Configuring Interface Characteristics  1

Finding Feature Information  1

Information About Configuring Interface Characteristics  1

Interface Types  1

Port-Based VLANs  2

Switch Ports  2

Routed Ports  3

Switch Virtual Interfaces  4

EtherChannel Port Groups  5

Power over Ethernet Ports  5

Using the Switch USB Ports  6

USB Mini-Type B Console Port  6

USB Type A Ports  7

Interface Connections  7

Interface Configuration Mode  7

Default Ethernet Interface Configuration  9

Interface Speed and Duplex Mode  10

Speed and Duplex Configuration Guidelines  10

IEEE 802.3x Flow Control  11

Layer 3 Interfaces  11

How to Configure Interface Characteristics  12

Configuring Interfaces  12

Adding a Description for an Interface  13

Configuring a Range of Interfaces  14
Configuring and Using Interface Range Macros 16
Configuring Ethernet Interfaces 17
  Setting the Interface Speed and Duplex Parameters 17
Configuring IEEE 802.3x Flow Control 19
Configuring Layer 3 Interfaces 20
Configuring SVI Autostate Exclude 22
Shutting Down and Restarting the Interface 23
Configuring the Console Media Type 24
Configuring the USB Inactivity Timeout 25
Monitoring Interface Characteristics 26
  Monitoring Interface Status 26
Clearing and Resetting Interfaces and Counters 27
Configuration Examples for Interface Characteristics 28
  Configuring a Range of Interfaces: Examples 28
  Configuring and Using Interface Range Macros: Examples 28
  Setting Interface Speed and Duplex Mode: Example 29
  Configuring Layer 3 Interfaces: Example 29
  Configuring the Console Media Type: Example 29
  Configuring the USB Inactivity Timeout: Example 30
Additional References for the Interface Characteristics Feature 30
Feature History and Information for Configuring Interface Characteristics 31

CHAPTER 2

Configuring Auto-MDIX 33
  Prerequisites for Auto-MDIX 33
  Restrictions for Auto-MDIX 33
  Information About Configuring Auto-MDIX 34
    Auto-MDIX on an Interface 34
  How to Configure Auto-MDIX 34
    Configuring Auto-MDIX on an Interface 34
  Example for Configuring Auto-MDIX 35
  Additional References 36
Feature History and Information for Auto-MDIX 36

Restrictions for Configuring IGMP 123

Information About IGMP 124

Role of the Internet Group Management Protocol 124

IGMP Multicast Addresses 124

IGMP Versions 124

IGMP Version 1 125

IGMP Version 2 125

IGMP Version 3 125

IGMPv3 Host Signalling 125

IGMP Versions Differences 125

IGMP Join and Leave Process 127

IGMP Join Process 127

IGMP Leave Process 128

Default IGMP Configuration 128

How to Configure IGMP 129

Configuring the Device as a Member of a Group 129

Controlling Access to IP Multicast Group 130

Changing the IGMP Version 132

Modifying the IGMP Host-Query Message Interval 134

Changing the IGMP Query Timeout for IGMPv2 135

Changing the Maximum Query Response Time for IGMPv2 137

Configuring the Device as a Statically Connected Member 138

Monitoring IGMP 140

Configuration Examples for IGMP 141

Example: Configuring the Device as a Member of a Multicast Group 141

Example: Controlling Access to IP Multicast Groups 141

Additional References 141

Feature History and Information for IGMP 142

CHAPTER 14 Configuring IGMP Snooping and Multicast VLAN Registration 143

Prerequisites for Configuring IGMP Snooping and MVR 143

Prerequisites for IGMP Snooping 143

Restrictions for Configuring IGMP Snooping and MVR 144

Restrictions for IGMP Snooping 144
Configuring MVR Interfaces  172
Configuring IGMP Profiles  174
Applying IGMP Profiles  176
Setting the Maximum Number of IGMP Groups  177
Configuring the IGMP Throttling Action  179
Monitoring IGMP Snooping and MVR  181
  Monitoring IGMP Snooping Information  181
  Monitoring MVR  182
  Monitoring IGMP Filtering and Throttling Configuration  183
Configuration Examples for IGMP Snooping and MVR  184
  Example: Configuring IGMP Snooping Using CGMPPackets  184
  Example: Enabling a Static Connection to a Multicast Router  184
  Example: Configuring a Host Statically to Join a Group  184
  Example: Enabling IGMP Immediate Leave  184
  Example: Setting the IGMP Snooping Querier Source Address  184
  Example: Setting the IGMP Snooping Querier Maximum Response Time  184
  Example: Setting the IGMP Snooping Querier Timeout  185
  Example: Setting the IGMP Snooping Querier Feature  185
  Example: Configuring IGMP Profiles  185
  Example: Applying IGMP Profile  185
  Example: Setting the Maximum Number of IGMP Groups  185
  Example: Configuring MVR Global Parameters  186
  Example: Configuring MVR Interfaces  186
Additional References  186

Information About Implementing IPv6 Multicast Routing 343

IPv6 Multicast Overview 343

IPv6 Multicast Routing Implementation 344

MLD Access Group 344

Explicit Tracking of Receivers 344

Protocol Independent Multicast 344

PIM-Sparse Mode 345

IPv6 BSR: Configure RP Mapping 345

PIM-Source Specific Multicast 346

Routable Address Hello Option 346

PIM IPv6 Stub Routing 346

Static Mroutes 347

MRIB 347

MFIB 348

Distributed MFIB 348

IPv6 Multicast Process Switching and Fast Switching 349

Implementing IPv6 Multicast 349

Enabling IPv6 Multicast Routing 349

Customizing and Verifying the MLD Protocol 350

Customizing and Verifying MLD on an Interface 350

Implementing MLD Group Limits 351

Configuring Explicit Tracking of Receivers to Track Host Behavior 351

Resetting the MLD Traffic Counters 352

Clearing the MLD Interface Counters 353

Configuring PIM 353

Configuring PIM-SM and Displaying PIM-SM Information for a Group Range 353

Configuring PIM Options 355

Resetting the PIM Traffic Counters 356

Clearing the PIM Topology Table to Reset the MRIB Connection 357

Configuring PIM IPv6 Stub Routing 358
CHAPTER 24

Configuring IPv6 ACL  371
Finding Feature Information  371
Information About Configuring IPv6 ACLs  371
Understanding IPv6 ACLs  371
Supported ACL Features  372
IPv6 ACL Limitations  372
Configuring IPv6 ACLs  373
Default IPv6 ACL Configuration  373
Interaction with Other Features and Switches  374
Creating an IPv6 ACL  374
Applying an IPv6 to an Interface  377
Displaying IPv6 ACLs  379
Configuration Examples for IPv6 ACL  379
Example: Creating an IPv6 ACL  379
Example: Applying IPv6 ACLs  380
Example: Displaying IPv6 ACLs  380
CHAPTER 26

Configuring Multiple Spanning-Tree Protocol 409

Finding Feature Information 409
Prerequisites for MSTP 409
Restrictions for MSTP 410
Information About MSTP 410
MSTP Configuration 410
MSTP Configuration Guidelines 411
Root Switch 411
Multiple Spanning-Tree Regions 412
IST, CIST, and CST 412
Operations Within an MST Region 413

  - End-to-End QoS Solution Using Classification  
- QoS Basic Model  
  - Actions at Ingress Port  
  - Actions at Egress Port  
- Classification Overview  
- Policing and Marking Overview  
- Mapping Tables Overview  
- Queueing and Scheduling Overview  
- Queueing and Scheduling on Egress Queues  
- Packet Modification
Standard QoS Default Configuration 762
  Default Egress Queue Configuration 762
  Default Mapping Table Configuration 763
DSCP Maps 764
  Default CoS-to-DSCP Map 764
  Default IP-Precedence-to-DSCP Map 764
  Default DSCP-to-CoS Map 765
How to Configure QoS 765
  Enabling QoS Globally 765
  Enabling VLAN-Based QoS on Physical Ports 766
Configuring Classification Using Port Trust States 767
  Configuring the Trust State on Ports Within the QoS Domain 768
  Configuring the CoS Value for an Interface 770
  Configuring a Trusted Boundary to Ensure Port Security 771
  Enabling DSCP Transparency Mode 774
  Configuring the DSCP Trust State on a Port Bordering Another QoS Domain 775
Configuring a QoS Policy 778
  Classifying Traffic by Using ACLs 778
  Classifying Traffic by Using Class Maps 785
  Classifying Traffic by Using Class Maps and Filtering IPv6 Traffic 788
  Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps 790
  Classifying, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps 794
  Classifying, Policing, and Marking Traffic by Using Aggregate Policers 803
Configuring DSCP Maps 805
  Configuring the CoS-to-DSCP Map 805
  Configuring the IP-Precedence-to-DSCP Map 806
  Configuring the Policed-DSCP Map 807
  Configuring the DSCP-to-CoS Map 808
  Configuring the DSCP-to-DSCP-Mutation Map 809
Configuring Ingress Queue Characteristics 811
  Configuration Guidelines 812
  Mapping DSCP or CoS Values to an Ingress Queue and Setting WTD Thresholds 812
  Allocating Buffer Space Between the Ingress Queues 814
  Allocating Bandwidth Between the Ingress Queues 815
Configuring Egress Queue Characteristics 816
  Configuration Guidelines 817
  Allocating Buffer Space to and Setting WTD Thresholds for an Egress Queue Set 817
  Mapping DSCP or CoS Values to an Egress Queue and to a Threshold ID 820
  Configuring SRR Shaped Weights on Egress Queues 822
  Configuring SRR Shared Weights on Egress Queues 824
  Configuring the Egress Expedite Queue 825
  Limiting the Bandwidth on an Egress Interface 827

Monitoring Standard QoS 828

Configuration Examples for QoS 829
  Example: Configuring Port to the DSCP-Trusted State and Modifying the DSCP-to-DSCP-Mutation Map 829
  Examples: Classifying Traffic by Using ACLs 829
  Examples: Classifying Traffic by Using Class Maps 830
  Examples: Classifying, Policing, and Marking Traffic on Physical Ports Using Policy Maps 832
  Examples: Classifying, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps 833
  Examples: Classifying, Policing, and Marking Traffic by Using Aggregate Policers 835
  Examples: Configuring DSCP Maps 836
  Examples: Configuring Egress Queue Characteristics 838

How to Configure Bidirectional Forwarding Detection 939
Configuring BFD Session Parameters on the Interface 939
Configuring BFD Support for Static Routing 940
Configuring the BFD Slow Timer 942
## Configuring IPv6 First Hop Security

- Finding Feature Information 963
- Prerequisites for First Hop Security in IPv6 963
- Restrictions for First Hop Security in IPv6 964
- Information about First Hop Security in IPv6 964
- How to Configure an IPv6 Snooping Policy 966
  - How to Attach an IPv6 Snooping Policy to an Interface 968
  - How to Attach an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface 969
- How to Configure the IPv6 Binding Table Content 970
- How to Configure an IPv6 Neighbor Discovery Inspection Policy 972
  - How to Attach an IPv6 Neighbor Discovery Inspection Policy to an Interface 973
  - How to Attach an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface 974
- How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy on a Device 976
  - How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy on an Interface 976
  - How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy to a Layer 2 EtherChannel Interface 977
- How to Configure an IPv6 Router Advertisement Guard Policy 978
  - How to Attach an IPv6 Router Advertisement Guard Policy to an Interface 981
  - How to Attach an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface 982
- How to Configure an IPv6 DHCP Guard Policy 983
  - How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface 985
  - How to Attach an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface 986
- How to Configure IPv6 Source Guard 987
  - How to Attach an IPv6 Source Guard Policy to an Interface 989
  - How to Attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface 989
- How to Configure IPv6 Prefix Guard 990
  - How to Attach an IPv6 Prefix Guard Policy to an Interface 991
  - How to Attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface 992

Finding Feature Information 1073
Prerequisites for Configuring RADIUS 1073
Restrictions for Configuring RADIUS 1074
Information about RADIUS 1074
  RADIUS and Switch Access 1074
  RADIUS Overview 1075
  RADIUS Operation 1075
  Default RADIUS Configuration 1076
  RADIUS Server Host 1076
  RADIUS Login Authentication 1077
  AAA Server Groups 1077
  AAA Authorization 1077
  RADIUS Accounting 1078
  Vendor-Specific RADIUS Attributes 1078
  RADIUS Disconnect-Cause Attribute Values 1089
  RADIUS Progress Codes 1093
  Vendor-Proprietary RADIUS Server Communication 1093
  Enhanced Test Command 1094
How to Configure RADIUS 1094
  Identifying the RADIUS Server Host 1094
  Configuring Settings for All RADIUS Servers 1096
  Configuring RADIUS Login Authentication 1097
  Defining AAA Server Groups 1100
  Configuring RADIUS Authorization for User Privileged Access and Network Services 1102
  Starting RADIUS Accounting 1103
  Verifying Attribute 196 1104
  Configuring the Device to Use Vendor-Specific RADIUS Attributes 1105
  Configuring the Device for Vendor-Proprietary RADIUS Server Communication 1106
  Configuring a User Profile and Associating it with the RADIUS Record 1108
  Verifying the Enhanced Test Command Configuration 1109
Configuration Examples for RADIUS 1109
  Examples: Identifying the RADIUS Server Host 1109
  Example: Using Two Different RADIUS Group Servers 1109
  Examples: AAA Server Groups 1110
Troubleshooting Tips for RADIUS Progress Codes 1110
Examples: Configuring the Switch to Use Vendor-Specific RADIUS Attributes 1111
Example: Configuring the Switch for Vendor-Proprietary RADIUS Server Communication 1111
Example: User Profile Associated With the test aaa group Command 1111
Additional References for RADIUS 1112
Feature Information for RADIUS 1113

CHAPTER 52 RADIUS Server Load Balancing 1115
Finding Feature Information 1115
Prerequisites for RADIUS Server Load Balancing 1115
Restrictions for RADIUS Server Load Balancing 1116
Information About RADIUS Server Load Balancing 1116
  RADIUS Server Load Balancing Overview 1116
  Transaction Load Balancing Across RADIUS Server Groups 1116
  RADIUS Server Status and Automated Testing 1117
How to Configure RADIUS Server Load Balancing 1118
  Enabling Load Balancing for a Named RADIUS Server Group 1118
  Enabling Load Balancing for a Global RADIUS Server Group 1119
Troubleshooting RADIUS Server Load Balancing 1120
Configuration Examples for RADIUS Server Load Balancing 1122
  Example: Enabling Load Balancing for a Named RADIUS Server Group 1122
  Example: Enabling Load Balancing for a Global RADIUS Server Group 1124
  Example: Monitoring Idle Timer 1126
  Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 1127
  Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 1127
  Example: Configuring the Preferred Server with Overlapping Authentication and Authorization Servers 1127
  Example: Configuring the Preferred Server with Authentication Servers As a Subset of Authorization Servers 1128
  Example: Configuring the Preferred Server with Authentication Servers As a Superset of Authorization Servers 1128
Additional References for RADIUS Server Load Balancing 1129
Feature Information for RADIUS Server Load Balancing 1129
CHAPTER 53  RADIUS Change of Authorization Support  1131
Finding Feature Information  1131
Information About RADIUS Change-of-Authorization  1131
  RADIUS Change of Authorization  1131
  Change-of-Authorization Requests  1133
RFC 5176 Compliance  1133
Preconditions  1135
  CoA Request Response Code  1135
Session Identification  1135
  Session Identification  1136
  CoA ACK Response Code  1136
  CoA NAK Response Code  1136
  Session Reauthentication  1136
  Session Reauthentication in a Switch Stack  1137
Session Termination  1137
  CoA Activate Service Command  1137
  CoA Deactivate Service Command  1138
  CoA Request: Disable Host Port  1139
  CoA Request: Bounce-Port  1140
  CoA Session Query Command  1140
  CoA Session Reauthenticate Command  1141
  CoA Session Terminate Command  1141
Stacking Guidelines for Session Termination  1141
  Stacking Guidelines for CoA-Request Bounce-Port  1142
  Stacking Guidelines for CoA-Request Disable-Port  1142
How to Configure RADIUS Change-of-Authorization  1142
  Configuring CoA on the Device  1142
  Monitoring and Troubleshooting CoA Functionality  1145
Additional References for RADIUS Change-of-Authorization  1145
  Feature Information for RADIUS Change-of-Authorization Support  1146

CHAPTER 54  Local AAA Server  1147
Finding Feature Information  1147
Contents

CHAPTER 55  Configuring Kerberos  1157
Finding Feature Information  1157
Prerequisites for Controlling Switch Access with Kerberos  1157
Restrictions for Controlling Switch Access with Kerberos  1158
Information about Kerberos  1158
   Kerberos and Switch Access  1158
   Kerberos Overview  1158
   Kerberos Operation  1160
      Authenticating to a Boundary Switch  1160
      Obtaining a TGT from a KDC  1161
      Authenticating to Network Services  1161
How to Configure Kerberos  1161
Monitoring the Kerberos Configuration  1161
Additional References  1162
Feature Information for Kerberos  1162

Prerequisites for Local AAA Server  1147
Information About Local AAA Server  1148
   Local Authorization Attributes Overview  1148
   Local AAA Attribute Support  1148
   AAA Attribute Lists  1148
      Converting from RADIUS Format to Cisco IOS AAA Format  1148
   Validation of Attributes  1149
How to Configure a Local AAA Server  1149
   Defining a AAA Attribute List  1149
   Defining a Subscriber Profile  1151
   Monitoring and Troubleshooting a Local AAA Server  1152
Configuration Examples for Local AAA Server  1154
   Example: Local AAA Server  1154
   Example: Mapping from the RADIUS Version of a Particular Attribute to the Cisco IOS AAA Version  1155
Additional References for Local AAA Server  1155
Feature Information for Local AAA Server  1156

Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)
CHAPTER 56  Configuring Accounting  1163

Finding Feature Information  1163
Prerequisites for Configuring Accounting  1163
Restrictions for Configuring Accounting  1164
Information About Configuring Accounting  1164
  Named Method Lists for Accounting  1164
    Method Lists and Server Groups  1165
    AAA Accounting Methods  1165
    Accounting Record Types  1166
    AAA Accounting Methods  1166
AAA Accounting Types  1166
  Network Accounting  1166
  EXEC Accounting  1169
  Command Accounting  1170
  Connection Accounting  1171
  System Accounting  1173
  Resource Accounting  1173
  VRSS Accounting  1175
AAA Accounting Enhancements  1176
  AAA Broadcast Accounting  1176
  AAA Session MIB  1176
  Accounting Attribute-Value Pairs  1177
How to Configure Accounting  1177
  Configuring AAA Accounting Using Named Method Lists  1177
    Configuring RADIUS System Accounting  1179
  Suppressing Generation of Accounting Records for Null Username Sessions  1180
  Generating Interim Accounting Records  1180
  Generating Accounting Records for Failed Login or Session  1181
  Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records  1181
  Configuring AAA Resource Failure Stop Accounting  1182
  Configuring AAA Resource Accounting for Start-Stop Records  1182
  Configuring AAA Broadcast Accounting  1182
  Configuring Per-DNIS AAA Broadcast Accounting  1182
Configuring AAA Session MIB 1183
Configuring VRRS Accounting 1183
Establishing a Session with a Device if the AAA Server is Unreachable 1185
Monitoring Accounting 1185
Troubleshooting Accounting 1186
Configuration Examples for Accounting 1186
  Example Configuring Named Method List 1186
  Example Configuring AAA Resource Accounting 1188
  Example Configuring AAA Broadcast Accounting 1188
  Example Configuring Per-DNIS AAA Broadcast Accounting 1189
  Example AAA Session MIB 1189
  Example Configuring VRRS Accounting 1189
Additional References for Configuring Accounting 1190
Feature Information for Configuring Accounting 1191

CHAPTER 57
Configuring Local Authentication and Authorization 1193
  Finding Feature Information 1193
  How to Configure Local Authentication and Authorization 1193
    Configuring the Switch for Local Authentication and Authorization 1193
  Monitoring Local Authentication and Authorization 1196
Additional References 1196
Feature Information for Local Authentication and Authorization 1196

CHAPTER 58
Certification Authority Interoperability 1197
  Finding Feature Information 1197
  Prerequisites For Certification Authority 1197
  Restrictions for Certification Authority 1197
  Information About Certification Authority 1198
    CA Supported Standards 1198
    Purpose of CAs 1198
  Implementing IPsec Without CAs 1199
  Implementing IPsec With CAs 1199
  Implementing IPsec with Multiple Root CAs 1200
  How CA Certificates Are Used by IPsec Devices 1200
Registration Authorities 1201
How to Configure Certification Authority 1201
Managing NVRAM Memory Usage 1201
Configuring the Device Host Name and IP Domain Name 1202
Generating an RSA Key Pair 1203
Declaring a Certification Authority 1203
Configuring a Root CA (Trusted Root) 1205
Authenticating the CA 1206
Requesting Signed Certificates 1207
Monitoring and Maintaining Certification Authority 1208
Requesting a Certificate Revocation List 1208
Querying a Certification Revocation List 1209
Deleting RSA Keys from a Device 1210
Deleting Public Keys for a Peer 1211
Deleting Certificates from the Configuration 1212
Viewing Keys and Certificates 1213

MAC Authentication Bypass 1215
Finding Feature Information 1215
Prerequisites for Configuring MAC Authentication Bypass 1215
Information About MAC Authentication Bypass 1216
Overview of the Cisco IOS Auth Manager 1216
Overview of the Configurable MAB Username and Password 1216
How to Configure MAC Authentication Bypass 1217
Enabling MAC Authentication Bypass 1217
Enabling Reauthentication on a Port 1218
Specifying the Security Violation Mode 1220
Enabling Configurable MAB Username and Password 1222
Configuration Examples for MAC Authentication Bypass 1223
Example: MAC Authentication Bypass Configuration 1223
Example: Enabling Configurable MAB Username and Password 1223
Additional References for MAC Authentication Bypass 1223
Feature Information for MAC Authentication Bypass 1224
Password Strength and Management for Common Criteria 1225

Finding Feature Information 1225

Restrictions for Password Strength and Management for Common Criteria 1226

Information About Password Strength and Management for Common Criteria 1226

Password Composition Policy 1226

Password Length Policy 1226

Password Lifetime Policy 1226

Password Expiry Policy 1226

Password Change Policy 1227

User Reauthentication Policy 1227

Support for Framed (Noninteractive) Session 1227

How to Configure Password Strength and Management for Common Criteria 1228

Configuring the Password Security Policy 1228

Verifying the Common Criteria Policy 1230

Configuration Examples for Password Strength and Management for Common Criteria 1231

Example: Password Strength and Management for Common Criteria 1231

Additional References for Password Strength and Management for Common Criteria 1231

Feature Information for Password Strength and Management for Common Criteria 1232

AAA-SERVER-MIB Set Operation 1233

Finding Feature Information 1233

Prerequisites for AAA-SERVER-MIB Set Operation 1233

Restrictions for AAA-SERVER-MIB Set Operation 1234

Information About AAA-SERVER-MIB Set Operation 1234

 CISCO-AAA-SERVER-MIB 1234

 CISCO-AAA-SERVER-MIB Set Operation 1234

How to Configure AAA-SERVER-MIB Set Operation 1234

Configuring AAA-SERVER-MIB Set Operations 1234

Verifying SNMP Values 1234

Configuration Examples for AAA-SERVER-MIB Set Operation 1235

RADIUS Server Configuration and Server Statistics Example 1235

Additional References for AAA-SERVER-MIB Set Operation 1237

Feature Information for AAA-SERVER-MIB Set Operation 1238
CHAPTER 62  Configuring Secure Shell  1239

Finding Feature Information  1239
Prerequisites for Configuring Secure Shell  1239
Restrictions for Configuring Secure Shell  1240
Information About Configuring Secure Shell  1240
  SSH and Switch Access  1240
  SSH Servers, Integrated Clients, and Supported Versions  1241
  RSA Authentication Support  1241
  SSL Configuration Guidelines  1241
  Secure Copy Protocol Overview  1242
  Secure Copy Protocol  1242
  How Secure Copy Works  1242
  Reverse Telnet  1243
  Reverse SSH  1243

How to Configure Secure Shell  1243
  Setting Up the Device to Run SSH  1243
  Configuring the SSH Server  1245
  Invoking an SSH Client  1247
  Troubleshooting Tips  1247
  Configuring Reverse SSH for Console Access  1248
  Configuring Reverse SSH for Modem Access  1249
  Troubleshooting Reverse SSH on the Client  1251
  Troubleshooting Reverse SSH on the Server  1252
  Monitoring the SSH Configuration and Status  1252
  Configuring Secure Copy  1253

Configuration Examples for Secure Shell  1254
  Example: Secure Copy Configuration Using Local Authentication  1254
  Example: SCP Server-Side Configuration Using Network-Based Authentication  1255
  Example Reverse SSH Console Access  1255
  Example Reverse SSH Modem Access  1255
  Example: Monitoring the SSH Configuration and Status  1256

Additional References for Secure Shell  1256

Feature Information for Configuring Secure Shell  1257
CHAPTER 63
Secure Shell Version 2 Support 1259
Finding Feature Information 1259
Information About Secure Shell Version 2 Support 1259
Secure Shell Version 2 1259
Secure Shell Version 2 Enhancements 1260
Secure Shell Version 2 Enhancements for RSA Keys 1260
SNMP Trap Generation 1261
SSH Keyboard Interactive Authentication 1262
How to Configure Secure Shell Version 2 Support 1263
Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 1263
Configuring a Device for SSH Version 2 Using RSA Key Pairs 1264
Configuring the Cisco SSH Server to Perform RSA-Based User Authentication 1265
Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication 1267
Starting an Encrypted Session with a Remote Device 1269
Enabling Secure Copy Protocol on the SSH Server 1270
Verifying the Status of the Secure Shell Connection 1272
Verifying the Secure Shell Status 1273
Monitoring and Maintaining Secure Shell Version 2 1274
Configuration Examples for Secure Shell Version 2 Support 1277
Example: Configuring Secure Shell Version 2 1277
Example: Starting an Encrypted Session with a Remote Device 1277
Example: Configuring Server-Side SCP 1277
Example: Setting an SNMP Trap 1278
Examples: SSH Keyboard Interactive Authentication 1278
Example: Enabling Client-Side Debugs 1278
Example: Enabling ChPass with a Blank Password Change 1279
Example: Enabling ChPass and Changing the Password on First Login 1279
Example: Enabling ChPass and Expiring the Password After Three Logins 1280
Example: SNMP Debugging 1281
Examples: SSH Debugging Enhancements 1281
Additional References for Secure Shell Version 2 Support 1282
Feature Information for Secure Shell Version 2 Support 1283
## CHAPTER 66
### Access Control List Overview  1313
- Finding Feature Information  1313
- Information About Access Control Lists  1313
  - Definition of an Access List  1313
  - Functions of an Access Control List  1314
  - Purpose of IP Access Lists  1314
  - Reasons to Configure ACLs  1315
- Software Processing of an Access List  1315
- Access List Rules  1316
- Helpful Hints for Creating IP Access Lists  1316
- IP Packet Fields You Can Filter to Control Access  1317
- Source and Destination Addresses  1318
- Wildcard Mask for Addresses in an Access List  1318
- Access List Sequence Numbers  1318
- ACL Supported Types  1319
- Supported ACLs  1319
  - ACL Precedence  1319
  - Port ACLs  1320
  - Router ACLs  1321
- Access Control Entries  1321
  - ACEs and Fragmented and Unfragmented Traffic  1321
  - ACEs and Fragmented and Unfragmented Traffic Examples  1322

## CHAPTER 67
### Configuring IPv4 Access Control Lists  1323
- Finding Feature Information  1323
- Prerequisites for Configuring IPv4 Access Control Lists  1323
- Restrictions for Configuring IPv4 Access Control Lists  1324
- Information About Configuring IPv4 Access Control Lists  1325
  - ACL Overview  1325
  - Standard and Extended IPv4 ACLs  1325
Example: Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry 1356
Example Resequencing Entries in an Access List 1357
Example Adding an Entry with a Sequence Number 1357
Example Adding an Entry with No Sequence Number 1358
Examples: Configuring Commented IP ACL Entries 1358
Examples: Using Time Ranges with ACLs 1359
Examples: Time Range Applied to an IP ACL 1360
Examples: ACL Logging 1360
Examples: Troubleshooting ACLs 1361
Additional References 1362
Feature Information for IPv4 Access Control Lists 1363

CHAPTER 68
IPv6 Access Control Lists 1365
Finding Feature Information 1365
Prerequisites for IPv6 ACLs 1365
Restrictions for IPv6 ACLs 1366
Information About Configuring IPv6 ACLs 1366
ACL Overview 1366
IPv6 ACLs Overview 1367
Understanding IPv6 ACLs 1367
Interactions with Other Features and Switches 1368
Default Configuration for IPv6 ACLs 1368
Supported ACL Features 1369
IPv6 Port-Based Access Control List Support 1369
ACLs and Traffic Forwarding 1369
How to Configure IPv6 ACLs 1369
Configuring IPv6 ACLs 1369
Attaching an IPv6 ACL to an Interface 1373
Monitoring IPv6 ACLs 1375
Configuring PACL Mode and Applying IPv6 PACL on an Interface 1375
Configuring IPv6 ACL Extensions for Hop by Hop Filtering 1376
Configuration Examples for IPv6 ACLs 1378
Example: Configuring IPv6 ACLs 1378
DHCP Server and Switch Stacks 1421
Configuring the DHCP Relay Agent 1421
Specifying the Packet Forwarding Address 1422
Prerequisites for Configuring DHCP Snooping and Option 82 1425
Enabling DHCP Snooping and Option 82 1426
Enabling the Cisco IOS DHCP Server Database 1429
Monitoring DHCP Snooping Information 1429
Configuring DHCP Server Port-Based Address Allocation 1429
Information About Configuring DHCP Server Port-Based Address Allocation 1429
Default Port-Based Address Allocation Configuration 1430
Port-Based Address Allocation Configuration Guidelines 1430
Enabling the DHCP Snooping Binding Database Agent 1430
Enabling DHCP Server Port-Based Address Allocation 1432
Monitoring DHCP Server Port-Based Address Allocation 1434
Additional References 1434
Feature Information for DHCP Snooping and Option 82 1435

CHAPTER 72
Configuring IP Source Guard 1437
Finding Feature Information 1437
Information About IP Source Guard 1437
IP Source Guard 1437
IP Source Guard for Static Hosts 1438
IP Source Guard Configuration Guidelines 1439
How to Configure IP Source Guard 1439
Enabling IP Source Guard 1439
Configuring IP Source Guard for Static Hosts on a Layer 2 Access Port 1441
Monitoring IP Source Guard 1442
Additional References 1443

CHAPTER 73
Configuring Dynamic ARP Inspection 1445
Finding Feature Information 1445
Restrictions for Dynamic ARP Inspection 1445
Understanding Dynamic ARP Inspection 1447
Interface Trust States and Network Security 1448
Rate Limiting of ARP Packets 1449
Relative Priority of ARP ACLs and DHCP Snooping Entries 1450
Logging of Dropped Packets 1450
Default Dynamic ARP Inspection Configuration 1450
Relative Priority of ARP ACLs and DHCP Snooping Entries 1451
Configuring ARP ACLs for Non-DHCP Environments 1451
Configuring Dynamic ARP Inspection in DHCP Environments 1454
Limiting the Rate of Incoming ARP Packets 1456
Performing Dynamic ARP Inspection Validation Checks 1458
Monitoring DAI 1460
Verifying the DAI Configuration 1460
Additional References 1461

CHAPTER 74

Configuring IEEE 802.1x Port-Based Authentication 1463
Finding Feature Information 1463
Information About 802.1x Port-Based Authentication 1463
   Port-Based Authentication Process 1464
   Port-Based Authentication Initiation and Message Exchange 1466
   Authentication Manager for Port-Based Authentication 1467
      Port-Based Authentication Methods 1467
      Per-User ACLs and Filter-Ids 1468
      Port-Based Authentication Manager CLI Commands 1469
   Ports in Authorized and Unauthorized States 1470
   Port-Based Authentication and Switch Stacks 1471
802.1x Host Mode 1472
802.1x Multiple Authentication Mode 1472
      Multi-auth Per User VLAN assignment 1473
MAC Move 1474
MAC Replace 1475
802.1x Accounting 1475
802.1x Accounting Attribute-Value Pairs 1476
802.1x Readiness Check 1477
Switch-to-RADIUS-Server Communication 1477
802.1x Authentication with VLAN Assignment 1477
802.1x Authentication with Per-User ACLs 1479
802.1x Authentication with Downloadable ACLs and Redirect URLs 1480
  Cisco Secure ACS and Attribute-Value Pairs for the Redirect URL 1481
  Cisco Secure ACS and Attribute-Value Pairs for Downloadable ACLs 1482
VLAN ID-Based MAC Authentication 1482
802.1x Authentication with Guest VLAN 1482
802.1x Authentication with Restricted VLAN 1483
802.1x Authentication with Inaccessible Authentication Bypass 1484
  Inaccessible Authentication Bypass Support on Multiple-Authentication Ports 1485
  Inaccessible Authentication Bypass Authentication Results 1485
  Inaccessible Authentication Bypass Feature Interactions 1485
802.1x Critical Voice VLAN 1486
802.1x User Distribution 1487
  802.1x User Distribution Configuration Guidelines 1487
IEEE 802.1x Authentication with Voice VLAN Ports 1487
IEEE 802.1x Authentication with Port Security 1488
IEEE 802.1x Authentication with Wake-on-LAN 1488
IEEE 802.1x Authentication with MAC Authentication Bypass 1489
Network Admission Control Layer 2 IEEE 802.1x Validation 1490
Flexible Authentication Ordering 1490
Open1x Authentication 1491
Multidomain Authentication 1491
Limiting Login for Users 1493
802.1x Supplicant and Authenticator Switches with Network Edge Access Topology (NEAT) 1493
Voice Aware 802.1x Security 1494
Common Session ID 1495
How to Configure 802.1x Port-Based Authentication 1496
Default 802.1x Authentication Configuration 1496
802.1x Authentication Configuration Guidelines 1497
  802.1x Authentication 1497
  VLAN Assignment, Guest VLAN, Restricted VLAN, and Inaccessible Authentication Bypass 1498
MAC Authentication Bypass 1499
Maximum Number of Allowed Devices Per Port 1499
Configuring Web-Based Authentication with VRF Aware 1581
Removing Web-Based Authentication Cache Entries 1583
Monitoring Web-Based Authentication Status 1583
  Displaying Web-Based Authentication Status 1584
  Monitoring HTTP Authentication Proxy 1584
Verifying HTTPS Authentication Proxy 1585
Configuration Examples for Web-Based Authentication 1586
  Example: Configuring the Authentication Rule and Interfaces 1586
Example: AAA Configuration 1586
Example: HTTP Server Configuration 1586
Example: Customizing the Authentication Proxy Web Pages 1587
Example: Specifying a Redirection URL for Successful Login 1587
Additional References for Web-Based Authentication 1588
Feature Information for Web-Based Authentication 1588

CHAPTER 76

Auto Identity 1589
Auto Identity 1589
  Finding Feature Information 1589
Information About Auto Identity 1589
  Auto Identity Overview 1589
  Auto Identity Global Template 1590
  Auto Identity Interface Templates 1591
  Auto Identity Built-in Policies 1591
  Auto Identity Class Maps Templates 1592
  Auto Identity Parameter Maps 1592
  Auto Identity Service Templates 1592
How to Configure Auto Identity 1593
  Configuring Auto Identity Globally 1593
  Configuring Auto Identity at an Interface Level 1594
Configuration Examples for Auto Identity 1595
  Example: Configuring Auto Identity Globally 1595
  Example: Configuring Auto Identity at an Interface Level 1595
Verifying Auto Identity 1596
Feature Information for Auto Identity 1599
PART XII  Configuring Cisco IOS IP SLAs 1641

CHAPTER 81  Configuring Cisco IP SLAs 1643
Finding Feature Information 1643
Restrictions on SLAs 1643
Information About SLAs 1644
Cisco IOS IP Service Level Agreements (SLAs) 1644
Network Performance Measurement with Cisco IOS IP SLAs 1645
IP SLA Responder and IP SLA Control Protocol 1645

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Interface Characteristics

Interface Types

This section describes the different types of interfaces supported by the device. The rest of the chapter describes configuration procedures for physical interface characteristics.

Note

The stack ports on the rear of the stacking-capable devices are not Ethernet ports and cannot be configured.
Port-Based VLANs

A VLAN is a switched network that is logically segmented by function, team, or application, without regard to the physical location of the users. Packets received on a port are forwarded only to ports that belong to the same VLAN as the receiving port. Network devices in different VLANs cannot communicate with one another without a Layer 3 device to route traffic between the VLANs.

VLAN partitions provide hard firewalls for traffic in the VLAN, and each VLAN has its own MAC address table. A VLAN comes into existence when a local port is configured to be associated with the VLAN, when the VLAN Trunking Protocol (VTP) learns of its existence from a neighbor on a trunk, or when a user creates a VLAN. VLANs can be formed with ports across the stack.

To configure VLANs, use the `vlan vlan-id` global configuration command to enter VLAN configuration mode. The VLAN configurations for normal-range VLANs (VLAN IDs 1 to 1005) are saved in the VLAN database. If VTP is version 1 or 2, to configure extended-range VLANs (VLAN IDs 1006 to 4094), you must first set VTP mode to transparent. Extended-range VLANs created in transparent mode are not added to the VLAN database but are saved in the device running configuration. With VTP version 3, you can create extended-range VLANs in client or server mode. These VLANs are saved in the VLAN database.

In a switch stack, the VLAN database is downloaded to all switches in a stack, and all switches in the stack build the same VLAN database. The running configuration and the saved configuration are the same for all switches in a stack.

Add ports to a VLAN by using the `switchport` interface configuration commands:

- Identify the interface.
- For a trunk port, set trunk characteristics, and, if desired, define the VLANs to which it can belong.
- For an access port, set and define the VLAN to which it belongs.
- For a tunnel port, set and define the VLAN ID for the customer-specific VLAN tag.

Switch Ports

Switch ports are Layer 2-only interfaces associated with a physical port. Switch ports belong to one or more VLANs. A switch port can be an access port or a trunk port. You can configure a port as an access port or trunk port or let the Dynamic Trunking Protocol (DTP) operate on a per-port basis to set the switchport mode by negotiating with the port on the other end of the link. Switch ports are used for managing the physical interface and associated Layer 2 protocols and do not handle routing or bridging.

Configure switch ports by using the `switchport` interface configuration commands.

Access Ports

An access port belongs to and carries the traffic of only one VLAN (unless it is configured as a voice VLAN port). Traffic is received and sent in native formats with no VLAN tagging. Traffic arriving on an access port is assumed to belong to the VLAN assigned to the port. If an access port receives a tagged packet (Inter-Switch Link [ISL] or IEEE 802.1Q tagged), the packet is dropped, and the source address is not learned.

The types of access ports supported are:

- Static access ports are manually assigned to a VLAN (or through a RADIUS server for use with IEEE 802.1x).
- VLAN membership of dynamic access ports is learned through incoming packets. By default, a dynamic access port is not a member of any VLAN, and forwarding to and from the port is enabled only when
the VLAN membership of the port is discovered. Dynamic access ports on the device are assigned to a VLAN by a VLAN Membership Policy Server (VMPS). The VMPS can be a Catalyst 6500 series switch; the device cannot be a VMPS server.

You can also configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.

Trunk Ports

A trunk port carries the traffic of multiple VLANs and by default is a member of all VLANs in the VLAN database. These trunk port types are supported:

- In an ISL trunk port, all received packets are expected to be encapsulated with an ISL header, and all transmitted packets are sent with an ISL header. Native (non-tagged) frames received from an ISL trunk port are dropped.

- An IEEE 802.1Q trunk port supports simultaneous tagged and untagged traffic. An IEEE 802.1Q trunk port is assigned a default port VLAN ID (PVID), and all untagged traffic travels on the port default PVID. All untagged traffic and tagged traffic with a NULL VLAN ID are assumed to belong to the port default PVID. A packet with a VLAN ID equal to the outgoing port default PVID is sent untagged. All other traffic is sent with a VLAN tag.

Although by default, a trunk port is a member of every VLAN known to the VTP, you can limit VLAN membership by configuring an allowed list of VLANs for each trunk port. The list of allowed VLANs does not affect any other port but the associated trunk port. By default, all possible VLANs (VLAN ID 1 to 4094) are in the allowed list. A trunk port can become a member of a VLAN only if VTP knows of the VLAN and if the VLAN is in the enabled state. If VTP learns of a new, enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of that VLAN and traffic is forwarded to and from the trunk port for that VLAN. If VTP learns of a new, enabled VLAN that is not in the allowed list for a trunk port, the port does not become a member of the VLAN, and no traffic for the VLAN is forwarded to or from the port.

Tunnel Ports

Tunnel ports are used in IEEE 802.1Q tunneling to segregate the traffic of customers in a service-provider network from other customers who are using the same VLAN number. You configure an asymmetric link from a tunnel port on a service-provider edge switch to an IEEE 802.1Q trunk port on the customer switch. Packets entering the tunnel port on the edge switch, already IEEE 802.1Q-tagged with the customer VLANs, are encapsulated with another layer of an IEEE 802.1Q tag (called the metro tag), containing a VLAN ID unique in the service-provider network, for each customer. The double-tagged packets go through the service-provider network keeping the original customer VLANs separate from those of other customers. At the outbound interface, also a tunnel port, the metro tag is removed, and the original VLAN numbers from the customer network are retrieved.

Tunnel ports cannot be trunk ports or access ports and must belong to a VLAN unique to each customer.

Routed Ports

A routed port is a physical port that acts like a port on a router; it does not have to be connected to a router. A routed port is not associated with a particular VLAN, as is an access port. A routed port behaves like a regular router interface, except that it does not support VLAN subinterfaces. Routed ports can be configured with a Layer 3 routing protocol. A routed port is a Layer 3 interface only and does not support Layer 2 protocols, such as DTP and STP.
Configure routed ports by putting the interface into Layer 3 mode with the `no switchport` interface configuration command. Then assign an IP address to the port, enable routing, and assign routing protocol characteristics by using the `ip routing` and `router protocol` global configuration commands.

**Note**

Entering a `no switchport` interface configuration command shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost.

The number of routed ports that you can configure is not limited by software. However, the interrelationship between this number and the number of other features being configured might impact CPU performance because of hardware limitations.

**Switch Virtual Interfaces**

A switch virtual interface (SVI) represents a VLAN of switch ports as one interface to the routing or bridging function in the system. You can associate only one SVI with a VLAN. You configure an SVI for a VLAN only to route between VLANs or to provide IP host connectivity to the device. By default, an SVI is created for the default VLAN (VLAN 1) to permit remote device administration. Additional SVIs must be explicitly configured.

**Note**

You cannot delete interface VLAN 1.

SVIs provide IP host connectivity only to the system. SVIs are created the first time that you enter the `vlan` interface configuration command for a VLAN interface. The VLAN corresponds to the VLAN tag associated with data frames on an ISL or IEEE 802.1Q encapsulated trunk or the VLAN ID configured for an access port. Configure a VLAN interface for each VLAN for which you want to route traffic, and assign it an IP address.

You can also use the interface range command to configure existing VLAN SVIs within the range. The commands entered under the interface range command are applied to all existing VLAN SVIs within the range. You can enter the command `interface range create vlan x - y` to create all VLANs in the specified range that do not already exist. When the VLAN interface is created, `interface range vlan id` can be used to configure the VLAN interface.

Although the switch stack or device supports a total of 1005 VLANs and SVIs, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might impact CPU performance because of hardware limitations.

When you create an SVI, it does not become active until it is associated with a physical port.

**SVI Autostate Exclude**

The line state of an SVI with multiple ports on a VLAN is in the up state when it meets these conditions:
• The VLAN exists and is active in the VLAN database on the device
• The VLAN interface exists and is not administratively down.
• At least one Layer 2 (access or trunk) port exists, has a link in the up state on this VLAN, and is in the spanning-tree forwarding state on the VLAN.

Note
The protocol link state for VLAN interfaces come up when the first switchport belonging to the corresponding VLAN link comes up and is in STP forwarding state.

The default action, when a VLAN has multiple ports, is that the SVI goes down when all ports in the VLAN go down. You can use the SVI autostate exclude feature to configure a port so that it is not included in the SVI link-state up-or-down calculation. For example, if the only active port on the VLAN is a monitoring port, you might configure autostate exclude on that port so that the VLAN goes down when all other ports go down. When enabled on a port, autostate exclude applies to all VLANs that are enabled on that port.

The VLAN interface is brought up when one Layer 2 port in the VLAN has had time to converge (transition from STP listening-learning state to forwarding state). This prevents features such as routing protocols from using the VLAN interface as if it were fully operational and minimizes other problems, such as routing black holes.

EtherChannel Port Groups
EtherChannel port groups treat multiple switch ports as one switch port. These port groups act as a single logical port for high-bandwidth connections between devices or between devices and servers. An EtherChannel balances the traffic load across the links in the channel. If a link within the EtherChannel fails, traffic previously carried over the failed link changes to the remaining links. You can group multiple trunk ports into one logical trunk port, group multiple access ports into one logical access port, group multiple tunnel ports into one logical tunnel port, or group multiple routed ports into one logical routed port. Most protocols operate over either single ports or aggregated switch ports and do not recognize the physical ports within the port group. Exceptions are the DTP, the Cisco Discovery Protocol (CDP), and the Port Aggregation Protocol (PAgP), which operate only on physical ports.

When you configure an EtherChannel, you create a port-channel logical interface and assign an interface to the EtherChannel. For Layer 3 interfaces, you manually create the logical interface by using the interface port-channel global configuration command. Then you manually assign an interface to the EtherChannel by using the channel-group interface configuration command. For Layer 2 interfaces, use the channel-group interface configuration command to dynamically create the port-channel logical interface. This command binds the physical and logical ports together.

Power over Ethernet Ports
A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

• a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
• an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.
Using the Switch USB Ports

The device has three USB ports on the front panel — a USB mini-Type B console port and two USB Type A ports.

USB Mini-Type B Console Port

The device has the following console ports:

- USB mini-Type B console connection
- RJ-45 console port

Console output appears on devices connected to both ports, but console input is active on only one port at a time. By default, the USB connector takes precedence over the RJ-45 connector.

**Note**

Windows PCs require a driver for the USB port. See the hardware installation guide for driver installation instructions.

Use the supplied USB Type A-to-USB mini-Type B cable to connect a PC or other device to the device. The connected device must include a terminal emulation application. When the device detects a valid USB connection to a powered-on device that supports host functionality (such as a PC), input from the RJ-45 console is immediately disabled, and input from the USB console is enabled. Removing the USB connection immediately reenables input from the RJ-45 console connection. An LED on the device shows which console connection is in use.

Console Port Change Logs

At software startup, a log shows whether the USB or the RJ-45 console is active. Each device in a stack issues this log. Every device always first displays the RJ-45 media type.

In the sample output, Device 1 has a connected USB console cable. Because the bootloader did not change to the USB console, the first log from Device 1 shows the RJ-45 console. A short time later, the console changes and the USB console log appears. Device 2 and Device 3 have connected RJ-45 console cables.

```
switch-stack-1
*Mar 1 00:01:00.171: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
*Mar 1 00:01:00.431: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.

switch-stack-2
*Mar 1 00:01:09.835: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.

switch-stack-3
*Mar 1 00:01:10.523: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

When the USB cable is removed or the PC de-activates the USB connection, the hardware automatically changes to the RJ-45 console interface:

```
switch-stack-1
Mar 1 00:20:48.635: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

You can configure the console type to always be RJ-45, and you can configure an inactivity timeout for the USB connector.
**USB Type A Ports**

The USB Type A ports provide access to external USB flash devices, also known as thumb drives or USB keys. The switch supports Cisco 64 MB, 256 MB, 512 MB, 1 GB, 4 GB, and 8 GB flash drives. You can use standard Cisco IOS command-line interface (CLI) commands to read, write, erase, and copy to or from the flash device. You can also configure the switch to boot from the USB flash drive.

For information about configuring the switch to boot from a USB flash drive, refer to the *Catalyst 2960-XR Switch System Management Configuration Guide*.

For information about reading, writing, erasing, and copying files to or from the flash device, refer to the *Catalyst 2960-XR Switch Managing Cisco IOS Image Files Configuration Guide*.

**Interface Connections**

Devices within a single VLAN can communicate directly through any switch. Ports in different VLANs cannot exchange data without going through a routing device. With a standard Layer 2 device, ports in different VLANs have to exchange information through a router. By using the device with routing enabled, when you configure both VLAN 20 and VLAN 30 with an SVI to which an IP address is assigned, packets can be sent from Host A to Host B directly through the device with no need for an external router.

*Figure 1: Connecting VLANs with the Switch*

The IP Lite image IP Lite feature set supports static routing and RIP. The IP Base image supports only static routing. The routing function can be enabled on all SVIs and routed ports. The device routes only IP traffic. When IP routing protocol parameters and address configuration are added to an SVI or routed port, any IP traffic received from these ports is routed.

---

**Note**

There is no limit to the number of static routes on devices running the IP Lite image.

---

**Note**

Devices running the LAN Base image support configuring only 16 static routes on SVIs.

**Interface Configuration Mode**

The device supports these interface types:
- Physical ports—device ports and routed ports
- VLANs—switch virtual interfaces
- Port channels—EtherChannel interfaces

You can also configure a range of interfaces.

To configure a physical interface (port), specify the interface type, module number, and device port number, and enter interface configuration mode.

