual attention to maintain. It is a journey that cannot be traveled alone. Trusted advisors such as auditors and vendors simplify the goal of maintaining compliance. The following provides a summary of the assessment results.

HIPAA Solution Summary Results

Table 6-1 lists the HIPAA citations that were addressed within the solution.

Addressing the individual HIPAA safeguards without an encompassing security framework is difficult; there are many grey areas that are contested by auditors and interpretations that can be made for corner cases. The best strategy is to use a common control structure that addresses multiple compliance standards using a “unified compliance” mindset. The intent is that regardless of the type of sensitive data, a single security strategy should meet the needs of an organization to protect it from a compliance perspective.

As an example, there is no specific mention of firewall technology in the HIPAA standard because HIPAA is written to be flexible enough to address all types of healthcare entities. However, when considering the common risks that are associated with enterprise organizations, such as the Internet and partner connections that share ePHI, Verizon cites the following controls that inductively requires the use of a firewall:

- 164.308(a)(4)(ii)(A) Isolating healthcare clearinghouse function. If a healthcare clearinghouse is part of a larger organization, the clearinghouse must implement policies and procedures that protect the electronic protected health information of the clearinghouse from unauthorized access by the larger organization. Requirements addressed include: Access Control, Integrity, Incident Response, and Auditing.

The word *procedures* requires the use of a technology to address the commensurate risk. In organizations that are represented in the Cisco solution, the Internet is a tremendous threat that can be addressed only through the use of a stateful firewall.

In HIPAA, regardless of inconsistencies and specifics from interpretation, the resonant idea is that reasonable controls must be in place to mitigate existing risks that threaten the integrity and ownership of sensitive Healthcare data. By implementing a broader and often more specific common industry

security framework such as HiTrust’s Common Security Framework (CSF), ISO 27002, or NIST Security Publications, as well as other industry-based standards, a comprehensive policy can be tailored to address the risk and governance needs specific to the enterprise organization.
Bill Of Material

Each Cisco Validated Design is a point-in-time effort. The following bill of materials represents the products selected before testing. Large encompassing validation efforts can take a significant length (12–18 months) to complete, during which product models may become outdated. Enterprise compliance needs can often still be met using newer/current versions of similar product lines and models.

The HIPAA assessment/validation of the existing laboratory infrastructure that was previously used for PCI compliance did not include any product updates, and therefore this bill of materials may contain items and models that are no longer available for sale.

### Data Center—Management

**Note**
Previous validation included ACS 4.2.1 on Windows as shown in the implementation section 5. Subsequent validation was achieved for the Cisco ACS 5.3 appliance and is the recommended product in this BOM.

1. Executive Summary

Cisco Systems, Inc. (Cisco) engaged Verizon’s Global Consulting and Integration Services (GCIS) to conduct a security controls assessment (Assessment) of Cisco’s “Healthcare Solution” designed architecture, based on maximizing the alignment of Cisco’s available security controls with the Healthcare Information Portability and Accountability Act (HIPAA) Security Rule safeguards. This Assessment reviewed how Cisco’s “reference security architecture” provided either direct security controls or compensating security controls, which are capable of meeting or exceeding the security “safeguards” as identified in HIPAA. This Assessment included the review of Cisco’s reference security architecture and the user, data, network, and system controls provided therein.

Cisco markets the assessed reference architecture solution to their customers looking to meet their healthcare security requirements, specifically within their IT environment and within their data center infrastructure. Cisco will use the findings from this assessment to design a solution that aligns with the security requirements that are generally accepted to fulfill security controls, with respect to the HIPAA security safeguards (requirements), and plan to provide the results of this Assessment to Cisco Sales Engineers interfacing with their enterprise Customers.

Verizon’s Assessment covered Cisco’s enterprise architectures including: datacenter; Internet edge; WAN; small, medium, and large clinic architectures; clinics/out-patient facilities; and small hospitals, among others.
The Cisco reference architecture is not designed or envisioned to directly fulfill the HIPAA Safeguards that are purely operational or organizational (for example, the assignment of the HIPAA Security Officer), or purely documentation oriented (for example, the assurance that documents are regularly reviewed). Verizon has found that Cisco’s reference architecture for Healthcare does provide a strong technology foundation for managing technical risks that meet the healthcare customer’s need to manage risks, specifically around the protection of electronic Patient Health Information (ePHI).

The Healthcare Security Requirements revolve around HIPAA Part 164 Part C. HIPAA Part 164 Subpart C is made up of nine sections. Three of the sections are administrative and are not part of this assessment. The remaining six sections (Security Standards: General Rules; Administrative Safeguards; Physical Safeguards; Technical Safeguards; Organizational Requirements; and Policies and Procedures and Documentation Requirements) consist of 52 Security Safeguards. Verizon performed an initial assessment to determine whether the safeguards could be met by using specific technology components provided by Cisco.

Of the 52 Safeguards in the current healthcare requirements, Verizon identified 29 Safeguards as not applicable in the context of this Assessment, because the Safeguard was either explicit and demanding direct (non-technology related) controls, or general but not allowing for the reasonable use of technology as a compensating control in the fulfillment of the Safeguard.

Of the remaining 23 Safeguard Areas in the current healthcare requirements, Verizon has further identified 8 Safeguards that call for universal security control requirements that are foundational across Cisco’s products and present in all network devices and systems that make up Cisco’s Healthcare Reference Architecture.

<table>
<thead>
<tr>
<th>Safeguard Areas where Cisco Security Controls are Not-Applicable</th>
<th>Safeguard Areas where Cisco Security Controls are Universally Applicable</th>
<th>Safeguard Areas where Cisco Security Controls are Specifically Applicable</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>8</td>
<td>15</td>
</tr>
</tbody>
</table>

In the remaining 15 Safeguard Areas in the current healthcare requirements, Verizon assessed the capability and capacity for Cisco’s Healthcare Reference Model to support technically Direct Control that meet the intent of the Safeguard, or to provide Compensating Controls that, when implemented in conjunction with layered controls, the Healthcare Reference Model could support the fulfillment of the Safeguard; as a technology implementation that would in turn allow for a less complex operating procedure or management process to meet this Safeguard. Verizon has identified the primary security controls that could be used to form a technical foundation of direct and compensating controls, for complying with the healthcare requirements.

Based on our assessment, Verizon believes that Cisco’s Healthcare Reference Architecture provides a robust networking core and infrastructure that can support a customer’s implementation of network security controls and system security controls as part of their security program and as a required HIPAA-Required Risk Management process. The architecture also provides both strong common security controls through network devices and security control and management systems that are highly capable to support data security, and specific security management components that are directly applicable to meet HIPAA safeguard control requirements. The fact that Cisco devices universally support the core security controls outlined in HIPAA Safeguards allows a customer to implement the reference architecture with the confidence that their resulting infrastructure will support HIPAA compliance from the outset, and with the knowledge that any additional use of Cisco’s security management tools will only enhance the protection of ePHI and further support Healthcare compliance.

Cisco’s Healthcare Reference Architecture also provides directly applicable security control features and capabilities owing to the depth of security management tools provided in this model. Directly Applicable controls include: Physical Access Control, Intrusion Detection, and Visual Surveillance;
Network Access and Authentication Controls for wired, wireless, and remote networks; Network Segmentation, Segregation, and Isolation Capabilities; Logging, Auditing, and Monitoring Capabilities; and Encryption.

**Figure C-1  Enterprise-wide Healthcare Reference Architecture**
2. Introduction

Reference Documentation

HIPAA (the “Act”) was signed into law in 1996 (Public Law 104-191). Title II (Fraud, Simplification, and Abuse) of the Act contains the Administrative Simplification provisions with which Covered Entities (CEs) must comply in order to facilitate the exchange of electronic Protected Health Information (ePHI) and to ensure the security and confidentiality of consumer information. The Act asserts that CEs that collect, store, and/or process PHI in electronic form must make a good faith effort to protect the corporate computing environment from reasonably anticipated threats and vulnerabilities, and take reasonable and appropriate measures to protect the integrity, confidentiality, and security of such electronic data. The security protections selected may be examined in the event that the CE and its associated business partners and service providers are the subjects of a compliance audit.

The HIPAA Security Final Rule that implements the Act requires CEs to perform an analysis of the potential risks to the electronic PHI for which they are responsible; and then develop, implement, and maintain appropriate security measures to safeguard the integrity, confidentiality, and availability of that data. Security plans must fully document the security measures implemented by the organization and should reflect the management of risk to acceptable levels. Periodic evaluation of the risks to the corporate computing environment and ePHI is also a requirement.

The HIPAA Security Final Rule is a regulatory framework that incorporates recognized security objectives and protections, but which is intentionally technology-neutral. The Final Rule provides standards and, in some cases, implementation specifications, that require CEs to implement predetermined controls. To achieve a baseline level of compliance, a covered entity must have a comprehensive information security program. The scope and nature of each covered entity’s security program will vary according to its specific environment and associated vulnerabilities as determined through its risk analytical processes. Although the standard is objective, a covered entity’s specific security controls may vary, as the Final Rule permits flexibility in approach to compliance. The Final Rule permits CEs to select “reasonable and appropriate” control measures according to level of risk and potential tolerance within the environment. For example, CEs can achieve compliance with authentication requirements by using strong passwords or through biometric technology. The choice to implement one authentication tool over another must be based in large part on the likelihood a security breach will occur and the potential damage that could result from such a breach.