- Type—Gigabit Ethernet (gigabitethernet or gi) for 10/100/1000 Mb/s Ethernet ports, or small form-factor pluggable (SFP) module Gigabit Ethernet interfaces (gigabitethernet or gi).
- Stack member number—The number that identifies the switch within the stack. The range is 1 to 8 for a stack of Catalyst 2960-X switches, and 1 to 4 for a mixed stack of Catalyst 2960-XR, Catalyst 2960-X, and Catalyst 2960-S switches. The switch number is assigned the first time the switch initializes. The default switch number, before it is integrated into a switch stack, is 1. When a switch has been assigned a stack member number, it keeps that number until another is assigned to it.

You can use the switch port LEDs in Stack mode to identify the stack member number of a switch.

- Stack member number—The number that identifies the switch within the stack. The range is 1 to 8 for a stack of Catalyst 2960-XR switches. The switch number is assigned the first time the switch initializes. The default switch number, before it is integrated into a switch stack, is 1. When a switch has been assigned a stack member number, it keeps that number until another is assigned to it.

You can use the switch port LEDs in Stack mode to identify the stack member number of a switch.

- Module number—The module or slot number on the switch (always 0).
- Port number—The interface number on the switch. The 10/100/1000 port numbers always begin at 1, starting with the far left port when facing the front of the switch, for example, gigabitethernet1/0/1 or gigabitethernet1/0/8. For a switch with 10/100/1000 ports and SFP module ports, SFP module ports are numbered consecutively following the 10/100/1000 ports.

You can identify physical interfaces by physically checking the interface location on the switch. You can also use the `show` privileged EXEC commands to display information about a specific interface or all the interfaces on the switch. The remainder of this chapter primarily provides physical interface configuration procedures.

These are examples of how to identify interfaces on a stacking-capable switch:

- To configure 10/100/1000 port 4 on a standalone device, enter this command:

  Device(config)# interface gigabitethernet1/0/4

- To configure 10/100/1000 port 4 on stack member 3, enter this command:

  Device(config)# interface gigabitethernet1/0/4
Default Ethernet Interface Configuration

This table shows the Ethernet interface default configuration, including some features that apply only to Layer 2 interfaces.

<table>

</tbody>
</table>

**Note**  
The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MIDX is enabled on the switch port.
### Interface Speed and Duplex Mode

Ethernet interfaces on the switch operate at 10, 100, 1000, or 10,000 Mb/s and in either full- or half-duplex mode. In full-duplex mode, two stations can send and receive traffic at the same time. Normally, 10-Mb/s ports operate in half-duplex mode, which means that stations can either receive or send traffic.

Switch modules include Gigabit Ethernet (10/100/1000-Mb/s) ports, 10-Gigabit Ethernet ports, and small form-factor pluggable (SFP) module slots supporting SFP modules.

### Speed and Duplex Configuration Guidelines

When configuring an interface speed and duplex mode, note these guidelines:

- The 10-Gigabit Ethernet ports do not support the speed and duplex features. These ports operate only at 10,000 Mb/s and in full-duplex mode.
- Do not disable Auto-Negotiation on PoE switches.
- Gigabit Ethernet (10/100/1000-Mb/s) ports support all speed options and all duplex options (auto, half, and full). However, Gigabit Ethernet ports operating at 1000 Mb/s do not support half-duplex mode.
- For SFP module ports, the speed and duplex CLI options change depending on the SFP module type:
  - The 1000BASE-x (where -x is -BX, -CWDM, -LX, -SX, and -ZX) SFP module ports support the `noregotiate` keyword in the `speed` interface configuration command. Duplex options are not supported.
  - The 1000BASE-T SFP module ports support the same speed and duplex options as the 10/100/1000-Mb/s ports.
- If both ends of the line support autonegotiation, we highly recommend the default setting of `auto` negotiation.
- If one interface supports autonegotiation and the other end does not, configure duplex and speed on both interfaces; do not use the `auto` setting on the supported side.
- When STP is enabled and a port is reconfigured, the device can take up to 30 seconds to check for loops. The port LED is amber while STP reconfigures.
- As best practice, we suggest configuring the speed and duplex options on a link to auto or to fixed on both the ends. If one side of the link is configured to auto and the other side is configured to fixed, the link will not be up and this is expected.
IEEE 802.3x Flow Control

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If one port experiences congestion and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

The switch ports can receive, but not send, pause frames.

You use the `flowcontrol` interface configuration command to set the interface’s ability to receive pause frames to on, off, or desired. The default state is off.

When set to desired, an interface can operate with an attached device that is required to send flow-control packets or with an attached device that is not required to but can send flow-control packets.

These rules apply to flow control settings on the device:

- **receive on** (or desired): The port cannot send pause frames but can operate with an attached device that is required to or can send pause frames; the port can receive pause frames.
- **receive off**: Flow control does not operate in either direction. In case of congestion, no indication is given to the link partner, and no pause frames are sent or received by either device.

For details on the command settings and the resulting flow control resolution on local and remote ports, see the `flowcontrol` interface configuration command in the command reference for this release.

Layer 3 Interfaces

The device supports these types of Layer 3 interfaces:

- **SVIs**: You should configure SVIs for any VLANs for which you want to route traffic. SVIs are created when you enter a VLAN ID following the `interface vlan` global configuration command. To delete an SVI, use the `no interface vlan` global configuration command. You cannot delete interface VLAN 1.

  When you create an SVI, it does not become active until it is associated with a physical port.

  When configuring SVIs, you can also configure SVI autostate exclude on a port in the SVI to exclude that port from being included in determining SVI line-state status.
• Routed ports: Routed ports are physical ports configured to be in Layer 3 mode by using the `no switchport` interface configuration command.

• Layer 3 EtherChannel ports: EtherChannel interfaces made up of routed ports.

A Layer 3 device can have an IP address assigned to each routed port and SVI. There is no defined limit to the number of SVIs and routed ports that can be configured in a device or in a device stack. However, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might have an impact on CPU usage because of hardware limitations. If the device is using its maximum hardware resources, attempts to create a routed port or SVI have these results:

• If you try to create a new routed port, the device generates a message that there are not enough resources to convert the interface to a routed port, and the interface remains as a switchport.

• If you try to create an extended-range VLAN, an error message is generated, and the extended-range VLAN is rejected.

• If the device is notified by VLAN Trunking Protocol (VTP) of a new VLAN, it sends a message that there are not enough hardware resources available and shuts down the VLAN. The output of the `show vlan` user EXEC command shows the VLAN in a suspended state.

• If the device attempts to boot up with a configuration that has more VLANs and routed ports than hardware can support, the VLANs are created, but the routed ports are shut down, and the device sends a message that this was due to insufficient hardware resources.

---

**Note**

All Layer 3 interfaces require an IP address to route traffic. This procedure shows how to configure an interface as a Layer 3 interface and how to assign an IP address to an interface:

If the physical port is in Layer 2 mode (the default), you must enter the `no switchport` interface configuration command to put the interface into Layer 3 mode. Entering a `no switchport` command disables and then re-enables the interface, which might generate messages on the device to which the interface is connected. Furthermore, when you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

---

**How to Configure Interface Characteristics**

**Configuring Interfaces**

These general instructions apply to all interface configuration processes.

<table>
<thead>
<tr>
<th><strong>Procedure</strong></th>
<th><strong>Command or Action</strong></th>
<th><strong>Purpose</strong></th>

**Adding a Description for an Interface**

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. description string
5. end
6. show interfaces interface-id description
7. copy running-config startup-config
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable | Enables privileged EXEC mode.  
Example:  
Device> enable |
| Step 2 | configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal |
| Step 3 | interface interface-id | Specifies the interface for which you are adding a description, and enter interface configuration mode.  
Example:  
Device(config)# interface gigabitethernet 1/0/2 |
| Step 4 | description string | Adds a description (up to 240 characters) for an interface.  
Example:  
Device(config-if)# description Connects to Marketing |
| Step 5 | end | Returns to privileged EXEC mode.  
Example:  
Device(config-if)# end |
| Step 6 | show interfaces interface-id description | Verifies your entry. |
| Step 7 | copy running-config startup-config | (Optional) Saves your entries in the configuration file.  
Example:  
Device# copy running-config startup-config |

**Configuring a Range of Interfaces**

To configure multiple interfaces with the same configuration parameters, use the `interface range` global configuration command. When you enter the interface-range configuration mode, all command parameters that you enter are attributed to all interfaces within that range until you exit this mode.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface range {port-range | macro macro_name}`
4. `end`
5. `show interfaces [interface-id]`
6. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>

<td>• You can use the <code>interface range</code> command to configure up to five port ranges or a previously defined macro.</td>
</tr>
<tr>
<td>`interface range {port-range</td>
<td>macro macro_name}`</td>
</tr>
<tr>
<td><code>Device(config)# interface range macro</code></td>
<td>• In a comma-separated <code>port-range</code>, you must enter the interface type for each entry and enter spaces before and after the comma.</td>
</tr>
<tr>
<td></td>
<td>• In a hyphen-separated <code>port-range</code>, you do not need to re-enter the interface type, but you must enter a space before the hyphen.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Use the normal configuration commands to apply the configuration parameters to all interfaces in the range. Each command is executed as it is entered.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
</tbody>
</table>
Configuring and Using Interface Range Macros

You can create an interface range macro to automatically select a range of interfaces for configuration. Before you can use the `macro` keyword in the `interface range macro` global configuration command string, you must use the `define interface-range` global configuration command to define the macro.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `define interface-range macro_name interface-range`
4. `interface range macro macro_name`
5. `end`
6. `show running-config | include define`
7. `copy running-config startup-config`

**DETAILED STEPS**

</tbody>
</table>

| **Step 2** configure terminal                          | Enters global configuration mode.                                       |
| Example:                                               |                                                                         |
| Device# `configure terminal`                           |                                                                         |

| **Step 3** define interface-range `macro_name interface-range` | Defines the interface-range macro, and save it in NVRAM.               |
| Example:                                               |                                                                         |
| Device# `define interface-range macro_name interface-range` |                                                                         |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| `Device(config)# define interface-range enet_list gigabitethernet 1/0/1 - 2` | - The `macro_name` is a 32-character maximum character string.  
- A macro can contain up to five comma-separated interface ranges.  
- Each `interface-range` must consist of the same port type.  

**Note** Before you can use the `macro` keyword in the `interface range macro` global configuration command string, you must use the `define interface-range` global configuration command to define the macro. |

### Step 4

**interface range macro `macro_name`**

**Example:**

`Device(config)# interface range macro enet_list`

Selects the interface range to be configured using the values saved in the interface-range macro called `macro_name`.  
You can now use the normal configuration commands to apply the configuration to all interfaces in the defined macro.

### Step 5

**end**

**Example:**

`Device(config)# end`

Returns to privileged EXEC mode.

### Step 6

**show running-config | include define**

**Example:**

`Device# show running-config | include define`

Shows the defined interface range macro configuration.

### Step 7

**copy running-config startup-config**

**Example:**

`Device# copy running-config startup-config`

(Optional) Saves your entries in the configuration file.

---

**Configuring Ethernet Interfaces**

**Setting the Interface Speed and Duplex Parameters**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
### Setting the Interface Speed and Duplex Parameters

3. `interface interface-id`
4. `speed {10 | 100 | 1000 | 2500 | 5000 | 10000 | auto [10 | 100 | 1000 | 2500 | 5000 | 10000] | nonegotiate}`
5. `duplex {auto | full | half}`
6. `end`
7. `show interfaces interface-id`
8. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  | Enables privileged EXEC mode.  
| `enable` | • Enter your password if prompted.  
| **Example:**  |  
| Device> `enable` | |
| **Step 2**  | Enters global configuration mode.  
| `configure terminal` |  
| **Example:**  |  
| Device# `configure terminal` | |
| **Step 3**  | Specifies the physical interface to be configured, and enter interface configuration mode.  
| `interface interface-id` |  
| **Example:**  |  
| Device(config)# `interface gigabitethernet 1/0/3` | |
| **Step 4**  | Enter the appropriate speed parameter for the interface:  
| `speed {10 | 100 | 1000 | 2500 | 5000 | 10000 | auto [10 | 100 | 1000 | 2500 | 5000 | 10000] | nonegotiate}` |  
| **Example:**  |  
| Device(config-if)# `speed 10` | • Enter 10, 100, 1000, 2500, 5000, or 10000 to set a specific speed for the interface.  
|  | • Enter `auto` to enable the interface to autonegotiate speed with the connected device. If you specify a speed and also set the `auto` keyword, the port autonegotiates only at the specified speeds.  
|  | • The `nonegotiate` keyword is available only for SFP module ports. SFP module ports operate only at 1000 Mb/s but can be configured to not negotiate if connected to a device that does not support autonegotiation.  
| **Step 5**  | This command is not available on a 10-Gigabit Ethernet interface.  
| `duplex {auto | full | half}` |  
| **Example:**  |  
| Device(config-if)# `duplex half` | Enter the duplex parameter for the interface.  
|  | Enable half-duplex mode (for interfaces operating only at 10 or 100 Mb/s). You cannot configure half-duplex mode for interfaces operating at 1000 Mb/s.

### Configuring the Console Media Type

Follow these steps to set the console media type to RJ-45. If you configure the console as RJ-45, USB console operation is disabled, and input comes only through the RJ-45 connector.

This configuration applies to all switches in a stack.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. line console 0
4. media-type rj45
5. end
6. copy running-config startup-config

#### DETAILED STEPS

<td></td>
</tr>
<tr>
<td>Device(config)# line console 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>media-type rj45</td>
<td>Configures the console media type to be only RJ-45 port. If you do not enter this command and both types are connected, the USB port is used by default.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device(config-line)# media-type rj45</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>

</tbody>
</table>

### Configuring the USB Inactivity Timeout

The configurable inactivity timeout reactivates the RJ-45 console port if the USB console port is activated but no input activity occurs on it for a specified time period. When the USB console port is deactivated due to a timeout, you can restore its operation by disconnecting and reconnecting the USB cable.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. line console 0
4. usb-inactivity-timeout timeout-minutes
5. copy running-config startup-config
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
<td>Enables privileged EXEC mode.&lt;br&gt;• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>line console 0&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# line console 0</td>
<td>Configures the console and enters line configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>usb-inactivity-timeout timeout-minutes&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-line)# usb-inactivity-timeout 30</td>
<td>Specify an inactivity timeout for the console port. The range is 1 to 240 minutes. The default is to have no timeout configured.</td>
</tr>
<tr>
<td>Step 5</td>
<td>copy running-config startup-config&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

**Monitoring Interface Characteristics**

**Monitoring Interface Status**

Commands entered at the privileged EXEC prompt display information about the interface, including the versions of the software and the hardware, the configuration, and statistics about the interfaces.

**Table 2: Show Commands for Interfaces**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show interfaces interface-number downshift module module-number</td>
<td>Displays the downshift status details of the specified interfaces and modules.</td>
</tr>
</tbody>
</table>
### Command and Purpose

**Table 3: Clear Commands for Interfaces**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear counters [interface-id]</td>
<td>Clears interface counters.</td>
</tr>
<tr>
<td>clear interface interface-id</td>
<td>Resets the hardware logic on an interface.</td>
</tr>
<tr>
<td>clear line [number</td>
<td>console 0</td>
</tr>
</tbody>
</table>
The clear counters privileged EXEC command does not clear counters retrieved by using Simple Network Management Protocol (SNMP), but only those seen with the show interface privileged EXEC command.

### Configuration Examples for Interface Characteristics

#### Configuring a Range of Interfaces: Examples

This example shows how to use the `interface range` global configuration command to set the speed to 100 Mb/s on ports 1 to 4 on switch 1:

```
Device# configure terminal
Device(config)# interface range gigabitethernet 1/0/1 - 4
Device(config-if-range)# speed 100
```

This example shows how to use a comma to add different interface type strings to the range to enable Gigabit Ethernet ports 1 to 3 and 10-Gigabit Ethernet ports 1 and 2 to receive flow-control pause frames:

```
Device# configure terminal
Device(config)# interface range gigabitethernet 1/0/1 - 3, tengigabitethernet 1/1/1 - 2
Device(config-if-range)# flowcontrol receive on
```

If you enter multiple configuration commands while you are in interface-range mode, each command is executed as it is entered. The commands are not batched and executed after you exit interface-range mode. If you exit interface-range configuration mode while the commands are being executed, some commands might not be executed on all interfaces in the range. Wait until the command prompt reappears before exiting interface-range configuration mode.

#### Configuring and Using Interface Range Macros: Examples

This example shows how to define an interface-range named `enet_list` to include ports 1 and 2 on switch 1 and to verify the macro configuration:

```
Device# configure terminal
Device(config)# define interface-range enet_list gigabitethernet 1/1/1 - 2
Device(config)# end
Device# show running-config | include define
define interface-range enet_list gigabitethernet 1/1/1 - 2
```

This example shows how to create a multiple-interface macro named `macro1`:

```
Device# configure terminal
Device(config)# define interface-range macro1 gigabitethernet 1/1/1 - 2, gigabitethernet 1/5 - 7, tengigabitethernet 1/1/1 - 2
Device(config)# end
```

This example shows how to enter interface-range configuration mode for the interface-range macro `enet_list`:
Device# configure terminal
Device(config)# interface range macro enet_list
Device(config-if-range)#

This example shows how to delete the interface-range macro `enet_list` and to verify that it was deleted.

Device# configure terminal
Device(config)# no define interface-range enet_list
Device(config)# end
Device# show run | include define
Device#

**Setting Interface Speed and Duplex Mode: Example**

This example shows how to set the interface speed to 100 Mb/s and the duplex mode to half on a 10/100/1000 Mb/s port:

Device# configure terminal
Device(config)# interface gigabitethernet 1/0/3
Device(config-if)# speed 10
Device(config-if)# duplex half

This example shows how to set the interface speed to 100 Mb/s on a 10/100/1000 Mb/s port:

Device# configure terminal
Device(config)# interface gigabitethernet 1/0/2
Device(config-if)# speed 100

**Configuring Layer 3 Interfaces: Example**

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 192.20.135.21 255.255.255.0
Device(config-if)# no shutdown

**Configuring the Console Media Type: Example**

This example disables the USB console media type and enables the RJ-45 console media type.

Device# configure terminal
Device(config)# line console 0
Device(config-line)# media-type rj45

This example reverses the previous configuration and immediately activates any USB console that is connected.

Device# configure terminal
Device(config)# line console 0
Device(config-line)# no media-type rj45

Configuring the USB Inactivity Timeout: Example

This example configures the inactivity timeout to 30 minutes:

Device# configure terminal
Device(config)# line console 0
Device(config-line)# usb-inactivity-timeout 30

To disable the configuration, use these commands:

Device# configure terminal
Device(config)# line console 0
Device(config-line)# no usb-inactivity-timeout

If there is no (input) activity on a USB console port for the configured number of minutes, the inactivity timeout setting applies to the RJ-45 port, and a log shows this occurrence:

*Mar 1 00:47:25.625: %USB_CONSOLE-6-INACTIVITY_DISABLE: Console media-type USB disabled due to inactivity, media-type reverted to RJ45.

At this point, the only way to reactivate the USB console port is to disconnect and reconnect the cable.

When the USB cable on the switch has been disconnected and reconnected, a log similar to this appears:

*Mar 1 00:48:28.640: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.

<tr>
<td>Cisco IOS Release 15.0(2)EX1</td>
<td>This feature was introduced.</td>
</tr>
</tbody>
</table>
Prerequisites for Auto-MDIX

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

Automatic medium-dependent interface crossover (auto-MDIX) is enabled by default.

Auto-MDIX is supported on all 10/100/1000-Mb/s and on 10/100/1000BASE-TX small form-factor pluggable (SFP)-module interfaces. It is not supported on 1000BASE-SX or -LX SFP module interfaces.

Restrictions for Auto-MDIX

The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MDIX is enabled on the switch port.
Information About Configuring Auto-MDIX

Auto-MDIX on an Interface

When automatic medium-dependent interface crossover (auto-MDIX) is enabled on an interface, the interface automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting devices without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other devices or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

This table shows the link states that result from auto-MDIX settings and correct and incorrect cabling.

How to Configure Auto-MDIX

Configuring Auto-MDIX on an Interface

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. speed auto
5. duplex auto
6. end
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>

<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**  
**Example:**  
Device# configure terminal

**Step 3**  
**Example:**  
Device(config)# interface gigabitethernet 1/0/1  
Spefies the physical interface to be configured, and enter interface configuration mode.

**Step 4**  
**Example:**  
Device(config-if)# speed auto

**Step 5**  
**Example:**  
Device(config-if)# duplex auto

**Step 6**  
**Example:**  
Device(config-if)# end

**Step 7**  
**Example:**  
Device# copy running-config startup-config  
(Optional) Saves your entries in the configuration file.

---

**Example for Configuring Auto-MDIX**

This example shows how to enable auto-MDIX on a port:

```
Device# configure terminal  
Device(config)# interface gigabitethernet 1/0/1  
Device(config-if)# speed auto  
Device(config-if)# duplex auto  
Device(config-if)# mdix auto
```
Device(config-if)# end

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Ethernet Management Ports

When connecting a PC to the Ethernet management port, you must first assign an IP address.

Information About the Ethernet Management Port

The Ethernet management port, also referred to as the Fa0 or fastethernet0 port, is a Layer 3 host port to which you can connect a PC. You can use the Ethernet management port instead of the device console port for network management. When managing a device stack, connect the PC to the Ethernet management port on a stack member.
Ethernet Management Port Direct Connection to a Device

*Figure 2: Connecting a Switch to a PC*

This figure displays how to connect the Ethernet management port to the PC for a device or a standalone device.

---

Ethernet Management Port Connection to Stack Devices using a Hub

In a stack with only stack devices, all the Ethernet management ports on the stack members are connected to a hub to which the PC is connected. The active link is from the Ethernet management port on the active switch stack master through the hub, to the PC. If the active device fails and a new active device is elected, the active link is now from the Ethernet management port on the new active device to the PC.

*Figure 3: Connecting a Device Stack to a PC*

This figure displays how a PC uses a hub to connect to a device stack.

---

Ethernet Management Port and Routing

By default, the Ethernet management port is enabled. The device cannot route packets from the Ethernet management port to a network port, and the reverse. Even though the Ethernet management port does not support routing, you may need to enable routing protocols on the port.

*Figure 4: Network Example with Routing Protocols Enabled*

Enable routing protocols on the Ethernet management port when the PC is multiple hops away from the device and the packets must pass through multiple Layer 3 devices to reach the PC.
In the above figure, if the Ethernet management port and the network ports are associated with the same routing process, the routes are propagated as follows:

- The routes from the Ethernet management port are propagated through the network ports to the network.
- The routes from the network ports are propagated through the Ethernet management port to the network.

Because routing is not supported between the Ethernet management port and the network ports, traffic between these ports cannot be sent or received. If this happens, data packet loops occur between the ports, which disrupt the device and network operation. To prevent the loops, configure route filters to avoid routes between the Ethernet management port and the network ports.

Supported Features on the Ethernet Management Port

The Ethernet management port supports these features:

- Express Setup (only in switch stacks)
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SMNP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features
  - Speed—10 Mb/s, 100 Mb/s, and autonegotiation
  - Duplex mode—Full, half, and autonegotiation
  - Loopback detection
- Cisco Discovery Protocol (CDP)
- DHCP relay agent
- IPv4 and IPv6 access control lists (ACLs)
- Routing protocols

Caution

Before enabling a feature on the Ethernet management port, make sure that the feature is supported. If you try to configure an unsupported feature on the Ethernet Management port, the feature might not work properly, and the device might fail.
How to Configure the Ethernet Management Port

Disabling and Enabling the Ethernet Management Port

SUMMARY STEPS

1. configure terminal
2. interface fastethernet0
3. shutdown
4. no shutdown
5. exit
6. show interfaces fastethernet0

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Specifies the Ethernet management port in the CLI.</td>
</tr>
<tr>
<td>interface fastethernet0</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface fastethernet0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Disables the Ethernet management port.</td>
</tr>
<tr>
<td>shutdown</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# shutdown</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Enables the Ethernet management port.</td>
</tr>
<tr>
<td>no shutdown</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# no shutdown</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Exits interface configuration mode.</td>
</tr>
<tr>
<td>exit</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Displays the link status.</td>
</tr>
<tr>
<td>show interfaces fastethernet0</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show interfaces fastethernet0</td>
<td></td>
</tr>
</tbody>
</table>

To find out the link status to the PC, you can monitor the LED for the Ethernet management port. The LED is green (on) when the link is active, and the LED is off when the link is down. The LED is amber when there is a POST failure.
What to do next

Proceed to manage or configure your switch using the Ethernet management port. Refer to the Catalyst 2960-XR Switch Network Management Configuration Guide.

Confusing LLDP, LLDP-MED, and Wired Location Service

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About LLDP, LLDP-MED, and Wired Location Service

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, switches, and controllers). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the device supports the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol
runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.

**LLDP Supported TLVs**

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. This protocol can advertise details such as configuration information, device capabilities, and device identity.

The switch supports these basic management TLVs. These are mandatory LLDP TLVs.

- Port description TLV
- System name TLV
- System description TLV
- System capabilities TLV
- Management address TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

- Port VLAN ID TLV (IEEE 802.1 organizationally specific TLVs)
- MAC/PHY configuration/status TLV (IEEE 802.3 organizationally specific TLVs)

**LLDP and Cisco Device Stacks**

A device stack appears as a single device in the network. Therefore, LLDP discovers the device stack, not the individual stack members.

**LLDP and Cisco Medianet**

When you configure LLDP or CDP location information on a per-port basis, remote devices can send Cisco Medianet location information to the device.

**LLDP-MED**

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet, inventory management and location information. By default, all LLDP-MED TLVs are enabled.

**LLDP-MED Supported TLVs**

LLDP-MED supports these TLVs:

- LLDP-MED capabilities TLV
  - Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and has enabled.
- Network policy TLV
Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify a phone of the VLAN number that it should use. The phone can connect to any device, obtain its VLAN number, and then start communicating with the call control.

By defining a network-policy profile TLV, you can create a profile for voice and voice-signaling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

• Power management TLV

Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows devices and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

LLDP-MED also supports an extended power TLV to advertise fine-grained power requirements, end-point power priority, and end-point and network connectivity-device power status. LLDP is enabled and power is applied to a port, the power TLV determines the actual power requirement of the endpoint device so that the system power budget can be adjusted accordingly. The device processes the requests and either grants or denies power based on the current power budget. If the request is granted, the switch updates the power budget. If the request is denied, the device turns off power to the port, generates a syslog message, and updates the power budget. If LLDP-MED is disabled or if the endpoint does not support the LLDP-MED power TLV, the initial allocation value is used throughout the duration of the connection.

You can change power settings by entering the **power inline {auto [max max-wattage] | never | static [max max-wattage]}** interface configuration command. By default the PoE interface is in **auto** mode; If no value is specified, the maximum is allowed (30 W).

• Inventory management TLV

Allows an endpoint to send detailed inventory information about itself to the device, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

• Location TLV

Provides location information from the device to the endpoint device. The location TLV can send this information:

• Civic location information

  Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

• ELIN location information

  Provides the location information of a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

**Wired Location Service**

The device uses the location service feature to send location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint,
a wired endpoint, or a wired device or controller. The device notifies the MSE of device link up and link down events through the Network Mobility Services Protocol (NMSP) location and attachment notifications.

The MSE starts the NMSP connection to the device, which opens a server port. When the MSE connects to the device there are a set of message exchanges to establish version compatibility and service exchange information followed by location information synchronization. After connection, the device periodically sends location and attachment notifications to the MSE. Any link up or link down events detected during an interval are aggregated and sent at the end of the interval.

When the device determines the presence or absence of a device on a link-up or link-down event, it obtains the client-specific information such as the MAC address, IP address, and username. If the client is LLDP-MED- or CDP-capable, the device obtains the serial number and UDI through the LLDP-MED location TLV or CDP.

Depending on the device capabilities, the device obtains this client information at link up:

- Slot and port specified in port connection
- MAC address specified in the client MAC address
- IP address specified in port connection
- 802.1X username if applicable
- Device category is specified as a wired station
- State is specified as new
- Serial number, UDI
- Model number
- Time in seconds since the device detected the association

Depending on the device capabilities, the device obtains this client information at link down:

- Slot and port that was disconnected
- MAC address
- IP address
- 802.1X username if applicable
- Device category is specified as a wired station
- State is specified as delete
- Serial number, UDI
- Time in seconds since the device detected the disassociation

When the device shuts down, it sends an attachment notification with the state delete and the IP address before closing the NMSP connection to the MSE. The MSE interprets this notification as disassociation for all the wired clients associated with the device.

If you change a location address on the device, the device sends an NMSP location notification message that identifies the affected ports and the changed address information.
Default LLDP Configuration

Table 5: Default LLDP Configuration

<table>
<thead>
<tr>

</tr>
<tr>
<td>LLDP med-tlv-select</td>
<td>Disabled to send all LLDP-MED TLVs. When LLDP is globally enabled, LLDP-MED-TLV is also enabled.</td>
</tr>
</tbody>
</table>

Restrictions for LLDP

- If the interface is configured as a tunnel port, LLDP is automatically disabled.
- If you first configure a network-policy profile on an interface, you cannot apply the `switchport voice vlan` command on the interface. If the `switchport voice vlan vlan-id` is already configured on an interface, you can apply a network-policy profile on the interface. This way the interface has the voice or voice-signaling VLAN network-policy profile applied on the interface.
- You cannot configure static secure MAC addresses on an interface that has a network-policy profile.
- When Cisco Discovery Protocol and LLDP are both in use within the same switch, it is necessary to disable LLDP on interfaces where Cisco Discovery Protocol is in use for power negotiation. LLDP can be disabled at interface level with the commands `no lldp tlv-select power-management` or `no lldp transmit / no lldp receive`.

How to Configure LLDP, LLDP-MED, and Wired Location Service

Enabling LLDP

SUMMARY STEPS

1. `enable`
2. `configure terminal`
### Enabling LLDP

3. `lldp run`  
4. `interface interface-id`  
5. `lldp transmit`  
6. `lldp receive`  
7. `end`  
8. `show lldp`  
9. `copy running-config startup-config`  

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable`  
Example:  
Device> `enable` | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Step 2** | `configure terminal`  
Example:  
Device# `configure terminal` | Enters global configuration mode. |
| **Step 3** | `lldp run`  
Example:  
Device (config)# `lldp run` | Enables LLDP globally on the device. |
| **Step 4** | `interface interface-id`  
Example:  
Device (config)# `interface gigabitethernet 2/0/1` | Specifies the interface on which you are enabling LLDP, and enter interface configuration mode. |
| **Step 5** | `lldp transmit`  
Example:  
Device(config-if)# `lldp transmit` | Enables the interface to send LLDP packets. |
| **Step 6** | `lldp receive`  
Example:  
Device(config-if)# `lldp receive` | Enables the interface to receive LLDP packets. |
| **Step 7** | `end`  
Example:  
Device(config-if)# `end` | Returns to privileged EXEC mode. |
## Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, and the initialization delay time. You can also select the LLDP and LLDP-MED TLVs to send and receive.

### Note
Steps 3 through 6 are optional and can be performed in any order.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `lldp holdtime seconds`
4. `lldp reinit delay`
5. `lldp timer rate`
6. `lldp tlv-select`
7. `interface interface-id`
8. `lldp med-tlv-select`
9. `end`
10. `show lldp`
11. `copy running-config startup-config`

</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>(Optional) Specifies the LLDP-MED TLVs to send or receive.</td>
</tr>
<tr>
<td><strong>lldp med-tlv-select</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Device (config-if)# lldp med-tlv-select inventory management</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>end</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
Configuring LLDP-MED TLVs

By default, the device only sends LLDP packets until it receives LLDP-MED packets from the end device. It then sends LLDP packets with MED TLVs, as well. When the LLDP-MED entry has been aged out, it again only sends LLDP packets.

By using the `lldp` interface configuration command, you can configure the interface not to send the TLVs listed in the following table.

**Table 6: LLDP-MED TLVs**

<table>
<thead>
<tr>
<th>LLDP-MED TLV</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inventory-management</td>
<td>LLDP-MED inventory management TLV</td>

</tr>
</tbody>
</table>

### Step 11

**copy running-config startup-config**

*Example:*

```
Device# copy running-config startup-config
```

### Configuring Location TLV and Wired Location Service

Beginning in privileged EXEC mode, follow these steps to configure location information for an endpoint and to apply it to an interface.

#### SUMMARY STEPS

1. `configure terminal`
2. `location {admin-tag string | civic-location identifier {id | host} | elin-location string identifier id | custom-location identifier {id | host} | geo-location identifier {id | host}}`
3. `exit`
4. `interface interface-id`
5. `location {additional-location-information word | civic-location-id {id | host} | elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host}}`
6. `end`
7. Use one of the following:
   - `show location admin-tag string`
   - `show location civic-location identifier id`
   - `show location elin-location identifier id`
8. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>  configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:  Device# <strong>configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong>  location {admin-tag string</td>
<td>civic-location identifier {id</td>
</tr>
<tr>
<td>Example:</td>
<td><strong>admin-tag</strong>—Specifies an administrative tag or site information.</td>
</tr>
<tr>
<td></td>
<td><strong>civic-location</strong>—Specifies civic location information.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| Device(config)# location civic-location identifier 1 | • **elin-location**—Specifies emergency location information (ELIN).  
| Device(config-civic)# number 3550 |  
| Device(config-civic)# primary-road-name “Cisco Way” | • **custom-location**—Specifies custom location information.  
| Device(config-civic)# city “San Jose” | • **geo-location**—Specifies geo-spatial location information.  
| Device(config-civic)# state CA | • **identifier id**—Specifies the ID for the civic, ELIN, custom, or geo location.  
| Device(config-civic)# building 19 | • **host**—Specifies the host civic, custom, or geo location.  
| Device(config-civic)# room C6 | • **string**—Specifies the site or location information in alphanumeric format.  
| Device(config-civic)# county “Santa Clara” |  
| Device(config-civic)# country US |  

**Step 3**  
**exit**  
**Example:**  
Device(config-civic)# exit  

**Step 4**  
**interface interface-id**  
**Example:**  
Device(config)# interface gigabitethernet2/0/1  

**Step 5**  
**location {additional-location-information word | civic-location-id {id | host} | elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host}}**  
**Example:**  
Device(config-if)# location elin-location-id 1  

Enters location information for an interface:  
• **additional-location-information**—Specifies additional information for a location or place.  
• **civic-location-id**—Specifies global civic location information for an interface.  
• **elin-location-id**—Specifies emergency location information for an interface.  
• **custom-location-id**—Specifies custom location information for an interface.  
• **geo-location-id**—Specifies geo-spatial location information for an interface.  
• **host**—Specifies the host location identifier.  
• **word**—Specifies a word or phrase with additional location information.  
• **id**—Specifies the ID for the civic, ELIN, custom, or geo location. The ID range is 1 to 4095.
### Command or Action

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
</tr>
</thead>
</table>
| Step 6 | **end**  
*Example:*  
Device(config-if)# *end* |
| Step 7 | **copy running-config startup-config**  
*Example:*  
Device# *copy running-config startup-config* |

### Purpose

- Returns to privileged EXEC mode.
- Verifies the configuration.
- (Optional) Saves your entries in the configuration file.

## Enabling Wired Location Service on the Device

**Before you begin**

For wired location to function, you must first enter the `ip device tracking` global configuration command.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `nmsp notification interval {attachment | location} interval-seconds`
4. `end`
5. `show network-policy profile`
6. `copy running-config startup-config`
# Enabling Wired Location Service on the Device

Configuration Examples for LLDP, LLDP-MED, and Wired Location Service

Configuring Network-Policy TLV: Examples

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
# configure terminal
(config)# network-policy 1
(config-network-policy)# voice vlan 100 cos 4
(config-network-policy)# exit
(config)# interface gigabitethernet 1/0/1
(config-if)# network-policy profile 1
(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
(config-network-policy)# voice vlan dot1p cos 4
(config-network-policy)# voice vlan dot1p dscp 34
```

Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service

Commands for monitoring and maintaining LLDP, LLDP-MED, and wired location service.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear lldp counters</td>
<td>Resets the traffic counters to zero.</td>
</tr>
<tr>
<td>clear lldp table</td>
<td>Deletes the LLDP neighbor information table.</td>
</tr>
<tr>
<td>clear nmsp statistics</td>
<td>Clears the N MSP statistic counters.</td>
</tr>
<tr>
<td>show lldp</td>
<td>Displays global information, such as frequency of transmissions, the holdtime for packets being sent, and the delay time before LLDP initializes on an interface.</td>
</tr>
<tr>
<td>show lldp entry entry-name</td>
<td>Displays information about a specific neighbor. You can enter an asterisk (*) to display all neighbors, or you can enter the neighbor name.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>show lldp interface [interface-id]</code></td>
<td>Displays information about interfaces with LLDP enabled. You can limit the display to a specific interface.</td>
</tr>
<tr>
<td><code>show lldp neighbors [interface-id] [detail]</code></td>
<td>Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, and port ID. You can limit the display to neighbors of a specific interface or expand the display for more detailed information.</td>
</tr>
<tr>
<td><code>show lldp traffic</code></td>
<td>Displays LLDP counters, including the number of packets sent and received, number of packets discarded, and number of unrecognized TLVs.</td>
</tr>
<tr>
<td><code>show location admin-tag string</code></td>
<td>Displays the location information for the specified administrative tag or site.</td>
</tr>
<tr>
<td><code>show location civic-location identifier id</code></td>
<td>Displays the location information for a specific global civic location.</td>
</tr>
<tr>
<td><code>show location elin-location identifier id</code></td>
<td>Displays the location information for an emergency location.</td>
</tr>
<tr>
<td><code>show network-policy profile</code></td>
<td>Displays the configured network-policy profiles.</td>
</tr>
<tr>
<td><code>show nmsp</code></td>
<td>Displays the NMSP information</td>
</tr>
</tbody>

Configuring System MTU

- Finding Feature Information, on page 63
- Information About the MTU, on page 63
- How to Configure MTU, on page 64
- Configuration Examples for System MTU, on page 65
- Additional References for System MTU, on page 65
- Feature Information for System MTU, on page 66

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About the MTU

The default maximum transmission unit (MTU) size for frames received and sent on all device interfaces is 1500 bytes.

You can change the MTU size to support switched jumbo frames on all Gigabit Ethernet and 10-Gigabit Ethernet interfaces and to support routed frames on all routed ports.

Restrictions for System MTU

When configuring the system MTU values, follow these guidelines:

- The device does not support the MTU on a per-interface basis.
How to Configure MTU

Configuring the System MTU

Beginning in privileged EXEC mode, follow these steps to change the MTU size for switched and routed packets:

SUMMARY STEPS

1.  configure terminal
2.  system mtu bytes
3.  system mtu jumbo bytes
4.  system mtu routing bytes
5.  end
6.  copy running-config startup-config
7.  show system mtu

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 system mtu bytes</td>
<td>(Optional) Changes the MTU size for all Fast Ethernet interfaces on the switch. The range is 1500 to 1998 bytes; the default is 1500 bytes.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# system mtu 2500</td>
<td></td>
</tr>
<tr>
<td>Step 3 system mtu jumbo bytes</td>
<td>(Optional) Changes the MTU size for all Gigabit Ethernet and 10-Gigabit Ethernet interfaces on the switch or the switch stack. The range is 1500 to 9198 bytes; the default is 1500 bytes.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# system mtu jumbo 7500</td>
<td></td>
</tr>
<tr>
<td>Step 4 system mtu routing bytes</td>
<td>(Optional) Changes the system MTU for routed ports. You can also set the maximum MTU to be advertised by the routing protocols that support the configured MTU size. The system routing MTU is the maximum MTU for routed packets and is also the maximum MTU that the switch advertises in routing updates for protocols such as OSPF. This command is not supported on switches running the LAN base feature set.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# system mtu routing 2000</td>
<td></td>
</tr>
<tr>
<td>Step 5 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td></td>
</tr>
<tr>
<td>show system mtu</td>
<td>Verifies your settings.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show system mtu</td>
<td></td>
</tr>
</tbody>
</table>

### Configuration Examples for System MTU

This example shows how to set the maximum packet size for a Gigabit Ethernet port to 7500 bytes:

```
Device(config)# system mtu 7500
System mtu 1900
Device(config)# system mtu jumbo 7500
Device(config)# exit
```

If you enter a value that is outside the allowed range for the specific type of interface, the value is not accepted. This example shows the response when you try to set Gigabit Ethernet interfaces to an out-of-range number:

```
Device(config)# system mtu jumbo 25000
% Invalid input detected at '^' marker.
```

Configuring Internal Power Supplies

Information About Internal Power Supplies

See the device installation guide for information about the power supplies.

How to Configure Internal Power Supplies

Configuring Internal Power Supply

You can use the power supply EXEC command to configure and manage the internal power supply on the device. The device does not support the no power supply EXEC command.

Follow these steps beginning in user EXEC mode:

SUMMARY STEPS

1. power supply switch_number slot{A | B} { off | on }
2. show environment power

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>power supply switch_number slot{A</td>
<td>B} { off</td>
<td>on }</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device# power supply 1 slot A on</td>
<td>• A —Selects the power supply in slot A.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• B —Selects power supply in slot B.</td>
<td></td>
</tr>
</tbody>
</table>
Monitoring Internal Power Supplies

<td>(Optional) Displays the status of the internal power supplies for the specified device. The device keywords are available only on stacking-capable devices.</td>
</tr>
</tbody>
</table>

Configuration Examples for Internal Power Supplies

This example shows how to set the power supply in slot A to off:

```
Device# power supply 1 slot A off
Disabling Power supply A may result in a power loss to PoE devices and/or switches ...
Continue? [yes/no]: yes
```

```
Device# show environment power
```

```
Jun 10 04:52:54.389: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered off
Jun 10 04:52:56.717: %PLATFORM_ENV-1-FAN_NOT_PRESENT: Fan is not present
```

This example shows how to set the power supply in slot A to on:

```
Device# power supply 1 slot A on
```

```
Jun 10 04:54:39.600: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered on
```

This example shows the output of the `show env power` command:
### Table 8: show env power Status Descriptions

Configuring Boot Fast

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Configuring Boot Fast on the switch

This feature, when enabled, helps the switch to Boot up fast. The Memory test is performed for a limited range, the switch skips Filesystem check (FSCK) and skips Post test.

Note

When Fast boot is enabled, you can still run the POST tests manually from the command line interface, once the switch has booted up, using diagnostic start command.

Enabling Boot Fast

To enable the boot fast feature, perform the following steps:

SUMMARY STEPS

1. enable
2. configure terminal
3. boot fast
4. end
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:

Information About PoE

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

• a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
• an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Supported Protocols and Standards

The device uses these protocols and standards to support PoE:

• CDP with power consumption—The powered device notifies the device of the amount of power it is consuming. The device does not reply to the power-consumption messages. The device can only supply power to or remove power from the PoE port.

• Cisco intelligent power management—The powered device and the device negotiate through power-negotiation CDP messages for an agreed-upon power-consumption level. The negotiation allows a high-power Cisco powered device, which consumes more than 7 W, to operate at its highest power mode. The powered device first boots up in low-power mode, consumes less than 7 W, and negotiates to obtain enough power to operate in high-power mode. The device changes to high-power mode only when it receives confirmation from the device.

High-power devices can operate in low-power mode on devices that do not support power-negotiation CDP.
Cisco intelligent power management is backward-compatible with CDP with power consumption; the device responds according to the CDP message that it receives. CDP is not supported on third-party powered devices; therefore, the device uses the IEEE classification to determine the power usage of the device.

- IEEE 802.3af—The major features of this standard are powered-device discovery, power administration, disconnect detection, and optional powered-device power classification. For more information, see the standard.

## Powered-Device Detection and Initial Power Allocation

The device detects a Cisco pre-standard or an IEEE-compliant powered device when the PoE-capable port is in the no-shutdown state, PoE is enabled (the default), and the connected device is not being powered by an AC adaptor.

After device detection, the device determines the device power requirements based on its type:

- The initial power allocation is the maximum amount of power that a powered device requires. The device initially allocates this amount of power when it detects and powers the powered device. As the device receives CDP messages from the powered device and as the powered device negotiates power levels with the device through CDP power-negotiation messages, the initial power allocation might be adjusted.

- The device classifies the detected IEEE device within a power consumption class. Based on the available power in the power budget, the device determines if a port can be powered. Table 9: IEEE Power Classifications, on page 76 lists these levels.

### Table 9: IEEE Power Classifications

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum Power Level Required from the Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (class status unknown)</td>
<td>15.4 W</td>
</tr>
<tr>
<td>1</td>
<td>4 W</td>
</tr>
<tr>
<td>2</td>
<td>7 W</td>
</tr>
<tr>
<td>3</td>
<td>15.4 W</td>
</tr>
<tr>
<td>4</td>
<td>30 W (For IEEE 802.3at Type 2 powered devices)</td>
</tr>
</tbody>
</table>

The device monitors and tracks requests for power and grants power only when it is available. The device tracks its power budget (the amount of power available on the device for PoE). The device performs power-accounting calculations when a port is granted or denied power to keep the power budget up to date.

After power is applied to the port, the device uses CDP to determine the CDP-specific power consumption requirement of the connected Cisco powered devices, which is the amount of power to allocate based on the CDP messages. The device adjusts the power budget accordingly. This does not apply to third-party PoE devices. The device processes a request and either grants or denies power. If the request is granted, the device updates the power budget. If the request is denied, the device ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. Powered devices can also negotiate with the device for more power.

With PoE+, powered devices use IEEE 802.3at and LLDP power with media dependent interface (MDI) type, length, and value descriptions (TLVs), Power-via-MDI TLVs, for negotiating power up to 30 W. Cisco
pre-standard devices and Cisco IEEE powered devices can use CDP or the IEEE 802.3at power-via-MDI power negotiation mechanism to request power levels up to 30 W.

**Note**
The initial allocation for Class 0, Class 3, and Class 4 powered devices is 15.4 W. When a device starts up and uses CDP or LLDP to send a request for more than 15.4 W, it can be allocated up to the maximum of 30 W.

**Note**
The CDP-specific power consumption requirement is referred to as the *actual* power consumption requirement in the software configuration guides and command references.

If the device detects a fault caused by an undervoltage, overvoltage, overtemperature, oscillator-fault, or short-circuit condition, it turns off power to the port, generates a syslog message, and updates the power budget and LEDs.

The PoE feature operates the same whether or not the device is a stack member. The power budget is per device and independent of any other device in the stack. Election of a new active device does not affect PoE operation. The active device keeps track of the PoE status for all devices and ports in the stack and includes the status in output displays.

### Power Management Modes

The device supports these PoE modes:

- **auto**—The device automatically detects if the connected device requires power. If the device discovers a powered device connected to the port and if the device has enough power, it grants power, updates the power budget, turns on power to the port on a first-come, first-served basis, and updates the LEDs. For LED information, see the hardware installation guide.

  If the device has enough power for all the powered devices, they all come up. If enough power is available for all powered devices connected to the device, power is turned on to all devices. If there is not enough available PoE, or if a device is disconnected and reconnected while other devices are waiting for power, it cannot be determined which devices are granted or are denied power.

  If granting power would exceed the system power budget, the device denies power, ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. After power has been denied, the device periodically rechecks the power budget and continues to attempt to grant the request for power.

  If a device being powered by the device is then connected to wall power, the device might continue to power the device. The device might continue to report that it is still powering the device whether the device is being powered by the device or receiving power from an AC power source.

  If a powered device is removed, the device automatically detects the disconnect and removes power from the port. You can connect a nonpowered device without damaging it.

  You can specify the maximum wattage that is allowed on the port. If the IEEE class maximum wattage of the powered device is greater than the configured maximum value, the device does not provide power to the port. If the device powers a powered device, but the powered device later requests through CDP messages more than the configured maximum value, the device removes power to the port. The power that was allocated to the powered device is reclaimed into the global power budget. If you do not specify a wattage, the device delivers the maximum value. Use the **auto** setting on any PoE port. The auto mode is the default setting.
Power Monitoring and Power Policing

When policing of the real-time power consumption is enabled, the device takes action when a powered device consumes more power than the maximum amount allocated, also referred to as the cutoff-power value.

When PoE is enabled, the device senses the real-time power consumption of the powered device. The device monitors the real-time power consumption of the connected powered device; this is called power monitoring or power sensing. The device also polices the power usage with the power policing feature.

Power monitoring is backward-compatible with Cisco intelligent power management and CDP-based power consumption. It works with these features to ensure that the PoE port can supply power to the powered device. The device senses the real-time power consumption of the connected device as follows:

1. The device monitors the real-time power consumption on individual ports.

2. The device records the power consumption, including peak power usage. The device reports the information through the CISCO-POWER-ETHERNET-EXT-MIB.

3. If power policing is enabled, the device polices power usage by comparing the real-time power consumption to the maximum power allocated to the device. The maximum power consumption is also referred to as the cutoff power on a PoE port.

   If the device uses more than the maximum power allocation on the port, the device can either turn off power to the port, or the device can generate a syslog message and update the LEDs (the port LED is now blinking amber) while still providing power to the device based on the device configuration. By default, power-usage policing is disabled on all PoE ports.

   If error recovery from the PoE error-disabled state is enabled, the device automatically takes the PoE port out of the error-disabled state after the specified amount of time.

   If error recovery is disabled, you can manually re-enable the PoE port by using the shutdown and no shutdown interface configuration commands.

4. If policing is disabled, no action occurs when the powered device consumes more than the maximum power allocation on the PoE port, which could adversely affect the device.
Maximum Power Allocation (Cutoff Power) on a PoE Port

When power policing is enabled, the device determines one of the these values as the cutoff power on the PoE port in this order:

1. Manually when you set the user-defined power level that the device budgets for the port by using the `power inline consumption default wattage` global or interface configuration command

2. Manually when you set the user-defined power level that limits the power allowed on the port by using the `power inline auto max max-wattage` or the `power inline static max max-wattage` interface configuration command

3. Automatically when the device sets the power usage of the device by using CDP power negotiation.

Use the first or second method in the previous list to manually configure the cutoff-power value by entering the `power inline consumption default wattage` or the `power inline [auto | static max] max-wattage` interface configuration command.

You should use `power inline consumption default wattage` command to manually set the power level for a port only in situations where CDP/LLDP power negotiations are not supported.

Power Consumption Values

You can configure the initial power allocation and the maximum power allocation on a port. However, these values are only the configured values that determine when the device should turn on or turn off power on the PoE port. The maximum power allocation is not the same as the actual power consumption of the powered device. The actual cutoff power value that the device uses for power policing is not equal to the configured power value.

When power policing is enabled, the device polices the power usage at the switch port, which is greater than the power consumption of the device. When you manually set the maximum power allocation, you must consider the power loss over the cable from the switch port to the powered device. The cutoff power is the sum of the rated power consumption of the powered device and the worst-case power loss over the cable.

We recommend that you enable power policing when PoE is enabled on your device. For example, if policing is disabled and you set the cutoff-power value by using the `power inline auto max 6300` interface configuration command, the configured maximum power allocation on the PoE port is 6.3 W (6300 mW). The device provides power to the connected devices on the port if the device needs up to 6.3 W. If the CDP-power negotiated value or the IEEE classification value exceeds the configured cutoff value, the device does not provide power to the connected device. After the device turns on power on the PoE port, the device does not police the real-time power consumption of the device, and the device can consume more power than the maximum allocated amount, which could adversely affect the device and the devices connected to the other PoE ports.
How to Configure PoE

Configuring a Power Management Mode on a PoE Port

When you make PoE configuration changes, the port being configured drops power. Depending on the new configuration, the state of the other PoE ports, and the state of the power budget, the port might not be powered up again. For example, port 1 is in the auto and on state, and you configure it for static mode. The device removes power from port 1, detects the powered device, and repowers the port. If port 1 is in the auto and on state and you configure it with a maximum wattage of 10 W, the device removes power from the port and then redetects the powered device. The device repowers the port only if the powered device is a class 1, class 2, or a Cisco-only powered device.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. power inline {auto [max max-wattage] | never | static [max max-wattage]}
5. end
6. show power inline [interface-id | module switch-number]
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the physical port to be configured, and enters interface</td>
</tr>
<tr>
<td>Example:</td>
<td>configuration mode.</td>
</tr>
<tr>
<td>Device(config)# interface</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> power inline</td>
<td>Configures the PoE mode on the port. The keywords have these meanings:</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# power inline</td>
<td></td>
</tr>
</tbody>
</table>
| auto [max max-wattage] | auto—Enables powered-device detection. If enough power is available, automatically allocates power to
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>the PoE port after device detection. This is the default setting.</td>
</tr>
<tr>
<td><strong>max max-wattage</strong></td>
<td>Limits the power allowed on the port. If no value is specified, the maximum is allowed.</td>
</tr>
<tr>
<td><strong>never</strong></td>
<td>Disables device detection, and disable power to the port.</td>
</tr>
</tbody>
</table>

**Note** If a port has a Cisco powered device connected to it, do not use the `power inline never` command to configure the port. A false link-up can occur, placing the port into the error-disabled state.

**Step 5**