HIPAA consists of three main Parts (sections) that are designed to put in place security and privacy requirements for protection of Protected Health Information (PHI). Each Part has multiple subparts that provide detail for the section.

- Part 160—General Administrative Requirements: Deals mostly with the legal, compliance, and penalty aspects of HIPAA.
- Part 162—Administrative Requirements: Deals with unique identifiers for Covered Entities in Healthcare, provisions for transactions, and many other administrative issues in Healthcare.
- Part 164—Security and Privacy: Deals with the Safeguards for protecting PHI in electronic and paper media. This section is generally broken down into General Provisions §164.1xx, Security Standards for the Protection of Electronic Protected Health Information §164.3xx,Notification in Case of Breach of Unsecured Protected Health Information §164.4xx and Privacy of Individually Identifiable Health Information §164.5xx. This report deals mainly with the Security Standards for the Protection of Electronic Protected Health Information Subpart C.
There have been multiple discussions surrounding the required security components an organization needs to implement in order to meet HIPAA guidelines. Specific technologies such as intrusion detection and firewalls are not mandated and implementing appropriate security controls to address the requirements are determined by the covered entity.

HIPAA as written includes a flexibility rule in the security standards for determining the appropriate security controls based on a covered entities size, technical infrastructure, and hardware and software capabilities. Under §164.306 Security Standards: General Rules it states:

(b) Flexibility of approach.

(1) Covered entities and business associates may use any security that allow the covered entity or business associate to reasonably and appropriately implement the standards and implementation specifications as specified in this subpart.

(2) In deciding which security to use, a covered entity or business associate must take into account the following factors:

(i) The size, complexity, and capabilities of the covered entity or business associate.

(ii) The covered entity’s or the business associate’s technical infrastructure, hardware, and software security capabilities.

(iii) The costs of security measures.

(iv) The probability and criticality of potential risks to electronic protected health information.

This flexibility has led to confusion on occasion as covered entities attempt to identify appropriate security controls for their organization. Assessors have used current industry-accepted security practices to assess the security controls to determine the level of compliance with the safeguards. Typical infrastructure components such as firewalls, intrusion detection/prevention, and network segmentation are among the technical controls that are industry-accepted security practices assessors typically review.

Business Associate

While HIPAA was written for CEs, consideration was taken into account for partners or Business Associates (BAs) that provide services to the CEs. The U.S. Department of Health and Human Services description of a business associate is: A “business associate” is a person or entity that performs certain functions or activities that involve the use or disclosure of protected health information on behalf of, or provides services to, a covered entity. Further the American Reinvestment and Recovery Act (ARRA) of 2009 and the recent Omnibus Ruling in 2013 placed additional requirements on BAs to implement controls to meet HIPAA Security requirements. This significantly expands the HIPAA security requirements to organizations outside of the healthcare field. Organizations failing to meet the requirements are subject to substantial financial penalties.

Timeframe

Verizon performed this assessment in Q1 and Q2 of 2013. The previous PCI assessment which was performed in 2012 was used as a reference to gather knowledge about Cisco product offerings and to review the reference architecture.
Cisco’s Healthcare Reference Architecture

Cisco’s Healthcare reference architecture supports the networking infrastructure commonly seen in national-level healthcare organizations down to individual clinics operating as part of a regional health group. The architecture supports the centralization of ePHI into regional data centers (i.e. in hospitals or regional data center facilities) or into a central (national data center with regional backups).

The Architecture supports data, system, and application segmentation, segregation, and isolation at the data center level to allow for structuring of systems/network segments containing ePHI (for example, clinical systems) from networks/workstations/systems not intended for ePHI processing or storage (for example, administrative systems). The architecture addresses Internet isolation and patient access, remote secure access into the infrastructure by authenticated users, and the stratification of clinics, administrative offices, hospitals, and out-patient facilities that each have a variable need for ePHI access.
## Reference Model Components

The architecture assessment included the following components:

<table>
<thead>
<tr>
<th>CISCO COMPONENT</th>
<th>SPECIFIC CISCO DEVICES INCLUDED IN THE REFERENCE MODEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco Routers (ISR)</td>
<td>891w-AGN, 1941w, ISR G2, 2921/51 ISR G2, 3945 ISR G2, ASR1002, ISRs are configured with Firewall and IDS feature set.</td>

<td>Configuration and central management of Cisco physical access control devices</td>
</tr>
<tr>
<td>Cisco Physical Access Gateway</td>
<td>Primary controlling device for physical access</td>
</tr>
<tr>
<td>Cisco Identity Services Engine (ISE)</td>
<td>Central Authentication, Policy / Configuration enforcement</td>
</tr>
<tr>
<td>RSA Access Manager</td>
<td>Used for central authentication/logging for access to RSA Data Protection Manager within the assessed environment.</td>
</tr>
<tr>
<td>RSA Authentication Manager</td>
<td>Central management/logging of RSA SecurID (two-factor) authentication for remote access into the data center environment.</td>
</tr>
<tr>
<td>RSA Data Protection Manager</td>
<td>formerly RSA Key Manager</td>
</tr>
<tr>
<td>RSA enVision</td>
<td>RSA’s solution for compliance and security information management. RSA enVision was used to centrally collect RSA SecurID authentication logs on the RSA Authentication Manager server, using a batch process that runs several times a day.</td>
</tr>
<tr>
<td>HyTrust</td>
<td>Network-based virtual infrastructure policy enforcement. Administrative access control, enforcement of policy across virtual infrastructure, hypervisor hardening, and audit logging. Access and User administration, change and configuration, and operations</td>
</tr>
</tbody>
</table>
Network Segmentation and Management

Cisco has designed several network architectures to account for small, medium, and large healthcare IT environments. Cisco chose Integrated Services Routers (ISRs) to provide firewall, IDS, and routing functionality. Access-lists are applied through firewall policies, which are pushed to the ISRs in each architecture. Access-lists implicitly deny all inbound and outbound traffic across the network; Approved traffic must be explicitly allowed to the IP address, port and service level thereby creating access control granularity. Additionally, Cisco has incorporated wireless into the design, using WPA2, WPA-TKIP for secure wireless networking to support seamless control strategies for both wireless and wired networks.

The data center environment is segmented into multiple VLANs, including Internet Edge, WAN aggregation, and Core service aggregation. Multiple layers of network security are included in each data center segment, including Cisco ASA Services Module and ASA stateful firewall filtering and integrated IDS/detection/prevention, access lists, secure VPN (WAN aggregation and remote VPN), and two-factor authentication. These devices allow for fine-grained control of network and system access between systems, and support isolating ePHI-containing systems/servers from IT resources that need not be exposed to ePHI. (e.g. Administrative systems) Network devices are centrally managed through the following:

- Cisco Security Manager (CSM)—(Central security management for ISRs and switches (e.g., firewall policy, IDS/signatures)
- Cisco Wireless Control System (WCS)—Central wireless management
- Cisco ACS—Central TACACS+ (central authentication) server for ASA firewall, Cisco ASA Services Module, ISR, ASR router, switch, wireless controller (RSA enVision and WCS).
- RSA enVision—Central logging/Correlation/Analysis/Alerting server. Alerts from IDS/alerts and firewall logs.
- Cisco ASDM—configuration for ASA firewalls.
- Cisco Device Manager (IDM)—IDS/configuration management.
- Cisco Prime LAN Management Solution (LMS)—Central configuration management, monitoring, and troubleshooting.
- Cisco Identity Services Engine (ISE) – Central Authentication, Policy / Configuration enforcement for ASA firewall, Cisco ASASM, ISR / VXR routers, Cisco switch, and wireless controllers

Wireless LANs and/or Wireless Applications

Wireless networks within the reference environment are configured to use WPA2, WPA-TKIP authentication for secure wireless networking. Wireless traffic must pass through the ISRs and IOS firewall access-lists to traverse any part of the network, thereby controlling wireless access to network segments and devices containing ePHI. Best practice security parameters have been applied to wireless networks, including: HTTPS access for wireless management, default SSID has been changed, SNMPv3 used (default strings changed), and HTTP access has been disabled.

Wireless technology in the PHI environment is a growing concern for organizations in the healthcare field. Implementing wireless requires that appropriate security controls are in place to prevent, detect, and respond to security violations. Appropriate controls include implementing a firewall to segment and protect the PHI data environment and intrusion detection services to identify potential intrusion attempts to the secured network. Encryption must be configured to adequately protect PHI transmitted over the wireless medium.
3. Assessment Findings and Conclusions

The Healthcare Security Requirements revolve around HIPAA Part 164 Part C. HIPAA Part 164 Subpart C is made up of nine sections. Three of the sections are administrative and are not part of this assessment. The remaining six sections consist of 52 Security Safeguards. Verizon performed an initial assessment to determine whether the safeguards could be met by using specific technology components provided by Cisco.