```plaintext
end
```

**Example:**

Device(config-if)# end

Returns to privileged EXEC mode.

**Step 6**

```plaintext
show power inline [interface-id | module switch-number]
```

**Example:**

Device# show power inline

Displays PoE status for a device or a device stack, for the specified interface, or for a specified stack member.

The `module switch-number` keywords are supported only on stacking-capable devices.

**Step 7**

```plaintext
copy running-config startup-config
```

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

**Budgeting Power for Devices Connected to a PoE Port**

When Cisco powered devices are connected to PoE ports, the device uses Cisco Discovery Protocol (CDP) to determine the protocol-specific power consumption of the devices, and the device adjusts the power budget accordingly. This does not apply to IEEE third-party powered devices. For these devices, when the device grants a power request, the device adjusts the power budget according to the powered-device IEEE classification. If the powered device is a class 0 (class status unknown) or a class 3, the device budgets 15,400 mW for the
device, regardless of the CDP-specific amount of power needed. If the powered device reports a higher class than its CDP-specific consumption or does not support power classification (defaults to class 0), the device can power fewer devices because it uses the IEEE class information to track the global power budget.

By using the `power inline consumption wattage` interface configuration command or the `power inline consumption default wattage` global configuration command, you can override the default power requirement specified by the IEEE classification. The difference between what is mandated by the IEEE classification and what is actually needed by the device is reclaimed into the global power budget for use by additional devices. You can then extend the device power budget and use it more effectively.

⚠️ **Caution**

You should carefully plan your device power budget, enable the power monitoring feature, and make certain not to oversubscribe the power supply.

🔍 **Note**

When you manually configure the power budget, you must also consider the power loss over the cable between the device and the powered device.

### Budgeting Power to All PoE ports

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no cdp run`
4. `power inline consumption default wattage`
5. `end`
6. `show power inline consumption default`
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>

<td></td>
</tr>
<tr>
<td><code>Device(config)# no cdp run</code></td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**  
Configure the power consumption of powered devices connected to each PoE port.

**Example:**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td><code>power inline consumption default wattage</code></td>
<td>Configures the power consumption of powered devices connected to each PoE port. The range for each device is 4000 to 30000 mW (PoE+). The default is 30000 mW.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# power inline consumption default 5000</code></td>
<td>Note: When you use this command, we recommend you also enable power policing.</td>
</tr>
</tbody>
</table>

### Step 5

**Command or Action**  
Returns to privileged EXEC mode.

**Example:**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

### Step 6

**Command or Action**  
Displays the power consumption status.

**Example:**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td><code>show power inline consumption default</code></td>
<td>Displays the power consumption status.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# show power inline consumption default</code></td>
<td></td>
</tr>
</tbody>
</table>

### Step 7

**Command or Action**  
(Optional) Saves your entries in the configuration file.

**Example:**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

### Budgeting Power to a Specific PoE Port

---

**Note:** This configuration guide provides detailed steps for managing power consumption on a Cisco Catalyst 2960-XR switch. The steps include enabling privileged EXEC mode, configuring power consumption limits, and managing power distribution among PoE ports. These settings are crucial for optimizing network performance and ensuring compliance with power limitations, especially in environments where PoE devices with high power consumption are deployed.
<table>
<thead>
<tr>
<th>Command or Action</th>

</tbody>
</table>

## Configuring Power Policing

By default, the device monitors the real-time power consumption of connected powered devices. You can configure the device to police the power usage. By default, policing is disabled.

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. power inline police [action {log | errdisable}]
5. exit
6. Use one of the following:
   - `errdisable detect cause inline-power`
   - `errdisable recovery cause inline-power`
   - `errdisable recovery interval interval`

7. `exit`

8. Use one of the following:
   - `show power inline police`
   - `show errdisable recovery`

9. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `enable`  
**Example:**

Device> enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| Step 2 | `configure terminal`  
**Example:**

Device# configure terminal | Enters global configuration mode. |
| Step 3 | `interface interface-id`  
**Example:**

Device(config)# interface gigabitethernet 2/0/1 | Specifies the physical port to be configured, and enter interface configuration mode. |
| Step 4 | `power inline police [action {log | errdisable}]`  
**Example:**

Device(config-if)# power inline police | If the real-time power consumption exceeds the maximum power allocation on the port, configures the device to take one of these actions:
   - `power inline police`—Shuts down the PoE port, turns off power to it, and puts it in the error-disabled state.  
   - `power inline police action errdisable`—Turns off power to the port if the real-time power consumption exceeds the maximum power allocation on the port. |

**Note**
You can enable error detection for the PoE error-disabled cause by using the `errdisable detect cause inline-power` global configuration command. You can also enable the timer to recover from the PoE error-disabled state by using the `errdisable recovery cause inline-power interval interval` global configuration command.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>power inline police action log</strong>—Generates a syslog message while still providing power to the port. If you do not enter the <code>action log</code> keywords, the default action shuts down the port and puts the port in the error-disabled state.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**  
**Example:**  
Device(config-if)# **exit**  
Returns to global configuration mode.

**Step 6**  
Use one of the following:  
• **errdisable detect cause inline-power**  
• **errdisable recovery cause inline-power**  
• **errdisable recovery interval** `interval`  
**Example:**  
Device(config)# **errdisable detect cause inline-power**  
Device(config)# **errdisable recovery cause inline-power**  
Device(config)# **errdisable recovery interval** 100  
(Optional) Enables error recovery from the PoE error-disabled state, and configures the PoE recover mechanism variables.  
By default, the recovery interval is 300 seconds.  
For `interval` `interval`, specifies the time in seconds to recover from the error-disabled state. The range is 30 to 86400.

**Step 7**  
**Example:**  
Device(config)# **exit**  
Returns to privileged EXEC mode.

**Step 8**  
Use one of the following:  
• **show power inline police**  
• **show errdisable recovery**  
**Example:**  
Device# **show power inline police**  
Device# **show errdisable recovery**  
Displays the power monitoring status, and verify the error recovery settings.

**Step 9**  
**Example:**  
Device# **copy running-config startup-config**  
(Optional) Saves your entries in the configuration file.
Monitoring Power Status

Table 10: Show Commands for Power Status

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show env power switch [switch-number]</code></td>
<td>(Optional) Displays the status of the internal power supplies for each switch in the stack or for the specified switch. The range is 1 to 8, depending on the switch member numbers in the stack. These keywords are available only on stacking-capable switches.</td>
</tr>
<tr>
<td>`show power inline [interface-id</td>
<td>module switch-number]`</td>
</tr>
<tr>
<td><code>show power inline police</code></td>
<td>Displays the power policing data.</td>
</tr>
</tbody>
</table>

Configuration Examples for Configuring PoE

Budgeting Power: Example

When you enter one of the following commands,

- `[no] power inline consumption default wattage` global configuration command
- `[no] power inline consumption wattage` interface configuration command

this caution message appears:

%CAUTION: Interface Gi1/0/1: Misconfiguring the 'power inline consumption/allocation' command may cause damage to the switch and void your warranty. Take precaution not to oversubscribe the power supply. It is recommended to enable power policing if the switch supports it. Refer to documentation.

Configuring 2-event Classification

- Finding Feature Information, on page 89
- Information about 2-event Classification, on page 89
- Configuring 2-event Classification, on page 89
- Example: Configuring 2-Event Classification, on page 90

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about 2-event Classification

When a class 4 device gets detected, IOS allocates 30W without any CDP or LLDP negotiation. This means that even before the link comes up the class 4 power device gets 30W.

Also, on the hardware level the PSE does a 2-event classification which allows a class 4 PD to detect PSE capability of providing 30W from hardware, register itself and it can move up to PoE+ level without waiting for any CDP/LLDP packet exchange.

Once 2-event is enabled on a port, you need to manually shut/un-shut the port or connect the PD again to start the IEEE detection again. Power budget allocation for a class-4 device will be 30W if 2-event classification is enabled on the port, else it will be 15.4W.

Configuring 2-event Classification

To configure the switch for a 2-event Classification, perform the steps given below:
### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. power inline port 2-event
5. end

### DETAILED STEPS

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for EEE

EEE has the following restrictions:

- Changing the EEE configuration resets the interface because the device has to restart Layer 1 autonegotiation.

- You might want to enable the Link Layer Discovery Protocol (LLDP) for devices that require longer wakeup times before they are able to accept data on their receive paths. Doing so enables the device to negotiate for extended system wakeup times from the transmitting link partner.
Information About EEE

EEE Overview

Energy Efficient Ethernet (IEEE) is an IEEE 802.3az standard that is designed to reduce power consumption in Ethernet networks during idle periods.

Default EEE Configuration

EEE is enabled by default.

How to Configure EEE

You can enable or disable EEE on an interface that is connected to an EEE-capable link partner.

Enabling or Disabling EEE

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. power efficient-ethernet auto
4. no power efficient-ethernet auto
5. end
6. copy running-config startup-config

IP Multicast Routing Technology Overview

Information About IP Multicast Technology

Role of IP Multicast in Information Delivery

IP multicast is a bandwidth-conserving technology that reduces traffic by delivering a single stream of information simultaneously to potentially thousands of businesses and homes. Applications that take advantage of multicast include video conferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address. The sending host inserts the multicast group address into the IP destination address field of the packet and IP multicast routers and multilayer switches forward incoming IP multicast packets out all interfaces that lead to the members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

IP Multicast Routing Protocols

The software supports the following protocols to implement IP multicast routing:

- IGMP is used between hosts on a LAN and the routers (and multilayer devices) on that LAN to track the multicast groups of which hosts are members. To participate in IP multicasting, multicast hosts, routers, and multilayer devices must have the Internet Group Management Protocol (IGMP) operating.

- Protocol Independent Multicast (PIM) is used between routers so that they can track which multicast packets to forward to each other and to their directly connected LANs.

- IGMP Snooping is used for multicasting in a Layer 2 switching environment. It helps reduce the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices.

This figure shows where these protocols operate within the IP multicast environment.
According to IPv4 multicast standards, the MAC destination multicast address begins with 0100:5e and is appended by the last 23 bits of the IP address. For example, if the IP destination address is 239.1.1.39, the MAC destination address is 0100:5e01:0127.

A multicast packet is unmatched when the destination IPv4 address does not match the destination MAC address. The device forwards the unmatched packet in hardware based upon the MAC address table. If the destination MAC address is not in the MAC address table, the device floods the packet to the all port in the same VLAN as the receiving port.

### Multicast Group Transmission Scheme

IP communication consists of hosts that act as senders and receivers of traffic as shown in the first figure. Senders are called sources. Traditional IP communication is accomplished by a single host source sending packets to another single host (unicast transmission) or to all hosts (broadcast transmission). IP multicast provides a third scheme, allowing a host to send packets to a subset of all hosts (multicast transmission). This subset of receiving hosts is called a multicast group. The hosts that belong to a multicast group are called group members.

Multicast is based on this group concept. A multicast group is an arbitrary number of receivers that join a group in order to receive a particular data stream. This multicast group has no physical or geographical boundaries—the hosts can be located anywhere on the Internet or on any private internetwork. Hosts that are interested in receiving data from a source to a particular group must join that group. Joining a group is accomplished by a host receiver by way of the Internet Group Management Protocol (IGMP).

In a multicast environment, any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group can receive packets sent to that group. Multicast packets are delivered to a group using best-effort reliability, just like IP unicast packets.
In the next figure, the receivers (the designated multicast group) are interested in receiving the video data stream from the source. The receivers indicate their interest by sending an IGMP host report to the routers in the network. The routers are then responsible for delivering the data from the source to the receivers. The routers use Protocol Independent Multicast (PIM) to dynamically create a multicast distribution tree. The video data stream will then be delivered only to the network segments that are in the path between the source and the receivers.
IP Multicast Boundary

As shown in the figure, address scoping defines domain boundaries so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

*Figure 6: Address Scoping at Boundaries*

You can set up an administratively scoped boundary on an interface for multicast group addresses using the `ip multicast boundary` command with the `access-list` argument. A standard access list defines the range of addresses affected. When a boundary is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The Internet Assigned Numbers Authority (IANA) has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. They would be considered local, not globally unique.

You can configure the `filter-autorp` keyword to examine and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group
range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

**IP Multicast Group Addressing**

A multicast group is identified by its multicast group address. Multicast packets are delivered to that multicast group address. Unlike unicast addresses that uniquely identify a single host, multicast IP addresses do not identify a particular host. To receive the data sent to a multicast address, a host must join the group that address identifies. The data is sent to the multicast address and received by all the hosts that have joined the group indicating that they wish to receive traffic sent to that group. The multicast group address is assigned to a group at the source. Network administrators who assign multicast group addresses must make sure the addresses conform to the multicast address range assignments reserved by the Internet Assigned Numbers Authority (IANA).

**IP Class D Addresses**

IP multicast addresses have been assigned to the IPv4 Class D address space by IANA. The high-order four bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 to 239.255.255.255. A multicast address is chosen at the source (sender) for the receivers in a multicast group.

**Note**

The Class D address range is used only for the group address or destination address of IP multicast traffic. The source address for multicast datagrams is always the unicast source address.

**IP Multicast Address Scoping**

The multicast address range is subdivided to provide predictable behavior for various address ranges and for address reuse within smaller domains. The table provides a summary of the multicast address ranges. A brief summary description of each range follows.

<table>
<thead>
<tr>
<th>Name</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved Link-Local Addresses</td>
<td>224.0.0.0 to 224.0.0.255</td>
<td>Reserved for use by network protocols on a local network segment.</td>
</tr>
<tr>
<td>Globally Scoped Addresses</td>
<td>224.0.1.0 to 238.255.255.255</td>
<td>Reserved to send multicast data between organizations and across the Internet.</td>
</tr>
<tr>
<td>Source Specific Multicast</td>
<td>232.0.0.0 to 232.255.255.255</td>
<td>Reserved for use with the SSM datagram delivery model where data is forwarded only to receivers that have explicitly joined the group.</td>
</tr>
<tr>
<td>GLOP Addresses</td>
<td>233.0.0.0 to 233.255.255.255</td>
<td>Reserved for statically defined addresses by organizations that already have an assigned autonomous system (AS) domain number.</td>
</tr>
<tr>
<td>Limited Scope Address</td>
<td>239.0.0.0 to 239.255.255.255</td>
<td>Reserved as administratively or limited scope addresses for use in private multicast domains.</td>
</tr>
</tbody>
</table>
Reserved Link-Local Addresses

The IANA has reserved the range 224.0.0.0 to 224.0.0.255 for use by network protocols on a local network segment. Packets with an address in this range are local in scope and are not forwarded by IP routers. Packets with link local destination addresses are typically sent with a time-to-live (TTL) value of 1 and are not forwarded by a router.

Within this range, reserved link-local addresses provide network protocol functions for which they are reserved. Network protocols use these addresses for automatic router discovery and to communicate important routing information. For example, Open Shortest Path First (OSPF) uses the IP addresses 224.0.0.5 and 224.0.0.6 to exchange link-state information.

IANA assigns single multicast address requests for network protocols or network applications out of the 224.0.1.xxx address range. Multicast routers forward these multicast addresses.

Note

All the packets with reserved link-local addresses are punted to CPU by default in the ASR 903 RSP2 Module.

Globally Scoped Addresses

Addresses in the range 224.0.1.0 to 238.255.255.255 are called globally scoped addresses. These addresses are used to send multicast data between organizations across the Internet. Some of these addresses have been reserved by IANA for use by multicast applications. For example, the IP address 224.0.1.1 is reserved for Network Time Protocol (NTP).

Source Specific Multicast Addresses

Addresses in the range 232.0.0.0/8 are reserved for Source Specific Multicast (SSM) by IANA. In Cisco IOS software, you can use the `ip pim ssm` command to configure SSM for arbitrary IP multicast addresses also. SSM is an extension of Protocol Independent Multicast (PIM) that allows for an efficient data delivery mechanism in one-to-many communications. SSM is described in the IP Multicast Delivery Modes, on page 107 section.

GLOP Addresses

GLOP addressing (as proposed by RFC 2770, GLOP Addressing in 233/8) proposes that the 233.0.0.0/8 range be reserved for statically defined addresses by organizations that already have an AS number reserved. This practice is called GLOP addressing. The AS number of the domain is embedded into the second and third octets of the 233.0.0.0/8 address range. For example, AS 62010 is written in hexadecimal format as F23A. Separating the two octets F2 and 3A results in 242 and 58 in decimal format. These values result in a subnet of 233.242.58.0/24 that would be globally reserved for AS 62010 to use.

Limited Scope Addresses

The range 239.0.0.0 to 239.255.255.255 is reserved as administratively or limited scoped addresses for use in private multicast domains. These addresses are constrained to a local group or organization. Companies, universities, and other organizations can use limited scope addresses to have local multicast applications that will not be forwarded outside their domain. Routers typically are configured with filters to prevent multicast traffic in this address range from flowing outside an autonomous system (AS) or any user-defined domain. Within an AS or domain, the limited scope address range can be further subdivided so that local multicast boundaries can be defined.
Network administrators may use multicast addresses in this range, inside a domain, without conflicting with others elsewhere in the Internet.

**Layer 2 Multicast Addresses**

Historically, network interface cards (NICs) on a LAN segment could receive only packets destined for their burned-in MAC address or the broadcast MAC address. In IP multicasting, several hosts need to be able to receive a single data stream with a common destination MAC address. Some means had to be devised so that multiple hosts could receive the same packet and still be able to differentiate between several multicast groups. One method to accomplish this is to map IP multicast Class D addresses directly to a MAC address. Using this method, NICs can receive packets destined to many different MAC addresses.

Cisco Group Management Protocol (CGMP) is used on routers connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary for those Catalyst switches that cannot distinguish between IP multicast data packets and IGMP report messages, both of which are addressed to the same group address at the MAC level.

**IP Multicast Delivery Modes**

IP multicast delivery modes differ only for the receiver hosts, not for the source hosts. A source host sends IP multicast packets with its own IP address as the IP source address of the packet and a group address as the IP destination address of the packet.

**Source Specific Multicast**

Source Specific Multicast (SSM) is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core network technology for the Cisco implementation of IP multicast targeted for audio and video broadcast application environments.

For the SSM delivery mode, an IP multicast receiver host must use IGMP Version 3 (IGMPv3) to subscribe to channel (S,G). By subscribing to this channel, the receiver host is indicating that it wants to receive IP multicast traffic sent by source host S to group G. The network will deliver IP multicast packets from source host S to group G to all hosts in the network that have subscribed to the channel (S, G).

SSM does not require group address allocation within the network, only within each source host. Different applications running on the same source host must use different SSM groups. Different applications running on different source hosts can arbitrarily reuse SSM group addresses without causing any excess traffic on the network.

Configuring Basic IP Multicast Routing

- Prerequisites for Basic IP Multicast Routing, on page 109
- Restrictions for Basic IP Multicast Routing, on page 109
- Information About Basic IP Multicast Routing, on page 110
- How to Configure Basic IP Multicast Routing, on page 111
- Monitoring and Maintaining Basic IP Multicast Routing, on page 119
- Additional References, on page 121
- Feature History and Information for IP Multicast, on page 122

Prerequisites for Basic IP Multicast Routing

The following are the prerequisites for configuring basic IP multicast routing:

- You must configure the PIM version and the PIM mode in order to perform IP multicast routing. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting. You can configure an interface to be in the PIM dense mode, sparse mode, or sparse-dense mode.

On a device running the IP base image, if you try to configure a VLAN interface with PIM dense-mode, sparse-mode, or dense-sparse-mode, the configuration is not allowed.

- Enabling PIM on an interface also enables IGMP operation on that interface. (To participate in IP multicasting, the multicast hosts, routers, and multilayer device must have IGMP operating.)

If you enable PIM on multiple interfaces, when most of these interfaces are not on the outgoing interface list, and IGMP snooping is disabled, the outgoing interface might not be able to sustain line rate for multicast traffic because of the extra replication.

Restrictions for Basic IP Multicast Routing

The following are the restrictions for IP multicast routing:

- The switch supports homogeneous stacking, but does not support mixed stacking.
Information About Basic IP Multicast Routing

IP multicasting is an efficient way to use network resources, especially for bandwidth-intensive services such as audio and video. IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address.

The sending host inserts the multicast group address into the IP destination address field of the packet, and IP multicast routers and multilayer devices forward incoming IP multicast packets out all interfaces that lead to members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

Multicast Routing and Device Stacks

For all multicast routing protocols, the entire stack appears as a single router to the network and operates as a single multicast router.

In a device stack, the active device performs these functions:

- It is responsible for completing the IP multicast routing functions of the stack. It fully initializes and runs the IP multicast routing protocols.
- It builds and maintains the multicast routing table for the entire stack.
- It is responsible for distributing the multicast routing table to all stack members.

The stack members perform these functions:

- They act as multicast routing standby devices and are ready to take over if there is a active device failure.

If the active device fails, all stack members delete their multicast routing tables. The newly elected active device starts building the routing tables and distributes them to the stack members.

- They do not build multicast routing tables. Instead, they use the multicast routing table that is distributed by the active device.

### Configuring sdr Listener Support

The MBONE is the small subset of Internet routers and hosts that are interconnected and capable of forwarding IP multicast traffic. Other multimedia content is often broadcast over the MBONE. Before you can join a multimedia session, you need to know what multicast group address and port are being used for the session, when the session is going to be active, and what sort of applications (audio, video, and so forth) are required on your workstation. The MBONE Session Directory Version 2 (sdr) tool provides this information. This freeware application can be downloaded from several sites on the World Wide Web, one of which is http://www.video.ja.net/mice/index.html.

SDR is a multicast application that listens to a well-known multicast group address and port for Session Announcement Protocol (SAP) multicast packets from SAP clients, which announce their conference sessions. These SAP packets contain a session description, the time the session is active, its IP multicast group addresses, media format, contact person, and other information about the advertised multimedia session. The information in the SAP packet is displayed in the SDR Session Announcement window.

### How to Configure Basic IP Multicast Routing

#### Configuring Basic IP Multicast Routing

By default, multicast routing is disabled, and there is no default mode setting.

This procedure is required.

**Before you begin**

You must configure the PIM version and the PIM mode. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting.

In populating the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream devices or when there is a directly connected member on the interface. When forwarding from a LAN, sparse-mode operation occurs if there is an RP known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver’s first-hop router might send join messages toward the source to build a source-based distribution tree.

**Example:** Enter your password, if prompted.  
Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
**Example:** |
| **Step 3** ip multicast-routing distributed | Enables IP multicast distributed switching  
**Note** To disable multicasting, use the **no ip multicast-routing distributed** global configuration command.  
**Example:** |
| **Step 4** interface interface-id | Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode.  
The specified interface must be one of the following:  
- A routed port—a physical port that has been configured as a Layer 3 port by entering the **no switchport** interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group.  
- An SVI—a VLAN interface created by using the **interface vlan vlan-id** global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group,  
**Example:**  
Device(config)# interface gigabitethernet 1/0/1 |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`ip pim version [1</td>
<td>2]`</td>
</tr>
</tbody>
</table>
| `ip pim {dense-mode | sparse-mode | sparse-dense-mode}` | Enables a PIM mode on the interface. By default, no mode is configured. The keywords have these meanings:  
  * dense-mode—Enables dense mode of operation.  
  * sparse-mode—Enables sparse mode of operation. If you configure sparse mode, you must also configure an RP.  
  * sparse-dense-mode—Causes the interface to be treated in the mode in which the group belongs. Sparse-dense mode is the recommended setting. **Note** To disable PIM on an interface, use the `no ip pim` interface configuration command. |
| `end` | Returns to privileged EXEC mode. |
| `show running-config` | Verifies your entries. |
| `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
Defining the IP Multicast Boundary

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information. This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. access-list access-list-number deny source [source-wildcard]
4. interface interface-id
5. ip multicast boundary access-list-number
6. end
7. show running-config
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>access-list access-list-number deny source [source-wildcard]</td>
<td>Creates a standard access list, repeating the command as many times as necessary.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# access-list 12 deny 224.0.1.39 access-list 12 deny 224.0.1.40</td>
<td></td>
</tr>
</tbody>
</table>

This procedure is optional.
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) For <code>source-wildcard</code>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. The access list is always terminated by an implicit deny statement for everything.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 4

**interface interface-id**

**Example:**

```
Device(config)# interface gigabitethernet 1/0/1
```

**Purpose:** Specifies the interface to be configured, and enters interface configuration mode.

### Step 5

**ip multicast boundary access-list-number**

**Example:**

```
Device(config-if)# ip multicast boundary 12
```

**Purpose:** Configures the boundary, specifying the access list you created in Step 2.

**Note** To remove the boundary, use the `no ip multicast boundary` interface configuration command.

### Step 6

**end**

**Example:**

```
Device(config)# end
```

**Purpose:** Returns to privileged EXEC mode.

### Step 7

**show running-config**

**Example:**

```
Device# show running-config
```

**Purpose:** Verifies your entries.

### Step 8

**copy running-config startup-config**

**Example:**

```
Device# copy running-config startup-config
```

**Purpose:** (Optional) Saves your entries in the configuration file.

Monitoring and Maintaining Basic IP Multicast Routing

Clearing Caches, Tables, and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure are or suspected to be invalid.

You can use any of the privileged EXEC commands in the following table to clear IP multicast caches, tables, and databases.

Table 14: Commands for Clearing Caches, Tables, and Databases

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ip cgmp</td>
<td>Clears all group entries the Catalyst switches have cached.</td>
</tr>
<tr>
<td>clear ip igmp group {group [hostname</td>
<td>IP address]</td>
</tr>
<tr>
<td>clear ip mroute { *</td>
<td>[hostname</td>
</tr>
<tr>
<td>clear ip sap [group-address</td>
<td>“session-name”]</td>
</tr>
</tbody>
</table>

Displaying System and Network Statistics

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

![Note]

This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

Table 15: Commands for Displaying System and Network Statistics

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

CHAPTER 13

Configuring IGMP

• Prerequisites for IGMP, on page 123
• Restrictions for Configuring IGMP, on page 123
• Information About IGMP, on page 124
• How to Configure IGMP, on page 129
• Monitoring IGMP, on page 140
• Configuration Examples for IGMP, on page 141
• Additional References, on page 141
• Feature History and Information for IGMP, on page 142

Prerequisites for IGMP

• Before performing the tasks in this module, you should be familiar with the concepts explained in the "IP Multicast Routing Technology Overview" module.

• The tasks in this module assume that IP multicast has been enabled and that the Protocol Independent Multicast (PIM) interfaces have been configured using the tasks described in the "Configuring Basic IP Multicast Routing" module.

Restrictions for Configuring IGMP

The following are the restrictions for configuring IGMP:

• The device supports IGMP Versions 1, 2, and 3.

  Note: For IGMP Version 3, only IGMP Version 3 BISS (Basic IGMPv3 Snooping Support) is supported.

• IGMP Version 3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.

• IGMPv3 can operate with both ISM and SSM. In ISM, both exclude and include mode reports are applicable. In SSM, only include mode reports are accepted by the last-hop router. Exclude mode reports are ignored.
Information About IGMP

Role of the Internet Group Management Protocol

IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Enabling PIM on an interface also enables IGMP. IGMP provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

- A querier is a network device, such as a router, that sends query messages to discover which network devices are members of a given multicast group.
- A host is a receiver, including routers, that sends report messages (in response to query messages) to inform the querier of a host membership. Hosts use IGMP messages to join and leave multicast groups.

Hosts identify group memberships by sending IGMP messages to their local multicast device. Under IGMP, devices listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP Multicast Addresses

IP multicast traffic uses group addresses, which are Class D IP addresses. The high-order four bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 to 239.255.255.255.

Multicast addresses in the range 224.0.0.0 to 224.0.0.255 are reserved for use by routing protocols and other network control traffic. The address 224.0.0.0 is guaranteed not to be assigned to any group.

IGMP packets are transmitted using IP multicast group addresses as follows:

- IGMP general queries are destined to the address 224.0.0.1 (all systems on a subnet).
- IGMP group-specific queries are destined to the group IP address for which the device is querying.
- IGMP group membership reports are destined to the group IP address for which the device is reporting.
- IGMPv2 leave-group messages are destined to the address 224.0.0.2 (all devices on a subnet).
- IGMPv3 membership reports are destined to the address 224.0.0.22; all IGMPv3-capable multicast devices must listen to this address.

IGMP Versions

The device supports IGMP version 1, IGMP version 2, and IGMP version 3. These versions are interoperable on the device. For example, if IGMP snooping is enabled and the querier's version is IGMPv2, and the device receives an IGMPv3 report from a host, then the device can forward the IGMPv3 report to the multicast router.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.
IGMP Version 1

IGMP version 1 (IGMPv1) primarily uses a query-response model that enables the multicast router and multilayer device to find which multicast groups are active (have one or more hosts interested in a multicast group) on the local subnet. IGMPv1 has other processes that enable a host to join and leave a multicast group. For more information, see RFC 1112.

IGMP Version 2

IGMPv2 extends IGMP functionality by providing such features as the IGMP leave process to reduce leave latency, group-specific queries, and an explicit maximum query response time. IGMPv2 also adds the capability for routers to elect the IGMP querier without depending on the multicast protocol to perform this task. For more information, see RFC 2236.

Note

IGMP version 2 is the default version for the device.

IGMP Version 3

The device supports IGMP version 3.

An IGMPv3 device supports Basic IGMPv3 Snooping Support (BISS), which includes support for the snooping features on IGMPv1 and IGMPv2 switches and for IGMPv3 membership report messages. BISS constrains the flooding of multicast traffic when your network includes IGMPv3 hosts. It constrains traffic to approximately the same set of ports as the IGMP snooping feature on IGMPv2 or IGMPv1 hosts.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

IGMPv3 Host Signalling

In IGMPv3, hosts signal membership to last hop routers of multicast groups. Hosts can signal group membership with filtering capabilities with respect to sources. A host can either signal that it wants to receive traffic from all sources sending to a group except for some specific sources (called exclude mode), or that it wants to receive traffic only from some specific sources sending to the group (called include mode).

IGMPv3 can operate with both Internet Standard Multicast (ISM) and Source Specific Multicast (SSM). In ISM, both exclude and include mode reports are applicable. In SSM, only include mode reports are accepted by the last-hop router. Exclude mode reports are ignored.

IGMP Versions Differences

There are three versions of IGMP, as defined by Request for Comments (RFC) documents of the Internet Engineering Task Force (IETF). IGMPv2 improves over IGMPv1 by adding the ability for a host to signal desire to leave a multicast group and IGMPv3 improves over IGMPv2 mainly by adding the ability to listen to multicast originating from a set of source IP addresses only.
Table 17: IGMP Versions

<table>
<thead>
<tr>
<th>IGMP Version</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGMPv1</td>
<td>Provides the basic query-response mechanism that allows the multicast device to determine which multicast groups are active and other processes that enable hosts to join and leave a multicast group. RFC 1112 defines the IGMPv1 host extensions for IP multicasting.</td>
</tr>
<tr>
<td>IGMPv2</td>
<td>Extends IGMP, allowing such capabilities as the IGMP leave process, group-specific queries, and an explicit maximum response time field. IGMPv2 also adds the capability for devices to elect the IGMP querier without dependence on the multicast protocol to perform this task. RFC 2236 defines IGMPv2.</td>
</tr>
</tbody>
</table>

Note: Devices That Run IGMPv1

IGMPv1 devices send IGMP queries to the “all-hosts” multicast address of 224.0.0.1 to solicit multicast groups with active multicast receivers. The multicast receivers also can send IGMP reports to the device to notify it that they are interested in receiving a particular multicast stream. Hosts can send the report asynchronously or in response to the IGMP queries sent by the device. If more than one multicast receiver exists for the same multicast group, only one of these hosts sends an IGMP report message; the other hosts suppress their report messages.

In IGMPv1, there is no election of an IGMP querier. If more than one device on the segment exists, all the devices send periodic IGMP queries. IGMPv1 has no special mechanism by which the hosts can leave the group. If the hosts are no longer interested in receiving multicast packets for a particular group, they simply do not reply to the IGMP query packets sent from the device. The device continues sending query packets. If the device does not hear a response in three IGMP queries, the group times out and the device stops sending multicast packets on the segment for the group. If the host later wants to receive multicast packets after the timeout period, the host simply sends a new IGMP join to the device, and the device begins to forward the multicast packet again.

If there are multiple devices on a LAN, a designated router (DR) must be elected to avoid duplicating multicast traffic for connected hosts. PIM devices follow an election process to select a DR. The PIM device with the highest IP address becomes the DR.

The DR is responsible for the following tasks:

- Sending PIM register and PIM Join and Prune messages toward the rendezvous point (RP) to inform it about host group membership.
- Sending IGMP host-query messages.
- Sending host-query messages by default every 60 seconds in order to keep the IGMP overhead on hosts and networks very low.
Devices That Run IGMPv2

IGMPv2 improves the query messaging capabilities of IGMPv1. The query and membership report messages in IGMPv2 are identical to the IGMPv1 messages with two exceptions:

- IGMPv2 query messages are broken into two categories: general queries (identical to IGMPv1 queries) and group-specific queries.
- IGMPv1 membership reports and IGMPv2 membership reports have different IGMP type codes.

IGMPv2 also enhances IGMP by providing support for the following capabilities:

- Querier election process--Provides the capability for IGMPv2 devices to elect the IGMP querier without having to rely on the multicast routing protocol to perform the process.
- Maximum Response Time field--A new field in query messages permits the IGMP querier to specify the maximum query-response time. This field permits the tuning of the query-response process to control response burstiness and to fine-tune leave latencies.
- Group-Specific Query messages--Permits the IGMP querier to perform the query operation on a specific group instead of all groups.
- Leave-Group messages--Provides hosts with a method of notifying devices on the network that they wish to leave the group.

Unlike IGMPv1, in which the DR and the IGMP querier are typically the same device, in IGMPv2 the two functions are decoupled. The DR and the IGMP querier are selected based on different criteria and may be different devices on the same subnet. The DR is the device with the highest IP address on the subnet, whereas the IGMP querier is the device with the lowest IP address.

Query messages are used to elect the IGMP querier as follows:

1. When IGMPv2 devices start, they each multicast a general query message to the all-systems group address of 224.0.0.1 with their interface address in the source IP address field of the message.
2. When an IGMPv2 device receives a general query message, the device compares the source IP address in the message with its own interface address. The device with the lowest IP address on the subnet is elected the IGMP querier.
3. All devices (excluding the querier) start the query timer, which is reset whenever a general query message is received from the IGMP querier. If the query timer expires, it is assumed that the IGMP querier has gone down, and the election process is performed again to elect a new IGMP querier.

By default, the timer is two times the query interval.

IGMP Join and Leave Process

IGMP Join Process

When a host wants to join a multicast group, the host sends one or more unsolicited membership reports for the multicast group it wants to join. The IGMP join process is the same for IGMPv1 and IGMPv2 hosts.

In IGMPv3, the join process for hosts proceeds as follows:
• When a host wants to join a group, it sends an IGMPv3 membership report to 224.0.0.22 with an empty EXCLUDE list.

• When a host wants to join a specific channel, it sends an IGMPv3 membership report to 224.0.0.22 with the address of the specific source included in the INCLUDE list.

• When a host wants to join a group excluding particular sources, it sends an IGMPv3 membership report to 224.0.0.22 excluding those sources in the EXCLUDE list.

Note

If some IGMPv3 hosts on a LAN wish to exclude a source and others wish to include the source, then the device will send traffic for the source on the LAN (that is, inclusion trumps exclusion in this situation).

IGMP Leave Process

The method that hosts use to leave a group varies depending on the version of IGMP in operation.

IGMPv1 Leave Process

There is no leave-group message in IGMPv1 to notify the devices on the subnet that a host no longer wants to receive the multicast traffic from a specific group. The host simply stops processing traffic for the multicast group and ceases responding to IGMP queries with IGMP membership reports for the group. As a result, the only way IGMPv1 devices know that there are no longer any active receivers for a particular multicast group on a subnet is when the devices stop receiving membership reports. To facilitate this process, IGMPv1 devices associate a countdown timer with an IGMP group on a subnet. When a membership report is received for the group on the subnet, the timer is reset. For IGMPv1 devices, this timeout interval is typically three times the query interval (3 minutes). This timeout interval means that the device may continue to forward multicast traffic onto the subnet for up to 3 minutes after all hosts have left the multicast group.

IGMPv2 Leave Process

IGMPv2 incorporates a leave-group message that provides the means for a host to indicate that it wishes to stop receiving multicast traffic for a specific group. When an IGMPv2 host leaves a multicast group, if it was the last host to respond to a query with a membership report for that group, it sends a leave-group message to the all-devices multicast group (224.0.0.2).

IGMPv3 Leave Process

IGMPv3 enhances the leave process by introducing the capability for a host to stop receiving traffic from a particular group, source, or channel in IGMP by including or excluding sources, groups, or channels in IGMPv3 membership reports.

Default IGMP Configuration

This table displays the default IGMP configuration for the device.

Table 18: Default IGMP Configuration

<table>
<thead>
<tr>

<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multilayer device as a member of a multicast group</td>
<td>No group memberships are defined.</td>
</tr>
</tbody>
</table>
How to Configure IGMP

Configuring the Device as a Member of a Group

You can configure the device as a member of a multicast group and discover multicast reachability in a network. If all the multicast-capable routers and multilayer devices that you administer are members of a multicast group, pinging that group causes all of these devices to respond. The devices respond to ICMP echo-request packets addressed to a group of which they are members. Another example is the multicast trace-route tools provided in the software.

⚠️ Caution
Performing this procedure might impact the CPU performance because the CPU will receive all data traffic for the group address.

This procedure is optional.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp join-group group-address`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

### Controlling Access to IP Multicast Group

The switch sends IGMP host-query messages to find which multicast groups have members on attached local networks. The switch then forwards to these group members all packets addressed to the multicast group.
You can place a filter on each interface to restrict the multicast groups that hosts on the subnet serviced by the interface can join.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp access-group access-list-number
5. exit
6. access-list access-list-number {deny | permit} source [source-wildcard]
7. end
8. show ip igmp interface [interface-id]

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<td>The range is 1 to 199.</td>
</tr>
<tr>
<td>Note</td>
<td>To disable groups on an interface, use the <strong>no ip igmp access-group</strong> interface configuration command.</td>
</tr>
</tbody>
</table>
### Command or Action

**Step 5**  
exit  
Example:  
Device(config-if)# exit

**Purpose**  
Returns to global configuration mode.

**Step 6**  
access-list access-list-number {deny | permit} source [source-wildcard]  
Example:  
Device(config)# access-list 10 permit

**Purpose**  
Creates a standard access list.  
- For access-list-number, specify the access list created in Step 3.  
- The *deny* keyword denies access if the conditions are matched. The *permit* keyword permits access if the conditions are matched.  
- For source, specify the multicast group that hosts on the subnet can join.  
- (Optional) For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

Recall that the access list is always terminated by an implicit deny statement for everything.

**Step 7**  
end  
Example:  
Device(config-igmp-profile)# end

**Purpose**  
Returns to privileged EXEC mode.

**Step 8**  
show ip igmp interface [interface-id]  
Example:  
Device# show ip igmp interface

**Purpose**  
Verifies your entries.

### Changing the IGMP Version

By default, the switch uses IGMP Version 2, which provides features such as the IGMP query timeout and the maximum query response time.

All systems on the subnet must support the same version. The switch does not automatically detect Version 1 systems and switch to Version 1. You can mix Version 1 and Version 2 hosts on the subnet because Version 2 routers or switches always work correctly with IGMPv1 hosts.

Configure the switch for Version 1 if your hosts do not support Version 2.  
This procedure is optional.
SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp version \{1 | 2 | 3 \}
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>

        | Example: |  
        | Device(config-if)# ip igmp version 2 | Note: If you change to Version 1, you cannot configure the ip igmp query-interval or the ip igmp query-max-response-time interface configuration commands.  
        | | To return to the default setting, use the no ip igmp version interface configuration command.  |
| Step 5 | end | Returns to privileged EXEC mode.  
        | Example: | |
| Step 6 | show ip igmp interface [interface-id] | Verifies your entries.  
        | Example: | |
### Modifying the IGMP Host-Query Message Interval

The device periodically sends IGMP host-query messages to discover which multicast groups are present on attached networks. These messages are sent to the all-hosts multicast group (224.0.0.1) with a time-to-live (TTL) of 1. The device sends host-query messages to refresh its knowledge of memberships present on the network. If, after some number of queries, the software discovers that no local hosts are members of a multicast group, the software stops forwarding multicast packets to the local network from remote origins for that group and sends a prune message upstream toward the source.

The device elects a PIM designated router (DR) for the LAN (subnet). The designated router is responsible for sending IGMP host-query messages to all hosts on the LAN. In sparse mode, the designated router also sends PIM register and PIM join messages toward the RP router. With IGMPv2, the DR is the router or multilayer device with the highest IP address. With IGMPv1, the DR is elected according to the multicast routing protocol that runs on the LAN.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface interface-id**
4. **ip igmp query-interval seconds**
5. **end**
6. **show ip igmp interface [interface-id]**
7. **copy running-config startup-config**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>

<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Device# configure terminal</th>
</tr>
</thead>
</table>

### Purpose

- Specifies the interface on which you want to enable multicast routing, and enters interface configuration mode.

### Step 3

**interface interface-id**

**Example:**

```
Device(config)# interface gigabitethernet 1/0/1
```

### Step 4

**ip igmp query-interval seconds**

**Example:**

```
Device(config-if)# ip igmp query-interval 75
```

- Configures the frequency at which the designated router sends IGMP host-query messages.

  - By default, the designated router sends IGMP host-query messages every 60 seconds to keep the IGMP overhead very low on hosts and networks.

  - The range is 1 to 18000.

  - **Note:** To return to the default setting, use the `no ip igmp query-interval interface configuration` command.

### Step 5

**end**

**Example:**

```
Device(config)# end
```

- Returns to privileged EXEC mode.

### Step 6

**show ip igmp interface [interface-id]**

**Example:**

```
Device# show ip igmp interface
```

- Verifies your entries.

### Step 7

**copy running-config startup-config**

**Example:**

```
Device# copy running-config startup-config
```

- (Optional) Saves your entries in the configuration file.

---

### Changing the IGMP Query Timeout for IGMPv2

If you are using IGMPv2, you can specify the period of time before the device takes over as the querier for the interface. By default, the device waits twice the query interval period controlled by the `ip igmp query-interval interface configuration` command. After that time, if the device has received no queries, it becomes the querier.

This procedure is optional.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp querier-timeout seconds`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

### DETAILED STEPS

<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** | |
| Device# configure terminal | |

| **Step 3** interface interface-id | Specifies the interface on which you want to enable multicast routing, and enters interface configuration mode. |
| **Example:** | |
| Device(config)# interface gigabitethernet 1/0/1 | |

| **Step 4** ip igmp querier-timeout seconds | Specifies the IGMP query timeout. |
| **Example:** | The default is 60 seconds (twice the query interval). The range is 60 to 300. |
| Device(config-if)# ip igmp querier-timeout 120 | **Note** To return to the default setting, use the no ip igmp querier-timeout interface configuration command. |

| **Step 5** end | Returns to privileged EXEC mode. |
| **Example:** | |
| Device(config)# end | |

| **Step 6** show ip igmp interface [interface-id] | Verifies your entries. |
| **Example:** | |
Changing the Maximum Query Response Time for IGMPv2

If you are using IGMPv2, you can change the maximum query response time advertised in IGMP queries. The maximum query response time enables the device to quickly detect that there are no more directly connected group members on a LAN. Decreasing the value enables the device to prune groups faster.

This procedure is optional.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp query-max-response-time seconds`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

DETAILED STEPS

**Step 4**  
**ip igmp query-max-response-time** *seconds*  
**Example:**  
Device(config-if)# ip igmp query-max-response-time 15  
**Note**  
Changes the maximum query response time advertised in IGMP queries.  
The default is 10 seconds. The range is 1 to 25.  

**Step 5**  
**end**  
**Example:**  
Device(config-if)# end  
**Returns to privileged EXEC mode.**

**Step 6**  
**show ip igmp interface** *[interface-id]*  
**Example:**  
Device# show ip igmp interface  
**Verifies your entries.**

**Step 7**  
**copy running-config startup-config**  
**Example:**  
Device# copy running-config startup-config  
**(Optional) Saves your entries in the configuration file.**

---

**Configuring the Device as a Statically Connected Member**

At various times, either there is not a group member on a network segment or a host that cannot report its group membership by using IGMP. However, you may want multicast traffic to be sent to that network segment. The following commands are used to pull multicast traffic down to a network segment:

- **ip igmp join-group** — The device accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the device from fast switching.

- **ip igmp static-group** — The device does not accept the packets itself, but only forwards them. This method enables fast switching. The outgoing interface appears in the IGMP cache, but the device itself is not a member, as evidenced by lack of an L (local) flag in the multicast route entry.

This procedure is optional.

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. interface interface-id
4. `ip igmp static-group group-address`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable | Enables privileged EXEC mode.  
  * Enter your password if prompted.  
  **Example:**  
  `Device> enable` |
| Step 2 | configure terminal | Enters global configuration mode.  
  **Example:**  
  `Device# configure terminal` |
| Step 3 | interface `interface-id` | Specifies the interface on which you want to enable multicast routing, and enters interface configuration mode.  
  **Example:**  
  `Device(config)# interface gigabitethernet 1/0/1` |
| Step 4 | `ip igmp static-group group-address` | Configures the device as a statically connected member of a group.  
  By default, this feature is disabled.  
  **Note** To remove the switch as a member of the group, use the `no ip igmp static-group group-address` interface configuration command.  
  **Example:**  
  `Device(config-if)# ip igmp static-group 239.100.100.101` |
| Step 5 | `end` | Returns to privileged EXEC mode.  
  **Example:**  
  `Device(config)# end` |
| Step 6 | `show ip igmp interface [interface-id]` | Verifies your entries.  
  **Example:**  
  `Device# show ip igmp interface gigabitethernet 1/0/1` |
### Monitoring IGMP

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

**Note**

This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 19: Commands for Displaying System and Network Statistics**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip igmp groups [type-number</td>
<td>detail ]`</td>
</tr>

Configuration Examples for IGMP

Example: Configuring the Device as a Member of a Multicast Group

This example shows how to enable the device to join multicast group 255.2.2.2:

```
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip igmp join-group 255.2.2.2
```

Example: Controlling Access to IP Multicast Groups

This example shows how to configure hosts attached to a port as able to join only group 255.2.2.2:

```
Switch(config)# access-list 1 255.2.2.2 0.0.0.0
Switch(config-if)# interface gigabitethernet1/0/1
Switch(config-if)# ip igmp access-group 1
```

Prerequisites for Configuring IGMP Snooping and MVR

Observe these guidelines when configuring the IGMP snooping querier:

- Configure the VLAN in global configuration mode.
- Configure an IP address on the VLAN interface. When enabled, the IGMP snooping querier uses the IP address as the query source address.
- If there is no IP address configured on the VLAN interface, the IGMP snooping querier tries to use the configured global IP address for the IGMP querier. If there is no global IP address specified, the IGMP querier tries to use the VLAN device virtual interface (SVI) IP address (if one exists). If there is no SVI IP address, the device uses the first available IP address configured on the device. The first IP address available appears in the output of the `show ip interface` privileged EXEC command. The IGMP snooping querier does not generate an IGMP general query if it cannot find an available IP address on the device.
- The IGMP snooping querier supports IGMP Versions 1 and 2.
- When administratively enabled, the IGMP snooping querier moves to the nonquerier state if it detects the presence of a multicast router in the network.
- When it is administratively enabled, the IGMP snooping querier moves to the operationally disabled state under these conditions:
Restrictions for Configuring IGMP Snooping and MVR

Restrictions for IGMP Snooping

The following are the restrictions for IGMP snooping:

- The switch supports homogeneous stacking, but does not support mixed stacking.
- The switch supports IGMPv3 snooping based only on the destination multicast MAC address. It does not support snooping based on the source MAC address or on proxy reports.
- IGMPv3 join and leave messages are not supported on devices running IGMP filtering or Multicast VLAN registration (MVR).
- IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.
- The IGMP configurable leave time is only supported on hosts running IGMP Version 2. IGMP version 2 is the default version for the device.

The actual leave latency in the network is usually the configured leave time. However, the leave time might vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

- The IGMP throttling action restriction can be applied only to Layer 2 ports. You can use `ip igmp max-groups action replace` interface configuration command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

When the maximum group limitation is set to the default (no maximum), entering the `ip igmp max-groups action {deny | replace}` command has no effect.

If you configure the throttling action and set the maximum group limitation after an interface has added multicast entries to the forwarding table, the forwarding-table entries are either aged out or removed, depending on the throttling action.

Restrictions for MVR

The following are restrictions for MVR:

- Only Layer 2 ports participate in MVR. You must configure ports as MVR receiver ports.
- Only one MVR multicast VLAN per device or device stack is supported.
- Receiver ports can only be access ports; they cannot be trunk ports. Receiver ports on a device can be in different VLANs, but should not belong to the multicast VLAN.
• The maximum number of multicast entries (MVR group addresses) that can be configured on a device (that is, the maximum number of television channels that can be received) is 256.

• MVR multicast data received in the source VLAN and leaving from receiver ports has its time-to-live (TTL) decremented by 1 in the device.

• Because MVR on the device uses IP multicast addresses instead of MAC multicast addresses, alias IP multicast addresses are allowed on the device. However, if the device is interoperating with Catalyst 3550 or Catalyst 3500 XL devices, you should not configure IP addresses that alias between themselves or with the reserved IP multicast addresses (in the range 224.0.0.xxx).

• Do not configure MVR on private VLAN ports.

• MVR is not supported when multicast routing is enabled on a device. If you enable multicast routing and a multicast routing protocol while MVR is enabled, MVR is disabled, and you receive a warning message. If you try to enable MVR while multicast routing and a multicast routing protocol are enabled, the operation to enable MVR is cancelled, and you receive an error message.

• MVR data received on an MVR receiver port is not forwarded to MVR source ports.

• MVR does not support IGMPv3 messages.

Information About IGMP Snooping and MVR

IGMP Snooping

Layer 2 devices can use IGMP snooping to constrain the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. As the name implies, IGMP snooping requires the LAN device to snoop on the IGMP transmissions between the host and the router and to keep track of multicast groups and member ports. When the device receives an IGMP report from a host for a particular multicast group, the device adds the host port number to the forwarding table entry; when it receives an IGMP Leave Group message from a host, it removes the host port from the table entry. It also periodically deletes entries if it does not receive IGMP membership reports from the multicast clients.

Note

For more information on IP multicast and IGMP, see RFC 1112 and RFC 2236.

The multicast router sends out periodic general queries to all VLANs. All hosts interested in this multicast traffic send join requests and are added to the forwarding table entry. The device creates one entry per VLAN in the IGMP snooping IP multicast forwarding table for each group from which it receives an IGMP join request.

The device supports IP multicast group-based bridging, instead of MAC-addressed based groups. With multicast MAC address-based groups, if an IP address being configured translates (aliases) to a previously configured MAC address or to any reserved multicast MAC addresses (in the range 224.0.0.xxx), the command fails. Because the device uses IP multicast groups, there are no address aliasing issues.

The IP multicast groups learned through IGMP snooping are dynamic. However, you can statically configure multicast groups by using the `ip igmp snooping vlan vlan-id static ip_address interface interface-id` global configuration command. If you specify group membership for a multicast group address statically, your setting...
supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can consist of both user-defined and IGMP snooping-learned settings.

You can configure an IGMP snooping querier to support IGMP snooping in subnets without multicast interfaces because the multicast traffic does not need to be routed.

If a port spanning-tree, a port group, or a VLAN ID change occurs, the IGMP snooping-learned multicast groups from this port on the VLAN are deleted.

These sections describe IGMP snooping characteristics:

**IGMP Versions**

The device supports IGMP version 1, IGMP version 2, and IGMP version 3. These versions are interoperable on the device. For example, if IGMP snooping is enabled and the querier’s version is IGMPv2, and the device receives an IGMPv3 report from a host, then the device can forward the IGMPv3 report to the multicast router.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

**Joining a Multicast Group**

*Figure 7: Initial IGMP Join Message*

When a host connected to the device wants to join an IP multicast group and it is an IGMP version 2 client, it sends an unsolicited IGMP join message, specifying the IP multicast group to join. Alternatively, when the device receives a general query from the router, it forwards the query to all ports in the VLAN. IGMP version 1 or version 2 hosts wanting to join the multicast group respond by sending a join message to the device. The device CPU creates a multicast forwarding-table entry for the group if it is not already present. The CPU also adds the interface where the join message was received to the forwarding-table entry. The host associated with that interface receives multicast traffic for that multicast group.

Router A sends a general query to the device, which forwards the query to ports 2 through 5, all of which are members of the same VLAN. Host 1 wants to join multicast group 224.1.2.3 and multicasts an IGMP membership report (IGMP join message) to the group. The device CPU uses the information in the IGMP report to set up a forwarding-table entry that includes the port numbers connected to Host 1 and to the router.
Table 20: IGMP Snooping Forwarding Table

<table>
<thead>
<tr>
<th>Destination Address</th>
<th>Type of Packet</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>224.1.2.3</td>
<td>IGMP</td>
<td>1, 2</td>
</tr>
</tbody>
</table>

The device hardware can distinguish IGMP information packets from other packets for the multicast group. The information in the table tells the switching engine to send frames addressed to the 224.1.2.3 multicast IP address that are not IGMP packets to the router and to the host that has joined the group.

Figure 8: Second Host Joining a Multicast Group

If another host (for example, Host 4) sends an unsolicited IGMP join message for the same group, the CPU receives that message and adds the port number of Host 4 to the forwarding table. Because the forwarding table directs IGMP messages only to the CPU, the message is not flooded to other ports on the device. Any known multicast traffic is forwarded to the group and not to the CPU.

Table 21: Updated IGMP Snooping Forwarding Table

<table>
<thead>
<tr>
<th>Destination Address</th>
<th>Type of Packet</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>224.1.2.3</td>
<td>IGMP</td>
<td>1, 2, 5</td>
</tr>
</tbody>
</table>

Leaving a Multicast Group

The router sends periodic multicast general queries, and the device forwards these queries through all ports in the VLAN. Interested hosts respond to the queries. If at least one host in the VLAN wants to receive multicast traffic, the router continues forwarding the multicast traffic to the VLAN. The device forwards multicast group traffic only to those hosts listed in the forwarding table for that IP multicast group maintained by IGMP snooping.

When hosts want to leave a multicast group, they can silently leave, or they can send a leave message. When the device receives a leave message from a host, it sends a group-specific query to learn if any other devices connected to that interface are interested in traffic for the specific multicast group. The device then updates the forwarding table for that MAC group so that only those hosts interested in receiving multicast traffic for the group are listed in the forwarding table. If the router receives no reports from a VLAN, it removes the group for the VLAN from its IGMP cache.
Immediate Leave

The device uses IGMP snooping Immediate Leave to remove from the forwarding table an interface that sends a leave message without the device sending group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original leave message. Immediate Leave ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are simultaneously in use.

Immediate Leave is only supported on IGMP version 2 hosts. IGMP version 2 is the default version for the device.

Note
You should use the Immediate Leave feature only on VLANs where a single host is connected to each port. If Immediate Leave is enabled on VLANs where more than one host is connected to a port, some hosts may be dropped inadvertently.

IGMP Configurable-Leave Timer

You can configure the time that the device waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 32767 milliseconds.

IGMP Report Suppression

Note
IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

The device uses IGMP report suppression to forward only one IGMP report per multicast router query to multicast devices. When IGMP report suppression is enabled (the default), the device sends the first IGMP report from all hosts for a group to all the multicast routers. The device does not send the remaining IGMP reports for the group to the multicast routers. This feature prevents duplicate reports from being sent to the multicast devices.

If the multicast router query includes requests only for IGMPv1 and IGMPv2 reports, the device forwards only the first IGMPv1 or IGMPv2 report from all hosts for a group to all the multicast routers.

If the multicast router query also includes requests for IGMPv3 reports, the device forwards all IGMPv1, IGMPv2, and IGMPv3 reports for a group to the multicast devices.

If you disable IGMP report suppression, all IGMP reports are forwarded to the multicast routers.

IGMP Snooping and Device Stacks

IGMP snooping functions across the device stack; that is, IGMP control information from one device is distributed to all devices in the stack. Regardless of the stack member through which IGMP multicast data enters the stack, the data reaches the hosts that have registered for that group.

If a device in the stack fails or is removed from the stack, only the members of the multicast group that are on that device will not receive the multicast data. All other members of a multicast group on other devices in the stack continue to receive multicast data streams. However, multicast groups that are common for both Layer 2 and Layer 3 (IP multicast routing) might take longer to converge if the active device is removed.
Default IGMP Snooping Configuration

This table displays the default IGMP snooping configuration for the device.

Multicast VLAN Registration

Multicast VLAN Registration (MVR) is designed for applications using wide-scale deployment of multicast traffic across an Ethernet ring-based service-provider network (for example, the broadcast of multiple television channels over a service-provider network). MVR allows a subscriber on a port to subscribe and unsubscribe to a multicast stream on the network-wide multicast VLAN. It allows the single multicast VLAN to be shared in the network while subscribers remain in separate VLANs. MVR provides the ability to continuously send multicast streams in the multicast VLAN, but to isolate the streams from the subscriber VLANs for bandwidth and security reasons.

These sections describe MVR:

MVR and IGMP

Note

MVR can coexist with IGMP snooping on a device.

MVR assumes that subscriber ports subscribe and unsubscribe (join and leave) these multicast streams by sending out IGMP join and leave messages. These messages can originate from an IGMP version-2-compatible host with an Ethernet connection. Although MVR operates on the underlying method of IGMP snooping, the two features operate independently of each other. One can be enabled or disabled without affecting the behavior of the other feature. However, if IGMP snooping and MVR are both enabled, MVR reacts only to join and leave messages from multicast groups configured under MVR. Join and leave messages from all other multicast groups are managed by IGMP snooping.

The device CPU identifies the MVR IP multicast streams and their associated IP multicast group in the device forwarding table, intercepts the IGMP messages, and modifies the forwarding table to include or remove the
subscriber as a receiver of the multicast stream, even though the receivers might be in a different VLAN from the source. This forwarding behavior selectively allows traffic to cross between different VLANs.

**Modes of Operation**

You can set the device for compatible or dynamic mode of MVR operation:

- **In compatible mode**, multicast data received by MVR hosts is forwarded to all MVR data ports, regardless of MVR host membership on those ports. The multicast data is forwarded only to those receiver ports that MVR hosts have joined, either by IGMP reports or by MVR static configuration. IGMP reports received from MVR hosts are never forwarded from MVR data ports that were configured in the device.

- **In dynamic mode**, multicast data received by MVR hosts on the device is forwarded from only those MVR data and client ports that the MVR hosts have joined, either by IGMP reports or by MVR static configuration. Any IGMP reports received from MVR hosts are also forwarded from all the MVR data ports in the host. This eliminates using unnecessary bandwidth on MVR data port links, which occurs when the device runs in compatible mode.

**MVR and Switch Stacks**

Only one MVR multicast VLAN per device or device stack is supported.

Receiver ports and source ports can be on different devices in a device stack. Multicast data sent on the multicast VLAN is forwarded to all MVR receiver ports across the stack. When a new device is added to a stack, by default it has no receiver ports.

If a device fails or is removed from the stack, only those receiver ports belonging to that device will not receive the multicast data. All other receiver ports on other devices continue to receive the multicast data.

**MVR in a Multicast Television Application**

In a multicast television application, a PC or a television with a set-top box can receive the multicast stream. Multiple set-top boxes or PCs can be connected to one subscriber port, which is a device port configured as an MVR receiver port.
Figure 9: Multicast VLAN Registration Example

The following is an example configuration.

In this example configuration, DHCP assigns an IP address to the set-top box or the PC. When a subscriber selects a channel, the set-top box or PC sends an IGMP report to Switch A to join the appropriate multicast. If the IGMP report matches one of the configured IP multicast group addresses, the device CPU modifies the hardware address table to include this receiver port and VLAN as a forwarding destination of the specified multicast stream when it is received from the multicast VLAN. Uplink ports that send and receive multicast data to and from the multicast VLAN are called MVR source ports.

When a subscriber changes channels or turns off the television, the set-top box sends an IGMP leave message for the multicast stream. The device CPU sends a MAC-based general query through the receiver port VLAN. If there is another set-top box in the VLAN still subscribing to this group, that set-top box must respond within the maximum response time specified in the query. If the CPU does not receive a response, it eliminates the receiver port as a forwarding destination for this group.

Without Immediate Leave, when the device receives an IGMP leave message from a subscriber on a receiver port, it sends out an IGMP query on that port and waits for IGMP group membership reports. If no reports
are received in a configured time period, the receiver port is removed from multicast group membership. With Immediate Leave, an IGMP query is not sent from the receiver port on which the IGMP leave was received. As soon as the leave message is received, the receiver port is removed from multicast group membership, which speeds up leave latency. Enable the Immediate-Leave feature only on receiver ports to which a single receiver device is connected.

MVR eliminates the need to duplicate television-channel multicast traffic for subscribers in each VLAN. Multicast traffic for all channels is only sent around the VLAN trunk once—only on the multicast VLAN. The IGMP leave and join messages are in the VLAN to which the subscriber port is assigned. These messages dynamically register for streams of multicast traffic in the multicast VLAN on the Layer 3 device. The access layer device, Switch A, modifies the forwarding behavior to allow the traffic to be forwarded from the multicast VLAN to the subscriber port in a different VLAN, selectively allowing traffic to cross between two VLANs.

IGMP reports are sent to the same IP multicast group address as the multicast data. The Switch A CPU must capture all IGMP join and leave messages from receiver ports and forward them to the multicast VLAN of the source (uplink) port, based on the MVR mode.

### IGMP Filtering and Throttling

In some environments, for example, metropolitan or multiple-dwelling unit (MDU) installations, you might want to control the set of multicast groups to which a user on a device port can belong. You can control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan. You might also want to limit the number of multicast groups to which a user on a device port can belong.

With the IGMP filtering feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual device ports. An IGMP profile can contain one or more multicast groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a device port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing. You can also set the maximum number of IGMP groups that a Layer 2 interface can join.

IGMP filtering controls only group-specific query and membership reports, including join and leave reports. It does not control general IGMP queries. IGMP filtering has no relationship with the function that directs
the forwarding of IP multicast traffic. The filtering feature operates in the same manner whether CGMP or MVR is used to forward the multicast traffic.

IGMP filtering applies only to the dynamic learning of IP multicast group addresses, not static configuration. With the IGMP throttling feature, you can set the maximum number of IGMP groups that a Layer 2 interface can join. If the maximum number of IGMP groups is set, the IGMP snooping forwarding table contains the maximum number of entries, and the interface receives an IGMP join report, you can configure an interface to drop the IGMP report or to replace the randomly selected multicast entry with the received IGMP report.

Note

IGMPv3 join and leave messages are not supported on devices running IGMP filtering.

Default IGMP Filtering and Throttling Configuration

This table displays the default IGMP filtering and throttling configuration for the device.

How to Configure IGMP Snooping and MVR

Enabling or Disabling IGMP Snooping on a Device

When IGMP snooping is globally enabled or disabled, it is also enabled or disabled in all existing VLAN interfaces. IGMP snooping is enabled on all VLANs by default, but can be enabled and disabled on a per-VLAN basis.

Global IGMP snooping overrides the VLAN IGMP snooping. If global snooping is disabled, you cannot enable VLAN snooping. If global snooping is enabled, you can enable or disable VLAN snooping.

Follow these steps to globally enable IGMP snooping on the device:

SUMMARY STEPS

1. enable
Enabling or Disabling IGMP Snooping on a VLAN Interface

Follow these steps to enable IGMP snooping on a VLAN interface:

**SUMMARY STEPS**

</tbody>
</table>

**Setting the Snooping Method**

Multicast-capable router ports are added to the forwarding table for every Layer 2 multicast entry. The switch learns of the ports through one of these methods:

- Snooping on IGMP queries, Protocol-Independent Multicast (PIM) packets, and Distance Vector Multicast Routing Protocol (DVMRP) packets.

- Listening to Cisco Group Management Protocol (CGMP) packets from other routers.

- Statically connecting to a multicast router port using the `ip igmp snooping mroutert` global configuration command.
You can configure the switch either to snoop on IGMP queries and PIM/DVMRP packets or to listen to CGMP self-join or proxy-join packets. By default, the switch snoops on PIM/DVMRP packets on all VLANs. To learn of multicast router ports through only CGMP packets, use the `ip igmp snooping vlan vlan-id mrouter learn cgmp` global configuration command. When this command is entered, the router listens to only CGMP self-join and CGMP proxy-join packets and to no other CGMP packets. To learn of multicast router ports through only PIM-DVMRP packets, use the `ip igmp snooping vlan vlan-id mrouter learn pim-dvmrp` global configuration command.

If you want to use CGMP as the learning method and no multicast routers in the VLAN are CGMP proxy-enabled, you must enter the `ip cgmp router-only` command to dynamically access the router.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id mrouter learn {cgmp | pim-dvmrp}`
4. `end`
5. `show ip igmp snooping`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>

### Configuring a Multicast Router Port

Perform these steps to add a multicast router port (enable a static connection to a multicast router) on the device.

**Note**

Static connections to multicast routers are supported only on device ports.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp snooping vlan *vlan-id* mrouter interface *interface-id*
4. end
5. show ip igmp snooping mrouter [vlan *vlan-id*]
6. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  
  - enable
  
  **Example:**
  
  Device> enable | Enables privileged EXEC mode.
  
  - Enter your password if prompted. |
| **Step 2**
  
  - configure terminal
  
  **Example:** | Enters global configuration mode. |
### Configuring a Host Statically to Join a Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure a host on an interface.

Follow these steps to add a Layer 2 port as a member of a multicast group:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping vlan vlan-id static ip_address interface interface-id
4. end
5. show ip igmp snooping groups
6. copy running-config startup-config

</tbody>
</table>
Enabling IGMP Immediate Leave

When you enable IGMP Immediate Leave, the device immediately removes a port when it detects an IGMP Version 2 leave message on that port. You should use the Immediate-Leave feature only when there is a single receiver present on every port in the VLAN.

Note
Immediate Leave is supported only on IGMP Version 2 hosts. IGMP Version 2 is the default version for the device.

SUMMARY STEPS
1. enable
2. configure terminal
3. ip igmp snooping vlan vlan-id immediate-leave
4. end
5. show ip igmp snooping vlan vlan-id
6. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal      | Enters global configuration mode. |
| Example:                           |         |
| Device# configure terminal         |         |

| **Step 3** ip igmp snooping vlan vlan-id immediate-leave | Enables IGMP Immediate Leave on the VLAN interface. |
| Example:                                               | Note |
| Device(config)# ip igmp snooping vlan 21 immediate-leave | To disable IGMP Immediate Leave on a VLAN, use the **no ip igmp snooping vlan vlan-id immediate-leave** global configuration command. |

| **Step 4** end                          | Returns to privileged EXEC mode. |
| Example:                               |         |
| Device(config)# end                    |         |
### Configuring the IGMP Leave Timer

You can configure the leave time globally or on a per-VLAN basis. Follow these steps to enable the IGMP configurable-leave timer:

#### SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp snooping last-member-query-interval time
4. ip igmp snooping vlan vlan-id last-member-query-interval time
5. end
6. show ip igmp snooping
7. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>configures the IGMP leave timer globally. The range is 100 to 32767 milliseconds. The default leave time is 1000 milliseconds.</td>
</tr>
<tr>
<td>ip igmp snooping last-member-query-interval time</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip igmp snooping</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring TCN-Related Commands

#### Controlling the Multicast Flooding Time After a TCN Event

You can configure the number of general queries by which multicast data traffic is flooded after a topology change notification (TCN) event. If you set the TCN flood query count to 1 the flooding stops after receiving 1 general query. If you set the count to 7, the flooding continues until 7 general queries are received. Groups are relearned based on the general queries received during the TCN event.

Some examples of TCN events are when the client location is changed and the receiver is on same port that was blocked but is now forwarding, and when a port goes down without sending a leave message.

Follow these steps to configure the TCN flood query count:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>last-member-query-interval 1000</code></td>
<td><strong>Note</strong> To globally reset the IGMP leave timer to the default setting, use the <code>no ip igmp snooping last-member-query-interval</code> global configuration command.</td>
</tr>
<tr>
<td><code>Step 4 ip igmp snooping vlan vlan-id last-member-query-interval time</code></td>
<td><strong>Note</strong> Configuring the leave time on a VLAN overrides the globally configured timer. <strong>Note</strong> To remove the configured IGMP leave-time setting from the specified VLAN, use the <code>no ip igmp snooping vlan vlan-id last-member-query-interval</code> global configuration command.</td>
</tr>
<tr>
<td><code>Step 5 end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>Step 6 show ip igmp snooping</code></td>
<td><strong>Optional</strong> Displays the configured IGMP leave time.</td>
</tr>
<tr>
<td><code>Step 7 copy running-config startup-config</code></td>
<td><strong>Optional</strong> Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. ip igmp snooping tcn flood query count \textit{count}  
4. end  
5. show ip igmp snooping  
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
* Enter your password if prompted. |
| **Example:** | |
| Device> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** | |
| Device# configure terminal | |
| **Step 3** ip igmp snooping tcn flood query count \textit{count} | Specifies the number of IGMP general queries for which the multicast traffic is flooded.  
The range is 1 to 10. The default, the flooding query count is 2.  
\textbf{Note} To return to the default flooding query count, use the \texttt{no ip igmp snooping tcn flood query count} global configuration command. |
| **Example:** | |
| Device(config)# ip igmp snooping tcn flood query count 3 | |
| **Step 4** end | Returns to privileged EXEC mode. |
| **Example:** | |
| Device(config)# end | |
| **Step 5** show ip igmp snooping | Verifies the TCN settings. |
| **Example:** | |
| Device# show ip igmp snooping | |
| **Step 6** copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| **Example:** | |
| Device# copy running-config startup-config | |
Recovering from Flood Mode

When a topology change occurs, the spanning-tree root sends a special IGMP leave message (also known as global leave) with the group multicast address 0.0.0.0. However, you can enable the device to send the global leave message whether it is the spanning-tree root or not. When the router receives this special leave, it immediately sends general queries, which expedite the process of recovering from the flood mode during the TCN event. Leaves are always sent if the device is the spanning-tree root regardless of this configuration.

Follow these steps to enable sending of leave messages:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping tcn query solicit
4. end
5. show ip igmp snooping
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip igmp snooping tcn query solicit</td>
<td>Sends an IGMP leave message (global leave) to speed the process of</td>
</tr>
<tr>
<td>Example:</td>
<td>recovering from the flood mode caused during a TCN event. By default,</td>
</tr>
<tr>
<td>Device(config)# ip igmp snooping tcn query solicit</td>
<td>query solicitation is disabled.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To return to the default query solicitation, use</td>
</tr>
<tr>
<td></td>
<td>the no ip igmp snooping tcn query solicit</td>
</tr>
<tr>
<td></td>
<td>global configuration command.</td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show ip igmp snooping</td>
<td>Verifies the TCN settings.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
Disabling Multicast Flooding During a TCN Event

When the device receives a TCN, multicast traffic is flooded to all the ports until 2 general queries are received. If the device has many ports with attached hosts that are subscribed to different multicast groups, this flooding might exceed the capacity of the link and cause packet loss. Follow these steps to control TCN flooding:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `no ip igmp snooping tcn flood`
5. `end`
6. `show ip igmp snooping`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>

</tbody>
</table>
### Configuring the IGMP Snooping Querier

Follow these steps to enable the IGMP snooping querier feature in a VLAN:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping querier
4. ip igmp snooping querier address `ip_address`
5. ip igmp snooping querier query-interval `interval-count`
6. ip igmp snooping querier tcn query [count `count` | interval `interval`]
7. ip igmp snooping querier timer expiry `timeout`
8. ip igmp snooping querier version `version`
9. end
10. show ip igmp snooping vlan `vlan-id`
11. copy running-config startup-config
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
|       | Example: |  |
|       | Device> enable |  |
| Step 2 | configure terminal | Enters global configuration mode. |
|       | Example: |  |
|       | Device# configure terminal |  |
| Step 3 | ip igmp snooping querier | Enables the IGMP snooping querier. |
|       | Example: |  |
|       | Device(config)# ip igmp snooping querier |  |
| Step 4 | ip igmp snooping querier address ip_address | (Optional) Specifies an IP address for the IGMP snooping querier. If you do not specify an IP address, the querier tries to use the global IP address configured for the IGMP querier.  
Note: The IGMP snooping querier does not generate an IGMP general query if it cannot find an IP address on the device. |
|       | Example: |  |
|       | Device(config)# ip igmp snooping querier address 172.16.24.1 |  |
| Step 5 | ip igmp snooping querier query-interval interval-count | (Optional) Sets the interval between IGMP queries. The range is 1 to 18000 seconds. |
|       | Example: |  |
|       | Device(config)# ip igmp snooping querier query-interval 30 |  |
| Step 6 | ip igmp snooping querier tcn query [count count | interval interval] | (Optional) Sets the time between Topology Change Notification (TCN) queries. The count range is 1 to 10. The interval range is 1 to 255 seconds. |
|       | Example: |  |
|       | Device(config)# ip igmp snooping querier tcn query interval 20 |  |
| Step 7 | ip igmp snooping querier timer expiry timeout | (Optional) Sets the length of time until the IGMP querier expires. The range is 60 to 300 seconds. |
|       | Example: |  |
|       | Device(config)# ip igmp snooping querier timer expiry 180 |  |
### Disabling IGMP Report Suppression

Follow these steps to disable IGMP report suppression:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no ip igmp snooping report-suppression`
4. `end`
5. `show ip igmp snooping`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
</tbody>
</table>

---

**Disabling IGMP Report Suppression**

(Optional) Selects the IGMP version number that the querier feature uses. Select 1 or 2.

Example:

Step 8

```
Device(config)# ip igmp snooping querier version 2
```

(Optional) Verifies that the IGMP snooping querier is enabled on the VLAN interface. The VLAN ID range is 1 to 1001 and 1006 to 4094.

Example:

Step 10

```
Device# show ip igmp snooping vlan 30
```

(Optional) Saves your entries in the configuration file.

Example:

Step 11

```
Device# copy running-config startup-config
```
<table>
<thead>
<tr>
<th><strong>Step 2</strong></th>
<th><strong>Command or Action</strong></th>
<th><strong>Purpose</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>

### Configuring MVR Global Parameters

You do not need to set the optional MVR parameters if you choose to use the default settings. If you want to change the default parameters (except for the MVR VLAN), you must first enable MVR.

**Note** For complete syntax and usage information for the commands used in this section, see the command reference for this release.
SUMMARY STEPS

1. enable
2. configure terminal
3. mvr
4. mvr group ip-address [count]
5. mvr querytime value
6. mvr vlan vlan-id
7. mvr mode {dynamic | compatible}
8. end
9. Use one of the following:
   • show mvr
   • show mvr members
10. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>

<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables MVR on the device.</td>
</tr>
<tr>
<td>mvr</td>
<td>Enables MVR on the device.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device (config)# mvr</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Configures an IP multicast address on the device or use the count parameter to configure a contiguous series of MVR group addresses (the range for count is 1 to 256; the default is 1). Any multicast data sent to this address is sent to all source ports on the device and all receiver ports that have elected to receive data on that multicast address. Each multicast address would correspond to one television channel.</td>
</tr>
<tr>
<td>mvr group ip-address [count]</td>
<td>Configures an IP multicast address on the device or use the count parameter to configure a contiguous series of MVR group addresses (the range for count is 1 to 256; the default is 1). Any multicast data sent to this address is sent to all source ports on the device and all receiver ports that have elected to receive data on that multicast address. Each multicast address would correspond to one television channel.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mvr group 228.1.23.4</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To return the switch to its default settings, use the no mvr [mode</td>
</tr>
</tbody>
</table>
### Configuring MVR Global Parameters

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td><strong>mvr querytime</strong> value</td>
<td>(Optional) Defines the maximum time to wait for IGMP report memberships on a receiver port before removing the port from multicast group membership. The value is in units of tenths of a second. The range is 1 to 100, and the default is 5 tenths or one-half second.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device(config)# mvr querytime 10</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td><strong>mvr vlan</strong> vlan-id</td>
<td>(Optional) Specifies the VLAN in which multicast data is received; all source ports must belong to this VLAN. The VLAN range is 1 to 1001 and 1006 to 4094. The default is VLAN 1.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device(config)# mvr vlan 22</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td><strong>mvr mode</strong> **{dynamic</td>
<td>compatible}**</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device(config)# mvr mode dynamic</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>dynamic</strong>—Allows dynamic MVR membership on source ports.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>compatible</strong>—Is compatible with Catalyst 3500 XL and Catalyst 2900 XL devices and does not support IGMP dynamic joins on source ports.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The default is <strong>compatible</strong> mode.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> To return the switch to its default settings, use the **no mvr [mode</td>
<td>group ip-address</td>
</tr>
<tr>
<td>8</td>
<td><strong>end</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>Use one of the following: • <strong>show mvr</strong> • <strong>show mvr members</strong></td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device# show mvr OR Device# show mvr members</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td><strong>copy running-config startup-config</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>

</tbody>
</table>
**Configuring MVR Interfaces**

Follow these steps to configure Layer 2 MVR interfaces:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `mvr`
4. `interface interface-id`
5. `mvr type {source | receiver}`
6. `mvr vlan vlan-id group [ip-address]`
7. `mvr immediate`
8. `end`
9. Use one of the following:
   - `show mvr`
   - `show mvr interface`
   - `show mvr members`
10. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>mvr</code></td>
<td>Enables MVR on the device.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device (config)# <code>mvr</code></td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

| Step 4 | `interface interface-id`  
Example:  
Device(config)# interface  
gigabitethernet1/0/2 | **Purpose**  
Specifies the Layer 2 port to configure, and enter interface configuration mode.  

| Step 5 | `mvr type {source | receiver}`  
Example:  
Device(config-if)# mvr type receiver | **Purpose**  
Configures an MVR port as one of these:  
- **source**—Configures uplink ports that receive and send multicast data as source ports. Subscribers cannot be directly connected to source ports. All source ports on a device belong to the single multicast VLAN.  
  - **receiver**—Configures a port as a receiver port if it is a subscriber port and should only receive multicast data. It does not receive data unless it becomes a member of the multicast group, either statically or by using IGMP leave and join messages. Receiver ports cannot belong to the multicast VLAN.  
  
The default configuration is as a non-MVR port. If you attempt to configure a non-MVR port with MVR characteristics, the operation fails.  
  **Note**  
To return the interface to its default settings, use the `no mvr [type | immediate | vlan vlan-id | group]` interface configuration commands.  

| Step 6 | `mvr vlan vlan-id group [ip-address]`  
Example:  
Device(config-if)# mvr vlan 22 group  
228.1.23.4 | **Purpose**  
(Optional) Statically configures a port to receive multicast traffic sent to the multicast VLAN and the IP multicast address. A port statically configured as a member of a group remains a member of the group until statically removed.  
  **Note**  
In compatible mode, this command applies to only receiver ports. In dynamic mode, it applies to receiver ports and source ports.  
  Receiver ports can also dynamically join multicast groups by using IGMP join and leave messages.  

| Step 7 | `mvr immediate`  
Example:  
Device(config-if)# mvr immediate | **Purpose**  
(Optional) Enables the Immediate-Leave feature of MVR on the port.  
  **Note**  
This command applies to only receiver ports and should only be enabled on receiver ports to which a single receiver device is connected.

### Configuring IGMP Profiles

Follow these steps to create an IGMP profile:

This task is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp profile profile number
4. permit | deny
5. range ip multicast address
6. end
7. show ip igmp profile profile number
8. show running-config
9. copy running-config startup-config

---

<table>
<thead>
<tr>
<th>Command or Action</th>

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | enable            | Enables privileged EXEC mode.  
  Example:  
  ```markdown
  Device> enable
  ``` |
| 2    | configure terminal | Enters global configuration mode.  
  Example:  
  ```markdown
  Device# configure terminal
  ``` |
| 3    | ip igmp profile profile number | Assigns a number to the profile you are configuring, and enters IGMP profile configuration mode. The profile number range is 1 to 4294967295. When you are in IGMP profile configuration mode, you can create the profile by using these commands:  
  - `deny`—Specifies that matching addresses are denied; this is the default.  
  - `exit`—Exits from igmp-profile configuration mode.  
  - `no`—Negates a command or returns to its defaults.  
  - `permit`—Specifies that matching addresses are permitted.  
  - `range`—Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with a start and an end address.  
  The default is for the device to have no IGMP profiles configured.  
  Note: To delete a profile, use the `no ip igmp profile profile number` global configuration command.  
  Example:  
  ```markdown
  Device(config)# ip igmp profile 3
  ``` |
| 4    | permit | (Optional) Sets the action to permit or deny access to the IP multicast address. If no action is configured, the default for the profile is to deny access.  
  Example:  
  ```markdown
  Device(config-igmp-profile)# permit
  ``` |
| 5    | range ip multicast address | Enters the IP multicast address or range of IP multicast addresses to which access is being controlled. If entering a range, enter the low IP multicast address, a space, and the high IP multicast address.  
  You can use the `range` command multiple times to enter multiple addresses or ranges of addresses.  
  Example:  
  ```markdown
  Device(config-igmp-profile)# range 229.9.0
  ``` |
### Applying IGMP Profiles

To control access as defined in an IGMP profile, you have to apply the profile to the appropriate interfaces. You can apply IGMP profiles only to Layer 2 access ports; you cannot apply IGMP profiles to routed ports or SVIs. You cannot apply profiles to ports that belong to an EtherChannel port group. You can apply a profile to multiple interfaces, but each interface can have only one profile applied to it.

Follow these steps to apply an IGMP profile to a switch port:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp filter profile number`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

### Command or Action | Purpose
--- | ---
| **Note** | To delete an IP multicast address or range of IP multicast addresses, use the `no range ip multicast address` IGMP profile configuration command.
| Step 6 | Returns to privileged EXEC mode.
| **Example:** | Device(config)# end
| **Step 7** | Verifies the profile configuration.
| **Example:** | Device# `show ip igmp profile 3`
| **Step 8** | Verifies your entries.
| **Example:** | Device# `show running-config`
| **Step 9** | (Optional) Saves your entries in the configuration file.
| **Example:** | Device# `copy running-config startup-config`
### DETAILED STEPS

### Setting the Maximum Number of IGMP Groups

Follow these steps to set the maximum number of IGMP groups that a Layer 2 interface can join:
### Before you begin

This restriction can be applied to Layer 2 ports only; you cannot set a maximum number of IGMP groups on routed ports or SVIs. You also can use this command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp max-groups number`
5. `end`
6. `show running-config interface interface-id`
7. `copy running-config startup-config`

### DETAILED STEPS

</tbody>
</table>
### Configuring the IGMP Throttling Action

After you set the maximum number of IGMP groups that a Layer 2 interface can join, you can configure an interface to replace the existing group with the new group for which the IGMP report was received.

Follow these steps to configure the throttling action when the maximum number of entries is in the forwarding table:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp max-groups action {deny | replace}`
5. `end`
6. `show running-config interface interface-id`
7. `copy running-config startup-config`

**DETAILED STEPS**

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)# <code>end</code></td>
</tr>
</tbody>
</table>

### Step 6

**show running-config interface interface-id**  
**Example:**  

```
Device# interface gigabitethernet1/0/1
```  

Verifies your entries.

### Step 7

**copy running-config startup-config**  
**Example:**  

```
Device# copy running-config startup-config
```  

(Optional) Saves your entries in the configuration file.
### Configuring the IGMP Throttling Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3** | **interface interface-id**  
**Example:**  
Device(config)# interface gigabitethernet1/0/1 | Specifies the physical interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or an EtherChannel interface. The interface cannot be a trunk port. |
| **Step 4** | **ip igmp max-groups action {deny | replace]**  
**Example:**  
Device(config-if)# ip igmp max-groups action replace | When an interface receives an IGMP report and the maximum number of entries is in the forwarding table, specifies the action that the interface takes:  
- **deny**—Drops the report. If you configure this throttling action, the entries that were previously in the forwarding table are not removed but are aged out. After these entries are aged out and the maximum number of entries is in the forwarding table, the device drops the next IGMP report received on the interface.  
- **replace**—Replaces the existing group with the new group for which the IGMP report was received. If you configure this throttling action, the entries that were previously in the forwarding table are removed. When the maximum number of entries is in the forwarding table, the device replaces a randomly selected entry with the received IGMP report.  
To prevent the device from removing the forwarding-table entries, you can configure the IGMP throttling action before an interface adds entries to the forwarding table.  
**Note** To return to the default action of dropping the report, use the **no ip igmp max-groups action** interface configuration command. |
| **Step 5** | **end**  
**Example:**  
Device(config)# end | Returns to privileged EXEC mode. |
| **Step 6** | **show running-config interface interface-id**  
**Example:**  
Device# show running-config interface gigabitethernet1/0/1 | Verifies your entries. |
| **Step 7** | **copy running-config startup-config**  
**Example:** | (Optional) Saves your entries in the configuration file. |
Monitoring IGMP Snooping and MVR

Monitoring IGMP Snooping Information

You can display IGMP snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display MAC address multicast entries for a VLAN configured for IGMP snooping.

Table 25: Commands for Displaying IGMP Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>show ip igmp snooping [vlan vlan-id [detail]]</strong></td>
<td>Displays the snooping configuration information for all VLANs on the device or for a specified VLAN. (Optional) Enter <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
</tbody>
</table>
| **show ip igmp snooping groups [count | dynamic [count] | user [count]]** | Displays multicast table information for the device or about a specific parameter:  
  - `count`—Displays the total number of entries for the specified command options instead of the actual entries.  
  - `dynamic`—Displays entries learned through IGMP snooping.  
  - `user`—Displays only the user-configured multicast entries. |
| **show ip igmp snooping groups vlan vlan-id [ip_address | count | dynamic [count] | user [count]]** | Displays multicast table information for a multicast VLAN or about a specific parameter for the VLAN:  
  - `vlan-id`—The VLAN ID range is 1 to 1001 and 1006 to 4094.  
  - `count`—Displays the total number of entries for the specified command options instead of the actual entries.  
  - `dynamic`—Displays entries learned through IGMP snooping.  
  - `ip_address`—Displays characteristics of the multicast group with the specified group IP address.  
  - `user`—Displays only the user-configured multicast entries. |
Commands for Displaying MVR Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show mvr</td>
<td>Displays MVR status and values for the switch—whether MVR is enabled or disabled, the multicast VLAN, the maximum (256) and current (0 through 256) number of multicast groups, the query response time, and the MVR mode.</td>
</tr>
</tbody>
</table>

Monitoring MVR

You can monitor MVR for the switch or for a specified interface by displaying the following MVR information.

Table 26: Commands for Displaying MVR Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show mvr</td>
<td>Displays MVR status and values for the switch—whether MVR is enabled or disabled, the multicast VLAN, the maximum (256) and current (0 through 256) number of multicast groups, the query response time, and the MVR mode.</td>
</tr>
<tr>
<td>Command</td>
<td>Purpose</td>
</tr>
<tr>
<td>--------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| show mvr interface [interface-id] [members [vlan vlan-id]] | Displays all MVR interfaces and their MVR configurations. When a specific interface is entered, displays this information:  
  - Type—Receiver or Source  
  - Status—One of these:  
    - Active means the port is part of a VLAN.  
    - Up/Down means that the port is forwarding or nonforwarding.  
    - Inactive means that the port is not part of any VLAN.  
    - Immediate Leave—Enabled or Disabled  
  If the members keyword is entered, displays all multicast group members on this port or, if a VLAN identification is entered, all multicast group members on the VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| show mvr members [ip-address] | Displays all receiver and source ports that are members of any IP multicast group or the specified IP multicast group IP address. |

### Monitoring IGMP Filtering and Throttling Configuration

You can display IGMP profile characteristics, and you can display the IGMP profile and maximum group configuration for all interfaces on the device or for a specified interface. You can also display the IGMP throttling configuration for all interfaces on the device or for a specified interface.

**Table 27: Commands for Displaying IGMP Filtering and Throttling Configuration**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip igmp profile [profile number]</td>
<td>Displays the specified IGMP profile or all the IGMP profiles defined on the device.</td>
</tr>
<tr>
<td>show running-config [interface interface-id]</td>
<td>Displays the configuration of the specified interface or the configuration of all interfaces on the device, including (if configured) the maximum number of IGMP groups to which an interface can belong and the IGMP profile applied to the interface.</td>
</tr>
</tbody>
</table>
Configuration Examples for IGMP Snooping and MVR

Example: Configuring IGMP Snooping Using CGMP Packets

This example shows how to configure IGMP snooping to use CGMP packets as the learning method:

```
Device# configure terminal
Device(config)# ip igmp snooping vlan 1 mrouter learn cgmp
Device(config)# end
```

Example: Enabling a Static Connection to a Multicast Router

This example shows how to enable a static connection to a multicast router:

```
Device# configure terminal
Device# ip igmp snooping vlan 200 mrouter interface gigabitethernet1/0/2
Device# end
```

Example: Configuring a Host Statically to Join a Group

This example shows how to statically configure a host on a port:

```
Device# configure terminal
Device# ip igmp snooping vlan 105 static 0100.1212.0000 interface gigabitethernet1/0/1
Device# end
```

Example: Enabling IGMP Immediate Leave

This example shows how to enable IGMP Immediate Leave on VLAN 130:

```
Device# configure terminal
Device(config)# ip igmp snooping vlan 130 immediate-leave
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Source Address

This example shows how to set the IGMP snooping querier source address to 10.0.0.64:

```
Device# configure terminal
Device(config)# ip igmp snooping querier 10.0.0.64
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Maximum Response Time

This example shows how to set the IGMP snooping querier maximum response time to 25 seconds:
Example: Setting the IGMP Snooping Querier Timeout

This example shows how to set the IGMP snooping querier timeout to 60 seconds:

```
Device# configure terminal
Device(config)# ip igmp snooping querier timeout expiry 60
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Feature

This example shows how to set the IGMP snooping querier feature to Version 2:

```
Device# configure terminal
Device(config)# no ip igmp snooping querier version 2
Device(config)# end
```

Example: Configuring IGMP Profiles

This example shows how to create IGMP profile 4 allowing access to the single IP multicast address and how to verify the configuration. If the action was to deny (the default), it would not appear in the `show ip igmp profile` output display.

```
Device(config)# ip igmp profile 4
Device(config-igmp-profile)# permit
Device(config-igmp-profile)# range 229.9.9.0
Device(config-igmp-profile)# end
Device# show ip igmp profile 4
IGMP Profile 4
  permit
  range 229.9.9.0 229.9.9.0
```

Example: Applying IGMP Profile

This example shows how to apply IGMP profile 4 to a port:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp filter 4
Device(config-if)# end
```

Example: Setting the Maximum Number of IGMP Groups

This example shows how to limit to 25 the number of IGMP groups that a port can join:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp max-groups 25
Device(config-if)# end
```
Example: Configuring MVR Global Parameters

This example shows how to enable MVR, configure the group address, set the query time to 1 second (10 tenths), specify the MVR multicast VLAN as VLAN 22, and set the MVR mode as dynamic:

```
Device(config)# mvr
Device(config)# mvr group 228.1.23.4
Device(config)# mvr querytime 10
Device(config)# mvr vlan 22
Device(config)# mvr mode dynamic
Device(config)# end
```

Example: Configuring MVR Interfaces

This example shows how to configure a port as a receiver port, statically configure the port to receive multicast traffic sent to the multicast group address, configure Immediate Leave on the port, and verify the results:

```
Device(config)# mvr
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# mvr type receiver
Device(config-if)# mvr vlan 22 group 228.1.23.4
Device(config-if)# mvr immediate
Device(config)# end
```

```
Device# show mvr interface
Port Type Status Immediate Leave
--- ---- ------- ---------------
Gi1/0/2 RECEIVER ACTIVE/DOWN ENABLED
```

 CHAPTER 15

Configuring CGMP

• Finding Feature Information, on page 189
• Prerequisites for Configuring CGMP, on page 189
• Restrictions for CGMP, on page 189
• Information About CGMP, on page 190
• Enabling CGMP Server Support, on page 190
• Monitoring CGMP, on page 192
• Additional References, on page 193
• Feature History and Information for CGMP, on page 194

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring CGMP

The following are the prerequisites for configuring CGMP:

• When multiple Cisco CGMP-capable devices are connected to a switched network and the `ip cgmp proxy` command is needed, we recommend that all devices be configured with the same CGMP option and have precedence for becoming the IGMP querier over non-Cisco routers.

Restrictions for CGMP

The following are the restrictions for CGMP:
Information About CGMP

Cisco Group Management Protocol or CGMP-server support is provided on the device; no client-side functionality is provided. The device serves as a CGMP server for devices that do not support IGMP snooping but have CGMP-client functionality.

CGMP is a protocol used on Cisco routers and multilayer devices connected to Layer 2 Catalyst devices to perform tasks similar to those performed by IGMP. CGMP permits Layer 2 group membership information to be communicated from the CGMP server to the device. The device can then learn on which interfaces multicast members reside instead of flooding multicast traffic to all device interfaces. (IGMP snooping is another method to constrain the flooding of multicast packets.)

CGMP is necessary because the Layer 2 device cannot distinguish between IP multicast data packets and IGMP report messages, which are both at the MAC level and are addressed to the same group address.

Enabling CGMP Server Support

When multiple Cisco CGMP-capable devices are connected to a switched network and you configure the `ip cgmp proxy` command, we recommend that all devices be configured with the same CGMP option and have precedence for becoming the IGMP querier over non-Cisco routers. Perform these steps to enable the CGMP server on the device interface:

This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip cgmp [proxy | router-only]
5. end
6. show running-config
7. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password, if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

- CGMP is mutually exclusive with HSRPv1. You cannot enable CGMP leaving processing and HSRPv1 at the same time. However, you can enable CGMP and HSRPv2 at the same time.
<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device#</td>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface interface-id</td>
<td>Specifies the interface that is connected to the Layer 2 Catalyst device, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>ip cgmp [proxy</td>
<td>router-only]</td>
</tr>
<tr>
<td>Example:</td>
<td>By default, CGMP is disabled on all interfaces.</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)#</td>
<td>Enabling CGMP triggers a CGMP join message. Enable CGMP only on Layer 3 interfaces connected to Layer 2 Catalyst devices.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(Optional) When you enter the proxy keyword, the CGMP proxy function is enabled. The proxy router advertises the existence of non-CGMP-capable routers by sending a CGMP join message with the non-CGMP-capable router MAC address and a group address of 0000.0000.0000.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Note</td>
<td>To perform CGMP proxy, the device must be the IGMP querier. If you configure the ip cgmp proxy command, you must manipulate the IP addresses so that the device is the IGMP querier, which might be the highest or lowest IP address, depending on which version of IGMP is running on the network. An IGMP Version 2 querier is selected based on the lowest IP address on the interface. An IGMP Version 1 querier is selected based on the multicast routing protocol used on the interface.</td>
</tr>
<tr>
<td></td>
<td>Note</td>
<td>To disable CGMP on the interface, use the no ip cgmp interface configuration command.</td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>

Prerequisites for PIM

Before you begin the PIM configuration process, decide which PIM mode to use. This is based on the applications you intend to support on your network. Use the following guidelines:

- In general, if the application is one-to-many or many-to-many in nature, then PIM-SM can be used successfully.

- For optimal one-to-many application performance, SSM is appropriate but requires IGMP version 3 support.

Before you configure PIM stub routing, check that you have met these conditions:

- You must have IP multicast routing configured on both the stub router and the central router. You must also have PIM mode (dense-mode, sparse-mode, or sparse-dense-mode) configured on the uplink interface of the stub router.

- You must also configure Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing on the device.

- The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior.
Restrictions for PIM

PIMv1 and PIMv2 Interoperability

To avoid misconfiguring multicast routing on your device, review the information in this section.

The Cisco PIMv2 implementation provides interoperability and transition between Version 1 and Version 2, although there might be some minor problems.