3.1 Safeguard Exclusions

Of the 52 Safeguard Areas in the current healthcare requirements, Verizon identified 29 Safeguards as not applicable in the context of this Assessment because the Safeguard was either explicit and demanding direct (non-technology related) controls, or general but not allowing for the reasonable use of technology as a compensating control in the fulfillment of the Safeguard. The Safeguards deemed as non-applicable under this assessment, and thereby removed for further consideration, include the following.

<table>
<thead>
<tr>
<th>Citation</th>
<th>Safeguard Title</th>
<th>Safeguard Description</th>
<th>Applicability of Technical Solutions to this Safeguard</th>
</tr>
</thead>
<tbody>
<tr>
<td>§164.308(a)(1)(ii)(C)</td>
<td>Risk Analysis</td>
<td>Conduct an accurate and thorough assessment of the potential risks and vulnerabilities to ePHI held by the covered entity or business associate.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. This Safeguard calls for a risk assessment to identify all areas of risk to ePHI. All infrastructure components that process, store or transmit ePHI must be addressed.</td>
</tr>
<tr>
<td>§164.308(a)(1)(ii)(C)</td>
<td>Risk Management</td>
<td>Implement security measures to sufficiently reduce the risks and vulnerabilities to a reasonable and appropriate level.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. This Safeguard calls for the implementation of appropriate controls to address the risks identified in the risk assessment. Technological controls for each infrastructure component need to be evaluated to determine if they can appropriately protect ePHI.</td>
</tr>
<tr>
<td>§164.308(a)(1)(ii)(C)</td>
<td>Sanction Policy (1)(ii)(C)</td>
<td>Ensure that sanctions are in place to discipline workforce members of the covered entity or business associate who fail to comply with the security policies and procedures for protecting ePHI.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. This Safeguard calls for the implementation of an operating Policy with the Customer's environment, and while a strong technical security baseline can support implementation of the Policy, it cannot substitute for a written policy that is distributed across the workforce.</td>
</tr>
<tr>
<td>§164.308(a)(2)</td>
<td>Assigned security responsibility</td>
<td>Assign responsibility for the development and implementation of the policies and procedures for protecting ePHI required by the covered entity and business associates.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. - This safeguard calls for the covered entity to formally assign an individual who is responsibility for the security program development and implementation of appropriate policies and procedures to protect ePHI. This is a personnel issue only and there is no technology requirements directly affiliated with this safeguard.</td>
</tr>
<tr>
<td>§164.308(a)(3)(ii)(B)</td>
<td>Workforce Clearance Procedure</td>
<td>Implement policies and procedures to determine that access of workforce members to ePHI is appropriate.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking for a policy and procedure to ensure that access to ePHI is appropriate. While technical controls may be used implement the policy, it Is not the direct intent of this safeguard.</td>
</tr>
<tr>
<td>§164.308(a)(5)(ii)(A)</td>
<td>Security Reminders</td>
<td>Identify and distribute periodic security updates to all members of the workforce including management.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that policies and procedures are in place for the occasional distribution of security reminders to reinforce or update all staff on new threats and vulnerabilities.</td>
</tr>
<tr>
<td>§164.308(a)(7)(ii)(A)</td>
<td>Data Backup Plan</td>
<td>Establish and implement procedures to create and maintain retrievable copies of ePHI.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. - This Safeguard calls for backing up data and storing copies off-site that can be retrieved in response to an emergency that damages systems that contain ePHI.</td>
</tr>
<tr>
<td>§164.308(a)(7)(ii)(B)</td>
<td>Disaster Recovery Plan</td>
<td>Establish and implement procedures to restore any loss of ePHI data.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. - This Safeguard calls for a documented plan to restore any loss of ePHI data.</td>
</tr>
<tr>
<td>§164.308(a)(7)(ii)(D)</td>
<td>Testing and Revision Procedures</td>
<td>Implement procedures for periodic testing and revision of contingency plans.</td>
<td>This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This Safeguard calls for the periodic testing and revision of the disaster recovery plan.</td>
</tr>
</tbody>
</table>
### 3. Assessment Findings and Conclusions

<p>| §164.308(a)(7)(ii)(E) | Applications and Data Criticality | Assess the relative criticality of specific applications and data in support of other contingency plan components. This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This Safeguard calls for the criticality of each application to be assessed to determine the priority required to restore applications in an emergency. |
| §164.308(b)(1) | Business Associate Contracts | Each covered entity is required to obtain satisfactory assurances that business associates that create, receive or maintain or transmit ePHI on the covered entities behalf will appropriately safeguard the information in accordance with HIPAA regulations. This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. - This safeguard calls for contractual assurances (legal) that ePHI will be appropriately protected when in custody of a business associate of the covered entity. |
| §164.310(a)(2)(i) | Contingency Operation | Establish and implement procedures that allow for facility access in support of restoration of lost data under disaster recovery plan and emergency access mode operations. This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This Safeguard calls for policies and procedures that allow for access to the facilities to restore lost data during a disaster or emergency. |
| §164.310(a)(2)(ii) | Facility Security Plan | Implement policies and procedures to safeguard the facility and the equipment inside from physical access, tampering and theft. This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. - This safeguard is looking to ensure that physical access is available to authorized personnel to support the restoration of lost data in contingency operations. |
| §164.310(a)(2)(iv) | Facility Access Controls - Maintenance Records | Description: Implement policies and procedures to document repairs and modifications to the physical components of a facility which are related to security. This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that devices providing physical security are maintained to prevent failure and allow unauthorized physical access to the facilities that process, store or transmit ePHI. |
| $\text{§164.310(b)}$ | Workstation Use-Workstation Use | Description: Implement policies and procedures that specify the proper functions and the physical attributes for workstations that can access ePHI. | This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that all employees or contractors that have access to a workstation that has or may have access to ePHI is aware of the appropriate use of the workstation. |
| $\text{§164.310(c)}$ | Workstation Security-Workstation Security | Description: Implement physical safeguards for all workstations that access ePHI. | This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that all workstations that have or may have access to ePHI are appropriately secured to prevent unauthorized access. |
| $\text{164.310(d)(2)(i)}$ | Device and Media Controls- Device and Media Disposal | Description: Implement policies and procedures to address the final disposition of electronic protected health information, and/or the hardware or electronic media on which it is stored. | This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that policies and procedures are in place remove ePHI from devices and media before disposal. |
| $\text{§164.310(d)(2)(ii)}$ | Device and Media Controls - Media Re-Use | Description: Implement procedures for removal of electronic protected health information from electronic media before the media are made available for re-use. | This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that policies and procedures are in place remove ePHI from devices and media before they are re-used. |
| $\text{§164.310(d)(2)(iii)}$ | Accountability - Asset Ownership and Location | Assign responsibility for recording and maintaining the movement of hardware and electronic media that contain ePHI. | This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. - Solution requires Asset and device ownership to identify where assets containing ePHI are located. Designed to ensure that data is not exposed unintentionally. |
| $\text{§164.310(d)(2)(iv)}$ | Device and Media Controls - Data Backup and Storage | Description: Create a retrievable exact copy of ePHI when needed before movement of equipment. | This safeguard does not require strong technical controls to meet the safeguards, it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that an exact backup copy of ePHI is made before a device is moved. |</p>

<td>Documentation Time Limit</td>
</tr>
</tbody>
</table>
§164.316(b)(2)  Documentation Availability  Ensure that documentation is available to the persons responsible for implementing the procedures.  This safeguard does not require strong technical controls to meet the safeguards; it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that policies and procedures are available to the person(s) responsible for implementing the procedures to which the documentation pertains.

§164.316(b)(2)  Documentation Updates  Review documentation periodically and update as needed in response to environmental or operational changes affecting the security of ePHI.  This safeguard does not require strong technical controls to meet the safeguards; it is designed to use policies and procedures to put the appropriate controls in place. Technology controls may be used for the implementation of part of the safeguard. – This safeguard is looking to ensure that policies and procedures are reviewed and periodically updated as needed in response to environmental or operational changes that could affect the security of ePHI.

### 3.2 Safeguards Provided throughout the Reference Model

Of the remaining 23 Safeguard Areas in the current healthcare requirements, Verizon has further identified 8 Safeguards that call for universal security control requirements that are foundational across Cisco’s products and present in all network devices and systems that make up Cisco’s Healthcare Reference Architecture. The Safeguards deemed as universally applicable under this assessment are explained here and removed for additional detailed consideration.