You can upgrade to PIMv2 incrementally. PIM Versions 1 and 2 can be configured on different routers and multilayer devices within one network. Internally, all routers and multilayer devices on a shared media network must run the same PIM version. Therefore, if a PIMv2 device detects a PIMv1 device, the Version 2 device downgrades itself to Version 1 until all Version 1 devices have been shut down or upgraded.

PIMv2 uses the BSR to discover and announce RP-set information for each group prefix to all the routers and multilayer devices in a PIM domain. PIMv1, together with the Auto-RP feature, can perform the same tasks as the PIMv2 BSR. However, Auto-RP is a standalone protocol, separate from PIMv1, and is a proprietary Cisco protocol. PIMv2 is a standards track protocol in the IETF.

Note

We recommend that you use PIMv2. The BSR function interoperates with Auto-RP on Cisco routers and multilayer devices.

When PIMv2 devices interoperate with PIMv1 devices, Auto-RP should have already been deployed. A PIMv2 BSR that is also an Auto-RP mapping agent automatically advertises the RP elected by Auto-RP. That is, Auto-RP sets its single RP on every router or multilayer device in the group. Not all routers and devices in the domain use the PIMv2 hash function to select multiple RPs.

Sparse-mode groups in a mixed PIMv1 and PIMv2 region are possible because the Auto-RP feature in PIMv1 interoperates with the PIMv2 RP feature. Although all PIMv2 devices can also use PIMv1, we recommend that the RPs be upgraded to PIMv2. To ease the transition to PIMv2, we recommend:

• Using Auto-RP throughout the region.
• Configuring sparse-dense mode throughout the region.

If Auto-RP is not already configured in the PIMv1 regions, configure Auto-RP.

Restrictions for Configuring PIM Stub Routing

• To use the PIM stub routing feature, the device or stack master or active device can be running the IP base image. The IP base image contains only PIM stub routing. The IP services image contains complete multicast routing.

• Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.

• In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing.
• The redundant PIM stub router topology is not supported. Only the nonredundant access router topology is supported by the PIM stub feature.

Restrictions for Configuring Auto-RP and BSR

Take into consideration your network configuration, and the following restrictions when configuring Auto-RP and BSR:

Restrictions for Configuring Auto-RP

The following are restrictions for configuring Auto-RP (if used in your network configuration):

• If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must manually configure an RP.

• If routed interfaces are configured in sparse mode, Auto-RP can still be used if all devices are configured with a manual RP address for the Auto-RP groups.

• If routed interfaces are configured in sparse mode and you enter the ip pim autorp listener global configuration command, Auto-RP can still be used even if all devices are not configured with a manual RP address for the Auto-RP groups.

Restrictions for Configuring BSR

The following are the restrictions for configuring BSR (if used in your network configuration):

• Configure the candidate BSRs as the RP-mapping agents for Auto-RP.

• For group prefixes advertised through Auto-RP, the PIMv2 BSR mechanism should not advertise a subrange of these group prefixes served by a different set of RPs. In a mixed PIMv1 and PIMv2 domain, have backup RPs serve the same group prefixes. This prevents the PIMv2 DRs from selecting a different RP from those PIMv1 DRs, due to the longest match lookup in the RP-mapping database.

Restrictions and Guidelines for Configuring Auto-RP and BSR

The following are restrictions for configuring Auto-RP and BSR (if used in your network configuration):

• If your network is all Cisco routers and multilayer devices, you can use either Auto-RP or BSR.

• If you have non-Cisco routers in your network, you must use BSR.

• If you have Cisco PIMv1 and PIMv2 routers and multilayer devices and non-Cisco routers, you must use both Auto-RP and BSR. If your network includes routers from other vendors, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 device. Ensure that no PIMv1 device is located in the path a between the BSR and a non-Cisco PIMv2 device.

Note

There are two approaches to using PIMv2. You can use Version 2 exclusively in your network or migrate to Version 2 by employing a mixed PIM version environment.
Because bootstrap messages are sent hop-by-hop, a PIMv1 device prevents these messages from reaching all routers and multilayer devices in your network. Therefore, if your network has a PIMv1 device in it and only Cisco routers and multilayer devices, it is best to use Auto-RP.

If you have a network that includes non-Cisco routers, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 router or multilayer device. Ensure that no PIMv1 device is on the path between the BSR and a non-Cisco PIMv2 router.

If you have non-Cisco PIMv2 routers that need to interoperate with Cisco PIMv1 routers and multilayer devices, both Auto-RP and a BSR are required. We recommend that a Cisco PIMv2 device be both the Auto-RP mapping agent and the BSR.

Information About PIM

Protocol Independent Multicast Overview

The Protocol Independent Multicast (PIM) protocol maintains the current IP multicast service mode of receiver-initiated membership. PIM is not dependent on a specific unicast routing protocol; it is IP routing protocol independent and can leverage whichever unicast routing protocols are used to populate the unicast routing table, including Enhanced Interior Gateway Routing Protocol (EIGRP), Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and static routes. PIM uses unicast routing information to perform the multicast forwarding function.

Although PIM is called a multicast routing protocol, it actually uses the unicast routing table to perform the reverse path forwarding (RPF) check function instead of building up a completely independent multicast routing table. Unlike other routing protocols, PIM does not send and receive routing updates between routers.

PIM is defined in RFC 4601, Protocol Independent Multicast - Sparse Mode (PIM-SM)

PIM can operate in dense mode or sparse mode. The router can also handle both sparse groups and dense groups at the same time (sparse-dense mode). The mode determines how the router populates its multicast routing table and how the router forwards multicast packets it receives from its directly connected LANs.

For information about PIM forwarding (interface) modes, see the following sections:

PIM Dense Mode

PIM dense mode (PIM-DM) uses a push model to flood multicast traffic to every corner of the network. This push model is a method for delivering data to the receivers without the receivers requesting the data. This method is efficient in certain deployments in which there are active receivers on every subnet in the network.

In dense mode, a router assumes that all other routers want to forward multicast packets for a group. If a router receives a multicast packet and has no directly connected members or PIM neighbors present, a prune message is sent back to the source. Subsequent multicast packets are not flooded to this router on this pruned branch. PIM builds source-based multicast distribution trees.

PIM-DM initially floods multicast traffic throughout the network. Routers that have no downstream neighbors prune back the unwanted traffic. This process repeats every 3 minutes.

Routers accumulate state information by receiving data streams through the flood and prune mechanism. These data streams contain the source and group information so that downstream routers can build up their multicast forwarding table. PIM-DM supports only source trees—that is, (S,G) entries—and cannot be used to build a shared distribution tree.
PIM Sparse Mode

PIM sparse mode (PIM-SM) uses a pull model to deliver multicast traffic. Only network segments with active receivers that have explicitly requested the data will receive the traffic.

Sparse mode interfaces are added to the multicast routing table only when periodic Join messages are received from downstream routers, or when a directly connected member is on the interface. When forwarding from a LAN, sparse mode operation occurs if an RP is known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense mode fashion. If the multicast traffic from a specific source is sufficient, the first hop router of the receiver may send Join messages toward the source to build a source-based distribution tree.

PIM-SM distributes information about active sources by forwarding data packets on the shared tree. Because PIM-SM uses shared trees (at least, initially), it requires the use of a rendezvous point (RP). The RP must be administratively configured in the network. See the Rendezvous Points, on page 202 section for more information.

In sparse mode, a router assumes that other routers do not want to forward multicast packets for a group, unless there is an explicit request for the traffic. When hosts join a multicast group, the directly connected routers send PIM Join messages toward the RP. The RP keeps track of multicast groups. Hosts that send multicast packets are registered with the RP by the first hop router of that host. The RP then sends Join messages toward the source. At this point, packets are forwarded on a shared distribution tree. If the multicast traffic from a specific source is sufficient, the first hop router of the host may send Join messages toward the source to build a source-based distribution tree.

Sources register with the RP and then data is forwarded down the shared tree to the receivers. The edge routers learn about a particular source when they receive data packets on the shared tree from that source through the RP. The edge router then sends PIM (S,G) Join messages toward that source. Each router along the reverse path compares the unicast routing metric of the RP address to the metric of the source address. If the metric for the source address is better, it will forward a PIM (S,G) Join message toward the source. If the metric for the RP is the same or better, then the PIM (S,G) Join message will be sent in the same direction as the RP. In this case, the shared tree and the source tree would be considered congruent.

If the shared tree is not an optimal path between the source and the receiver, the routers dynamically create a source tree and stop traffic from flowing down the shared tree. This behavior is the default behavior in software. Network administrators can force traffic to stay on the shared tree by using the ip pim spt-threshold infinity command.

PIM-SM scales well to a network of any size, including those with WAN links. The explicit join mechanism prevents unwanted traffic from flooding the WAN links.

Sparse-Dense Mode

If you configure either sparse mode or dense mode on an interface, then sparseness or denseness is applied to the interface as a whole. However, some environments might require PIM to run in a single region in sparse mode for some groups and in dense mode for other groups.

An alternative to enabling only dense mode or only sparse mode is to enable sparse-dense mode. In this case, the interface is treated as dense mode if the group is in dense mode; the interface is treated in sparse mode if
the group is in sparse mode. You must have an RP if the interface is in sparse-dense mode and you want to treat the group as a sparse group.

If you configure sparse-dense mode, the idea of sparseness or denseness is applied to the groups for which the router is a member.

Another benefit of sparse-dense mode is that Auto-RP information can be distributed in a dense mode; yet, multicast groups for user groups can be used in a sparse mode manner. Therefore there is no need to configure a default RP at the leaf routers.

When an interface is treated in dense mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

- Members or DVMRP neighbors are on the interface.
- There are PIM neighbors and the group has not been pruned.

When an interface is treated in sparse mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

- Members or DVMRP neighbors are on the interface.
- An explicit Join message has been received by a PIM neighbor on the interface.

### PIM Versions

PIMv2 includes these improvements over PIMv1:

- A single, active rendezvous point (RP) exists per multicast group, with multiple backup RPs. This single RP compares to multiple active RPs for the same group in PIMv1.

- A bootstrap router (BSR) provides a fault-tolerant, automated RP discovery and distribution function that enables routers and multilayer devices to dynamically learn the group-to-RP mappings.

- Sparse mode and dense mode are properties of a group, as opposed to an interface.

---

**Note**

We strongly recommend using sparse-dense mode as opposed to either sparse mode or dense mode only.

- PIM join and prune messages have more flexible encoding for multiple address families.
- A more flexible hello packet format replaces the query packet to encode current and future capability options.
- Register messages sent to an RP specify whether they are sent by a border router or a designated router.
- PIM packets are no longer inside IGMP packets; they are standalone packets.

### PIM Stub Routing

The PIM stub routing feature, available in all of the device software images, reduces resource usage by moving routed traffic closer to the end user.
The IP Base image contains only PIM stub routing. The IP Services image contains complete multicast routing. On a switch running the IP Base image, if you try to configure a VLAN interface with PIM dense-mode, sparse-mode, or dense-sparse-mode, the configuration is not allowed.

The PIM stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards IGMP traffic.

In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IP multicast routing and configure only the device as a PIM stub router. The device does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the device. The device uplink port cannot be used with SVIs. If you need PIM for an SVI uplink port, you should upgrade to the IP Services feature set.

You must also configure EIGRP stub routing when configuring PIM stub routing on the device.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM asset and designated router election mechanisms are not supported on the PIM passive interfaces. Only the nonredundant access router topology is supported by the PIM stub feature. By using a nonredundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

The PIM stub feature is enforced in the IP Base image. If you upgrade to a higher software version, the PIM stub configuration remains until you reconfigure the interfaces.

In the following figure, the Device A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source 200.1.1.3.
IGMP Helper

PIM stub routing moves routed traffic closer to the end user and reduces network traffic. You can also reduce traffic by configuring a stub router (switch) with the IGMP helper feature.

You can configure a stub router (switch) with the `ip igmp helper-address ip-address` interface configuration command to enable the switch to send reports to the next-hop interface. Hosts that are not directly connected to a downstream router can then join a multicast group sourced from an upstream network. The IGMP packets from a host wanting to join a multicast stream are forwarded upstream to the next-hop device when this feature is configured. When the upstream central router receives the helper IGMP reports or leaves, it adds or removes the interfaces from its outgoing interface list for that group.

Rendezvous Points

A rendezvous point (RP) is a role that a device performs when operating in Protocol Independent Multicast (PIM) Sparse Mode (SM). An RP is required only in networks running PIM SM. In the PIM-SM model, only network segments with active receivers that have explicitly requested multicast data will be forwarded the traffic.

This method of delivering multicast data is in contrast to PIM Dense Mode (PIM DM). In PIM DM, multicast traffic is initially flooded to all segments of the network. Routers that have no downstream neighbors or directly connected receivers prune back the unwanted traffic.

An RP acts as the meeting place for sources and receivers of multicast data. In a PIM-SM network, sources must send their traffic to the RP. This traffic is then forwarded to receivers down a shared distribution tree. By default, when the first hop device of the receiver learns about the source, it will send a Join message directly to the source, creating a source-based distribution tree from the source to the receiver. This source tree does not include the RP unless the RP is located within the shortest path between the source and receiver.

In most cases, the placement of the RP in the network is not a complex decision. By default, the RP is needed only to start new sessions with sources and receivers. Consequently, the RP experiences little overhead from traffic flow or processing. In PIM version 2, the RP performs less processing than in PIM version 1 because sources must only periodically register with the RP to create state.

Auto-RP

In the first version of PIM-SM, all leaf routers (routers directly connected to sources or receivers) were required to be manually configured with the IP address of the RP. This type of configuration is also known as static
RP configuration. Configuring static RPs is relatively easy in a small network, but it can be laborious in a large, complex network.

Following the introduction of PIM-SM version 1, Cisco implemented a version of PIM-SM with the Auto-RP feature. Auto-RP automates the distribution of group-to-RP mappings in a PIM network. Auto-RP has the following benefits:

- Configuring the use of multiple RPs within a network to serve different groups is easy.
- Auto-RP allows load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Auto-RP avoids inconsistent, manual RP configurations that can cause connectivity problems.

Multiple RPs can be used to serve different group ranges or serve as backups to each other. For Auto-RP to work, a router must be designated as an RP-mapping agent, which receives the RP-announcement messages from the RPs and arbitrates conflicts. The RP-mapping agent then sends the consistent group-to-RP mappings to all other routers. Thus, all routers automatically discover which RP to use for the groups they support.

**Note** If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must statically configure an RP.

If router interfaces are configured in sparse mode, Auto-RP can still be used if all routers are configured with a static RP address for the Auto-RP groups.

To make Auto-RP work, a router must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other routers by dense mode flooding. Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP. One advantage of Auto-RP is that any change to the RP designation must be configured only on the routers that are RPs and not on the leaf routers. Another advantage of Auto-RP is that it offers the ability to scope the RP address within a domain. Scoping can be achieved by defining the time-to-live (TTL) value allowed for the Auto-RP advertisements.

Each method for configuring an RP has its own strengths, weaknesses, and level of complexity. In conventional IP multicast network scenarios, we recommend using Auto-RP to configure RPs because it is easy to configure, well-tested, and stable. The alternative ways to configure an RP are static RP, Auto-RP, and bootstrap router.

**Sparse-Dense Mode for Auto-RP**

A prerequisite of Auto-RP is that all interfaces must be configured in sparse-dense mode using the `ip pim sparse-dense-mode` interface configuration command. An interface configured in sparse-dense mode is treated in either sparse mode or dense mode of operation, depending on which mode the multicast group operates. If a multicast group has a known RP, the interface is treated in sparse mode. If a group has no known RP, by default the interface is treated in dense mode and data will be flooded over this interface. (You can prevent dense-mode fallback; see the module “Configuring Basic IP Multicast.”)

To successfully implement Auto-RP and prevent any groups other than 224.0.1.39 and 224.0.1.40 from operating in dense mode, we recommend configuring a “sink RP” (also known as “RP of last resort”). A sink RP is a statically configured RP that may or may not actually exist in the network. Configuring a sink RP...
does not interfere with Auto-RP operation because, by default, Auto-RP messages supersede static RP configurations. We recommend configuring a sink RP for all possible multicast groups in your network, because it is possible for an unknown or unexpected source to become active. If no RP is configured to limit source registration, the group may revert to dense mode operation and be flooded with data.

**Bootstrap Router**

Another RP selection model called bootstrap router (BSR) was introduced after Auto-RP in PIM-SM version 2. BSR performs similarly to Auto-RP in that it uses candidate routers for the RP function and for relaying the RP information for a group. RP information is distributed through BSR messages, which are carried within PIM messages. PIM messages are link-local multicast messages that travel from PIM router to PIM router. Because of this single hop method of disseminating RP information, TTL scoping cannot be used with BSR. A BSR performs similarly as an RP, except that it does not run the risk of reverting to dense mode operation, and it does not offer the ability to scope within a domain.

**PIM Domain Border**

As IP multicast becomes more widespread, the chance of one PIMv2 domain bordering another PIMv2 domain increases. Because two domains probably do not share the same set of RPs, BSR, candidate RPs, and candidate BSRs, you need to constrain PIMv2 BSR messages from flowing into or out of the domain. Allowing messages to leak across the domain borders could adversely affect the normal BSR election mechanism and elect a single BSR across all bordering domains and comingle candidate RP advertisements, resulting in the election of RPs in the wrong domain.

**Multicast Forwarding**

Forwarding of multicast traffic is accomplished by multicast-capable routers. These routers create distribution trees that control the path that IP multicast traffic takes through the network in order to deliver traffic to all receivers.

Multicast traffic flows from the source to the multicast group over a distribution tree that connects all of the sources to all of the receivers in the group. This tree may be shared by all sources (a shared tree) or a separate distribution tree can be built for each source (a source tree). The shared tree may be one-way or bidirectional.

Before describing the structure of source and shared trees, it is helpful to explain the notations that are used in multicast routing tables. These notations include the following:

- \((S,G)\) = (unicast source for the multicast group \(G\), multicast group \(G\))
- \((*,G)\) = (any source for the multicast group \(G\), multicast group \(G\))

The notation of \((S,G)\), pronounced “S comma G,” enumerates a shortest path tree where \(S\) is the IP address of the source and \(G\) is the multicast group address.

Shared trees are \((*,G)\) and the source trees are \((S,G)\) and always routed at the sources.

**Multicast Distribution Source Tree**

The simplest form of a multicast distribution tree is a source tree. A source tree has its root at the source host and has branches forming a spanning tree through the network to the receivers. Because this tree uses the shortest path through the network, it is also referred to as a shortest path tree (SPT).

The figure shows an example of an SPT for group 224.1.1.1 rooted at the source, Host A, and connecting two receivers, Hosts B and C.
Using standard notation, the SPT for the example shown in the figure would be (192.168.1.1, 224.1.1.1). The (S,G) notation implies that a separate SPT exists for each individual source sending to each group—which is correct.

**Multicast Distribution Shared Tree**

Unlike source trees that have their root at the source, shared trees use a single common root placed at some chosen point in the network. This shared root is called a rendezvous point (RP).

The following figure shows a shared tree for the group 224.2.2.2 with the root located at Router D. This shared tree is unidirectional. Source traffic is sent towards the RP on a source tree. The traffic is then forwarded down the shared tree from the RP to reach all of the receivers (unless the receiver is located between the source and the RP, in which case it will be serviced directly).
In this example, multicast traffic from the sources, Hosts A and D, travels to the root (Router D) and then down the shared tree to the two receivers, Hosts B and C. Because all sources in the multicast group use a common shared tree, a wildcard notation written as (*, G), pronounced “star comma G,” represents the tree. In this case, * means all sources, and G represents the multicast group. Therefore, the shared tree shown in the figure would be written as (*, 224.2.2.2).

Both source trees and shared trees are loop-free. Messages are replicated only where the tree branches. Members of multicast groups can join or leave at any time; therefore the distribution trees must be dynamically updated. When all the active receivers on a particular branch stop requesting the traffic for a particular multicast group, the routers prune that branch from the distribution tree and stop forwarding traffic down that branch. If one receiver on that branch becomes active and requests the multicast traffic, the router will dynamically modify the distribution tree and start forwarding traffic again.

Source Tree Advantage

Source trees have the advantage of creating the optimal path between the source and the receivers. This advantage guarantees the minimum amount of network latency for forwarding multicast traffic. However, this optimization comes at a cost. The routers must maintain path information for each source. In a network that has thousands of sources and thousands of groups, this overhead can quickly become a resource issue on the routers. Memory consumption from the size of the multicast routing table is a factor that network designers must take into consideration.

Shared Tree Advantage

Shared trees have the advantage of requiring the minimum amount of state in each router. This advantage lowers the overall memory requirements for a network that only allows shared trees. The disadvantage of shared trees is that under certain circumstances the paths between the source and receivers might not be the optimal paths, which might introduce some latency in packet delivery. For example, in the figure above the shortest path between Host A (source 1) and Host B (a receiver) would be Router A and Router C. Because we are using Router D as the root for a shared tree, the traffic must traverse Routers A, B, D and then C.
Network designers must carefully consider the placement of the rendezvous point (RP) when implementing a shared tree-only environment.

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination address and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)--which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is described in the following section.

**PIM Shared Tree and Source Tree**

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

*Figure 12: Shared Tree and Source Tree (Shortest-Path Tree)*

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software devices to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.
4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.

5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.

6. By default, reception of the first data packet prompts Router C to send a join message toward the source.

7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.

8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the `ip pim spt-threshold` global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

### Reverse Path Forwarding

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination network and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric) -- which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is an algorithm used for forwarding multicast datagrams.

Protocol Independent Multicast (PIM) uses the unicast routing information to create a distribution tree along the reverse path from the receivers towards the source. The multicast routers then forward packets along the distribution tree from the source to the receivers. RPF is a key concept in multicast forwarding. It enables
routers to correctly forward multicast traffic down the distribution tree. RPF makes use of the existing unicast routing table to determine the upstream and downstream neighbors. A router will forward a multicast packet only if it is received on the upstream interface. This RPF check helps to guarantee that the distribution tree will be loop-free.

**RPF Check**

When a multicast packet arrives at a router, the router performs an RPF check on the packet. If the RPF check succeeds, the packet is forwarded. Otherwise, it is dropped.

For traffic flowing down a source tree, the RPF check procedure works as follows:

1. The router looks up the source address in the unicast routing table to determine if the packet has arrived on the interface that is on the reverse path back to the source.
2. If the packet has arrived on the interface leading back to the source, the RPF check succeeds and the packet is forwarded out the interfaces present in the outgoing interface list of a multicast routing table entry.
3. If the RPF check in Step 2 fails, the packet is dropped.

The figure shows an example of an unsuccessful RPF check.

*Figure 13: RPF Check Fails*

As the figure illustrates, a multicast packet from source 151.10.3.21 is received on serial interface 0 (S0). A check of the unicast route table shows that S1 is the interface this router would use to forward unicast data to 151.10.3.21. Because the packet has arrived on interface S0, the packet is discarded.

The figure shows an example of a successful RPF check.

*Figure 14: RPF Check Succeeds*

In this example, the multicast packet has arrived on interface S1. The router refers to the unicast routing table and finds that S1 is the correct interface. The RPF check passes, and the packet is forwarded.
PIM uses both source trees and RP-rooted shared trees to forward datagrams. The RPF check is performed differently for each:

- If a PIM router or multilayer device has a source-tree state (that is, an (S, G) entry is present in the multicast routing table), it performs the RPF check against the IP address of the source of the multicast packet.
- If a PIM router or multilayer device has a shared-tree state (and no explicit source-tree state), it performs the RPF check on the RP address (which is known when members join the group).

DVMRP and dense-mode PIM use only source trees and use RPF.

Note

DVMRP is not supported on the device.

Sparse-mode PIM uses the RPF lookup function to decide where it needs to send joins and prunes:

- (S, G) joins (which are source-tree states) are sent toward the source.
- (*,G) joins (which are shared-tree states) are sent toward the RP.

## Default PIM Routing Configuration

This table displays the default PIM routing configuration for the device.

**Table 29: Default Multicast Routing Configuration**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>

### Configuring a Rendezvous Point

You must have a rendezvous point (RP), if the interface is in sparse-dense mode and if you want to handle the group as a sparse group. You can use these methods:

- By manually assigning an RP to multicast groups.
- As a standalone, Cisco-proprietary protocol separate from PIMv1, which includes:
  - Setting up Auto-RP in a new internetwork
  - Adding Auto-RP to an existing sparse-mode cloud
  - Preventing join messages to false RPs
  - Filtering incoming RP announcement messages
- By using a standards track protocol in the Internet Engineering Task Force (IETF), which includes configuring PIMv2 BSR.

**Note**

You can use Auto-RP, BSR, or a combination of both, depending on the PIM version that you are running and the types of routers in your network. For information about working with different PIM versions in your network, see [PIMv1 and PIMv2 Interoperability](#), on page 196.
Manually Assigning an RP to Multicast Groups

If the rendezvous point (RP) for a group is learned through a dynamic mechanism (such as Auto-RP or BSR), you need not perform this task for that RP.

Senders of multicast traffic announce their existence through register messages received from the source first-hop router (designated router) and forwarded to the RP. Receivers of multicast packets use RPs to join a multicast group by using explicit join messages.

Note

RPs are not members of the multicast group; they serve as a meeting place for multicast sources and group members.

You can configure a single RP for multiple groups defined by an access list. If there is no RP configured for a group, the multilayer device responds to the group as dense and uses the dense-mode PIM techniques. This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim rp-address ip-address [access-list-number] [override]
4. access-list access-list-number {deny | permit} source [source-wildcard]
5. end
6. show running-config
7. copy running-config startup-config

### Setting Up Auto-RP in a New Internetwork

If you are setting up Auto-RP in a new internetwork, you do not need a default RP because you configure all the interfaces for sparse-dense mode.

**Note**

Omit Step 3 in the following procedure, if you want to configure a PIM router as the RP for the local group.

#### SUMMARY STEPS

1. `enable`
2. `show running-config`
3. `configure terminal`
4. `ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds`
5. `access-list access-list-number {deny | permit} source [source-wildcard]`
6. `ip pim send-rp-discovery scope ttl`
7. `end`
8. `show running-config`
9. `show ip pim rp mapping`
10. `show ip pim rp`
11. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td><code>show running-config</code></td>
<td>Verifies that a default RP is already configured on all PIM devices and the RP in the sparse-mode network. It was</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><strong>Device# show running-config</strong></td>
<td>previously configured with the <code>ip pim rp-address</code> global configuration command.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This step is not required for spare-dense-mode environments.</td>
<td></td>
</tr>
<tr>
<td>The selected RP should have good connectivity and be available across the network. Use this RP for the global groups (for example, 224.x.x.x and other global groups). Do not reconfigure the group address range that this RP serves. RPs dynamically discovered through Auto-RP take precedence over statically configured RPs. Assume that it is desirable to use a second RP for the local groups.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Step 3

**configure terminal**

**Example:**

```
Device# configure terminal
```

Enters global configuration mode.

### Step 4

**ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds**

**Example:**

```
Device(config)# ip pim send-rp-announce gigabitethernet 1/0/5 scope 20 group-list 10 interval 120
```

Configures another PIM device to be the candidate RP for local groups.

- For `interface-id`, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs.
- For `scope ttl`, specify the time-to-live value in hops. Enter a hop count that is high enough so that the RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255.
- For `group-list access-list-number`, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.
- For `interval seconds`, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383.

### Step 5

**access-list access-list-number {deny | permit} source [source-wildcard]**

**Example:**

```
Device(config)# access-list 10 permit 10.10.0.0
```

Creates a standard access list, repeating the command as many times as necessary.

- For `access-list-number`, enter the access list number specified in Step 3.
- The `deny` keyword denies access if the conditions are matched.
- The `permit` keyword permits access if the conditions are matched.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| • For source, enter the multicast group address range for which the RP should be used.  
• (Optional) For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. |
| **Step 6** | ip pim send-rp-discovery scope ttl  
Example:  
Device(config)# ip pim send-rp-discovery scope 50 |
| Finds a device whose connectivity is not likely to be interrupted, and assign it the role of RP-mapping agent.  
For **scope ttl**, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255. |
| **Step 7** | end  
Example:  
Device(config)# end |
| Returns to privileged EXEC mode. |
| **Step 8** | show running-config  
Example:  
Device# show running-config |
| Verifies your entries. |
| **Step 9** | show ip pim rp mapping  
Example:  
Device# show ip pim rp mapping |
| Displays active RPs that are cached with associated multicast routing entries. |
| **Step 10** | show ip pim rp  
Example:  
Device# show ip pim rp |
| Displays the information cached in the routing table. |
| **Step 11** | copy running-config startup-config  
Example:  
Device# copy running-config startup-config |
| (Optional) Saves your entries in the configuration file. |
Adding Auto-RP to an Existing Sparse-Mode Cloud

This section contains suggestions for the initial deployment of Auto-RP into an existing sparse-mode cloud to minimize disruption of the existing multicast infrastructure.

This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `show running-config`
3. `configure terminal`
4. `ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds`
5. `access-list access-list-number {deny | permit} source [source-wildcard]`
6. `ip pim send-rp-discovery scope ttl`
7. `end`
8. `show running-config`
9. `show ip pim rp mapping`
10. `show ip pim rp`
11. `copy running-config startup-config`

</table>
### Command or Action

<table>
<thead>
<tr>
<th>Device# configure terminal</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds</td>
<td>Configures another PIM device to be the candidate RP for local groups.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device(config)# ip pim send-rp-announce
gigabitethernet 1/0/5 scope 20 group-list 10 interval 120
```

**Step 4**
- For `interface-id`, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs.
- For `scope ttl`, specify the time-to-live value in hops. Enter a hop count that is high enough so that the RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255.
- For `group-list access-list-number`, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.
- For `interval seconds`, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383.

**Note** To remove the PIM device configured as the candidate RP, use the `no ip pim send-rp-announce` interface-id global configuration command.

### Step 5

| access-list access-list-number [deny | permit] source [source-wildcard] | Creates a standard access list, repeating the command as many times as necessary. |
|-------------------------------|-----------------------------------|

**Example:**
```
Device(config)# access-list 10
permit 224.0.0.0 15.255.255.255
```

- For `access-list-number`, enter the access list number specified in Step 3.
- The `deny` keyword denies access if the conditions are matched.
- The `permit` keyword permits access if the conditions are matched.
- For `source`, enter the multicast group address range for which the RP should be used.
- (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

Recall that the access list is always terminated by an implicit deny statement for everything.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 6**  
  ip pim send-rp-discovery scope ttl  
  Example:  
  Device(config)# ip pim send-rp-discovery scope 50 | Finds a device whose connectivity is not likely to be interrupted, and assigns it the role of RP-mapping agent.  
  For scope ttl, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255.  
  **Note** To remove the device as the RP-mapping agent, use the no ip pim send-rp-discovery global configuration command. |
| **Step 7**  
  end  
  Example:  
  Device(config)# end | Returns to privileged EXEC mode. |
| **Step 8**  
  show running-config  
  Example:  
  Device# show running-config | Verifies your entries. |
| **Step 9**  
  show ip pim rp mapping  
  Example:  
  Device#  
  show ip pim rp mapping | Displays active RPs that are cached with associated multicast routing entries. |
| **Step 10**  
  show ip pim rp  
  Example:  
  Device# show ip pim rp | Displays the information cached in the routing table. |
| **Step 11**  
  copy running-config startup-config  
  Example:  
  Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
### Configuring Sparse Mode with a Single Static RP (CLI)

A rendezvous point (RP) is required in networks running Protocol Independent Multicast sparse mode (PIM-SM). In PIM-SM, traffic will be forwarded only to network segments with active receivers that have explicitly requested multicast data.

This section describes how to configure sparse mode with a single static RP.

#### Before you begin

All access lists that are needed when sparse mode is configured with a single static RP should be configured prior to beginning the configuration task.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast-routing [distributed]
4. interface type number
5. ip pim sparse-mode
6. Repeat Steps 1 through 5 on every interface that uses IP multicast.
7. exit
8. ip pim rp-address rp-address [access-list] [override]
9. end
10. show ip pim rp [mapping] [rp-address]
11. show ip igmp groups [group-name | group-address | interface-type interface-number] [detail]
12. show ip mroute

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
| **Example:**
  - device> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:**
  - device# configure terminal | |
| **Step 3** ip multicast-routing [distributed] | Enables IP multicast routing. |
| **Example:**
  - device(config)# ip multicast-routing | |
<p>| <strong>Step 4</strong> interface type number | Selects an interface that is connected to hosts on which PIM can be enabled. |
| <strong>Example:</strong> | |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device(config)# interface gigabitethernet 1/0/0</code></td>
<td>Enables PIM on an interface. You must use sparse mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>ip pim sparse-mode</code> <strong>Example:</strong> &lt;br&gt;<code>device(config-if)# ip pim sparse-mode</code></td>

<tr>
<td><strong>Step 10</strong> <code>show ip pim rp mapping</code> <strong>Example:</strong> &lt;br&gt;<code>device# show ip pim rp mapping</code></td>
<td>(Optional) Displays RPs known in the network and shows how the router learned about each RP.</td>
</tr>
<tr>
<td><strong>Step 11</strong> `show ip igmp groups [group-name</td>
<td>group-address] [interface-type interface-number] [detail]` <strong>Example:</strong></td>
</tr>
</tbody>
</table>
### Preventing Join Messages to False RPs

Determine whether the `ip pim accept-rp` command was previously configured throughout the network by using the `show running-config` privileged EXEC command. If the `ip pim accept-rp` command is not configured on any device, this problem can be addressed later. In those routers or multilayer devices already configured with the `ip pim accept-rp` command, you must enter the command again to accept the newly advertised RP.

To accept all RPs advertised with Auto-RP and reject all other RPs by default, use the `ip pim accept-rp auto-rp` global configuration command.

If all interfaces are in sparse mode, use a default-configured RP to support the two well-known groups 224.0.1.39 and 224.0.1.40. Auto-RP uses these two well-known groups to collect and distribute RP-mapping information. When this is the case and the `ip pim accept-rp auto-rp` command is configured, another `ip pim accept-rp` command accepting the RP must be configured as follows:

```plaintext
Switch(config)# ip pim accept-rp 172.10.20.1 1
Switch(config)# access-list 1 permit 224.0.1.39
Switch(config)# access-list 1 permit 224.0.1.40
```

This procedure is optional.

### Filtering Incoming RP Announcement Messages

You can add configuration commands to the mapping agents to prevent a maliciously configured router from masquerading as a candidate RP and causing problems.

This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip pim rp-announce-filter rp-list access-list-number group-list access-list-number`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
**Example:**  
Device> `enable`  
- Enter your password if prompted. |
| **Step 2** | `configure terminal` | Enters global configuration mode.  
**Example:**  
Device# `configure terminal` |
| **Step 3** | `ip pim rp-announce-filter rp-list access-list-number group-list access-list-number` | Filters incoming RP announcement messages.  
**Example:**  
Device(config)# `ip pim rp-announce-filter rp-list 10 group-list 14`  
- Enter this command on each mapping agent in the network.  
Without this command, all incoming RP-announce messages are accepted by default.  
- For **rp-list access-list-number**, configure an access list of candidate RP addresses that, if permitted, is accepted for the group ranges supplied in the **group-list access-list-number** variable. If this variable is omitted, the filter applies to all multicast groups.  
- If more than one mapping agent is used, the filters must be consistent across all mapping agents to ensure that no conflicts occur in the group-to-RP mapping information.  
**Note**  
To remove a filter on incoming RP announcement messages, use the `no ip pim rp-announce-filter rp-list access-list-number [group-list access-list-number]` global configuration command. |
| **Step 4** | `access-list access-list-number {deny | permit} source [source-wildcard]` | Creates a standard access list, repeating the command as many times as necessary.  
**Example:**  
Device(config)# `access-list 10 permit 10.8.1.0 255.255.224.0`  
- For **access-list-number**, enter the access list number specified in Step 2.  
- The **deny** keyword denies access if the conditions are matched.  
- The **permit** keyword permits access if the conditions are matched.  
- Create an access list that specifies from which routers and multilayer devices the mapping agent accepts candidate RP announcements (rp-list ACL). |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Create an access list that specifies the range of multicast groups from which to accept or deny (group-list ACL).</td>
</tr>
<tr>
<td></td>
<td>• For <code>source</code>, enter the multicast group address range for which the RP should be used.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For <code>source-wildcard</code>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</td>
</tr>
<tr>
<td>The access list is always terminated by an implicit deny statement for everything.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 5

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

### Step 6

**Example:**

```
Device# show running-config
```

Verifies your entries.

### Step 7

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

### Configuring PIMv2 BSR

The process for configuring PIMv2 BSR may involve the following optional tasks:

- Defining the PIM domain border
- Defining the IP multicast boundary
- Configuring candidate BSRs
- Configuring candidate RPs

### Defining the PIM Domain Border

Perform the following steps to configure the PIM domain border. This procedure is optional.
SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip pim bsr-border
5. end
6. show running-config
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
  Example:  
  Device# configure terminal |
| **Step 3** interface interface-id | Specifies the interface to be configured, and enters interface configuration mode.  
  Example:  
  Device(config)# interface gigabitethernet 1/0/1 |
| **Step 4** ip pim bsr-border | Defines a PIM bootstrap message boundary for the PIM domain.  
  Example:  
  Device(config-if)# ip pim bsr-border |
| **Step 5** end | Returns to privileged EXEC mode.  
  Example:  
  Device(config)# end |
| **Step 6** show running-config | Verifies your entries.  
  Example:  
  |

Note: To remove the PIM border, use the no ip pim bsr-border interface configuration command.
### Defining the IP Multicast Boundary

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. access-list access-list-number deny source [source-wildcard]
4. interface interface-id
5. ip multicast boundary access-list-number
6. end
7. show running-config
8. copy running-config startup-config

**DETAILED STEPS**

</thead>
</table>
| **access-list 12 deny 224.0.1.40**                    | • For *source*, enter multicast addresses 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.  
  • (Optional) For *source-wildcard*, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
The access list is always terminated by an implicit deny statement for everything. |

**Step 4**

interface *interface-id*

**Example:**

Device(config)# interface gigabitethernet 1/0/1

**Step 5**

ip multicast boundary *access-list-number*

**Example:**

Device(config-if)# ip multicast boundary 12

**Note**

To remove the boundary, use the **no ip multicast boundary** interface configuration command.

**Step 6**

end

**Example:**

Device(config)# end

**Step 7**

show running-config

**Example:**

Device# show running-config

**Step 8**

copy running-config startup-config

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

**Configuring Candidate BSRs**

You can configure one or more candidate BSRs. The devices serving as candidate BSRs should have good connectivity to other devices and be in the backbone portion of the network.

This procedure is optional.
SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim bsr-candidate interface-id hash-mask-length [priority]
4. end
5. show running-config
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
Example:  
Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal |
| **Step 3** ip pim bsr-candidate interface-id hash-mask-length [priority] | Configures your device to be a candidate BSR.  
Example:  
Device(config)# ip pim bsr-candidate gigabitethernet 1/0/3 28 100 |
| **Step 4** end | Returns to privileged EXEC mode.  
Example:  
Device# end |

Note: To remove this device as a candidate BSR, use the no ip pim bsr-candidate global configuration command.
### Configuring the Candidate RPs

You can configure one or more candidate RPs. Similar to BSRs, the RPs should also have good connectivity to other devices and be in the backbone portion of the network. An RP can serve the entire IP multicast address space or a portion of it. Candidate RPs send candidate RP advertisements to the BSR.

This procedure is optional.

#### Before you begin

When deciding which devices should be RPs, consider these options:

- In a network of Cisco routers and multilayer devices where only Auto-RP is used, any device can be configured as an RP.
- In a network that includes only Cisco PIMv2 routers and multilayer devices and with routers from other vendors, any device can be used as an RP.
- In a network of Cisco PIMv1 routers, Cisco PIMv2 routers, and routers from other vendors, configure only Cisco PIMv2 routers and multilayer devices as RPs.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip pim rp-candidate interface-id [group-list access-list-number]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enters your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Configures your device to be a candidate RP.</td>
</tr>
<tr>
<td><code>ip pim rp-candidate interface-id [group-list access-list-number]</code></td>
<td>For <code>interface-id</code>, specify the interface whose associated IP address is advertised as a candidate RP address. Valid interfaces include physical ports, port channels, and VLANs.</td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;Device(config)# ip pim rp-candidate gigabitethernet 1/0/5 group-list 10</td>
<td>(Optional) For <code>group-list access-list-number</code>, enter an IP standard access list number from 1 to 99. If no group-list is specified, the device is a candidate RP for all groups.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To remove this device as a candidate RP, use the <code>no ip pim rp-candidate</code> interface-id global configuration command.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Creates a standard access list, repeating the command as many times as necessary.</td>
</tr>
<tr>
<td>`access-list access-list-number {deny</td>
<td>permit} source [source-wildcard]`</td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;Device(config)# access-list 10 permit 239.0.0.0 0.255.255.255</td>
<td>The <code>deny</code> keyword denies access if the conditions are matched. The <code>permit</code> keyword permits access if the conditions are matched.</td>
</tr>
<tr>
<td></td>
<td>For <code>source</code>, enter the number of the network or host from which the packet is being sent.</td>
</tr>
<tr>
<td></td>
<td>(Optional) For <code>source-wildcard</code>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</td>
</tr>
<tr>
<td></td>
<td>The access list is always terminated by an implicit deny statement for everything.</td>
</tr>
</tbody>
</table>
### Delaying the Use of PIM Shortest-Path Tree

Perform these steps to configure a traffic rate threshold that must be reached before multicast routing is switched from the source tree to the shortest-path tree.

This procedure is optional.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `access-list access-list-number {deny | permit} source [source-wildcard]`
4. `ip pim spt-threshold {kbps | infinity} [group-list access-list-number]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong> access-list access-list-number {deny</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Device(config)# access-list 16 permit 225.0.0.0 0.255.255.255</td>
</tr>
</tbody>
</table>

Creates a standard access list.
- For `access-list-number`, the range is 1 to 99.
- The `deny` keyword denies access if the conditions are matched.
- The `permit` keyword permits access if the conditions are matched.
- For `source`, specify the multicast group to which the threshold will apply.
- (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

The access list is always terminated by an implicit deny statement for everything.

### Step 4

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip pim spt-threshold {kbps</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Device(config)# ip pim spt-threshold infinity group-list 16</td>
</tr>
</tbody>
</table>

Specifies the threshold that must be reached before moving to shortest-path tree (spt).
- For `kbps`, specify the traffic rate in kilobits per second. The default is 0 kbps.

**Note** Because of device hardware limitations, 0 kbps is the only valid entry even though the range is 0 to 4294967.

- Specify `infinity` if you want all sources for the specified group to use the shared tree, never switching to the source tree.
- (Optional) For `group-list access-list-number`, specify the access list created in Step 2. If the value is 0 or if the group list is not used, the threshold applies to all groups.

**Note** To return to the default setting, use the `no ip pim spt-threshold {kbps | infinity}` global configuration command.

### Step 5

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>end</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Device(config)# end</td>
</tr>
</tbody>
</table>

Returns to privileged EXEC mode.
Modifying the PIM Router-Query Message Interval

PIM routers and multilayer devices send PIM router-query messages to find which device will be the designated router (DR) for each LAN segment (subnet). The DR is responsible for sending IGMP host-query messages to all hosts on the directly connected LAN.

With PIM DM operation, the DR has meaning only if IGMPv1 is in use. IGMPv1 does not have an IGMP querier election process, so the elected DR functions as the IGMP querier. With PIM-SM operation, the DR is the device that is directly connected to the multicast source. It sends PIM register messages to notify the RP that multicast traffic from a source needs to be forwarded down the shared tree. In this case, the DR is the device with the highest IP address.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip pim query-interval seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td>Specifies the interface to be configured, and enters interface configuration mode.</td>
</tr>
</tbody>
</table>

**Step 3**

**interface interface-id**

**Example:**

```bash
Device(config)# interface gigabitethernet 1/0/1
```

**Step 4**

**ip pim query-interval seconds**

**Example:**

```bash
Device(config-if)# ip pim query-interval 45
```

**Note** To return to the default setting, use the `no ip pim query-interval [seconds]` interface configuration command.

**Step 5**

**end**

**Example:**

```bash
Device(config)# end
```

**Step 6**

**show ip igmp interface [interface-id]**

**Example:**

```bash
Device# show ip igmp interface
```

**Step 7**

**copy running-config startup-config**

**Example:**

```bash
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

### Verifying PIM Operations

#### Verifying IP Multicast Operation in a PIM-SM or a PIM-SSM Network

When you verify the operation of IP multicast in a PIM-SM network environment or in a PIM-SSM network environment, a useful approach is to begin the verification process on the last hop router, and then continue the verification process on the routers along the SPT until the first hop router has been reached. The goal of the verification is to ensure that IP multicast traffic is being routed properly through an IP multicast network.

Perform the following optional tasks to verify IP multicast operation in a PIM-SM or a PIM-SSM network. The steps in these tasks help to locate a faulty hop when sources and receivers are not operating as expected.
If packets are not reaching their expected destinations, you might want to consider disabling IP multicast fast switching, which would place the router in process switching mode. If packets begin reaching their proper destinations after IP multicast fast switching has been disabled, then the issue most likely was related to IP multicast fast switching.

Verifying IP Multicast on the First Hop Router

Enter these commands on the first hop router to verify IP multicast operations on the first hop router:

**SUMMARY STEPS**

1. `enable`
2. `show ip mroute [group-address]`
3. `show ip mroute active [kb/s]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>show ip mroute [group-address]</code></td>
<td>Confirms that the F flag has been set for mroutes on the first hop router.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>show ip mroute 239.1.2.3</code></td>
<td></td>
</tr>
<tr>
<td>(*, 239.1.2.3), 00:18:10/stopped, RP 172.16.0.1, flags: SPF</td>
<td></td>
</tr>
<tr>
<td>Incoming interface: Serial1/0, RPF nbr 172.31.200.2</td>
<td></td>
</tr>
<tr>
<td>Outgoing interface list: Null</td>
<td></td>
</tr>
<tr>
<td>(10.0.0.1, 239.1.2.3), 00:18:10/00:03:22, flags: FT</td>
<td></td>
</tr>
<tr>
<td>Incoming interface: GigabitEthernet0/0/0, RPF nbr 0.0.0.0</td>
<td></td>
</tr>
<tr>
<td>Outgoing interface list:</td>
<td></td>
</tr>
<tr>
<td>Serial1/0, Forward/Sparse-Dense,</td>
<td></td>
</tr>
<tr>
<td>00:18:10/00:03:19</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>show ip mroute active [kb/s]</code></td>
<td>Displays information about active multicast sources sending to groups. The output of this command provides information about the multicast packet rate for active sources.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>show ip mroute active</code></td>
<td></td>
</tr>
<tr>
<td>Active IP Multicast Sources - sending &gt;= 4 kb/s</td>
<td></td>
</tr>
</tbody>
</table>
By default, the output of the `show ip mroute` command with the `active` keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the `kb/s` argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.

**Verifying IP Multicast on Routers Along the SPT**

Enter these commands on routers along the SPT to verify IP multicast operations on routers along the SPT in a PIM-SM or PIM-SSM network:

**SUMMARY STEPS**

1. `enable`
2. `show ip mroute [group-address]`
3. `show ip mroute active`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>show ip mroute [group-address]</code></td>
<td>Confirms the RPF neighbor towards the source for a particular group or groups.</td>
</tr>
</tbody>
</table>
| **Example:** Device# show ip mroute 239.1.2.3 (*, 239.1.2.3), 00:17:56/00:03:02, RP 172.16.0.1, flags: S
  Incoming interface: Null, RPF nbr 0.0.0.0
  Outgoing interface list:
  GigabitEthernet0/0/0, Forward/Sparse-Dense, 00:17:56/00:03:02
(10.0.0.1, 239.1.2.3), 00:15:34/00:03:28, flags: T
  Incoming interface: Serial1/0, RPF nbr 172.31.200.1
  Outgoing interface list:
  GigabitEthernet0/0/0, Forward/Sparse-Dense, 00:15:34/00:03:02 |
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 3</th>
<th>show ip mroute active</th>
</tr>
</thead>
</table>

**Example:**

Device# show ip mroute active  
Active IP Multicast Sources = sending >= 4 kbps  
Group: 239.1.2.3, (?)  
Source: 10.0.0.1 (?)  
Rate: 20 pps/4 kbps(1sec), 4 kbps(last 30 secs), 4 kbps(life avg)

**Purpose**

Displays information about active multicast sources sending traffic to groups. The output of this command provides information about the multicast packet rate for active sources.

**Note**

By default, the output of the `show ip mroute` command with the `active` keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the `kb/s` argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.

### Verifying IP Multicast Operation on the Last Hop Router

Enter these commands on the last hop router to verify IP multicast operations on the last hop router:

**SUMMARY STEPS**

1. `enable`  
2. `show ip igmp groups`  
3. `show ip pim rp mapping`  
4. `show ip mroute`  
5. `show ip interface [type number]`  
6. `show ip pim interface count`  
7. `show ip mroute count`  
8. `show ip mroute active [kb/s]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
|        | `enable`          | Enables privileged EXEC mode.  
  **Example:**  
  Device> `enable`  
  - Enter your password if prompted. |

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
|        | `show ip igmp groups` | Verifies IGMP memberships on the last hop router. This information will confirm the multicast groups with receivers that are directly connected to the last hop router and that are learned through IGMP.  
  **Example:**  
  Device# `show ip igmp groups`  
  IGMP Connected Group Membership  
  Group Address        Interface       Uptime  
  Expires             Last Reporter |
Verifying IP Multicast Operation on the Last Hop Router

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>239.1.2.3 GigabitEthernet1/0/0 00:05:14 00:02:14 10.1.0.6 224.0.1.39 GigabitEthernet0/0/0 00:09:11 00:02:08 172.31.100.1</td>
<td>Confirms that the group-to-RP mappings are being populated correctly on the last hop router.</td>
</tr>
<tr>
<td><strong>Step 3</strong> show ip pim rp mapping</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show ip pim rp mapping</td>
<td>PIM Group-to-RP Mappings</td>
</tr>
<tr>

### Note

Verifying IP Multicast Operation on the Last Hop Router

#### Step 6

**Example:**

```
Device# show ip pim interface count
```

<table>
<thead>
<tr>
<th>State: * - Fast Switched, D - Distributed Fast Switched</th>
</tr>
</thead>
<tbody>
<tr>
<td>H - Hardware Switching Enabled</td>
</tr>
<tr>
<td>Address</td>
</tr>
<tr>
<td>Mpackets In/Out</td>
</tr>
<tr>
<td>172.31.100.2</td>
</tr>
<tr>
<td>4122/0</td>
</tr>
</tbody>
</table>

**Step 7**

**Example:**

```
Device# show ip mroute count
```

**Purpose**

**Step 6**

Confirms that multicast traffic is being forwarded on the last hop router.