<table>
<thead>
<tr>
<th>Citation</th>
<th>Safeguard Title</th>
<th>Safeguard Description</th>
<th>Applicability of Technical Solutions to this Safeguard</th>
</tr>
</thead>
<tbody>
<tr>
<td>164.308(a)(1)(i)</td>
<td>Security Management Process</td>
<td>Implement policies and procedures to prevent, detect, contain and correct security violations.</td>
<td>Cisco devices provide security to help an organization prevent, detect and contain security violations. When combining multiple devices in the design guide, multiple levels of security can be put in place to help an organization meet the security requirements of HIPAA.</td>
</tr>
<tr>
<td>§164.308(a)(5)(i)</td>
<td>Protection from Malicious Software (5)(ii)(B)</td>
<td>Ensure that appropriate protections against malicious software are in place.</td>
<td>Patch management and protection from malicious software is a hallmark of Cisco’s vulnerability management process and services provided around all Cisco products. Cisco continually reviews potential network, systems and applications threat, attack vectors being used to attempt to penetrate network and systems services, assesses the applicability of these attacks to Cisco products, and, as warranted, issues software patches and improvements to continually stay in front of the impact of malicious software or attacks. Additionally, Cisco firewalls and routers provide network segmentation that can help contain malicious software to a network segment.</td>
</tr>
<tr>
<td>§164.308(a)(5)(i)</td>
<td>Password Management (5)(ii)(D)</td>
<td>Ensure that appropriate policies and procedures are in place to manage passwords for network access and access to sensitive data to ensure that passwords are strong enough to prevent them from being guessed or exposed to brute force attacks and processes are in place to manage and protect passwords from compromise or exposure.</td>
<td>Cisco systems and devices all use strong passwords in support of this requirement. Passwords can be configured for AES encryption during transit and in storage providing a higher layer of security and preventing password theft by physical compromise of the device. Administrator passwords can be set to match current industry accepted practices for length, complexity, history, lifetime, failed login attempts and can be authenticated using TACACS or Active Directory.</td>
</tr>
<tr>
<td>§164.308(a)(8)</td>
<td>Periodic Technical and Non-Technical Evaluation</td>
<td>Ensure that periodic technical (pen/vulnerability tests, etc.) and non-technical (policy/procedural, etc.) evaluations are occurring to continue to meet the regulatory security requirements and any changes in the environmental and operational that may affect sensitive (ePHI) data. To ensure that systems and networks are tested periodically to ensure that protections are still in place and working effectively.</td>
<td>Most Cisco systems and network devices included in the Healthcare Reference Model comply with generally accepted industry practices in the support of network and system testing and validation. Cisco routers and switches support SPAN and RSPAN for analyzing network traffic.</td>
</tr>
<tr>
<td>§164.312(a)(1)</td>
<td>Unique User Identification (a)(2)(i)</td>
<td>Ensure that each user who has access to sensitive (ePHI) data has a unique user id. Solution requires Identification controls.</td>
<td>Most Cisco applications, systems and devices support assigning unique user identifiers in support of this requirement. Unique Ids can be assigned to network users to access systems and applications and to network administrators to monitor and update the network infrastructure.</td>
</tr>
</tbody>
</table>
4. Safeguard Mapping to Security Control Areas

In the remaining 15 Safeguard Areas in the current healthcare requirements, Verizon assessed the capability and capacity for Cisco’s Healthcare Reference Model to support technically Direct Control that meet the intent of the Safeguard, or to provide Compensating Controls that, when implemented together in the Healthcare Reference Model, could support the fulfillment of the Safeguard; as a technology implementation that would in turn allow for a less complex operating procedure or management process to meet this Safeguard.

Verizon has identified the primary Physical, Network, System, and Application layer security controls that could be used to form a technical foundation of direct and compensating controls, for complying with the healthcare requirements. The breakdown of the remaining Safeguards into major control groups is as follows.

| §164.312(a)(1) | Automatic Logoff (a)(2)(iii) | Ensure that policies, procedures and technical controls are in place to automatically logoff (terminate) a session after a predetermined period of inactivity. | Most Cisco applications, systems and devices support automatic logoff in support of this requirement. The time for session timeout can be configured based on policy requirements. Session timeout can vary by device or be configured for a universal timeout for all devices. |
| §164.312(d) | Person or Entity Authentication | Ensure that policies and procedures are in place to identify person or entity seeking access to sensitive (ePHI) data. Solution requires Authentication mechanisms. | Most Cisco applications, systems and devices support authentication in support of this requirement. Authentication can be Role-based authentication or Unique User Id accounts depending on the organizations policies, regulatory and business requirements. |
| §164.312(e)(1) | Integrity Controls (e)(2)(i) | Ensure that policies and procedures are in place to verify that data has not been altered or destroyed in an unauthorized manner during transmission. Solution requires signing of data or other integrity controls. | Cisco systems and devices use multiple forms of integrity monitoring to protect information from improper alteration or destruction of data at rest or in transit. Cisco devices support File-integrity monitoring or change- detection software on logs to ensure that existing log data cannot be changed without generating alerts. Integrity during transmission |

Cisco’s Healthcare Reference architecture provides a robust networking core and infrastructure that can support a customer’s implementation of network security controls and system security controls as part of their security program and as required HIPAA-Required Risk Management process.