**Step 7**

Confirms that multicast traffic is being forwarded on the last hop router.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Device# show ip mroute count | **Purpose**

**IP Multicast Statistics**
- 6 routes using 4008 bytes of memory
- 3 groups, 1.00 average sources per group
- Forwarding Counts: Pkt Count/Pkts per second/Avg
- Pkt Size/Kilobits per second
- Other counts: Total/RPF failed/Other drops(OIF-null, rate-limit etc)

**Group:** 239.1.2.3, Source count: 1, Packets forwarded: 3165, Packets received: 3165
  - RP-tree: Forwarding: 0/0/0/0, Other: 0/0/0
  - Source: 10.0.0.1/32, Forwarding: 3165/20/28/4, Other: 0/0/0

**Group:** 224.0.1.39, Source count: 1, Packets forwarded: 21, Packets received: 120
  - Source: 172.16.0.1/32, Forwarding: 21/1/48/0, Other: 120/0/99

**Group:** 224.0.1.40, Source count: 1, Packets forwarded: 10, Packets received: 10
  - Source: 172.16.0.1/32, Forwarding: 10/1/48/0, Other: 10/0/0

**Step 8**
```
show ip mroute active [kb/s]
```

**Example:**
```
Device# show ip mroute active
Active IP Multicast Sources - sending >= 4 kbps

Group: 239.1.2.3, (?)
  Source: 10.0.0.1 (?)
  Rate: 20 pps/4 kbps(1sec), 4 kbps(last 50 secs), 4 kbps(life avg)
```

**Note** By default, the output of the `show ip mroute` command with the `active` keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the `kb/s` argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.

**Using PIM-Enabled Routers to Test IP Multicast Reachability**

If all the PIM-enabled routers and access servers that you administer are members of a multicast group, pinging that group causes all routers to respond, which can be a useful administrative and debugging tool.

To use PIM-enabled routers to test IP multicast reachability, perform the following tasks:

**Configuring Routers to Respond to Multicast Pings**

Follow these steps to configure a router to respond to multicast pings. Perform the task on all the interfaces of a router and on all the routers participating in the multicast network:
**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip igmp join-group group-address`
5. Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network.
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enters interface configuration mode. For the <code>type</code> and <code>number</code> arguments, specify an interface that is directly connected to hosts or is facing hosts.</td>
</tr>
<tr>
<td><code>interface type number</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# interface gigabitethernet 1/0/0</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>(Optional) Configures an interface on the router to join the specified group. For the purpose of this task, configure the same group address for the <code>group-address</code> argument on all interfaces on the router participating in the multicast network. Note With this method, the router accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the router from fast switching.</td>
</tr>
<tr>
<td><code>ip igmp join-group group-address</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# ip igmp join-group 225.2.2.2</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Ends the current configuration session and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# end</code></td>
<td></td>
</tr>
</tbody>
</table>
Pinging Routers Configured to Respond to Multicast Pings

Follow these steps on a router to initiate a ping test to the routers configured to respond to multicast pings. This task is used to test IP multicast reachability in a network.

**SUMMARY STEPS**

1. `enable`
2. `ping group-address`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>

</tbody>
</table>

---

**Monitoring and Troubleshooting PIM**

**Monitoring PIM Information**

Use the privileged EXEC commands in the following table to monitor your PIM configurations.

*Table 30: PIM Monitoring Commands*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip pim all-vrfs tunnel [tunnel tunnel_number</td>
<td>Displays all VRFs.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><code>show ip pim autorp</code></td>
<td>Displays global auto-RP information.</td>
</tr>
<tr>
<td><code>show ip pim boundary</code></td>
<td>Displays information about mroutes filtered by administratively scoped IPv4 multicast boundaries configured on an interface.</td>
</tr>
<tr>
<td><code>show ip pim interface</code></td>
<td>Displays information about interfaces configured for Protocol Independent Multicast (PIM).</td>
</tr>
<tr>
<td><code>show ip pim mdt [bgp]</code></td>
<td>Displays details about the Border Gateway Protocol (BGP) advertisement of the route distinguisher (RD) for the multicast distribution tree (MDT) default group.</td>
</tr>
<tr>
<td>Command</td>
<td>Purpose</td>
</tr>
<tr>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td><code>show ip pim neighbor</code></td>
<td>Displays the PIM neighbor information.</td>
</tr>
<tr>
<td>`show ip pim rp [group-name</td>
<td>group-address]`</td>
</tr>
<tr>
<td>`show ip pim tunnel [tunnel</td>
<td>verbose]`</td>
</tr>
<tr>
<td>`show ip pim vrf { word { all-vrfs</td>
<td>autorp</td>
</tr>
<tr>
<td><code>show ip igmp groups detail</code></td>
<td>Displays the interested clients that have joined the specific multicast source group.</td>
</tr>
<tr>
<td><code>show ip igmp snooping mroute</code></td>
<td>Verifies that the multicast stream forwards from the source to the interested clients.</td>
</tr>
</tbody>
</table>

### Monitoring the RP Mapping and BSR Information

Use the privileged EXEC mode in the following table to verify the consistency of group-to-RP mappings:

#### Table 31: RP Mapping Monitoring Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `show ip pim rp [hostname or IP address | mapping [hostname or IP address | elected | in-use ] | metric [hostname or IP address ] ]` | Displays all available RP mappings and metrics. This tells you how the device learns of the RP (through the BSR or the Auto-RP mechanism).  
  - (Optional) For the `hostname`, specify the IP name of the group about which to display RPs.  
  - (Optional) For the `IP address`, specify the IP address of the group about which to display RPs.  
  - (Optional) Use the `mapping` keyword to display all group-to-RP mappings of which the Cisco device is aware (either configured or learned from Auto-RP).  
  - (Optional) Use the `metric` keyword to display the RP RPF metric. |
| `show ip pim rp-hash group` | Displays the RP that was selected for the specified group. That is, on a PIMv2 router or multilayer device, confirms that the same RP is the one that a PIMv1 system chooses. For group, enter the group address for which to display RP information. |
Use the privileged EXEC commands in the following table to monitor BSR information:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip pim bsr</td>
<td>Displays information about the elected BSR.</td>
</tr>
<tr>
<td>show ip pim bsr-router</td>
<td>Displays information about the BSRv2.</td>
</tr>
</tbody>
</table>

### Troubleshooting PIMv1 and PIMv2 Interoperability Problems

When debugging interoperability problems between PIMv1 and PIMv2, check these in the order shown:

1. Verify RP mapping with the `show ip pim rp-hash` privileged EXEC command, making sure that all systems agree on the same RP for the same group.

2. Verify interoperability between different versions of DRs and RPs. Make sure that the RPs are interacting with the DRs properly (by responding with register-stops and forwarding decapsulated data packets from registers).

### Configuration Examples for PIM

#### Example: Enabling PIM Stub Routing

In this example, IP multicast routing is enabled, Switch A PIM uplink port 25 is configured as a routed uplink port with `spare-dense-mode` enabled. PIM stub routing is enabled on the VLAN 100 interfaces and on Gigabit Ethernet port 20.

```plaintext
Device(config)# ip multicast-routing distributed
Device(config)# interface GigabitEthernet3/0/25
Device(config-if)# no switchport
Device(config-if)# ip address 3.1.1.2 255.255.255.0
Device(config-if)# ip pim sparse-dense-mode
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# no switchport
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# end
```
Example: Verifying PIM Stub Routing

To verify that PIM stub is enabled for each interface, use the `show ip pim interface` privileged EXEC command:

```
Device# show ip pim interface
Address Interface Ver/ Nbr Query DR DR
Mode Count Intvl Prior
3.1.1.2 GigabitEthernet3/0/25 v2/SD 1 30 1 3.1.1.2
100.1.1.1 Vlan100 v2/P 0 30 1 100.1.1.1
10.1.1.1 GigabitEthernet3/0/20 v2/P 0 30 1 10.1.1.1
```

Example: Manually Assigning an RP to Multicast Groups

This example shows how to configure the address of the RP to 147.106.6.22 for multicast group 225.2.2.2 only:

```
Device(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Device(config)# ip pim rp-address 147.106.6.22 1
```

Example: Configuring Auto-RP

This example shows how to send RP announcements out all PIM-enabled interfaces for a maximum of 31 hops. The IP address of port 1 is the RP. Access list 5 describes the group for which this device serves as RP:

```
Device(config)# ip pim send-rp-announce gigabitethernet1/0/1 scope 31 group-list 5
Device(config)# access-list 5 permit 224.0.0.0 15.255.255.255
```

Example: Defining the IP Multicast Boundary to Deny Auto-RP Information

This example shows a portion of an IP multicast boundary configuration that denies Auto-RP information:

```
Device(config)# access-list 1 deny 224.0.1.39
Device(config)# access-list 1 deny 224.0.1.40
Device(config)# access-list 1 permit all
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip multicast boundary 1
```

Example: Filtering Incoming RP Announcement Messages

This example shows a sample configuration on an Auto-RP mapping agent that is used to prevent candidate RP announcements from being accepted from unauthorized candidate RPs:

```
Device(config)# ip pim rp-announce-filter rp-list 10 group-list 20
Device(config)# access-list 10 permit host 172.16.5.1
Device(config)# access-list 10 permit host 172.16.2.1
Device(config)# access-list 20 deny 239.0.0.0 0.0.255.255
```
The mapping agent accepts candidate RP announcements from only two devices, 172.16.5.1 and 172.16.2.1. The mapping agent accepts candidate RP announcements from these two devices only for multicast groups that fall in the group range of 224.0.0.0 to 239.255.255.255. The mapping agent does not accept candidate RP announcements from any other devices in the network. Furthermore, the mapping agent does not accept candidate RP announcements from 172.16.5.1 or 172.16.2.1 if the announcements are for any groups in the 239.0.0.0 through 239.255.255.255 range. This range is the administratively scoped address range.

Example: Preventing Join Messages to False RPs

If all interfaces are in sparse mode, use a default-configured RP to support the two well-known groups 224.0.1.39 and 224.0.1.40. Auto-RP uses these two well-known groups to collect and distribute RP-mapping information. When this is the case and the `ip pim accept-rp auto-rp` command is configured, another `ip pim accept-rp` command accepting the RP must be configured as follows:

```
Device(config)# ip pim accept-rp 172.10.20.1 1
Device(config)# access-list 1 permit 224.0.1.39
Device(config)# access-list 1 permit 224.0.1.40
```

Example: Configuring Candidate BSRs

This example shows how to configure a candidate BSR, which uses the IP address 172.21.24.18 on a port as the advertised BSR address, uses 30 bits as the hash-mask-length, and has a priority of 10.

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip address 172.21.24.18 255.255.255.0
Device(config-if)# ip pim sparse-mode
Device(config-if)# ip pim bsr-candidate gigabitethernet1/0/2 30 10
```

Example: Configuring Candidate RPs

This example shows how to configure the device to advertise itself as a candidate RP to the BSR in its PIM domain. Standard access list number 4 specifies the group prefix associated with the RP that has the address identified by a port. That RP is responsible for the groups with the prefix 239.

```
Device(config)# ip pim rp-candidate gigabitethernet1/0/2 group-list 4
Device(config)# access-list 4 permit 239.0.0.0 0.255.255.255
```

CHAPTER 17

Configuring HSRP Aware PIM

• HSRP Aware PIM, on page 251

HSRP Aware PIM

This module describes how to configure the HSRP Aware PIM feature for enabling multicast traffic to be forwarded through the Hot Standby Router Protocol (HSRP) active router (AR), allowing Protocol Independent Multicast (PIM) to leverage HSRP redundancy, avoid potential duplicate traffic, and enable failover.

Restrictions for HSRP Aware PIM

• HSRP IPv6 is not supported.

• Stateful failover is not supported. During PIM stateless failover, the HSRP group’s virtual IP address transfers to the standby router but no mrouting state information is transferred. PIM listens and responds to state change events and creates mroutest states upon failover.

• The maximum number of HSRP groups that can be tracked by PIM on each interface is 16.

• The redundancy priority for a PIM DR must be greater than the configured or default value (1) of the PIM DR priority on any device for which the same HSRP group is enabled or the HSRP Active will fail to win the DR election.

• Dense mode is not supported.

Information About HSRP Aware PIM

HSRP

Hot Standby Router Protocol (HSRP) is a Cisco proprietary redundancy protocol for establishing a fault-tolerant default gateway.

The protocol establishes a framework between network devices in order to achieve default gateway failover if the primary gateway becomes inaccessible. By sharing an IP address and a MAC (Layer 2) address, two or more devices can act as a single virtual router. The members of a virtual router group continually exchange status messages and one device can assume the routing responsibility of another, should it go out of commission.
for either planned or unplanned reasons. Hosts continue to forward IP packets to a consistent IP and MAC addresses and the changeover of devices doing the routing is transparent.

HSRP is useful for hosts that do not support a router discovery protocol and cannot switch to a new device when their selected device reloads or loses power. Because existing TCP sessions can survive the failover, this protocol also provides a more transparent recovery for hosts that dynamically choose a next hop for routing IP traffic.

When HSRP is configured on a network segment, it provides a virtual MAC address and an IP address that is shared among a group of devices running HSRP. The address of this HSRP group is referred to as the virtual IP address. One of these devices is selected by the protocol to be the active router (AR). The AR receives and routes packets destined for the MAC address of the group.

HSRP uses a priority mechanism to determine which HSRP configured device is to be the default AR. To configure a device as the AR, you assign it a priority that is higher than the priority of all the other HSRP-configured devices. The default priority is 100, so if you configure just one device to have a higher priority, that device will be the default AR.

Devices that are running HSRP send and receive multicast User Datagram Protocol (UDP)-based hello messages to detect device failure and to designate active and standby devices. When the AR fails to send a hello message within a configurable period of time, the standby device with the highest priority becomes the AR. The transition of packet forwarding functions between devices is completely transparent to all hosts on the network.

You can configure multiple Hot Standby groups on an interface, thereby making fuller use of redundant devices and load sharing.

HSRP is not a routing protocol as it does not advertise IP routes or affect the routing table in any way.

HSRP has the ability to trigger a failover if one or more interfaces on the device fail. This can be useful for dual branch devices each with a single serial link back to the head end. If the serial link of the primary device goes down, the backup device takes over the primary functionality and thus retains connectivity to the head end.

**HSRP Aware PIM**

Protocol Independent Multicast (PIM) has no inherent redundancy capabilities and its operation is completely independent of Hot Standby Router Protocol (HSRP) group states. As a result, IP multicast traffic is forwarded not necessarily by the same device as is elected by HSRP. The HSRP Aware PIM feature provides consistent IP multicast forwarding in a redundant network with virtual routing groups enabled.

HSRP Aware PIM enables multicast traffic to be forwarded through the HSRP active router (AR), allowing PIM to leverage HSRP redundancy, avoid potential duplicate traffic, and enable failover, depending on the HSRP states in the device. The PIM designated router (DR) runs on the same gateway as the HSRP AR and maintains mroutestate.

In a multiaccess segment (such as LAN), PIM DR election is unaware of the redundancy configuration, and the elected DR and HSRP AR may not be the same router. In order to ensure that the PIM DR is always able to forward PIM Join/Prune message towards RP or FHR, the HSRP AR becomes the PIM DR (if there is only one HSRP group). PIM is responsible for adjusting DR priority based on the group state. When a failover occurs, multicast states are created on the new AR elected by the HSRP group and the AR assumes responsibility for the routing and forwarding of all the traffic addressed to the HSRP virtual IP address.

With HSRP Aware PIM enabled, PIM sends an additional PIM Hello message using the HSRP virtual IP addresses as the source address for each active HSRP group when a device becomes HSRP Active. The PIM Hello will carry a new GenID in order to trigger other routers to respond to the failover. When a downstream
device receives this PIM Hello, it will add the virtual address to its PIM neighbor list. The new GenID carried in the PIM Hello will trigger downstream routers to resend PIM Join messages towards the virtual address. Upstream routers will process PIM Join/Prunes (J/P) based on HSRP group state.

If the J/P destination matches the HSRP group virtual address and if the destination device is in HSRP active state, the new AR processes the PIM Join because it is now the acting PIM DR. This allows all PIM Join/Prunes to reach the HSRP group virtual address and minimizes changes and configurations at the downstream routers side.

The IP routing service utilizes the existing virtual routing protocol to provide basic stateless failover services to client applications, such as PIM. Changes in the local HSRP group state and standby router responsibility are communicated to interested client applications. Client applications may build on top of IRS to provide stateful or stateless failover. PIM, as an HSRP client, listens to the state change notifications from HSRP and automatically adjusts the priority of the PIM DR based on the HSRP state. The PIM client also triggers communication between upstream and downstream devices upon failover in order to create an mroutestate on the new AR.

How to Configure HSRP Aware PIM

Configuring an HSRP Group on an Interface

Before you begin

- IP multicast must already be configured on the device.
- PIM must already be configured on the interface.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number [name-tag]`
4. `ip address ip-address mask`
5. `standby [group-number] ip [ip-address [secondary]]`
6. `standby [group-number] timers msec [msec] hellotime msec holdtime`
7. `standby [group-number] priority priority`
8. `standby [group-number] name group-name`
9. `end`
10. `show standby [type number [group]] [all | brief]`

DETAILED STEPS

<table>

CHAPTER 18

Configuring VRRP Aware PIM

- VRRP Aware PIM, on page 259

VRRP Aware PIM

The Virtual Router Redundancy Protocol (VRRP) eliminates the single point of failure inherent in the static default routed environment. VRRP is an election protocol that dynamically assigns responsibility for one or more virtual routers to the VRRP routers on a LAN, allowing several routers on a multi access link to utilize the same virtual IP address.

VRRP Aware PIM is a redundancy mechanism for the Protocol Independent Multicast (PIM) to interoperate with VRRP. It allows PIM to track VRRP state and to preserve multicast traffic upon failover in a redundant network with virtual routing groups enabled.

This module explains how to configure VRRP Aware PIM in a network.

Restrictions for VRRP Aware PIM

- Only PIM sparse mode (SM) and source specific multicast (SSM) modes are supported. Bidirectional (BiDir) PIM is not supported.
- PIM interoperability with Hot Standby Router Protocol (HSRP) IPv6 is not supported.
- PIM tracks only one virtual group, either Virtual Router Redundancy Protocol (VRRP) or HSRP, per interface.
- VRRP Aware PIM is not supported on a Transit network. PIM redundancy enabled interface does not support the PIM joining the network from down stream.

Information About VRRP Aware PIM

Overview of VRRP Aware PIM

Virtual Router Redundancy Protocol (VRRP) is a redundancy protocol for establishing a fault-tolerant default gateway. The protocol establishes a framework between network devices in order to achieve default gateway failover if the primary gateway becomes inaccessible.

Protocol Independent Multicast (PIM) has no inherent redundancy capabilities and its operation is completely independent of VRRP group states. As a result, IP multicast traffic is forwarded not necessarily by the same
device as is elected by VRRP. The VRRP Aware PIM feature provides consistent IP multicast forwarding in a redundant network with virtual routing groups enabled.

In a multi-access segment (such as LAN), PIM designated router (DR) election is unaware of the redundancy configuration, and the elected DR and VRRP master router (MR) may not be the same router. In order to ensure that the PIM DR is always able to forward PIM Join/Prune message towards RP or FHR, the VRRP MR becomes the PIM DR (if there is only one VRRP group). PIM is responsible for adjusting DR priority based on the group state. When a fail over occurs, multicast states are created on the new MR elected by the VRRP group and the MR assumes responsibility for the routing and forwarding of all the traffic addressed to the VRRP virtual IP address. This ensures the PIM DR runs on the same gateway as the VRRP MR and maintains mroutestates. It enables multicast traffic to be forwarded through the VRRP MR, allowing PIM to leverage VRRP redundancy, avoid potential duplicate traffic, and enable fail over, depending on the VRRP states in the device.

Virtual Router Redundancy Service (VRRS) provides public APIs for a client to communicate with VRRP. VRRP Aware PIM is a feature of VRRS that supports VRRPv3 (unified VRRP) in both IPv4 and IPv6.

PIM, as a VRRS client, uses the VRRS client API to obtain generic First Hop Redundancy Protocol (FHRP) state and configuration information in order to provide multicast redundancy functionalities.

PIM performs the following as a VRRS client:

- Listens to state change and update notification from VRRS server (i.e., VRRP).
- Automatically adjust PIM DR priority based on VRRP state.
- Upon VRRP fail over, PIM receives state change notification from VRRS for the tracked VRRP group and ensures traffic is forwarded through VRRP MR.

### How to Configure VRRP Aware PIM

#### Configuring VRRP Aware PIM

##### SUMMARY STEPS

1. enable
2. configure terminal
3. fhrp version vrrp version
4. interface type number
5. ip address address {primary | secondary}
6. vrrp group id address-family ipv4
7. vrrs leader group name
8. vrrp group id ip ip address {primary | secondary}
9. exit
10. interface type number
11. ip pim redundancy group name vrrp dr-priority priority-value
12. end

### Configuration Examples for VRRP Aware PIM

**Example: VRRP Aware PIM**

```conf terminal
   fhrp version vrrp v3
   interface Ethernet0/0
   ip address 192.0.2.2
   vrrp 1 address-family ipv4
   vrrp 1 ip 10.1.6.1
   vrrs leader VRRP1
   interface Ethernet0/0
   ip pim redundancy VRRP1 vrrp dr-priority 90
```

Configuring SSM

Prerequisites for Configuring SSM

The following are the prerequisites for configuring source-specific multicast (SSM) and SSM mapping:

- Before you configure SSM mapping, you must perform the following tasks:
  - Enable IP multicast routing.
  - Enable PIM sparse mode.
  - Configure SSM.

- Before you configure static SSM mapping, you must configure access control lists (ACLs) that define the group ranges to be mapped to source addresses.

- Before you can configure and use SSM mapping with DNS lookups, you need to add records to a running DNS server. If you do not already have a DNS server running, you need to install one.

  Note
  You can use a product such as Cisco Network Registrar to add records to a running DNS server.

Restrictions for Configuring SSM

The following are the restrictions for configuring SSM:
Restrictions for Configuring SSM

- To run SSM with IGMPv3, SSM must be supported in the Cisco IOS router, the host where the application is running, and the application itself.

- Existing applications in a network predating SSM will not work within the SSM range unless they are modified to support (S, G) channel subscriptions. Therefore, enabling SSM in a network may cause problems for existing applications if they use addresses within the designated SSM range.

- IGMP Snooping—IGMPv3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.

- Address management is still necessary to some degree when SSM is used with Layer 2 switching mechanisms. Cisco Group Management Protocol (CGMP), IGMP snooping, or Router-Port Group Management Protocol (RGMP) support only group-specific filtering, not (S, G) channel-specific filtering. If different receivers in a switched network request different (S, G) channels sharing the same group, they do not benefit from these existing mechanisms. Instead, both receivers receive all (S, G) channel traffic and filter out the unwanted traffic on input. Because SSM can re-use the group addresses in the SSM range for many independent applications, this situation can lead to decreased traffic filtering in a switched network. For this reason, it is important to use random IP addresses from the SSM range for an application to minimize the chance for re-use of a single address within the SSM range between different applications. For example, an application service providing a set of television channels should, even with SSM, use a different group for each television (S, G) channel. This setup guarantees that multiple receivers to different channels within the same application service never experience traffic aliasing in networks that include Layer 2 devices.

- In PIM-SSM, the last hop router will continue to periodically send (S, G) join messages if appropriate (S, G) subscriptions are on the interfaces. Therefore, as long as receivers send (S, G) subscriptions, the shortest path tree (SPT) state from the receivers to the source will be maintained, even if the source is not sending traffic for longer periods of time (or even never).

  The opposite situation occurs with PIM-SM, where (S, G) state is maintained only if the source is sending traffic and receivers are joining the group. If a source stops sending traffic for more than 3 minutes in PIM-SM, the (S, G) state is deleted and only reestablished after packets from the source arrive again through the RPT (rendezvous point tree). Because no mechanism in PIM-SSM notifies a receiver that a source is active, the network must maintain the (S, G) state in PIM-SSM as long as receivers are requesting receipt of that channel.

The following are the restrictions for configuring SSM mapping:

- The SSM Mapping feature does not share the benefit of full SSM. SSM mapping takes a group G join from a host and identifies this group with an application associated with one or more sources, therefore, it can only support one such application per group G. Nevertheless, full SSM applications may still share the same group also used in SSM mapping.

- Enable IGMPv3 with care on the last hop router when you rely solely on SSM mapping as a transition solution for full SSM. When you enable both SSM mapping and IGMPv3 and the hosts already support IGMPv3 (but not SSM), the hosts send IGMPv3 group reports. SSM mapping does not support these IGMPv3 group reports, and the router does not correctly associate sources with these reports.
Information About SSM and SSM Mapping

SSM Components Overview

SSM is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. It is an extension of IP multicast in which datagram traffic is forwarded to receivers from only those multicast sources that the receivers have explicitly joined. For multicast groups configured for SSM, only SSM distribution trees (no shared trees) are created.

SSM is a core networking technology for Cisco's implementation of IP multicast solutions targeted for audio and video broadcast application environments and is described in RFC 3569. The following components together support the implementation of SSM:

- Protocol Independent Multicast source-specific mode (PIM-SSM)
- Internet Group Management Protocol Version 3 (IGMPv3)

Protocol Independent Multicast (PIM) SSM, or PIM-SSM, is the routing protocol that supports the implementation of SSM and is derived from PIM sparse mode (PIM-SM). IGMP is the Internet Engineering Task Force (IETF) standards track protocol used for hosts to signal multicast group membership to routers. IGMP Version 3 supports source filtering, which is required for SSM. IGMP For SSM to run with IGMPv3, SSM must be supported in the router, the host where the application is running, and the application itself.

How SSM Differs from Internet Standard Multicast

The standard IP multicast infrastructure in the Internet and many enterprise intranets is based on the PIM-SM protocol and Multicast Source Discovery Protocol (MSDP). These protocols have proved to be reliable, extensive, and efficient. However, they are bound to the complexity and functionality limitations of the Internet Standard Multicast (ISM) service model. For example, with ISM, the network must maintain knowledge about which hosts in the network are actively sending multicast traffic. With SSM, this information is provided by receivers through the source addresses relayed to the last-hop devices by IGMPv3. SSM is an incremental response to the issues associated with ISM and is intended to coexist in the network with the protocols developed for ISM. In general, SSM provides IP multicast service for applications that utilize SSM.

ISM service is described in RFC 1112. This service consists of the delivery of IP datagrams from any source to a group of receivers called the multicast host group. The datagram traffic for the multicast host group consists of datagrams with an arbitrary IP unicast source address S and the multicast group address G as the IP destination address. Systems will receive this traffic by becoming members of the host group. Membership in a host group simply requires signaling the host group through IGMP Version 1, 2, or 3.

In SSM, delivery of datagrams is based on (S, G) channels. Traffic for one (S, G) channel consists of datagrams with an IP unicast source address S and the multicast group address G as the IP destination address. Systems will receive this traffic by becoming members of the (S, G) channel. In both SSM and ISM, no signaling is required to become a source. However, in SSM, receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources. In other words, receivers can receive traffic only from (S, G) channels to which they are subscribed, whereas in ISM, receivers need not know the IP addresses of sources from which they receive their traffic. The proposed standard approach for channel subscription signaling utilizes IGMP INCLUDE mode membership reports, which are supported only in IGMP Version 3.
SSM can coexist with the ISM service by applying the SSM delivery model to a configured subset of the IP multicast group address range. The Internet Assigned Numbers Authority (IANA) has reserved the address range from 232.0.0.0 through 232.255.255.255 for SSM applications and protocols. The software allows SSM configuration for an arbitrary subset of the IP multicast address range from 224.0.0.0 through 239.255.255.255. When an SSM range is defined, an existing IP multicast receiver application will not receive any traffic when it tries to use addresses in the SSM range unless the application is modified to use explicit (S, G) channel subscription or is SSM-enabled through a URL Rendezvous Directory (URD).

SSM Operations

An established network in which IP multicast service is based on PIM-SM can support SSM services. SSM can also be deployed alone in a network without the full range of protocols that are required for interdomain PIM-SM. That is, SSM does not require an RP, so there is no need for an RP mechanism such as Auto-RP, MSDP, or bootstrap router (BSR).

If SSM is deployed in a network that is already configured for PIM-SM, then only the last-hop routers must be upgraded to a software image that supports SSM. Routers that are not directly connected to receivers do not have to upgrade to a software image that supports SSM. In general, these non-last-hop routers must only run PIM-SM in the SSM range. They may need additional access control configuration to suppress MSDP signaling, registering, or PIM-SM shared-tree operations from occurring within the SSM range.

The SSM mode of operation is enabled by configuring the SSM range using the `ip pim ssm` global configuration command. This configuration has the following effects:

- For groups within the SSM range, (S, G) channel subscriptions are accepted through IGMPv3 INCLUDE mode membership reports.
- PIM operations within the SSM range of addresses change to PIM-SSM, a mode derived from PIM-SM. In this mode, only PIM (S, G) Join and Prune messages are generated by the router. Incoming messages related to rendezvous point tree (RPT) operations are ignored or rejected, and incoming PIM register messages are immediately answered with Register-Stop messages. PIM-SSM is backward-compatible with PIM-SM unless a router is a last-hop router. Therefore, routers that are not last-hop routers can run PIM-SM for SSM groups (for example, if they do not yet support SSM).
- For groups within the SSM range, no MSDP Source-Active (SA) messages within the SSM range will be accepted, generated, or forwarded.

IGMPv3 Host Signaling

IGMPv3 is the third version of the IETF standards track protocol in which hosts signal membership to last-hop routers of multicast groups. IGMPv3 introduces the ability for hosts to signal group membership that allows filtering capabilities with respect to sources. A host can signal either that it wants to receive traffic from all sources sending to a group except for some specific sources (a mode called EXCLUDE) or that it wants to receive traffic only from some specific sources sending to the group (a mode called INCLUDE).

IGMPv3 can operate with both ISM and SSM. In ISM, both EXCLUDE and INCLUDE mode reports are accepted by the last-hop router. In SSM, only INCLUDE mode reports are accepted by the last-hop router.
Benefits of SSM

**IP Multicast Address Management Not Required**

In the ISM service, applications must acquire a unique IP multicast group address because traffic distribution is based only on the IP multicast group address used. If two applications with different sources and receivers use the same IP multicast group address, then receivers of both applications will receive traffic from the senders of both applications. Even though the receivers, if programmed appropriately, can filter out the unwanted traffic, this situation would cause generally unacceptable levels of unwanted traffic.

Allocating a unique IP multicast group address for an application is still a problem. Most short-lived applications use mechanisms like Session Description Protocol (SDP) and Session Announcement Protocol (SAP) to get a random address, a solution that does not work well with a rising number of applications in the Internet. The best current solution for long-lived applications is described in RFC 2770, but this solution suffers from the restriction that each autonomous system is limited to only 255 usable IP multicast addresses.

In SSM, traffic from each source is forwarded between routers in the network independent of traffic from other sources. Thus different sources can reuse multicast group addresses in the SSM range.

**Denial of Service Attacks from Unwanted Sources Inhibited**

In SSM, multicast traffic from each individual source will be transported across the network only if it was requested (through IGMPv3, IGMP v3lite, or URD memberships) from a receiver. In contrast, ISM forwards traffic from any active source sending to a multicast group to all receivers requesting that multicast group. In Internet broadcast applications, this ISM behavior is highly undesirable because it allows unwanted sources to easily disturb the actual Internet broadcast source by simply sending traffic to the same multicast group. This situation depletes bandwidth at the receiver side with unwanted traffic and thus disrupts the undisturbed reception of the Internet broadcast. In SSM, this type of denial of service (DoS) attack cannot be made by simply sending traffic to a multicast group.

**Easy to Install and Manage**

SSM is easy to install and provision in a network because it does not require the network to maintain which active sources are sending to multicast groups. This requirement exists in ISM (with IGMPv1, IGMPv2, or IGMPv3).

The current standard solutions for ISM service are PIM-SM and MSDP. Rendezvous point (RP) management in PIM-SM (including the necessity for Auto-RP or BSR) and MSDP is required only for the network to learn about active sources. This management is not necessary in SSM, which makes SSM easier than ISM to install and manage, and therefore easier than ISM to operationally scale in deployment. Another factor that contributes to the ease of installation of SSM is the fact that it can leverage preexisting PIM-SM networks and requires only the upgrade of last hop routers to support IGMPv3, IGMP v3lite, or URD.

**Ideal for Internet Broadcast Applications**

The three benefits previously described make SSM ideal for Internet broadcast-style applications for the following reasons:

- The ability to provide Internet broadcast services through SSM without the need for unique IP multicast addresses allows content providers to easily offer their service (IP multicast address allocation has been a serious problem for content providers in the past).

- The prevention against DoS attacks is an important factor for Internet broadcast services because, with their exposure to a large number of receivers, they are the most common targets for such attacks.
• The ease of installation and operation of SSM makes it ideal for network operators, especially in those cases where content needs to be forwarded between multiple independent PIM domains (because there is no need to manage MSDP for SSM between PIM domains).

SSM Mapping Overview

SSM mapping supports SSM transition when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. Using SSM to deliver live streaming video to legacy STBs that do not support IGMPv3 or for applications that do not use the IGMPv3 host stack is a typical application of SSM mapping.

In a typical STB deployment, each TV channel uses one separate IP multicast group and has one active server host sending the TV channel. A single server may of course send multiple TV channels, but each to a different group. In this network environment, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group G, the report implicitly addresses the well-known TV server for the TV channel associated with the multicast group.

SSM mapping introduces a means for the last hop router to discover sources sending to groups. When SSM mapping is configured, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group G, the router translates this report into one or more (S, G) channel memberships for the well-known sources associated with this group.

When the router receives an IGMPv1 or IGMPv2 membership report for group G, the router uses SSM mapping to determine one or more source IP addresses for group G. SSM mapping then translates the membership report as an IGMPv3 report INCLUDE (G, [S1, G], [S2, G]...[Sn, G]) and continues as if it had received an IGMPv3 report. The router then sends out PIM joins toward (S1, G) to (Sn, G) and continues to be joined to these groups as long as it continues to receive the IGMPv1 or IGMPv2 membership reports and as long as it continues to receive the IGMPv1 or IGMPv2 membership reports, and the SSM mapping for the group remains the same. SSM mapping, thus, enables you to leverage SSM for video delivery to legacy STBs that do not support IGMPv3 or for applications that do not take advantage of the IGMPv3 host stack.

SSM mapping enables the last hop router to determine the source addresses either by a statically configured table on the router or by consulting a DNS server. When the statically configured table is changed, or when the DNS mapping changes, the router will leave the current sources associated with the joined groups.

Static SSM Mapping

SSM static mapping enables you to configure the last hop router to use a static map to determine the sources sending to groups. Static SSM mapping requires that you configure access lists (ACLs) to define group ranges. The groups permitted by those ACLs then can be mapped to sources using the `ip igmp static ssm-map` global configuration command.

You can configure static SSM mapping in smaller networks when a DNS is not needed or to locally override DNS mappings that may be temporarily incorrect. When configured, static SSM mappings take precedence over DNS mappings.

DNS-Based SSM Mapping

DNS-based SSM mapping enables you to configure the last hop router to perform a reverse DNS lookup to determine sources sending to groups (see the figure below). When DNS-based SSM mapping is configured, the router constructs a domain name that includes the group address G and performs a reverse lookup into the DNS. The router looks up IP address resource records (IP A RRs) to be returned for this constructed domain
name and uses the returned IP addresses as the source addresses associated with this group. SSM mapping supports up to 20 sources for each group. The router joins all sources configured for a group.

**Figure 15: DNS-Based SSM-Mapping**

The SSM mapping mechanism that enables the last hop router to join multiple sources for a group can be used to provide source redundancy for a TV broadcast. In this context, the redundancy is provided by the last hop router using SSM mapping to join two video sources simultaneously for the same TV channel. However, to prevent the last hop router from duplicating the video traffic, it is necessary that the video sources utilize a server-side switchover mechanism where one video source is active while the other backup video source is passive. The passive source waits until an active source failure is detected before sending the video traffic for the TV channel. The server-side switchover mechanism, thus, ensures that only one of the servers is actively sending the video traffic for the TV channel.

To look up one or more source addresses for a group G that includes G1, G2, G3, and G4, the following DNS resource records (RRs) must be configured on the DNS server:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IN A source-address-2</td>
</tr>
<tr>
<td></td>
<td>IN A source-address-n</td>
</tr>
</tbody>
</table>

The `multicast-domain` argument is a configurable DNS prefix. The default DNS prefix is in-addr.arpa. You should only use the default prefix when your installation is either separate from the internet or if the group names that you map are global scope group addresses (RFC 2770 type addresses that you configure for SSM) that you own.

The `timeout` argument configures the length of time for which the router performing SSM mapping will cache the DNS lookup. This argument is optional and defaults to the timeout of the zone in which this entry is configured. The timeout indicates how long the router will keep the current mapping before querying the DNS server for this group. The timeout is derived from the cache time of the DNS RR entry and can be configured for each group/source entry on the DNS server. You can configure this time for larger values if you want to minimize the number of DNS queries generated by the router. Configure this time for a low value if you want to be able to quickly update all routers with new source addresses.
SSM Mapping Benefits

- The SSM Mapping feature provides almost the same ease of network installation and management as a pure SSM solution based on IGMPv3. Some additional configuration is necessary to enable SSM mapping.

- The SSM benefit of inhibition of DoS attacks applies when SSM mapping is configured. When SSM mapping is configured the only segment of the network that may still be vulnerable to DoS attacks are receivers on the LAN connected to the last hop router. Since those receivers may still be using IGMPv1 and IGMPv2, they are vulnerable to attacks from unwanted sources on the same LAN. SSM mapping, however, does protect those receivers (and the network path leading towards them) from multicast traffic from unwanted sources anywhere else in the network.

- Address assignment within a network using SSM mapping needs to be coordinated, but it does not need assignment from outside authorities, even if the content from the network is to be transited into other networks.

How to Configure SSM and SSM Mapping

Configuring SSM

Follow these steps to configure SSM:

This procedure is optional.

**Before you begin**

If you want to use an access list to define the Source Specific Multicast (SSM) range, configure the access list before you reference the access list in the `ip pim ssm` command.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip pim ssm [default | range access-list]
4. interface type number
5. ip pim {sparse-mode | sparse-dense-mode}
6. ip igmp version 3
7. end
8. show running-config
### 9. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | **enable**  
Example: Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| Step 2 | **configure terminal**  
Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | **ip pim ssm [default | range access-list]**  
Example: Device(config)# ip pim ssm range 20 | Defines the SSM range of IP multicast addresses. |
| Step 4 | **interface type number**  
Example: Device(config)# interface gigabitethernet 1/0/1 | Selects an interface that is connected to hosts on which IGMPv3 can be enabled, and enters the interface configuration mode. |
| Step 5 | **ip pim {sparse-mode | sparse-dense-mode}**  
Example: Device(config-if)# ip pim sparse-mode | Enables PIM on an interface. |
| Step 6 | **ip igmp version 3**  
Example: Device(config-if)# ip igmp version 3 | Enables IGMPv3 on this interface. The default version of IGMP is set to Version 2. |
| Step 7 | **end**  
Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 8 | **show running-config**  
Example: | Verifies your entries. |
Configuring SSM Mapping

Configuring Static SSM Mapping

Follow these steps to configure static SSM Mapping:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp ssm-map enable
4. no ip igmp ssm-map query dns
5. ip igmp ssm-map static access-list source-address
6. end
7. show running-config
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| enable
| Example:
| Device> enable |
| Enables privileged EXEC mode.
| • Enter your password if prompted. |
| **Step 2**
| configure terminal
| Example:
| Device# configure terminal |
| Enters global configuration mode. |
| **Step 3**
| ip igmp ssm-map enable
| Example:
| Device(config)# ip igmp ssm-map enable |
| Enables SSM mapping for groups in the configured SSM range.
<p>| Note: By default, this command enables DNS-based SSM mapping. |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>(Optional) Disables DNS-based SSM mapping.</td>
</tr>
<tr>
<td>no ip igmp ssm-map query dns</td>
<td><strong>Example:</strong> Device(config)# no ip igmp ssm-map query dns</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Disable DNS-based SSM mapping if you only want to rely on static SSM mapping. By default, the <code>ip igmp ssm-map</code> command enables DNS-based SSM mapping.</td>
</tr>
</tbody>
</table>

| **Step 5** | Configures static SSM mapping. |
| ip igmp ssm-map static access-list source-address | **Example:** Device(config)# ip igmp ssm-map static 11 172.16.8.11 |
| **Note** | - The ACL supplied for the `access-list` argument defines the groups to be mapped to the source IP address entered for the `source-address` argument. |
| | - You can configure additional static SSM mappings. If additional SSM mappings are configured and the router receives an IGMPv1 or IGMPv2 membership report for a group in the SSM range, the device determines the source addresses associated with the group by walking each configured `ip igmp ssm-map static` command. The device associates up to 20 sources per group. |
| | Repeat Step to configure additional static SSM mappings, if required. |

| **Step 6** | Returns to privileged EXEC mode. |
| end | **Example:** Device(config)# end |

| **Step 7** | Verifies your entries. |
| show running-config | **Example:** Device# show running-config |

| **Step 8** | (Optional) Saves your entries in the configuration file. |
| copy running-config startup-config | **Example:** Device# copy running-config startup-config |

### Configuring DNS-Based SSM Mapping (CLI)

Perform this task to configure the last hop router to perform DNS lookups to learn the IP addresses of sources sending to a group.
Before you begin

- Enable IP multicast routing, enable PIM sparse mode, and configure SSM before performing this task. For more information, see the "Configuring Basic Multicast" module.
- Before you can configure and use SSM mapping with DNS lookups, you need to be able to add records to a running DNS server. If you do not already have a DNS server running, you need to install one.

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. ip igmp ssm-map enable  
4. ip igmp ssm-map query dns  
5. ip domain multicast domain-prefix  
6. ip name-server server-address1 [server-address2 server-address6]  
7. Repeat Step 6 to configure additional DNS servers for redundancy, if required.  
8. end  
9. show running-config  
10. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device# enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip igmp ssm-map enable</td>
<td>Enables SSM mapping for groups in a configured SSM range.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip igmp ssm-map enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip igmp ssm-map query dns</td>
<td>(Optional) Enables DNS-based SSM mapping.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip igmp ssm-map query dns</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ip domain multicast domain-prefix</td>
<td>(Optional) Changes the domain prefix used by the Cisco IOS XE software for DNS-based SSM mapping.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

*(Optional) Enables DNS-based SSM mapping.*

- By default, the `ip igmp ssm-map` command enables DNS-based SSM mapping. Only the *no* form of this command is saved to the running configuration.

**Note**

Use this command to reenable DNS-based SSM mapping if DNS-based SSM mapping is disabled.
### Configuring Static Traffic Forwarding with SSM Mapping

Follow these steps to configure static traffic forwarding with SSM mapping on the last hop router:

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp static-group group-address source ssm-map`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Purpose</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**

**Device**

configure terminal

**Example:**

Device# configure terminal

**Step 3**

**Device(config)**

interface interface-id

**Example:**

Device(config)# interface gigabitethernet 1/0/1

**Note**

Static forwarding of traffic with SSM mapping works with either DNS-based SSM mapping or statically configured SSM mapping.

**Step 4**

**Device(config-if)**

ip igmp static-group group-address source ssm-map

**Example:**

Device(config-if)# ip igmp static-group 239.1.2.1 source ssm-map

Confirms SSM mapping to statically forward a (S, G) channel from the interface.

Use this command if you want to statically forward SSM traffic for certain groups. Use DNS-based SSM mapping to determine the source addresses of the channels.

**Step 5**

**Device(config)**

end

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 6**

**Device**

show running-config

**Example:**

Device# show running-config

Verifies your entries.

**Step 7**

**Device**

copy running-config startup-config

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

**Verifying SSM Mapping Configuration and Operation**

Follow these steps to verify SSM mapping configuration and operation:
SUMMARY STEPS

1. enable
2. show ip igmp ssm-mapping
3. show ip igmp ssm-mapping group-address
4. show ip igmp groups [group-name | group-address | interface-type interface-number] [detail]
5. show host
6. debug ip igmp group-address

DETAILED STEPS

<table>
<thead>
<tr>

<tr>
<td></td>
<td></td>
<td>CSR Grp Exp: 00:02:59</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Group source list: (C - Cisco Src Report, U - URD, R - Remote, S - Static, M - SSM Mapping)</td>
</tr>
</tbody>
</table>
### Step 5

**show host**

**Example:**

```
Device# show host
Default domain is cisco.com
Name/address lookup uses domain service
Name servers are 10.48.81.21
Codes: UN - unknown, EX - expired, OK - OK, ?? - revalidate
        temp - temporary, perm - permanent
        NA - Not Applicable None - Not defined
Host Port Flags Age
Type Address(es)
10.0.0.0.ssm-map.cisco.c None (temp, OK) 0
IP 172.16.8.5
    172.16.8.6
    172.16.8.3
```

(Optional) Displays the default domain name, the style of name lookup service, a list of name server hosts, and the cached list of hostnames and addresses.

### Step 6

**debug ip igmp**  **group-address**

**Example:**

```
Device# debug ip igmp
IGMP(0): Convert IGMPv2 report (*,232.1.2.3) to IGMPv3 with 2 source(s) using STATIC.
Device# debug ip igmp
IGMP(0): Convert IGMPv2 report (*,232.1.2.3) to IGMPv3 with 2 source(s) using DNS.
Device# debug ip igmp
IGMP(0): DNS source lookup failed for (*, 232.1.2.3), IGMPv2 report failed
```

(Optional) Displays the IGMP packets received and sent and IGMP host-related events.

In the first example, the output indicates that the router is converting an IGMPv2 join for group G into an IGMPv3 join.

In the second example, the output indicates that a DNS lookup has succeeded.

In the third example, the output indicates that DNS-based SSM mapping is enabled and a DNS lookup has failed.

---

### Monitoring SSM and SSM Mapping

#### Monitoring SSM

To monitor SSM, use the following commands in privileged EXEC mode, as needed:
### Purpose

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# show ip igmp groups detail</td>
<td>Displays the (S, G) channel subscription through IGMPv3.</td>
</tr>
<tr>
<td>Device# show ip mroute</td>
<td>Displays whether a multicast group supports SSM service or whether a source-specific host report was received.</td>
</tr>
</tbody>
</table>

### Monitoring SSM Mapping

Use the privileged EXEC commands in the following table to monitor SSM mapping.

**Table 34: SSM Mapping Monitoring Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# show ip igmp ssm-mapping</td>
<td>Displays information about SSM mapping.</td>
</tr>
<tr>
<td>Device# show ip igmp ssm-mapping group-address</td>
<td>Displays the sources that SSM mapping uses for a particular group.</td>
</tr>
<tr>
<td>Device# show ip igmp groups [group-name</td>
<td>Displays the multicast groups with receivers that are [group-address]</td>
</tr>
<tr>
<td>Device# show host</td>
<td>Displays the default domain name, the style of name [detail] lookup service, a list of name server hosts, and the cached list of hostnames and addresses.</td>
</tr>
<tr>
<td>Device# debug ip igmp group-address</td>
<td>Displays the IGMP packets received and sent and IGMP host-related events.</td>
</tr>
</tbody>
</table>

### Configuration Examples for SSM and SSM Mapping

#### SSM with IGMPv3 Example

The following example shows how to configure a device (running IGMPv3) for SSM:

```
ip multicast-routing
!
interface GigabitEthernet3/1/0
  ip address 172.21.200.203 255.255.255.0
decription backbone interface
  ip pim sparse-mode
!
interface GigabitEthernet3/2/0
  ip address 131.108.1.2 255.255.255.0
decription ethernet connected to hosts
  ip pim sparse-mode
  ip igmp version 3
```
SSM Filtering Example

The following example shows how to configure filtering on legacy RP routers running software releases that do not support SSM routing. This filtering will suppress all unwanted PIM-SM and MSDP traffic in the SSM range. Without this filtering, SSM will still operate, but there may be additional RPT traffic if legacy first hop and last hop routers exist in the network.

```plaintext
ip access-list extended no-ssm-range
deny ip any 232.0.0.0 0.255.255.255 ! SSM range
permit ip any any
! Deny registering in SSM range
ip pim accept-register list no-ssm-range
ip access-list extended msdp-nono-list
deny ip any 232.0.0.0 0.255.255.255 ! SSM Range
!
!
! See ftp://ftpeng.cisco.com/ipmulticast/config-notes/msdp-sa-filter.txt for other SA messages that typically need to be filtered.
! Filter generated SA messages in SSM range. This configuration is only needed if there are directly connected sources to this router. The “ip pim accept-register” command filters remote sources.
ip msdp redistribute list msdp-nono-list
! Filter received SA messages in SSM range. “Filtered on receipt” means messages are neither processed or forwarded. Needs to be configured for each MSDP peer.
ip msdp sa-filter in msdp-peer1 list msdp-nono-list
!
!
ip msdp sa-filter in msdp-peerN list msdp-nono-list
```

SSM Mapping Example

The following configuration example shows a router configuration for SSM mapping. This example also displays a range of other IGMP and SSM configuration options to show compatibility between features. Do not use this configuration example as a model unless you understand all of the features used in the example.