The architecture also provides both strong common security controls through network devices and security control and management systems that are highly capable to support data security, and specific security management components that are directly applicable to meet HIPAA safeguard control requirements.

### Strong Common Controls:

- Protection from Malicious Software (§164.308(a)(5)(i)).
- Password Management (§164.308(a)(5)(i))
- Periodic Technical and Non-Technical Evaluation (§164.312(a)(1))
- Unique User Identification (§164.312(a)(1))

### Technical Safeguards

- **Automatic Logoff** (§164.312(a)(1))
- **Person or Entity Authentication** (§164.312(d))
- **Integrity Controls** (§164.312(e)(1))

The fact that Cisco devices universally support the core security controls outlined in HIPAA safeguards, allows a customer to implement the reference architecture with the confidence that their resulting infrastructure will support HIPAA compliance from the outset, and with the knowledge that any additional use of Cisco’s security management tools, will only enhance the protection of ePHI and further support Healthcare compliance.

Cisco’s Healthcare Reference Architecture also provides directly applicable security control features and capabilities owing to the depth of security management tools provided in this model. Directly Applicable control include:

- **Physical Access Control, Intrusion Detection, and Visual Surveillance.** Cisco’s Physical Access Manager and Physical Access Gateway products provide the control structure for to use electronic access controls, intrusion detection, and visual surveillance components to control physical access to a wide range of healthcare facilities from landlord closets housing Clinic IT equipment in leasing situations, to the control of physical security at remote and co-located Clinics, to the development and integration of remote facilities into Hospital physical security systems.

- **Network Access and Authentication Controls for wired, wireless, and remote Networks.** Cisco’s Reference architecture provides for network access control and authentication of both users and systems operating on wired WAN/LANs, access wireless networks, and access Customer networks remotely, in a seamless approach that supports multiple HIPAA safeguard requirements for Identify Management, Access Controls, user and system authorization, and authentication.

- **Network Segmentation, Segregation, and Isolation Capabilities.** Cisco’s healthcare reference architecture provide unsurpassed capability to deliver fine grained control over the ability of a user on a clinical or administrative workstation, on a medical device, or administrative console to have network access to systems, servers, and storage devices that contain ePHI. Cisco’s architecture allow a Customer to develop and maintain segmentation between administrative and clinical systems, to structure sub-networks for only administrative workstations, medical devices, server farms, and publicly-facing web servers. Customers can establish and maintain user and system segregation by their role/function within Clinics and Hospitals, and Customers can demonstrate isolation of EPHI-containing systems/storage as a part of their overall ePHI protection strategy. Customer can meet HIPAA’s clearinghouse isolation requirements. Customers can plan for and execute emergency rerouting and access strategies to support continued operations during natural disasters, in order to maintain patient data security while support emergency care. Customers can ensure that workforce members are granted access based on their role in the institution, and can also terminate access at the network level to support HIPAA's Sanction/Termination requirements.

- **Logging, Auditing, and Monitoring Capabilities.** Cisco’s Healthcare Reference Architecture also provides robust and well managed logging capabilities, support routine and event-driven authoring, support continuous monitoring of the network and system environment for control, and provides the ability to investigate and interrogate devices as needed in support of data breach events. The Reference Architecture supports HIPAA’s Information System Activity Review requirements by providing an infrastructure to log, audit, and monitor network and system behavior and support the tracking of user and system access or patient information. While used as part of a total activity review strategy, Cisco’s Security Manager, Identity Service Engine, and Suite of RSA products, for a solid platform for developing a total activity review and control solution. Cisco’s Reference Architecture provide the centralized logging capabilities and auditing features to support effective audit of ePHI controls by Customer’s security team, internal auditors, external auditors, and regulators. Cisco’s suite of IDS/IPS products in the Reference Architecture provide the Customer with ab alerting foundation to support the “Response and Reporting” Safeguard requirements.
Encryption of ePHI. Cisco’s reference architecture allows Customers to realize the substantial security control that can be exerted through ePHI encryption while at rest and in transit to further protect ePHI when application layer security control might fail or be bypassed, or when operational errors inadvertently release patient information or lose track of servers containing ePHI. The reference architecture core and vBlock products support seamless data encryption and decryption on the fly, without the traditional performance concerns. The reference architecture also support HIPAA’s data integrity requirements, protecting ePHI from “improper alteration” while stored or while in transit across private and public networks.