```plaintext
Note
Address assignment in the global SSM range 232.0.0.0/8 should be random. If you copy parts or all of this sample configuration, make sure to select a random address range but not 232.1.1.x as shown in this example. Using a random address range minimizes the possibility of address collision and may prevent conflicts when other SSM content is imported while SSM mapping is used.

!
no ip domain lookup
ip domain multicast ssm.map.cisco.com
ip name-server 10.48.81.21
!
ip multicast-routing distributed
ip igmp ssm-map enable
```
ip igmp ssm-map static 10 172.16.8.10
ip igmp ssm-map static 11 172.16.8.11
!

### Table 35: SSM Mapping Configuration Example Command Descriptions

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no ip domain lookup</td>
<td>Disables IP DNS-based hostname-to-address translation. <strong>Note</strong> The <code>no ip domain-list</code> command is shown in the configuration only to demonstrate that disabling IP DNS-based hostname-to-address translation does not conflict with configuring SSM mapping. If this command is enabled, the Cisco IOS XE software will try to resolve unknown strings as hostnames.</td>
</tr>
<tr>
<td>ip domain multicast ssm-map.cisco.com</td>
<td>Specifies ssm-map.cisco.com as the domain prefix for SSM mapping.</td>
</tr>
<tr>
<td>ip name-server 10.48.81.21</td>
<td>Specifies 10.48.81.21 as the IP address of the DNS server to be used by SSM mapping and any other service in the software that utilizes DNS.</td>
</tr>
<tr>
<td>ip multicast-routing</td>
<td>Enables IP multicast routing.</td>
</tr>
<tr>
<td>ip igmp ssm-map enable</td>
<td>Enables SSM mapping.</td>
</tr>
</tbody>
</table>
| ip igmp ssm-map static 10 172.16.8.10 | Configures the groups permitted by ACL 10 to use source address 172.16.8.10.  
  - In this example, ACL 10 permits all groups in the 232.1.2.0/25 range except 232.1.2.10. |
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| **ip igmp ssm-map static 11 172.16.8.11** | Configures the groups permitted by ACL 11 to use source address 172.16.8.11.  
  - In this example, ACL 11 permits group 232.1.2.10. |
| **ip pim sparse-mode** | Enables PIM sparse mode. |
| **ip igmp last-member-query-interval 100** | Reduces the leave latency for IGMPv2 hosts.  
  **Note** This command is not required for configuring SSM mapping; however, configuring this command can be beneficial for IGMPv2 hosts relying on SSM mapping. |
| **ip igmp static-group 232.1.2.1 source ssm-map** | Configures SSM mapping to be used to determine the sources associated with group 232.1.2.1. The resulting (S, G) channels are statically forwarded. |
| **ip igmp version 3** | Enables IGMPv3 on this interface.  
  **Note** This command is shown in the configuration only to demonstrate that IGMPv3 can be configured simultaneously with SSM mapping; however, it is not required. |
| **ip igmp explicit-tracking** | Minimizes the leave latency for IGMPv3 host leaving a multicast channel.  
  **Note** This command is not required for configuring SSM mapping. |
| **ip igmp limit 2** | Limits the number of IGMP states resulting from IGMP membership states on a per-interface basis.  
  **Note** This command is not required for configuring SSM mapping. |
| **ip igmp v3lite** | Enables the acceptance and processing of IGMP v3lite membership reports on this interface.  
  **Note** This command is shown in the configuration only to demonstrate that IGMP v3lite can be configured simultaneously with SSM mapping; however, it is not required. |
| **ip urd** | Enables interception of TCP packets sent to the reserved URD port 465 on an interface and processing of URD channel subscription reports.  
  **Note** This command is shown in the configuration only to demonstrate that URD can be configured simultaneously with SSM mapping; however, it is not required. |
| **ip pim ssm default** | Configures SSM service.  
  The **default** keyword defines the SSM range access list as 232/8. |
**Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-list 10 permit 232.1.2.10 0.0.0.255</td>
<td>Configures the ACLs to be used for static SSM mapping.</td>
</tr>
<tr>
<td>access-list 11 permit 232.1.2.0 0.0.0.255</td>
<td>Note: These are the ACLs that are referenced by the <code>ip igmp ssm-map static</code> commands in this configuration example.</td>
</tr>
</tbody>
</table>

**DNS Server Configuration Example**

To configure DNS-based SSM mapping, you need to create a DNS server zone or add records to an existing zone. If the routers that are using DNS-based SSM mapping are also using DNS for other purposes besides SSM mapping, you should use a normally-configured DNS server. If DNS-based SSM mapping is the only DNS implementation being used on the router, you can configure a fake DNS setup with an empty root zone, or a root zone that points back to itself.

The following example shows how to create a zone and import the zone data using Network Registrar:

```
Router> zone 1.1.232.ssm-map.cisco.com. create primary file=named.ssm-map
100 Ok
Router> dns reload
100 Ok
```

The following example shows how to import the zone files from a `named.conf` file for BIND 8:

```
Router> ::import named.conf /etc/named.conf
Router> dns reload
100 Ok:
```

**Note**

Network Registrar version 8.0 and later support import BIND 8 format definitions.

First Hop Protocols

- Configuring HSRP and VRRP, on page 289
CHAPTER 20

Configuring HSRP and VRRP

• Configuring HSRP and VRRP, on page 289

Configuring HSRP and VRRP

This chapter describes how to use Hot Standby Router Protocol (HSRP) to provide routing redundancy for routing IP traffic without being dependent on the availability of any single router.

You can also use a version of HSRP in Layer 2 mode to configure a redundant command switch to take over cluster management if the cluster command switch fails.

Virtual Router Redundancy Protocol (VRRP) is supported for IPv4 on switches running IP Lite image.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring HSRP

HSRP Overview

HSRP is Cisco’s standard method of providing high network availability by providing first-hop redundancy for IP hosts on an IEEE 802 LAN configured with a default gateway IP address. HSRP routes IP traffic without relying on the availability of any single router. It enables a set of router interfaces to work together to present the appearance of a single virtual router or default gateway to the hosts on a LAN. When HSRP is configured on a network or segment, it provides a virtual Media Access Control (MAC) address and an IP address that is shared among a group of configured routers. HSRP allows two or more HSRP-configured routers to use the MAC address and IP network address of a virtual router. The virtual router does not exist; it represents the common target for routers that are configured to provide backup to each other. One of the routers is selected
to be the active router and another to be the standby router, which assumes control of the group MAC address and IP address should the designated active router fail.

**Note**

Routers in an HSRP group can be any router interface that supports HSRP, including routed ports and switch virtual interfaces (SVIs).

HSRP provides high network availability by providing redundancy for IP traffic from hosts on networks. In a group of router interfaces, the active router is the router of choice for routing packets; the standby router is the router that takes over the routing duties when an active router fails or when preset conditions are met.

HSRP is useful for hosts that do not support a router discovery protocol and cannot switch to a new router when their selected router reloads or loses power. When HSRP is configured on a network segment, it provides a virtual MAC address and an IP address that is shared among router interfaces in a group of router interfaces running HSRP. The router selected by the protocol to be the active router receives and routes packets destined for the group's MAC address. For n routers running HSRP, there are n+1 IP and MAC addresses assigned.

HSRP detects when the designated active router fails, and a selected standby router assumes control of the Hot Standby group's MAC and IP addresses. A new standby router is also selected at that time. Devices running HSRP send and receive multicast UDP-based hello packets to detect router failure and to designate active and standby routers. When HSRP is configured on an interface, Internet Control Message Protocol (ICMP) redirect messages are automatically enabled for the interface.

You can configure multiple Hot Standby groups among switches and switch stacks that are operating in Layer 3 to make more use of the redundant routers.

To do so, specify a group number for each Hot Standby command group you configure for an interface. For example, you might configure an interface on switch 1 as an active router and one on switch 2 as a standby router and also configure another interface on switch 2 as an active router with another interface on switch 1 as its standby router.

The following figure shows a segment of a network configured for HSRP. Each router is configured with the MAC address and IP network address of the virtual router. Instead of configuring hosts on the network with the IP address of Router A, you configure them with the IP address of the virtual router as their default router. When Host C sends packets to Host B, it sends them to the MAC address of the virtual router. If for any reason, Router A stops transferring packets, Router B responds to the virtual IP address and virtual MAC address and becomes the active router, assuming the active router duties. Host C continues to use the IP address of the virtual router to address packets destined for Host B, which Router B now receives and sends to Host B. Until Router A resumes operation, HSRP allows Router B to provide uninterrupted service to users on Host C’s segment that need to communicate with users on Host B’s segment and also continues to perform its normal function of handling packets between the Host A segment and Host B.
HSRP Versions

and later support these Hot Standby Router Protocol (HSRP) versions:

The switch supports these HSRP versions:

- **HSRPv1** - Version 1 of the HSRP, the default version of HSRP. It has these features:
  - The HSRP group number can be from 0 to 255.
  - HSRPv1 uses the multicast address 224.0.0.2 to send hello packets, which can conflict with Cisco Group Management Protocol (CGMP) leave processing. You cannot enable HSRPv1 and CGMP at the same time; they are mutually exclusive.

- **HSRPv2** - Version 2 of the HSRP has these features:
  - To match the HSRP group number to the VLAN ID of a subinterface, HSRPv2 can use a group number from 0 to 4095 and a MAC address from 0000.0C9F.F000 to 0000.0C9F.FFFF.
  - HSRPv2 uses the multicast address 224.0.0.102 to send hello packets. HSRPv2 and CGMP leave processing are no longer mutually exclusive, and both can be enabled at the same time.
  - HSRPv2 has a different packet format than HSRPv1.

A switch running HSRPv1 cannot identify the physical router that sent a hello packet because the source MAC address of the router is the virtual MAC address.

HSRPv2 has a different packet format than HSRPv1. A HSRPv2 packet uses the type-length-value (TLV) format and has a 6-byte identifier field with the MAC address of the physical router that sent the packet.
If an interface running HSRPv1 gets an HSRPv2 packet, the type field is ignored.

**Multiple HSRP**

The switch supports Multiple HSRP (MHSRP), an extension of HSRP that allows load sharing between two or more HSRP groups. You can configure MHSRP to achieve load-balancing and to use two or more standby groups (and paths) from a host network to a server network.

In the figure below, half the clients are configured for Router A, and half the clients are configured for Router B. Together, the configuration for Routers A and B establishes two HSRP groups. For group 1, Router A is the default active router because it has the assigned highest priority, and Router B is the standby router. For group 2, Router B is the default active router because it has the assigned highest priority, and Router A is the standby router. During normal operation, the two routers share the IP traffic load. When either router becomes unavailable, the other router becomes active and assumes the packet-transfer functions of the router that is unavailable.

---

**Note**

For MHSRP, you need to enter the `standby preempt` interface configuration command on the HSRP interfaces so that if a router fails and then comes back up, preemption restores load sharing.

---

**Figure 17: MHSRP Load Sharing**

---

**SSO HSRP**

SSO HSRP alters the behavior of HSRP when a device with redundant Route Processors (RPs) is configured for stateful switchover (SSO) redundancy mode. When an RP is active and the other RP is standby, SSO enables the standby RP to take over if the active RP fails.

With this functionality, HSRP SSO information is synchronized to the standby RP, allowing traffic that is sent using the HSRP virtual IP address to be continuously forwarded during a switchover without a loss of data or a path change. Additionally, if both RPs fail on the active HSRP device, then the standby HSRP device takes over as the active HSRP device.

The feature is enabled by default when the redundancy mode of operation is set to SSO.
HSRP and Switch Stacks

HSRP hello messages are generated by the stack master. If an HSRP-active stack master fails, a flap in the HSRP active state might occur. This is because HSRP hello messages are not generated while a new stack master is elected and initialized, and the standby router might become active after the stack master fails.

How to Configure HSRP

Default HSRP Configuration

</tbody>
</table>

HSRP Configuration Guidelines

- HSRPv2 and HSRPv1 are mutually exclusive. HSRPv2 is not interoperable with HSRPv1 on an interface and the reverse.

- In the procedures, the specified interface must be one of these Layer 3 interfaces:
  - Routed port: A physical port configured as a Layer 3 port by entering the `no switchport` command in interface configuration mode.
  - SVI: A VLAN interface created by using the `interface vlan vlan_id` in global configuration mode, and by default a Layer 3 interface.
  - Etherchannel port channel in Layer 3 mode: A port-channel logical interface created by using the `interface port-channel port-channel-number` in global configuration mode, and binding the Ethernet interface into the channel group.

- All Layer 3 interfaces must have IP addresses assigned to them.

- The version of an HSRP group can be changed from HSRPv2 to HSRPv1 only if the group number is less than 256.
If you change the HSRP version on an interface, each HSRP group resets because it now has a new virtual MAC address.

Only on mixed stacks of Catalyst switches:

- HSRP groups can be configured up to 32 instances.

- Configure only one instance of a First Hop Redundancy Protocol (FHRP). The switches support HSRPv1, HSRPv2, and HSRP for IPv6.

- HSRP for IPv4 and HSRP for IPv6 are mutually exclusive. You cannot enable both at the same time.

- When configuring group numbers for HSRPv2 and HSRP, you must use group numbers in ranges that are multiples of 256. Valid ranges are 0 to 255, 256 to 511, 512 to 767, 3840 to 4095, and so on.

Examples of valid and invalid group numbers:

- If you configure groups with the numbers 2, 150, and 225, you cannot configure another group with the number 3850. It is not in the range of 0 to 255.

- If you configure groups with the numbers 520, 600, and 700, you cannot configure another group with the number 900. It is not in the range of 512 to 767.

Enabling HSRP

The **standby ip** interface configuration command activates HSRP on the configured interface. If an IP address is specified, that address is used as the designated address for the Hot Standby group. If no IP address is specified, the address is learned through the standby function. You must configure at least one Layer 3 port on the LAN with the designated address. Configuring an IP address always overrides another designated address currently in use.

When the **standby ip** command is enabled on an interface and proxy ARP is enabled, if the interface's Hot Standby state is active, proxy ARP requests are answered using the Hot Standby group MAC address. If the interface is in a different state, proxy ARP responses are suppressed.

**SUMMARY STEPS**

1. configure terminal
2. interface *interface-id*
3. standby version { 1 | 2 }
4. standby [group-number] ip [ip-address [secondary]]
5. end
6. show standby [interface-id [group]]
7. copy running-config startup-config

**DETAILED STEPS**

Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)
### Enabling HSRP

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 2 | `interface interface-id`  
**Example:**  
Switch(config)# interface gigabitethernet1/0/1 | Enters interface configuration mode, and enter the Layer 3 interface on which you want to enable HSRP. |
| Step 3 | `standby version { 1 | 2 }`  
**Example:**  
Switch(config-if)# standby version 1 | (Optional) Configures the HSRP version on the interface.  
- 1 - Selects HSRPv1.  
- 2 - Selects HSRPv2.  
If you do not enter this command or do not specify a keyword, the interface runs the default HSRP version, HSRP v1. |
| Step 4 | `standby [group-number] ip [ip-address [secondary]]`  
**Example:**  
Switch(config-if)# standby 1 ip | Creates (or enable) the HSRP group using its number and virtual IP address.  
- (Optional) group-number- The group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number.  
- (Optional on all but one interface) ip-address- The virtual IP address of the hot standby router interface. You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces.  
- (Optional) secondary- The IP address is a secondary hot standby router interface. If neither router is designated as a secondary or standby router and no priorities are set, the primary IP addresses are compared and the higher IP address is the active router, with the next highest as the standby router. |
| Step 5 | `end`  
**Example:**  
Switch(config-if)# end | Returns to privileged EXEC mode |
| Step 6 | `show standby [interface-id [group]]`  
**Example:**  
Switch # show standby | Verifies the configuration of the standby groups. |
| Step 7 | `copy running-config startup-config`  
**Example:**  
Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
Configuring HSRP Priority

The **standby priority**, **standby preempt**, and **standby track** interface configuration commands are all used to set characteristics for finding active and standby routers and behavior regarding when a new active router takes over.

When configuring HSRP priority, follow these guidelines:

- Assigning a priority allows you to select the active and standby routers. If preemption is enabled, the router with the highest priority becomes the active router. If priorities are equal, the current active router does not change.
- The highest number (1 to 255) represents the highest priority (most likely to become the active router).
- When setting the priority, preempt, or both, you must specify at least one keyword (**priority**, **preempt**, or both)
- The priority of the device can change dynamically if an interface is configured with the **standby track** command and another interface on the router goes down.
- The **standby track** interface configuration command ties the router hot standby priority to the availability of its interfaces and is useful for tracking interfaces that are not configured for HSRP. When a tracked interface fails, the hot standby priority on the device on which tracking has been configured decreases by 10. If an interface is not tracked, its state changes do not affect the hot standby priority of the configured device. For each interface configured for hot standby, you can configure a separate list of interfaces to be tracked
- The **standby track interface-priority** interface configuration command specifies how much to decrement the hot standby priority when a tracked interface goes down. When the interface comes back up, the priority is incremented by the same amount.
- When multiple tracked interfaces are down and **interface-priority** values have been configured, the configured priority decrements are cumulative. If tracked interfaces that were not configured with priority values fail, the default decrement is 10, and it is noncumulative.
- When routing is first enabled for the interface, it does not have a complete routing table. If it is configured to preempt, it becomes the active router, even though it is unable to provide adequate routing services. To solve this problem, configure a delay time to allow the router to update its routing table.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP priority characteristics on an interface:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `standby [group-number] priority priority`
4. `standby [group-number] preempt [delay [minimumseconds] [reloadseconds] [syncseconds]]`
5. `standby [group-number] track type number [interface-priority]`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`
# DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
|  | Example:  
Switch # configure terminal | | |
| **Step 2** | interface interface-id | Enters interface configuration mode, and enter the HSRP interface on which you want to set priority. |
|  | Example:  
Switch(config)# interface gigabitethernet1/0/1 | | |
| **Step 3** | standby [group-number] priority priority | Sets a priority value used in choosing the active router. The range is 1 to 255; the default priority is 100. The highest number represents the highest priority.  
• (Optional) group-number—The group number to which the command applies.  
Use the no form of the command to restore the default values. |
|  | Example:  
Switch(config-if)# standby 120 priority 50 | | |
| **Step 4** | standby [group-number] preempt [delay [minimum seconds] [reload seconds] [sync seconds]] | Configures the router to preempt, which means that when the local router has a higher priority than the active router, it becomes the active router.  
• (Optional) group-number—The group number to which the command applies.  
• (Optional) delay minimum—Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over).  
• (Optional) delay reload—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload).  
• (Optional) delay sync—Set to cause the local router to postpone taking over the active role so that IP redundancy clients can reply (either with an ok or wait reply) for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over).  
Use the no form of the command to restore the default values. |
|  | Example:  
Switch(config-if)# standby 1 preempt delay 300 | | |
| **Step 5** | standby [group-number] track type number [interface-priority] | Configures an interface to track other interfaces so that if one of the other interfaces goes down, the device's Hot Standby priority is lowered.  
• (Optional) group-number—The group number to which the command applies. |
|  | Example: | | |
Configuring MHSRP

To enable MHSRP and load-balancing, you configure two routers as active routers for their groups, with virtual routers as standby routers as shown in the MHSRP Load Sharing figure in the Multiple HSRP section. You need to enter the `standby preempt` interface configuration command on each HSRP interface so that if a router fails and comes back up, the preemption occurs and restores load-balancing.

Router A is configured as the active router for group 1, and Router B is configured as the active router for group 2. The HSRP interface for Router A has an IP address of 10.0.0.1 with a group 1 standby priority of 110 (the default is 100). The HSRP interface for Router B has an IP address of 10.0.0.2 with a group 2 standby priority of 110.

Group 1 uses a virtual IP address of 10.0.0.3 and group 2 uses a virtual IP address of 10.0.0.4.

Configuring Router A

**SUMMARY STEPS**

1. configure terminal
2. interface type number
3. no switchport
4. ip address ip-address mask
5. standby [group-number] ip [ip-address [secondary]]
6. standby [group-number] priority priority
7. standby [group-number] preempt [delay [minimum seconds] [reload seconds] [sync seconds]]
8. standby [group-number] ip [ip-address [secondary]]
9. standby [group-number] preempt [delay [minimum seconds] [reload seconds] [sync seconds]]
10. end
11. show running-config
12. copy running-config startup-config

Use the `no` form of the command to restore the default values.

### Configuring Router B

#### Step 10

**end**

Example:

```
Switch(config-if)# end
```

Returns to privileged EXEC mode.

#### Step 11

**show running-config**

Verifies the configuration of the standby groups.

#### Step 12

**copy running-config startup-config**

(Optional) Saves your entries in the configuration file.

### SUMMARY STEPS

1. configure terminal
2. interface type number
3. no switchport
4. ip address ip-address mask
5. standby [group-number] ip [ip-address [secondary]]
6. standby [group-number] priority priority

Use the no form of the command to restore the default values.

**Step 10**

```plaintext
end
```

Returns to privileged EXEC mode.

**Step 11**

```plaintext
show running-config
```

Verifies the configuration of the standby groups.

**Step 12**

```plaintext
copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

## Configuring HSRP Authentication and Timers

You can optionally configure an HSRP authentication string or change the hello-time interval and holdtime. When configuring these attributes, follow these guidelines:

- The authentication string is sent unencrypted in all HSRP messages. You must configure the same authentication string on all routers and access servers on a cable to ensure interoperability. Authentication mismatch prevents a device from learning the designated Hot Standby IP address and timer values from other routers configured with HSRP.
- Routers or access servers on which standby timer values are not configured can learn timer values from the active or standby router. The timers configured on an active router always override any other timer settings.
- All routers in a Hot Standby group should use the same timer values. Normally, the **holdtime** is greater than or equal to 3 times the **hello-time**.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP authentication and timers on an interface:

**SUMMARY STEPS**

1. configure terminal
2. interface `interface-id`
3. standby [group-number] authentication string  
4. standby [group-number] timers hellotime holdtime  
5. end  
6. show running-config  
7. copy running-config startup-config

**DETAILED STEPS**

| 4.     | standby [group-number] timers hellotime holdtime | (Optional) Configure the time between hello packets and the time before other routers declare the active router to be down.  
- group-number—The group number to which the command applies.  
- hellotime—Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over).  
- holdtime—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload). |
| Example: |                                        |                                                  |
|        | Switch(config-if) # standby 1 timers 5 15 |                                                  |
| 5.     | end                                    | Returns to privileged EXEC mode.                  |
| Example: |                                        |                                                  |
|        | Switch(config-if) # end                |                                                  |
| 6.     | show running-config                    | Verifies the configuration of the standby groups. |
| 7.     | copy running-config startup-config     | (Optional) Saves your entries in the configuration file. |
Enabling HSRP Support for ICMP Redirect Messages

ICMP redirect messages are automatically enabled on interfaces configured with HSRP. ICMP is a network layer Internet protocol that provides message packets to report errors and other information relevant to IP processing. ICMP provides diagnostic functions, such as sending and directing error packets to the host. This feature filters outgoing ICMP redirect messages through HSRP, in which the next hop IP address might be changed to an HSRP virtual IP address. For more information, see the Cisco IOS IP Configuration Guide, Release 12.4.

Configuring HSRP Groups and Clustering

When a device is participating in an HSRP standby routing and clustering is enabled, you can use the same standby group for command switch redundancy and HSRP redundancy. Use the `cluster standby-group HSRP-group-name [routing-redundancy]` global configuration command to enable the same HSRP standby group to be used for command switch and routing redundancy. If you create a cluster with the same HSRP standby group name without entering the `routing-redundancy` keyword, HSRP standby routing is disabled for the group.

Troubleshooting HSRP

If one of the situations as shown in the following table occurs, this message appears:

%FHRP group not consistent with already configured groups on the switch stack - virtual MAC reservation failed

<table>
<thead>
<tr>
<th>Situation</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>You configure more than 32 HSRP group instances.</td>
<td>Remove HSRP groups so that up to 32 group instances are configured.</td>
</tr>
<tr>
<td>You configure HSRP for IPv4 and HSRP for IPv6 at the same time</td>
<td>Configure either HSRP for IPv4 or HSRP for IPv6 on the switch.</td>
</tr>
<tr>
<td>You configure group numbers that are not in valid ranges of 256.</td>
<td>Configure group numbers in a valid range.</td>
</tr>
</tbody>
</table>

Verifying HSRP

Verifying HSRP Configurations

From privileged EXEC mode, use this command to display HSRP settings:

```
show standby [interface-id [group]] [brief] [detail]
```

You can display HSRP information for the whole switch, for a specific interface, for an HSRP group, or for an HSRP group on an interface. You can also specify whether to display a concise overview of HSRP information or detailed HSRP information. The default display is `detail`. If there are a large number of HSRP groups, using the `show standby` command without qualifiers can result in an unwieldy display.
**Example**

Switch # `show standby`

VLAN1 - Group 1
Local state is Standby, priority 105, may preempt
Hello time 3 holdtime 10
Next hello sent in 00:00:02.182
Hot standby IP address is 172.20.128.3 configured
Active router is 172.20.128.1 expires in 00:00:09
Standby router is local
Standby virtual mac address is 0000.0c07.ac01
Name is bbb

VLAN1 - Group 100
Local state is Standby, priority 105, may preempt
Hello time 3 holdtime 10
Next hello sent in 00:00:02.262
Hot standby IP address is 172.20.138.51 configured
Active router is 172.20.128.1 expires in 00:00:09
Active router is local
Standby router is unknown expired
Standby virtual mac address is 0000.0c07.ac64
Name is test

### Configuration Examples for Configuring HSRP

#### Enabling HSRP: Example

This example shows how to activate HSRP for group 1 on an interface. The IP address used by the hot standby group is learned by using HSRP.

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# standby 1 ip
Switch(config-if)# end
Switch # show standby
```

**Note**

This procedure is the minimum number of steps required to enable HSRP. Other configurations are optional.

#### Configuring HSRP Priority: Example

This example activates a port, sets an IP address and a priority of 120 (higher than the default value), and waits for 300 seconds (5 minutes) before attempting to become the active router:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# standby 1 ip 172.20.128.3
Switch(config-if)# standby priority 120 preempt delay 300
Switch(config-if)# end
Switch # show standby
```
Configuring MHSRP: Example

This example shows how to enable the MHSRP configuration shown in the figure MHSRP Load Sharing.

Router A Configuration

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # ip address 10.0.0.1 255.255.255.0
Switch(config-if) # standby ip 10.0.0.3
Switch(config-if) # standby 1 priority 110
Switch(config-if) # standby 1 preempt
Switch(config-if) # standby 2 ip 10.0.0.4
Switch(config-if) # standby 2 preempt
Switch(config-if) # end
```

Router B Configuration

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # ip address 10.0.0.2 255.255.255.0
Switch(config-if) # standby ip 10.0.0.3
Switch(config-if) # standby 1 preempt
Switch(config-if) # standby 2 ip 10.0.0.4
Switch(config-if) # standby 1 priority 110
Switch(config-if) # standby 2 preempt
Switch(config-if) # end
```

Configuring HSRP Authentication and Timer: Example

This example shows how to configure `word` as the authentication string required to allow Hot Standby routers in group 1 to interoperate.

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 authentication word
Switch(config-if) # end
```

This example shows how to set the timers on standby group 1 with the time between hello packets at 5 seconds and the time after which a router is considered down to be 15 seconds:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 ip
Switch(config-if) # standby 1 timers 5 15
Switch(config-if) # end
```

Configuring HSRP Groups and Clustering: Example

This example shows how to bind standby group `my_hsrp` to the cluster and enable the same HSRP group to be used for command switch redundancy and router redundancy. The command can only be executed on the
Information About VRRP

Configuring VRRP

Virtual Router Redundancy Protocol (VRRP) is an election protocol that enables a group of routers to form a single virtual router to provide redundancy. In a VRRP configuration, one router is elected as the virtual router master, and the other routers act as backups in case it fails. The LAN clients can then be configured with the virtual router as their default gateway, allowing several routers on a multi-access link to use the same virtual IP address. The virtual router, representing a group of routers, forms a VRRP group.

Both HSRP and VRRP perform the same function. You can choose to configure either IETF standard VRRP or Cisco’s more powerful HSRP protocol on a device or device stack.

Restrictions for VRRP

- The VRRP implementation on the switch does not support the MIB specified in RFC 2787.
- The VRRP implementation on the switch supports only text-based authentication.
- VRRPv3 is not supported.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 MLD Snooping

---

**Note**

To use IPv6 MLD Snooping, the switch must be running the LAN Base image.

You can use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP Version 6 (IPv6) multicast data to clients and routers in a switched network on the switch. Unless otherwise noted, the term switch refers to a standalone switch and to a switch stack.

---

**Note**

Stacking is supported only on Catalyst 2960-X switches running the LAN base image.
To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch.

On switches running the LAN Base feature set, the routing template is not supported.

Note For complete syntax and usage information for the commands used in this chapter, see the command reference for this release or the Cisco IOS documentation referenced in the procedures.

Understanding MLD Snooping

In IP Version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on the links that are directly attached to the routers and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD Version 1 (MLDv1) is equivalent to IGMPv2, and MLD Version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol Version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

Note The switch does not support MLDv2 enhanced snooping, which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

MLD Messages

MLDv1 supports three types of messages:
• Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
• Multicast Listener Reports are the equivalent of IGMPv2 reports
• Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.

MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages. Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

**MLD Queries**

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast group address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

---

**Note**

When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the Catalyst 2960, 2960-S, 2960-C, 2960-X or 2960-CX switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

**Multicast Client Aging Robustness**

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

**Multicast Router Discovery**

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

• Ports configured by a user never age out.
• Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
if there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).

Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.

IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.

Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether or not MLD snooping is enabled on the switch.

After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address is entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port. The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the `ipv6 mld snooping last-listener-query count` global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the `ipv6 mld snooping last-listener-query-interval` global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.
Topology Change Notification Processing

When topology change notification (TCN) solicitation is enabled by using the `ipv6 mld snooping tcn query solicit` global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the `ipv6 mld snooping tcn flood query count` global configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This is same as done in IGMP snooping.

MLD Snooping in Switch Stacks

The MLD IPv6 group address databases are maintained on all switches in the stack, regardless of which switch learns of an IPv6 multicast group. Report suppression and proxy reporting are done stack-wide. During the maximum response time, only one received report for a group is forwarded to the multicast routers, regardless of which switch the report arrives on.

The election of a new stack master does not affect the learning or bridging of IPv6 multicast data; bridging of IPv6 multicast data does not stop during a stack master re-election. When a new switch is added to the stack, it synchronizes the learned IPv6 multicast information from the stack master. Until the synchronization is complete, data ingress on the newly added switch is treated as unknown multicast data.

How to Configure IPv6 MLD Snooping

Default MLD Snooping Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>MLD snooping (Global)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLD snooping (per VLAN)</td>
<td>Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place.</td>
</tr>
<tr>
<td>IPv6 Multicast addresses</td>
<td>None configured.</td>

</tr>
<tr>
<td></td>
<td><strong>Note</strong> The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.</td>
</tr>
<tr>
<td>Last listener query count</td>
<td>Global: 2; Per VLAN: 0.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.</td>
</tr>
</tbody>
</table>
### MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the `ipv6 mld snooping` global configuration command for the configuration to take effect.

- When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch.

- The maximum number of multicast entries allowed on the switch or switch stack is determined by the configured SDM template.

- The maximum number of address entries allowed for the switch or switch stack is 1000.

### Enabling or Disabling MLD Snooping on the Switch

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis or for a range of VLANs, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

To globally enable MLD snooping on the switch, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
Enabling or Disabling MLD Snooping on a VLAN

To enable MLD snooping on a VLAN, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

configure terminal

Example:

Device# configure terminal

**Step 3**

ipv6 mld snooping

Example:

Device(config)# ipv6 mld snooping

**Step 4**

derend

Example:

Device(config)# end

**Step 5**

copy running-config startup-config

Example:

Device(config)# copy running-config startup-config

**Step 6**

reload

Example:

Device(config)# reload

(8) Optional) Save your entries in the configuration file.

## IPv6

Enabling or Disabling MLD Snooping on a VLAN

To enable MLD snooping on a VLAN, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
Configure a Static Multicast Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ipv6 mld snooping vlan vlan-id static ipv6_multicast_address interface interface-id</td>
<td>Configures a multicast group with a Layer 2 port as a member of a multicast group:</td>
</tr>
</tbody>
</table>
### Configuring a Multicast Router Port

**Note**
Static connections to multicast routers are supported only on switch ports.

To add a multicast router port to a VLAN, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device#</code></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Enabling MLD Immediate Leave

To enable MLDv1 immediate leave, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device&gt; enable</code></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>ipv6 mld snooping vlan vlan-id immediate-leave</code></td>
<td>Enables MLD Immediate Leave on the VLAN interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# ipv6 mld snooping vlan 1 immediate-leave</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring MLD Snooping Queries

To configure MLD snooping query characteristics for the switch or for a VLAN, perform this procedure:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>3</td>
<td>ipv6 mld snooping robustness-variable value</td>
<td>(Optional) Sets the number of queries that are sent before switch will deletes a listener (port) that does not respond to a general query. The range is 1 to 3; the default is 2.</td>
</tr>
<tr>
<td>4</td>
<td>ipv6 mld snooping vlan vlan-id robustness-variable value</td>
<td>(Optional) Sets the robustness variable on a VLAN basis, which determines the number of general queries that MLD snooping sends before aging out a multicast address when there is no MLD report response. The range is 1 to 3; the default is 0. When set to 0, the number used is the global robustness variable value.</td>
</tr>
<tr>
<td>5</td>
<td>ipv6 mld snooping last-listener-query-count count</td>
<td>(Optional) Sets the number of MASQs that the switch sends before aging out an MLD client. The range is 1 to 7; the default is 2. The queries are sent 1 second apart.</td>
</tr>
<tr>
<td>6</td>
<td>ipv6 mld snooping vlan vlan-id last-listener-query-count count</td>
<td>(Optional) Sets the last-listener query count on a VLAN basis. This value overrides the value configured globally. The range is 1 to 7; the default is 0. When set to 0, the global count value is used. Queries are sent 1 second apart.</td>
</tr>
</tbody>
</table>
### Disabling MLD Listener Message Suppression

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

To disable MLD listener message suppression, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
### Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display IPv6 group address multicast entries for a VLAN configured for MLD snooping.

#### Table 39: Commands for Displaying MLD Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>show ipv6 mld snooping</strong> [ vlan vlan-id ]</td>
<td>Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN. (Optional) Enter <strong>vlan vlan-id</strong> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td><strong>show ipv6 mld snooping mrouter</strong> [ vlan vlan-id ]</td>
<td>Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces. (Optional) Enters <strong>vlan vlan-id</strong> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
</tbody>
</table>
### Configuration Examples for Configuring MLD Snooping

#### Configuring a Static Multicast Group: Example

This example shows how to statically configure an IPv6 multicast group:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 2 static 3333.0000.1111 interface gigabitethernet1/0/1
Device(config)# end
```

#### Configuring a Multicast Router Port: Example

This example shows how to add a multicast router port to VLAN 200:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet 0/2
Device(config)# exit
```

#### Enabling MLD Immediate Leave: Example

This example shows how to enable MLD Immediate Leave on VLAN 130:

```
Device# configure terminal
```

---

**Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ipv6 mld snooping querier</code></td>
<td>Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN. (Optional) Enters <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
</tbody>
</table>
| `show ipv6 mld snooping address` | Displays all IPv6 multicast address information or specific IPv6 multicast address information for the switch or a VLAN.  
|                                 | • Enters `count` to show the group count on the switch or in a VLAN.  
|                                 | • Enters `dynamic` to display MLD snooping learned group information for the switch or for a VLAN.  
|                                 | • Enters `user` to display MLD snooping user-configured group information for the switch or for a VLAN. |
| `show ipv6 mld snooping address vlan vlan-id [ count | dynamic | user ]` | Displays MLD snooping for the specified VLAN and IPv6 multicast address. |
Configuring MLD Snooping Queries: Example

This example shows how to set the MLD snooping global robustness variable to 3:

```
Device# configure terminal
Device(config)# ipv6 mld snooping robustness-variable 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```
Device# configure terminal
Device(config)# ipv6 mld snooping last-listener-query-interval 2000
Device(config)# exit
```
Configuring MLD Snooping Queries: Example
CHAPTER 22

Configuring IPv6 Unicast Routing

- Finding Feature Information, on page 329
- Information About Configuring IPv6 Host Functions, on page 329
- Configuration Examples for IPv6 Unicast Routing, on page 341

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 Host Functions

This chapter describes how to configure IPv6 host functions on the Catalyst 2960, 2960-S, and 2960-C.

Note

To use IPv6 Host Functions, the switch must be running the LAN Base image.

For information about configuring IPv6 Multicast Listener Discovery (MLD) snooping, see Configuring MLD Snooping.

To enable dual stack environments (supporting both IPv4 and IPv6) on a Catalyst 2960 switch, you must configure the switch to use the a dual IPv4 and IPv6 switch database management (SDM) template. See the "Dual IPv4 and IPv6 Protocol Stacks" section. This template is not required on Catalyst 2960-S switches.

Note

For complete syntax and usage information for the commands used in this chapter, see the Cisco IOS documentation referenced in the procedures.
Understanding IPv6

IPv4 users can move to IPv6 and receive services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to:

For information about IPv6 and other features in this chapter
• See the Cisco IOS IPv6 Configuration Library.
• Use the Search field on Cisco.com to locate the Cisco IOS software documentation. For example, if you want information about static routes, you can enter Implementing Static Routes for IPv6 in the search field to learn about static routes.

IPv6 Addresses

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses, or anycast addresses.

The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: n:n:n:n:n:n:n:n. This is an example of an IPv6 address:
2031:0000:130F:0000:0000:09C0:080F:130B

For easier implementation, leading zeros in each field are optional. This is the same address without leading zeros:
2031:0:130F:0:0:9C0:80F:130B

You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:
2031:0:130F::09C0:80F:130B

• IPv6 Address Formats
• IPv6 Address Type: Multicast
• IPv6 Address Output Display
• Simplified IPv6 Packet Header

Supported IPv6 Unicast Routing Features

These sections describe the IPv6 protocol features supported by the switch:

128-Bit Wide Unicast Addresses

The switch supports aggregatable global unicast addresses and link-local unicast addresses. It does not support site-local unicast addresses.
• Aggregatable global unicast addresses are IPv6 addresses from the aggregatable global unicast prefix. The address structure enables strict aggregation of routing prefixes and limits the number of routing table entries in the global routing table. These addresses are used on links that are aggregated through organizations and eventually to the Internet service provider.

These addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). Addresses with a prefix of 2000::/3(001) through E000::/3(111) must have 64-bit interface identifiers in the extended unique identifier (EUI)-64 format.

• Link local unicast addresses can be automatically configured on any interface by using the link-local prefix FE80::/10(1111111010) and the interface identifier in the modified EUI format. Link-local addresses are used in the neighbor discovery protocol (NDP) and the stateless autoconfiguration process. Nodes on a local link use link-local addresses and do not require globally unique addresses to communicate. IPv6 routers do not forward packets with link-local source or destination addresses to other links.

For more information, see the section about IPv6 unicast addresses in the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

DNS for IPv6

IPv6 supports Domain Name System (DNS) record types in the DNS name-to-address and address-to-name lookup processes. The DNSAAAA resource record types support IPv6 addresses and are equivalent to an A address record in IPv4. The switch supports DNS resolution for IPv4 and IPv6.

ICMPv6

The Internet Control Message Protocol (ICMP) in IPv6 generates error messages, such as ICMP destination unreachable messages, to report errors during processing and other diagnostic functions. In IPv6, ICMP packets are also used in the neighbor discovery protocol and path MTU discovery.

Neighbor Discovery

The switch supports NDP for IPv6, a protocol running on top of ICMPv6, and static neighbor entries for IPv6 stations that do not support NDP. The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), to verify the reachability of the neighbor, and to keep track of neighboring routers.

The switch supports ICMPv6 redirect for routes with mask lengths less than 64 bits. ICMP redirect is not supported for host routes or for summarized routes with mask lengths greater than 64 bits.

Neighbor discovery throttling ensures that the switch CPU is not unnecessarily burdened while it is in the process of obtaining the next hop forwarding information to route an IPv6 packet. The switch drops any additional IPv6 packets whose next hop is the same neighbor that the switch is actively trying to resolve. This drop avoids further load on the CPU.

IPv6 Stateless Autoconfiguration and Duplicate Address Detection

The switch uses stateless autoconfiguration to manage link, subnet, and site addressing changes, such as management of host and mobile IP addresses. A host autonomously configures its own link-local address, and booting nodes send router solicitations to request router advertisements for configuring interfaces.

For more information about autoconfiguration and duplicate address detection, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of Cisco IOS IPv6 Configuration Library on Cisco.com.
IPv6 Applications

The switch has IPv6 support for these applications:

- Ping, traceroute, Telnet
- Secure Shell (SSH) over an IPv6 transport
- HTTP server access over IPv6 transport
- DNS resolver for AAAA over IPv4 transport
- Cisco Discovery Protocol (CDP) support for IPv6 addresses

For more information about managing these applications, see the Cisco IOS IPv6 Configuration Library on Cisco.com.

Dual IPv4 and IPv6 Protocol Stacks

This figure shows a router forwarding both IPv4 and IPv6 traffic through the same interface, based on the IP packet and destination addresses.

*Figure 18: Dual IPv4 and IPv6 Support on an Interface*

Use the dual IPv4 and IPv6 switch database management (SDM) template to enable IPv6 routing dual stack environments (supporting both IPv4 and IPv6). For more information about the dual IPv4 and IPv6 SDM template, see Configuring SDM Templates.

The dual IPv4 and IPv6 templates allow the switch to be used in dual stack environments.

- If you try to configure IPv6 without first selecting a dual IPv4 and IPv6 template, a warning message appears.
- In IPv4-only environments, the switch routes IPv4 packets and applies IPv4 QoS and ACLs in hardware. IPv6 packets are not supported.
- In dual IPv4 and IPv6 environments, the switch applies IPv4 QoS and ACLs in hardware.
- If you do not plan to use IPv6, do not use the dual stack template because this template results in less hardware memory capacity for each resource.

For more information about IPv4 and IPv6 protocol stacks, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of Cisco IOS IPv6 Configuration Library on Cisco.com.

SNMP and Syslog Over IPv6

To support both IPv4 and IPv6, IPv6 network management requires both IPv6 and IPv4 transports. Syslog over IPv6 supports address data types for these transports.
Simple Network Management Protocol (SNMP) and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and to modify the SNMP agent to support traps for an IPv6 host
- SNMP- and syslog-related MIBs to support IPv6 addressing
- Configuration of IPv6 hosts as trap receivers

For support over IPv6, SNMP modifies the existing IP transport mapping to simultaneously support IPv4 and IPv6. These SNMP actions support IPv6 transport management:

- Opens User Datagram Protocol (UDP) SNMP socket with default settings
- Provides a new transport mechanism called `SR_IPV6_TRANSPORT`
- Sends SNMP notifications over IPv6 transport
- Supports SNMP-named access lists for IPv6 transport
- Supports SNMP proxy forwarding using IPv6 transport
- Verifies SNMP Manager feature works with IPv6 transport

For information on SNMP over IPv6, including configuration procedures, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

For information about syslog over IPv6, including configuration procedures, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**HTTP(S) Over IPv6**

The HTTP client sends requests to both IPv4 and IPv6 HTTP servers, which respond to requests from both IPv4 and IPv6 HTTP clients. URLs with literal IPv6 addresses must be specified in hexadecimal using 16-bit values between colons.

The accept socket call chooses an IPv4 or IPv6 address family. The accept socket is either an IPv4 or IPv6 socket. The listening socket continues to listen for both IPv4 and IPv6 signals that indicate a connection. The IPv6 listening socket is bound to an IPv6 wildcard address.

The underlying TCP/IP stack supports a dual-stack environment. HTTP relies on the TCP/IP stack and the sockets for processing network-layer interactions.

Basic network connectivity (ping) must exist between the client and the server hosts before HTTP connections can be made.

For more information, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**EIGRP IPv6**

Switches support the Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address. Switches running IP Lite only support EIGRPv6 stub routing.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv6 address, so any IPv6 node always has an available router ID. However, EIGRP...
IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv6 router ID.

For more information about EIGRP for IPv6, see the “Implementing EIGRP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**EIGRPv6 Stub Routing**

The EIGRPv6 stub routing feature, reduces resource utilization by moving routed traffic closer to the end user.

In a network using EIGRPv6 stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with EIGRPv6 stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRPv6 stub routing, you need to configure the distribution and remote routers to use EIGRPv6 and to configure only the switch as a stub. Only specified routes are propagated from the switch. The switch responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In the figure given below, switch B is configured as an EIGRPv6 stub router. Switches A and C are connected to the rest of the WAN. Switch B advertises connected, static, redistribution, and summary routes to switch A and C. Switch B does not advertise any routes learned from switch A (and the reverse).

*Figure 19: EIGRP Stub Router Configuration*

**IPv6 and Switch Stacks**

The switch supports IPv6 forwarding across the stack and IPv6 host functionality on the stack master. The stack master runs IPv6 host functionality and IPv6 applications.

While the new stack master is being elected and is resetting, the switch stack does not forward IPv6 packets. The stack MAC address changes, which also changes the IPv6 address. When you specify the stack IPv6 address with an extended unique identifier (EUI) by using the `ipv6 address ipv6-prefix/prefix length eui-64`
interface configuration command, the address is based on the interface MAC address. See the "Configuring IPv6 Addressing and Enabling IPv6 Host" section.

If you configure the persistent MAC address feature on the stack and the stack master changes, the stack MAC address does not change for approximately 4 minutes. For more information, see the "Enabling Persistent MAC Address" section in "Managing Switch Stacks."

**Default IPv6 Configuration**

<td>None configured</td>
</tr>
</tbody>
</table>

**Configuring IPv6 Addressing and Enabling IPv6 Routing**

This section describes how to assign IPv6 addresses to individual Layer 3 interfaces and to globally forward IPv6 traffic on the switch.

Before configuring IPv6 on the switch, consider these guidelines:

- Be sure to select a dual IPv4 and IPv6 SDM template.

- In the `ipv6 address` interface configuration command, you must enter the `ipv6-address` and `ipv6-prefix` variables with the address specified in hexadecimal using 16-bit values between colons. The `prefix-length` variable (preceded by a slash `/`) is a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address).

To forward IPv6 traffic on an interface, you must configure a global IPv6 address on that interface. Configuring an IPv6 address on an interface automatically configures a link-local address and activates IPv6 for the interface. The configured interface automatically joins these required multicast groups for that link:

- solicited-node multicast group FF02::1/104 for each unicast address assigned to the interface (this address is used in the neighbor discovery process.)

- all-nodes link-local multicast group FF02::1

- all-routers link-local multicast group FF02::2

For more information about configuring IPv6 routing, see the “Implementing Addressing and Basic Connectivity for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to assign an IPv6 address to a Layer 3 interface and enable IPv6 forwarding:
## IPv6

### Configuring IPv6 Addressing and Enabling IPv6 Routing

**Procedure**

<td>Enables IPv6 processing on the interface. This command enables IPv6 processing on the interface.</td>
</tr>
<tr>
<td><code>Device(config-if)# ipv6 address 2001:0DB8:c18:1:: link-local</code></td>
<td>Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link.</td>
</tr>
<tr>
<td><code>Device(config-if)# ipv6 enable</code></td>
<td>Returns to global configuration mode.</td>
</tr>
</tbody>
</table>

### Step 8

**Example:**

```
Device(config-if)# exit
```

### Step 9

**Example:**

```
Device(config)# end
```

### Step 10

**Example:**

```
Device# show ipv6 interface gigabitethernet 1/0/1
```

### Step 11

**Example:**

```
Device# copy running-config startup-config
```

### Configuring IPv6 ICMP Rate Limiting

ICMP rate limiting is enabled by default with a default interval between error messages of 100 milliseconds and a bucket size (maximum number of tokens to be stored in a bucket) of 10.

To change the ICMP rate-limiting parameters, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>

</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
**Step 2** configure terminal  
Example:  
Device# configure terminal  
| Enters global configuration mode.  
**Step 3** ipv6 icmp error-interval interval [bucketsize]  
Example:  
Device(config)# ipv6 icmp error-interval 50 20  
| Configures the interval and bucket size for IPv6 ICMP error messages:  
- interval—The interval (in milliseconds) between tokens being added to the bucket. The range is from 0 to 2147483647 milliseconds.  
- bucketsize—(Optional) The maximum number of tokens stored in the bucket. The range is from 1 to 200.  
**Step 4** end  
Example:  
Device(config)# end  
| Returns to privileged EXEC mode.  
**Step 5** show ipv6 interface [interface-id]  
Example:  
Device# show ipv6 interface gigabitethernet0/1  
| Verifies your entries.  
**Step 6** copy running-config startup-config  
Example:  
Device# copy running-config startup-config  
| (Optional) Saves your entries in the configuration file.  

### Configuring Static Routing for IPv6

For more information about configuring static IPv6 routing, see the “Implementing Static Routes for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

To configure static IPv6 routing, perform this procedure:

**Before you begin**

You must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on at least one Layer 3 interface by configuring an IPv6 address on the interface.
# Procedure

</tr>
</tbody>
</table>

- **ipv6-prefix** — The IPv6 network that is the destination of the static route. It can also be a hostname when static host routes are configured.
- **/prefix length** — The length of the IPv6 prefix. A decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark must precede the decimal value.
- **ipv6-address** — The IPv6 address of the next hop that can be used to reach the specified network. The IPv6 address of the next hop need not be directly connected; recursion is done to find the IPv6 address of the directly connected next hop. The address must be in the form documented in RFC 2373, specified in hexadecimal using 16-bit values between colons.
- **interface-id** — Specifies direct static routes from point-to-point and broadcast interfaces. With point-to-point interfaces, there is no need to specify the IPv6 address of the next hop. With broadcast interfaces, you should always specify the IPv6 address of the next hop, or ensure that the specified prefix is assigned to the link, specifying a link-local address as the next hop. You can optionally specify the IPv6 address of the next hop to which packets are sent.

**Note** You must specify an **interface-id** when using a link-local address as the next hop (the link-local next hop must also be an adjacent router).

- **administrative distance** — (Optional) An administrative distance. The range is 1 to 254; the default value is 1, which gives static routes precedence over any other type of route except connected routes. To configure a

### IPv6 Configuration Examples for IPv6 Unicast Routing

#### Configuring IPv6 Addressing and Enabling IPv6 Routing: Example

This example shows how to enable IPv6 with both a link-local address and a global address based on the IPv6 prefix 2001:0DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the `show ipv6 interface` EXEC command is included to show how the interface ID (20B:46FF:FE2F:D940) is appended to the link-local prefix FE80::/64 of the interface.

```
Device(config)# ipv6 unicast-routing
Device(config)# interface gigabitethernet0/11
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
Device# show ipv6 interface gigabitethernet0/11
GigabitEthernet0/11 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
Global unicast address(es):
  2001:0DB8:c18:1::20B:46FF:FE2F:D940, subnet is 2001:0DB8:c18:1::/64 [EUI]
  Joined group address(es):
    FF02::1
    FF02::1:FF2F:D940
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
Hosts use stateless autoconfig for addresses.
```

</tbody>
</table>
Configuring IPv6 ICMP Rate Limiting: Example

This example shows how to configure an IPv6 ICMP error message interval of 50 milliseconds and a bucket size of 20 tokens.

```
Device(config)#ipv6 icmp error-interval 50 20
```

Configuring Static Routing for IPv6: Example

This example shows how to configure a floating static route to an interface with an administrative distance of 130:

```
Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet 1/0/1 130
```

Displaying IPv6: Example

This is an example of the output from the `show ipv6 interface` privileged EXEC command:

```
Device# show ipv6 interface
Vlan1 is up, line protocol is up
  IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
  Global unicast address(es):
    3FFE:C000:0:1:20B:46FF:FE2F:D940, subnet is 3FFE:C000:0:1::/64 [EUI]
  Joined group address(es):
    FF02::1
    FF02::2
    FF02::1:FF2F:D940
  MTU is 1500 bytes
  ICMP error messages limited to one every 100 milliseconds
  ICMP redirects are enabled
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisements are sent every 200 seconds
  ND router advertisements live for 1800 seconds
<output truncated>
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Implementing IPv6 Multicast Routing

This chapter describes how to implement IPv6 multicast routing on the switch.

Traditional IP communication allows a host to send packets to a single host (unicast transmission) or to all hosts (broadcast transmission). IPv6 multicast provides a third scheme, allowing a host to send a single data stream to a subset of all hosts (group transmission) simultaneously.

IPv6 Multicast Overview

An IPv6 multicast group is an arbitrary group of receivers that want to receive a particular data stream. This group has no physical or geographical boundaries—receivers can be located anywhere on the Internet or in any private network. Receivers that are interested in receiving data flowing to a particular group must join the group by signaling their local switch. This signaling is achieved with the MLD protocol.

Switches use the MLD protocol to learn whether members of a group are present on their directly attached subnets. Hosts join multicast groups by sending MLD report messages. The network then delivers data to a potentially unlimited number of receivers, using only one copy of the multicast data on each subnet. IPv6 hosts that wish to receive the traffic are known as group members.
Packets delivered to group members are identified by a single multicast group address. Multicast packets are delivered to a group using best-effort reliability, just like IPv6 unicast packets.

The multicast environment consists of senders and receivers. Any host, regardless of whether it is a member of a group, can send to a group. However, only members of a group can listen to and receive the message.

A multicast address is chosen for the receivers in a multicast group. Senders use that address as the destination address of a datagram to reach all members of the group.

Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time.

How active a multicast group is, its duration, and its membership can vary from group to group and from time to time. A group that has members may have no activity.

IPv6 Multicast Routing Implementation

The Cisco IOS software supports the following protocols to implement IPv6 multicast routing:

- **MLD** is used by IPv6 switches to discover multicast listeners (nodes that want to receive multicast packets destined for specific multicast addresses) on directly attached links. There are two versions of MLD:
  - MLD version 1 is based on version 2 of the Internet Group Management Protocol (IGMP) for IPv4, and MLD version 2 is based on version 3 of the IGMP for IPv4. IPv6 multicast for Cisco IOS software uses both MLD version 2 and MLD version 1. MLD version 2 is fully backward-compatible with MLD version 1 (described in RFC 2710). Hosts that support only MLD version 1 will interoperate with a switch running MLD version 2. Mixed LANs with both MLD version 1 and MLD version 2 hosts are likewise supported.
  - PIM-SM is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs.
  - PIM in Source Specific Multicast (PIM-SSM) is similar to PIM-SM with the additional ability to report interest in receiving packets from specific source addresses (or from all but the specific source addresses) to an IP multicast address.

MLD Access Group

The MLD access group provides receiver access control in Cisco IOS IPv6 multicast switches. This feature limits the list of groups a receiver can join, and it allows or denies sources used to join SSM channels.

Explicit Tracking of Receivers

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network. This feature also enables the fast leave mechanism to be used with MLD version 2 host reports.

Protocol Independent Multicast

Protocol Independent Multicast (PIM) is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs. PIM works independently of the unicast routing protocol to perform send or receive multicast route updates like other protocols. Regardless of which unicast routing protocols are being used in the LAN to populate the unicast routing table, Cisco IOS PIM uses the existing unicast table content to perform the Reverse Path Forwarding (RPF) check instead of building and maintaining its own separate routing table.
You can configure IPv6 multicast to use either PIM-SM or PIM-SSM operation, or you can use both PIM-SM and PIM-SSM together in your network.

**PIM-Sparse Mode**

IPv6 multicast provides support for intradomain multicast routing using PIM-SM. PIM-SM uses unicast routing to provide reverse-path information for multicast tree building, but it is not dependent on any particular unicast routing protocol.

PIM-SM is used in a multicast network when relatively few switches are involved in each multicast and these switches do not forward multicast packets for a group, unless there is an explicit request for the traffic. PIM-SM distributes information about active sources by forwarding data packets on the shared tree. PIM-SM initially uses shared trees, which requires the use of an RP.

Requests are accomplished via PIM joins, which are sent hop by hop toward the root node of the tree. The root node of a tree in PIM-SM is the RP in the case of a shared tree or the first-hop switch that is directly connected to the multicast source in the case of a shortest path tree (SPT). The RP keeps track of multicast groups and the hosts that send multicast packets are registered with the RP by that host's first-hop switch.

As a PIM join travels up the tree, switches along the path set up multicast forwarding state so that the requested multicast traffic will be forwarded back down the tree. When multicast traffic is no longer needed, a switch sends a PIM prune up the tree toward the root node to prune (or remove) the unnecessary traffic. As this PIM prune travels hop by hop up the tree, each switch updates its forwarding state appropriately. Ultimately, the forwarding state associated with a multicast group or source is removed.

A multicast data sender sends data destined for a multicast group. The designated switch (DR) of the sender takes those data packets, unicast-encapsulates them, and sends them directly to the RP. The RP receives these encapsulated data packets, de-encapsulates them, and forwards them onto the shared tree. The packets then follow the (*, G) multicast tree state in the switches on the RP tree, being replicated wherever the RP tree branches, and eventually reaching all the receivers for that multicast group. The process of encapsulating data packets to the RP is called registering, and the encapsulation packets are called PIM register packets.

**IPv6 BSR: Configure RP Mapping**

PIM switches in a domain must be able to map each multicast group to the correct RP address. The BSR protocol for PIM-SM provides a dynamic, adaptive mechanism to distribute group-to-RP mapping information rapidly throughout a domain. With the IPv6 BSR feature, if an RP becomes unreachable, it will be detected and the mapping tables will be modified so that the unreachable RP is no longer used, and the new tables will be rapidly distributed throughout the domain.

Every PIM-SM multicast group needs to be associated with the IP or IPv6 address of an RP. When a new multicast sender starts sending, its local DR will encapsulate these data packets in a PIM register message and send them to the RP for that multicast group. When a new multicast receiver joins, its local DR will send a PIM join message to the RP for that multicast group. When any PIM switch sends a (*, G) join message, the PIM switch needs to know which is the next switch toward the RP so that G (Group) can send a message to that switch. Also, when a PIM switch is forwarding data packets using (*, G) state, the PIM switch needs to know which is the correct incoming interface for packets destined for G, because it needs to reject any packets that arrive on other interfaces.

A small set of switches from a domain are configured as candidate bootstrap switches (C-BSRs) and a single BSR is selected for that domain. A set of switches within a domain are also configured as candidate RPs (C-RPs); typically, these switches are the same switches that are configured as C-BSRs. Candidate RPs periodically unicast candidate-RP-advertisement (C-RP-Adv) messages to the BSR of that domain, advertising their willingness to be an RP. A C-RP-Adv message includes the address of the advertising C-RP, and an optional list of group addresses and mask length fields, indicating the group prefixes for which the candidacy
is advertised. The BSR then includes a set of these C-RPs, along with their corresponding group prefixes, in bootstrap messages (BSMs) it periodically originates. BSMs are distributed hop-by-hop throughout the domain. Bidirectional BSR support allows bidirectional RPs to be advertised in C-RP messages and bidirectional ranges in the BSM. All switches in a system must be able to use the bidirectional range in the BSM; otherwise, the bidirectional RP feature will not function.

PIM-Source Specific Multicast

PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM-SM. However, unlike PIM-SM where data from all multicast sources are sent when there is a PIM join, the SSM feature forwards datagram traffic to receivers from only those multicast sources that the receivers have explicitly joined, thus optimizing bandwidth utilization and denying unwanted Internet broadcast traffic. Further, instead of the use of RP and shared trees, SSM uses information found on source addresses for a multicast group. This information is provided by receivers through the source addresses relayed to the last-hop switches by MLD membership reports, resulting in shortest-path trees directly to the sources.

In SSM, delivery of datagrams is based on (S, G) channels. Traffic for one (S, G) channel consists of datagrams with an IPv6 unicast source address S and the multicast group address G as the IPv6 destination address. Systems will receive this traffic by becoming members of the (S, G) channel. Signaling is not required, but receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources.

MLD version 2 is required for SSM to operate. MLD allows the host to provide source information. Before SSM can run with MLD, SSM must be supported in the Cisco IOS IPv6 switch, the host where the application is running, and the application itself.

 Routable Address Hello Option

When an IPv6 interior gateway protocol is used to build the unicast routing table, the procedure to detect the upstream switch address assumes the address of a PIM neighbor is always same as the address of the next-hop switch, as long as they refer to the same switch. However, it may not be the case when a switch has multiple addresses on a link.

Two typical situations can lead to this situation for IPv6. The first situation can occur when the unicast routing table is not built by an IPv6 interior gateway protocol such as multicast BGP. The second situation occurs when the address of an RP shares a subnet prefix with downstream switches (note that the RP switch address has to be domain-wide and therefore cannot be a link-local address).

The routable address hello option allows the PIM protocol to avoid such situations by adding a PIM hello message option that includes all the addresses on the interface on which the PIM hello message is advertised. When a PIM switch finds an upstream switch for some address, the result of RPF calculation is compared with the addresses in this option, in addition to the PIM neighbor's address itself. Because this option includes all the possible addresses of a PIM switch on that link, it always includes the RPF calculation result if it refers to the PIM switch supporting this option.

Because of size restrictions on PIM messages and the requirement that a routable address hello option fits within a single PIM hello message, a limit of 16 addresses can be configured on the interface.

PIM IPv6 Stub Routing

The PIM stub routing feature reduces resource usage by moving routed traffic closer to the end user.

In a network using PIM stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains,
such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IPv6 multicast routing and configure only the switch as a PIM stub router. The switch does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the switch. The switch uplink port cannot be used with SVIs.

You must also configure EIGRP stub routing when configuring PIM stub routing on the switch.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM assert and designated router election mechanisms are not supported on the PIM passive interfaces. Only the non-redundant access router topology is supported by the PIM stub feature. By using a non-redundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

In the figure shown below, Switch A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source.

**Figure 20: PIM Stub Router Configuration**

---

**Static Mroutes**

IPv6 static mroutes behave much in the same way as IPv4 static mroutes used to influence the RPF check. IPv6 static mroutes share the same database as IPv6 static routes and are implemented by extending static route support for RPF checks. Static mroutes support equal-cost multipath mroutes, and they also support unicast-only static routes.

**MRIB**

The Multicast Routing Information Base (MRIB) is a protocol-independent repository of multicast routing entries instantiated by multicast routing protocols (routing clients). Its main function is to provide independence between routing protocols and the Multicast Forwarding Information Base (MFIB). It also acts as a coordination and communication point among its clients.

Routing clients use the services provided by the MRIB to instantiate routing entries and retrieve changes made to routing entries by other clients. Besides routing clients, MRIB also has forwarding clients (MFIB instances) and special clients such as MLD. MFIB retrieves its forwarding entries from MRIB and notifies the MRIB.
of any events related to packet reception. These notifications can either be explicitly requested by routing clients or spontaneously generated by the MFIB.

Another important function of the MRIB is to allow for the coordination of multiple routing clients in establishing multicast connectivity within the same multicast session. MRIB also allows for the coordination between MLD and routing protocols.

**MFIB**

The MFIB is a platform-independent and routing-protocol-independent library for IPv6 software. Its main purpose is to provide a Cisco IOS platform with an interface with which to read the IPv6 multicast forwarding table and notifications when the forwarding table changes. The information provided by the MFIB has clearly defined forwarding semantics and is designed to make it easy for the platform to translate to its specific hardware or software forwarding mechanisms.

When routing or topology changes occur in the network, the IPv6 routing table is updated, and those changes are reflected in the MFIB. The MFIB maintains next-hop address information based on the information in the IPv6 routing table. Because there is a one-to-one correlation between MFIB entries and routing table entries, the MFIB contains all known routes and eliminates the need for route cache maintenance that is associated with switching paths such as fast switching and optimum switching.

**Distributed MFIB**

**Note**

Distributed MFIB has its significance only in a stacked environment where the Master distributes the MFIB information to the other stack members. In the following section the line cards are nothing but the member switches in the stack.

Distributed MFIB (dMFIB) is used to switch multicast IPv6 packets on distributed platforms. dMFIB may also contain platform-specific information on replication across line cards. The basic MFIB routines that implement the core of the forwarding logic are common to all forwarding environments.

dMFIB implements the following functions:

- Distributes a copy of the MFIB to the line cards.
- Relays data-driven protocol events generated in the line cards to PIM.
- Provides an MFIB platform application program interface (API) to propagate MFIB changes to platform-specific code responsible for programming the hardware acceleration engine. This API also includes entry points to switch a packet in software (necessary if the packet is triggering a data-driven event) and to upload traffic statistics to the software.
- Provides hooks to allow clients residing on the RP to read traffic statistics on demand. (dMFIB does not periodically upload these statistics to the RP.)

The combination of dMFIB and MRIB subsystems also allows the switch to have a "customized" copy of the MFIB database in each line card and to transport MFIB-related platform-specific information from the RP to the line cards.
IPv6 Multicast Process Switching and Fast Switching

A unified MFIB is used to provide both fast switching and process switching support for PIM-SM and PIM-SSM in IPv6 multicast. In process switching, the Route Processor must examine, rewrite, and forward each packet. The packet is first received and copied into the system memory. The switch then looks up the Layer 3 network address in the routing table. The Layer 2 frame is then rewritten with the next-hop destination address and sent to the outgoing interface. The RP also computes the cyclic redundancy check (CRC). This switching method is the least scalable method for switching IPv6 packets.

IPv6 multicast fast switching allows switches to provide better packet forwarding performance than process switching. Information conventionally stored in a route cache is stored in several data structures for IPv6 multicast switching. The data structures provide optimized lookup for efficient packet forwarding.

In IPv6 multicast forwarding, the first packet is fast-switched if the PIM protocol logic allows it. In IPv6 multicast fast switching, the MAC encapsulation header is precomputed. IPv6 multicast fast switching uses the MFIB to make IPv6 destination prefix-based switching decisions. In addition to the MFIB, IPv6 multicast fast switching uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all MFIB entries.

The adjacency table is populated as adjacencies are discovered. Each time an adjacency entry is created (such as through ARP), a link-layer header for that adjacent node is precomputed and stored in the adjacency table. Once a route is determined, it points to a next hop and corresponding adjacency entry. It is subsequently used for encapsulation during switching of packets.

A route might have several paths to a destination prefix, such as when a switch is configured for simultaneous load balancing and redundancy. For each resolved path, a pointer is added for the adjacency corresponding to the next-hop interface for that path. This mechanism is used for load balancing across several paths.

Implementing IPv6 Multicast

Enabling IPv6 Multicast Routing

To enable IPv6 multicast routing, perform this procedure:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> ipv6 multicast-routing</td>
<td>Enables multicast routing on all IPv6-enabled interfaces and enables multicast forwarding for PIM and MLD on all enabled interfaces of the switch.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ipv6 multicast-routing</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>
# Customizing and Verifying the MLD Protocol

## Customizing and Verifying MLD on an Interface

To customize and verify MLD on an interface, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>interface type number</code></td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# <code>interface GigabitEthernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>`ipv6 mld join-group [group-address] [include</td>
<td>exclude] {source-address</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# <code>ipv6 mld join-group FF04::10</code></td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td><code>ipv6 mld access-group access-list-name</code></td>
<td>Allows the user to perform IPv6 multicast receiver access control.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# <code>ipv6 access-list acc-grp-1</code></td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>`ipv6 mld static-group [group-address] [include</td>
<td>exclude] {source-address</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# <code>ipv6 mld static-group FF04::10 include 100::1</code></td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td><code>ipv6 mld query-max-response-time seconds</code></td>
<td>Configures the timeout value before the switch takes over as the querier for the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# <code>ipv6 mld query-timeout 130</code></td>
<td></td>
</tr>
<tr>
<td>Step 8</td>
<td><code>exit</code></td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# <code>exit</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Displays the multicast groups that are directly connected to the switch and that were learned through MLD.</td>
<td></td>
</tr>
<tr>
<td>show ipv6 mld groups [link-local] [group-name</td>
<td>group-address] [interface-type interface-number] [detail</td>
<td>explicit]</td>
</tr>
<tr>
<td>Device# show ipv6 mld groups GigabitEthernet 1/0/1</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Displays the number of (*, G) and (S, G) membership reports present in the MLD cache.</td>
<td></td>
</tr>
<tr>
<td>show ipv6 mld groups summary</td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 mld groups summary</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>Displays multicast-related information about an interface.</td>
<td></td>
</tr>
<tr>
<td>show ipv6 mld interface [type number]</td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 mld interface GigabitEthernet 1/0/1</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong></td>
<td>Enables debugging on MLD protocol activity.</td>
<td></td>
</tr>
<tr>
<td>debug ipv6 mld [group-name</td>
<td>group-address</td>
<td>interface-type]</td>
</tr>
<tr>
<td>Device# debug ipv6 mld</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 13</strong></td>
<td>Displays information related to the explicit tracking of hosts.</td>
<td></td>
</tr>
<tr>
<td>debug ipv6 mld explicit [group-name</td>
<td>group-address</td>
<td>interface-type]</td>
</tr>
<tr>
<td>Device# debug ipv6 mld explicit</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 14</strong></td>
<td>(Optional) Save your entries in the configuration file.</td>
<td></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Implementing MLD Group Limits**

Per-interface and global MLD limits operate independently of each other. Both per-interface and global MLD limits can be configured on the same switch. The number of MLD limits, globally or per interface, is not configured by default; the limits must be configured by the user. A membership report that exceeds either the per-interface or the global state limit is ignored.

**Configuring Explicit Tracking of Receivers to Track Host Behavior**

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network and enables the fast leave mechanism to be used with MLD version 2 host reports.

To configure explicit tracking of receivers to track host behavior, perform this procedure:
### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ipv6 mld explicit-tracking access-list-name</td>
<td>Enables explicit tracking of hosts.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ipv6 mld explicit-tracking list1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Resetting the MLD Traffic Counters

To reset the MLD traffic counters, perform this procedure:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> clear ipv6 mld traffic</td>
<td>Resets all MLD traffic counters.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# clear ipv6 mld traffic</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> show ipv6 mld traffic</td>
<td>Displays the MLD traffic counters.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show ipv6 mld traffic</td>
<td></td>
</tr>
</tbody>
</table>
Clearing the MLD Interface Counters

To clearing the MLD interface counters, perform this procedure

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 clear ipv6 mld counters interface-type</td>
<td>Clears the MLD interface counters.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# clear ipv6 mld counters Ethernet1/0</td>
<td></td>
</tr>
<tr>
<td>Step 4 copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

Configuring PIM

This section explains how to configure PIM.

Configuring PIM-SM and Displaying PIM-SM Information for a Group Range

To configuring PIM-SM and view PIM-SM information for a group range, perform this procedure:

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ipv6 pim rp-address ipv6-address[group-access-list]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 pim rp-address 2001:DB8::01:800:200E:8C6C acc-grp-1</td>
<td>Configures the address of a PIM RP for a particular group range.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>exit</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# exit</td>
<td>Exits global configuration mode, and returns the switch to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>show ipv6 pim interface [state-on] [state-off] [type-number]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 pim interface</td>
<td>Displays information about interfaces configured for PIM.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>show ipv6 pim group-map [group-name</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 pim group-map</td>
<td>Displays an IPv6 multicast group mapping table.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>show ipv6 pim neighbor [detail] [interface-type interface-number</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 pim neighbor</td>
<td>Displays the PIM neighbors discovered by the Cisco IOS software.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>show ipv6 pim range-list [config] [rp-address</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 pim range-list</td>
<td>Displays information about IPv6 multicast range lists.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>show ipv6 pim tunnel [interface-type interface-number]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 pim tunnel</td>
<td>Displays information about the PIM register encapsulation and de-encapsulation tunnels on an interface.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>debug ipv6 pim [group-name</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Enables debugging on PIM protocol activity.</td>
</tr>
</tbody>
</table>
### Configuring PIM Options

To configure PIM options, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ipv6 pim spt-threshold infinity [group-list access-list-name]</td>
<td>Configures when a PIM leaf switch joins the SPT for the specified groups.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ipv6 pim spt-threshold infinity group-list acc-grp-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>ipv6 pim accept-register {list access-list</td>
<td>route-map map-name}</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ipv6 pim accept-register route-map reg-filter</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>ipv6 pim dr-priority value</td>
<td>Configures the DR priority on a PIM switch.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# ipv6 pim dr-priority 3</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure</td>
<td>Configures the frequency of PIM hello messages on an interface.</td>
</tr>
<tr>
<td>ipv6 pim hello-interval seconds</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ipv6 pim hello-interval 45</td>
<td></td>
</tr>
<tr>
<td>ipv6 pim join-prune-interval seconds</td>
<td>Configures periodic join and prune announcement intervals for a specified interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ipv6 pim join-prune-interval 75</td>
<td></td>
</tr>
<tr>
<td>exit</td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td>ipv6 pim join-prune statistic [interface-type]</td>
<td>Displays the average join-prune aggregation for the most recently aggregated packets for each interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# show ipv6 pim join-prune statistic</td>
<td></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Resetting the PIM Traffic Counters

If PIM malfunctions or in order to verify that the expected number of PIM packets are received and sent, the user can clear PIM traffic counters. Once the traffic counters are cleared, the user can enter the show ipv6 pim traffic command to verify that PIM is functioning correctly and that PIM packets are being received and sent correctly.

To resetting the PIM traffic counters, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
Clearing the PIM Topology Table to Reset the MRIB Connection

No configuration is necessary to use the MRIB. However, users may in certain situations want to clear the PIM topology table in order to reset the MRIB connection and verify MRIB information.

To clear the PIM topology table to reset the MRIB connection, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
</tr>
</thead>
</table>
| Resets the PIM traffic counters. | Step 3 clear ipv6 pim traffic  
Device# clear ipv6 pim traffic |
| Displays the PIM traffic counters. | Step 4 show ipv6 pim traffic  
Device# show ipv6 pim traffic |
| (Optional) Save your entries in the configuration file. | Step 5 copy running-config startup-config |

**Step 1**

- **Command or Action**: enable
  - **Example**: Device> enable
  - **Purpose**: Enables privileged EXEC mode. Enter your password if prompted.

**Step 2**

- **Command or Action**: configure terminal
  - **Example**: Device# configure terminal
  - **Purpose**: Enters global configuration mode.

**Step 3**

- **Command or Action**: clear ipv6 pim topology [group-name | group-address]
  - **Example**: Device# clear ipv6 pim topology FF04::10
  - **Purpose**: Clears the PIM topology table.

**Step 4**

- **Command or Action**: show ipv6 mrib client [filter] [name {client-name | client-name : client-id}]
  - **Example**: Device# show ipv6 mrib client
  - **Purpose**: Displays multicast-related information about an interface.

**Step 5**

- **Command or Action**: show ipv6 mrib route [link-local | summary | [sourceaddress-or-name | *] [groupname-or-address[ prefix-length]]]
  - **Purpose**: Displays the MRIB route information.
### Command or Action

**Step 6**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ipv6 pim topology [groupname-or-address [sourceaddress-or-name]</td>
<td>link-local</td>
</tr>
<tr>
<td><code>show ipv6 pim topology</code></td>
<td>Example:</td>
</tr>
<tr>
<td><code>debug ipv6 mrib client</code></td>
<td>Enables debugging on MRIB client management activity.</td>
</tr>
<tr>
<td><code>debug ipv6 mrib io</code></td>
<td>Enables debugging on MRIB I/O events.</td>
</tr>
<tr>
<td><code>debug ipv6 mrib proxy</code></td>
<td>Enables debugging on MRIB proxy activity between the switch processor and line cards on distributed switch platforms.</td>
</tr>
<tr>
<td>`debug ipv6 mrib route [group-name</td>
<td>group-address]`</td>
</tr>
<tr>
<td><code>debug ipv6 mrib table</code></td>
<td>Enables debugging on MRIB table management activity.</td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Configuring PIM IPv6 Stub Routing

The PIM Stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards MLD traffic.
PIM IPv6 Stub Routing Configuration Guidelines

- Before configuring PIM stub routing, you must have IPv6 multicast routing configured on both the stub router and the central router. You must also have PIM mode (sparse-mode) configured on the uplink interface of the stub router.
- The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior. For more information, see the EIGRP Stub Routing section.
- Only directly connected multicast (MLD) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- The redundant PIM stub router topology is not supported.

Default IPv6 PIM Routing Configuration

This table displays the default IPv6 PIM routing configuration for the Device.

Table 42: Default Multicast Routing Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multicast routing</td>
<td>Disabled on all interfaces.</td>
</tr>
<tr>
<td>PIM version</td>
<td>Version 2.</td>
</tr>
<tr>
<td>PIM mode</td>
<td>No mode is defined.</td>
</tr>
<tr>
<td>PIM stub routing</td>
<td>None configured.</td>
</tr>
<tr>
<td>PIM RP address</td>
<td>None configured.</td>
</tr>
<tr>
<td>PIM domain border</td>
<td>Disabled.</td>
</tr>
<tr>
<td>PIM multicast boundary</td>
<td>None.</td>
</tr>
<tr>
<td>Candidate BSRs</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Candidate RPs</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Shortest-path tree threshold rate</td>
<td>0 kb/s.</td>
</tr>
<tr>
<td>PIM router query message interval</td>
<td>30 seconds.</td>
</tr>
</tbody>
</table>

Enabling IPV6 PIM Stub Routing

To enable IPV6 PIM stub routing, perform this procedure:

Before you begin
PIM stub routing is disabled in IPv6 by default.

SUMMARY STEPS

1. enable
2. configure terminal
### Enabling IPV6 PIM Stub Routing

3. ipv6 multicast pim-passive-enable
4. interface interface-id
5. ipv6 pim
6. ipv6 pim {bsr} | {dr-priority | value} | {hello-interval | seconds} | {join-prune-interval | seconds} | {passive}
7. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>

### Monitoring IPv6 PIM Stub Routing

**Table 43: PIM Stub Configuration show Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ipv6 pim interface</code></td>
<td>Displays the PIM stub that is enabled on each interface.</td>
</tr>
<tr>
<td><code>show ipv6 mld groups</code></td>
<td>Displays the interested clients that have joined the specific multicast source group.</td>
</tr>
<tr>
<td><code>show ipv6 mroute</code></td>
<td>Verifies that the multicast stream forwards from the source to the interested clients.</td>
</tr>
</tbody>
</table>

### Configuring a BSR

The tasks included here are described below.
# Configuring a BSR and Verifying BSR Information

To configure and verify BSR Information, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>ipv6 pim bsr candidate bsr ipv6-address[hash-mask-length] [priority priority-value]</code></td>
<td>Configures a switch to be a candidate BSR.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# ipv6 pim bsr candidate bsr 2001:DB8::3000:3000::42 124 priority 10</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>interface type number</code></td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# interface GigabitEthernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>ipv6 pim bsr border</code></td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-if)# ipv6 pim bsr border</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>exit</code></td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-if)# exit</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>`show ipv6 pim bsr {election</td>
<td>rp-cache</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-if)# show ipv6 pim bsr election</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>
## Sending PIM RP Advertisements to the BSR

To sending PIM RP advertisements to the BSR, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ipv6 pim bsr candidate rp ipv6-address [group-list access-list-name] [priority priority-value] [interval seconds]</td>
<td>Sends PIM RP advertisements to the BSR.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 pim bsr candidate rp 2001:DB8:3000:3000::42 priority 0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ipv6 pim bsr border</td>
<td>Configures a border for all BSMs of any scope on a specified interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ipv6 pim bsr border</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

## Configuring BSR for Use Within Scoped Zones

To configure BSR for use within scoped zones, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**

**configure terminal**

Example:

```
Device# configure terminal
```

**Step 3**

```
ipv6 pim bsr candidate rp ipv6-address [hash-mask-length] [priority priority-value]
```

Example:

```
Device(config)# ipv6 pim bsr candidate bsr 2001:DB8:1:1:4
```

**Step 4**

```
ipv6 pim bsr candidate rp ipv6-address [group-list access-list-name] [priority priority-value] [interval seconds]
```

Example:

```
Device(config)# ipv6 pim bsr candidate rp 2001:DB8:1:1:1 group-list list scope 6
```

**Step 5**

```
interface type number
```

Example:

```
Device(config-if)# interface GigabitEthernet 1/0/1
```

**Step 6**

```
ipv6 multicast boundary scope scope-value
```

Example:

```
Device(config-if)# ipv6 multicast boundary scope 6
```

**Step 7**

```
copy running-config startup-config
```

(Optional) Save your entries in the configuration file.

---

### Configuring BSR Switches to Announce Scope-to-RP Mappings

IPv6 BSR switches can be statically configured to announce scope-to-RP mappings directly instead of learning them from candidate-RP messages. A user might want to configure a BSR switch to announce scope-to-RP mappings so that an RP that does not support BSR is imported into the BSR. Enabling this feature also allows an RP positioned outside the enterprise's BSR domain to be learned by the known remote RP on the local candidate BSR switch.

To configure BSR switches to announce Scope-to-RP mappings, perform this procedure:
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ipv6 pim bsr announced rp ipv6-address [group-list access-list-name] [priority priority-value]</td>
<td>Announces scope-to-RP mappings directly from the BSR for the specified candidate RP.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# ipv6 pim bsr announced rp 2001:DB8:3000:3000::42 priority 0</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

## Configuring SSM Mapping

When the SSM mapping feature is enabled, DNS-based SSM mapping is automatically enabled, which means that the switch will look up the source of a multicast MLD version 1 report from a DNS server.

You can use either DNS-based or static SSM mapping, depending on your switch configuration. If you choose to use static SSM mapping, you can configure multiple static SSM mappings. If multiple static SSM mappings are configured, the source addresses of all matching access lists will be used.

### Note
To use DNS-based SSM mapping, the switch needs to find at least one correctly configured DNS server, to which the switch may be directly attached.

To configuring SSM mapping, perform this procedure:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Enables the SSM mapping feature for groups in the configured SSM range.</td>
</tr>
</tbody>
</table>

#### Step 3

**Purpose**: Enables the SSM mapping feature for groups in the configured SSM range.

**Command or Action**: `ipv6 mld ssm-map enable`

**Example**:

```
Device(config)# ipv6 mld ssm-map enable
```

#### Step 4

**Purpose**: Disables DNS-based SSM mapping.

**Command or Action**: `no ipv6 mld ssm-map query dns`

**Example**:

```
Device(config)# no ipv6 mld ssm-map query dns
```

#### Step 5

**Purpose**: Configures static SSM mappings.

**Command or Action**: `ipv6 mld ssm-map static access-list source-address`

**Example**:

```
Device(config-if)# ipv6 mld ssm-map static SSM_MAP_ACL_2 2001:DB8:1::1
```

#### Step 6

**Purpose**: Exits global configuration mode, and returns the switch to privileged EXEC mode.

**Command or Action**: `exit`

**Example**:

```
Device(config-if)# exit
```

#### Step 7

**Purpose**: Displays SSM mapping information.

**Command or Action**: `show ipv6 mld ssm-map [source-address]`

**Example**:

```
Device(config-if)# show ipv6 mld ssm-map
```

#### Step 8

**Purpose**: (Optional) Save your entries in the configuration file.

**Command or Action**: `copy running-config startup-config`

**Example**:

```
Device(config-if)# copy running-config startup-config
```

### Configuring Static Mroutes

Static multicast routes (mroutes) in IPv6 can be implemented as an extension of IPv6 static routes. You can configure your switch to use a static route for unicast routing only, to use a static multicast route for multicast RPF selection only, or to use a static route for both unicast routing and multicast RPF selection.

To configure static mroutes, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Example**:

```
Device> enable
```

Enter your password if prompted.
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>ipv6 route {ipv6-prefix / prefix-length ipv6-address</td>
<td>Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.</td>
</tr>
<tr>
<td>interface-type interface-number ipv6-address}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>[administrative-distance] [administrative-multicast-distance</td>
<td></td>
<td></td>
</tr>
<tr>
<td>unicast</td>
<td>multicast] [tag tag]</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ipv6 route 2001::DB8::/64 6::6 100</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>exit</td>
<td>Exits global configuration mode, and returns the switch to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# exit</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>show ipv6 mroute [link-local</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>[group-name]</td>
<td>group-address [source-address</td>
<td></td>
</tr>
<tr>
<td>[source-name]] [summary] [count]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show ipv6 mroute ff07::1</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>show ipv6 mroute [link-local</td>
<td>Displays the active multicast streams on the switch.</td>
</tr>
<tr>
<td>[group-name]</td>
<td>group-address] active [kbps]</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# show ipv6 mroute active</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>show ipv6 rpf [ipv6-prefix]</td>
<td>Checks RPF information for a given unicast host address and prefix.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# show ipv6 rpf 2001::1:1:2</td>
<td></td>
</tr>
<tr>
<td>Step 8</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Using MFIB in IPv6 Multicast

Multicast forwarding is automatically enabled when IPv6 multicast routing is enabled.

### Verifying MFIB Operation in IPv6 Multicast

To verify MFIB operation in IPv6 multicast
### Verifying MFIB Operation in IPv6 Multicast

<table>
<thead>
<tr>

Configuring IPv6 ACL

- Finding Feature Information, on page 371
- Information About Configuring IPv6 ACLs, on page 371
- Configuring IPv6 ACLs, on page 373
- Configuration Examples for IPv6 ACL, on page 379

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 ACLs

You can filter IP version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic.

**Note**

To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch. You select the template by entering the `sdm prefer {default}` global configuration command.

Understanding IPv6 ACLs

A switch image supports two types of IPv6 ACLs:

- IPv6 router ACLs - Supported on inbound or outbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. Applied to only IPv6 packets that are routed.
IPv6 port ACLs - Supported on inbound traffic on Layer 2 interfaces only. Applied to all IPv6 packets entering the interface.

**Note**

If you configure unsupported IPv6 ACLs, an error message appears and the configuration does not take affect.

The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.

You can apply both IPv4 and IPv6 ACLs to an interface.

As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs:

- When an input router ACL and input port ACL exist in an SVI, packets received on ports to which a port ACL is applied are filtered by the port ACL. Routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.

- When an output router ACL and input port ACL exist in an SVI, packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IPv6 packets are filtered by the router ACL. Other packets are not filtered.

**Note**

If any port ACL (IPv4, IPv6, or MAC) is applied to an interface, that port ACL is used to filter packets, and any router ACLs attached to the SVI of the port VLAN are ignored.

**Supported ACL Features**

IPv6 ACLs on the switch have these characteristics:

- Fragmented frames (the fragments keyword as in IPv4) are supported.

- The same statistics supported in IPv4 are supported for IPv6 ACLs.

- If the switch runs out of TCAM space, packets associated with the ACL label are forwarded to the CPU, and the ACLs are applied in software.

- Routed or bridged packets with hop-by-hop options have IPv6 ACLs applied in software.

- Logging is supported for router ACLs, but not for port ACLs.

**IPv6 ACL Limitations**

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs.

The switch supports most Cisco IOS-supported IPv6 ACLs with some exceptions:

- IPv6 source and destination addresses-ACL matching is supported only on prefixes from /0 to /64 and host addresses (/128) that are in the extended universal identifier (EUI)-64 format. The switch supports only these host addresses with no loss of information:
  - aggregatable global unicast addresses
  - link local addresses
• The switch does not support matching on these keywords: flowlabel, routing header, and undetermined-transport.

• The switch does not support reflexive ACLs (the reflect keyword).

• This release supports only port ACLs and router ACLs for IPv6; it does not support VLAN ACLs (VLAN maps).

• The switch does not apply MAC-based ACLs on IPv6 frames.

• You cannot apply IPv6 port ACLs to Layer 2 EtherChannels.

• The switch does not support output port ACLs.

• Output router ACLs and input port ACLs for IPv6 are supported only on . Switches support only control plane (incoming) IPv6 ACLs.

• When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the switch checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.

• If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the switch does not allow the ACE to be added to the ACL that is currently attached to the interface.

**Configuring IPv6 ACLs**

To filter IPv6 traffic, you perform these steps:

**Before you begin**

Before configuring IPv6 ACLs, you must select one of the dual IPv4 and IPv6 SDM templates.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Create an IPv6 ACL, and enter IPv6 access list configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Configure the IPv6 ACL to block (deny) or pass (permit) traffic.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.</td>
</tr>
</tbody>
</table>

**Default IPv6 ACL Configuration**

There are no IPv6 ACLs configured or applied.
Interaction with Other Features and Switches

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.

- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.

- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.

- If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.

---

**Note**

Only packets of the same type as the ACL that could not be added (ipv4, ipv6, MAC) will be dropped on the interface.

---

Creating an IPv6 ACL

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  - enable
  - Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
  - configure terminal
  - Example: Device# configure terminal | Enters global configuration mode. |
| **Step 3**
  - ipv6 access-list acl_name
  - Example: Device# ipv6 access-list access-list-name | Use a name to define an IPv6 access list and enter IPv6 access-list configuration mode. |

<tr>
<td>[dscp-value]</td>
<td>• For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons.</td>
</tr>
<tr>
<td>[fragments]</td>
<td>• (Optional) For operator, specify an operand that compares the source or destination ports of the specified protocol. Operands are <code>lt</code> (less than), <code>gt</code> (greater than), <code>eq</code> (equal), <code>neq</code> (not equal), and <code>range</code>.</td>
</tr>
<tr>
<td>[log]</td>
<td>If the operator follows the source-ipv6-prefix/prefix-length argument, it must match the source port. If the operator follows the destination-ipv6-prefix/prefix-length argument, it must match the destination port.</td>
</tr>
<tr>
<td>[log-input]</td>
<td>• (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP.</td>
</tr>
<tr>
<td>[routing]</td>
<td>• (Optional) Enter dscp-value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63.</td>
</tr>
<tr>
<td>[sequence value]</td>
<td>• (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6.</td>
</tr>
</tbody>
</table>
| [time-range name] | • (Optional) Enter log to cause an logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface.
### Purpose

Logging is supported only for router ACLs.

- (Optional) Enter routing to specify that IPv6 packets be routed.
- (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295
- (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement.

### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>command</td>
<td>purpose</td>
</tr>
<tr>
<td>action</td>
<td>process</td>
</tr>
</tbody>
</table>

### Step 5

**{deny|permit} tcp**

**Example:**

```
{deny | permit} tcp
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}
[operator]
[port-number]]{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}
[operator [port-number]]{ack | dscp value | established | fin}
[log | log-input] {neq | port | protocol} {psh | range | port | protocol} [rst | routing] {sequence value | time-range name | urg}
```

(Optional) Define a TCP access list and the access conditions.

Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:

- **ack**—Acknowledgment bit set.
- **established**—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set.
- **fin**—Finished bit set; no more data from sender.
- **neq** {port | protocol}—Matches only packets that are not on a given port number.
- **psh**—Push function bit set.
- **range** {port | protocol}—Matches only packets in the port number range.
- **rst**—Reset bit set.
- **syn**—Synchronize bit set.
- **urg**—Urgent pointer bit set.

### Step 6

**{deny|permit} udp**

**Example:**

```
{deny | permit} udp
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}
[operator]
[port-number]]{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}
[operator [port-number]]{dscp value | log | log-input}
[neq | port | protocol] [range | port | protocol] [routing] {sequence value | time-range name}
```

(Optional) Define a UDP access list and the access conditions.

Enter udp for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the operator [port] port number or name must be a UDP port number or name, and the established parameter is not valid for UDP.
Applying an IPv6 to an Interface

This section describes how to apply IPv6 ACLs to network interfaces. You can apply an IPv6 ACL to outbound or inbound traffic on layer 2 and Layer 3 interfaces. You can apply IPv6 ACLs only to inbound management traffic on Layer 3 interfaces.

To control access to an interface, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### Applying an IPv6 to an Interface

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**

**configure terminal**  
Example:  
Device# configure terminal

**Step 3**

**interface interface_id**  
Example:  
Device# interface interface-id

**Step 4**

**no switchport**  
Example:  
Device# no switchport

**Step 5**

**ipv6 address ipv6_address**  
Example:  
Device# ipv6 address ipv6-address

**Note**  
This command is not required on Layer 2 interfaces or if the interface has already been configured with an explicit IPv6 address.

**Step 6**

**ipv6 traffic-filter acl_name**  
Example:  
Device# ipv6 traffic-filter access-list-name {in | out}

**Step 7**

**end**  
Example:  
Device(config)# end

**Step 8**

**show running-config interface tenGigabitEthernet 1/0/3**  
Example:  
Device# show running-config interface tenGigabitEthernet 1/0/3  
.................  
.................  
Building configuration ..........  
.................  
Current configuration : 98 bytes  
!  
interface TenGigabitEthernet1/0/3  
switchport mode trunk  
ipv6 traffic-filter MyFilter out  
end

**Step 9**

**copy running-config startup-config**  
Example:  
(Optional) Saves your entries in the configuration file.
### Displaying IPv6 ACLs

To display IPv6 ACLs, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>show access-list</td>
<td>Displays all access lists configured on the device</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# show access-lists</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>show ipv6 access-list acl_name</td>
<td>Displays all configured IPv6 access list or the access list specified by name.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# show ipv6 access-list [access-list-name]</td>
<td></td>
</tr>
</tbody>
</table>

### Configuration Examples for IPv6 ACL

#### Example: Creating an IPv6 ACL

This example configures the IPv6 access list named CISCO. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny -all condition is at the end of each IPv6 access list.

Note: Logging is supported only on Layer 3 interfaces.
Example: Applying IPv6 ACLs

This example shows how to apply the access list Cisco to outbound traffic on a Layer 3 interface.

Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001::/64 eui-64
Device(config-if)# ipv6 traffic-filter CISCO out

Example: Displaying IPv6 ACLs

This is an example of the output from the `show access-lists` privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

Device #show access-lists
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10

This is an example of the output from the `show ipv6 access-lists` privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

Device# show ipv6 access-list
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30

IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20

CHAPTER 25

Configuring Spanning Tree Protocol

This chapter describes how to configure the Spanning Tree Protocol (STP) on port-based VLANs on the Catalyst devices. The device can use either the per-VLAN spanning-tree plus (PVST+) protocol based on the IEEE 802.1D standard and Cisco proprietary extensions, or the rapid per-VLAN spanning-tree plus (rapid-PVST+) protocol based on the IEEE 802.1w standard. A switch stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for STP

- An attempt to configure a device as the root device fails if the value necessary to be the root device is less than 1.

- If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected devices running older software.
• The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Information About Spanning Tree Protocol

Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Devices might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

The STP uses a spanning-tree algorithm to select one device of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

• Root—A forwarding port elected for the spanning-tree topology
• Designated—A forwarding port elected for every switched LAN segment
• Alternate—A blocked port providing an alternate path to the root bridge in the spanning tree
• Backup—A blocked port in a loopback configuration

The device that has all of its ports as the designated role or as the backup role is the root device. The device that has at least one of its ports in the designated role is called the designated device.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Devices send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The devices do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending device and its ports, including device and MAC addresses, device priority, port priority, and path cost. Spanning tree uses this information to elect the root device and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a device are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

Note

By default, the device sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the [no] keepalive interface configuration command with no keywords.
Spanning-Tree Topology and BPDUs

The stable, active spanning-tree topology of a switched network is controlled by these elements:

- The unique bridge ID (device priority and MAC address) associated with each VLAN on each device. In a device stack, all devices use the same bridge ID for a given spanning-tree instance.
- The spanning-tree path cost to the root device.
- The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the devices in a network are powered up, each functions as the root device. Each device sends a configuration BPDU through all of its ports. The BPDU's communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the device that the sending device identifies as the root device
- The spanning-tree path cost to the root
- The bridge ID of the sending device
- Message age
- The identifier of the sending interface
- Values for the hello, forward delay, and max-age protocol timers

When a device receives a configuration BPDU that contains superior information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the device, the device also forwards it with an updated message to all attached LANs for which it is the designated device.

If a device receives a configuration BPDU that contains inferior information to that currently stored for that port, it discards the BPDU. If the device is a designated device for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:

- One device in the network is elected as the root device (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.
  
  For each VLAN, the device with the highest device priority (the lowest numerical priority value) is elected as the root device. If all devices are configured with the default priority (32768), the device with the lowest MAC address in the VLAN becomes the root device. The device priority value occupies the most significant bits of the bridge ID, as shown in the following figure.

- A root port is selected for each device (except the root device). This port provides the best path (lowest cost) when the device forwards packets to the root device.

- Only one outgoing port on the stack root device is selected as the root port. The remaining devices in the stack become its designated devices (Device 2 and Device 3) as shown in the following figure.

- The shortest distance to the root device is calculated for each device based on the path cost.

- A designated device for each LAN segment is selected. The designated device incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
One stack member is elected as the stack root device. The stack root device contains the outgoing root port (Device 1).

All paths that are not needed to reach the root device from anywhere in the switched network are placed in the spanning-tree blocking mode.

**Bridge ID, Device Priority, and Extended System ID**

The IEEE 802.1D standard requires that each device has an unique bridge identifier (bridge ID), which controls the selection of the root device. Because each VLAN is considered as a different logical bridge with PVST+ and Rapid PVST+, the same device must have a different bridge ID for each configured VLAN. Each VLAN on the device has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the device priority, and the remaining 6 bytes are derived from the device MAC address.

The device supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the device priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for the device, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.
The 2 bytes previously used for the device priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

Table 44: Device Priority Value and Extended System ID

<table>
<thead>
<tr>
<th>Priority Value</th>
<th>Extended System ID (Set Equal to the VLAN ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 16</td>
<td>Bit 15</td>
</tr>
<tr>
<td>32768</td>
<td>16384</td>
</tr>
</tbody>
</table>

Spanning tree uses the extended system ID, the device priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the device stack appears as a single device to the rest of the network, all devices in the stack use the same bridge ID for a given spanning tree. If the stack master fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack master.

Support for the extended system ID affects how you manually configure the root device, the secondary root device, and the device priority of a VLAN. For example, when you change the device priority value, you change the probability that the device will be elected as the root device. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root device for the specified VLAN has a device priority lower than 24576, the device sets its own priority for the specified VLAN to 4096 less than the lowest device priority. 4096 is the value of the least-significant bit of a 4-bit device priority value as shown in the table.

Port Priority Versus Path Cost

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your device is a member of a device stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see Related Topics.

Spanning-Tree Interface States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

Each Layer 2 interface on a device using spanning tree exists in one of these states:
• Blocking—The interface does not participate in frame forwarding.
• Listening—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.
• Learning—The interface prepares to participate in frame forwarding.
• Forwarding—The interface forwards frames.
• Disabled—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:
• From initialization to blocking
• From blocking to listening or to disabled
• From listening to learning or to disabled
• From learning to forwarding or to disabled
• From forwarding to disabled

Figure 22: Spanning-Tree Interface States

An interface moves through the states.

When you power up the device, spanning tree is enabled by default, and every interface in the device, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:

1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.
2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.
3. In the learning state, the interface continues to block frame forwarding as the device learns end-station location information for the forwarding database.
4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

**Blocking State**

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each device interface. A device initially functions as the root until it exchanges BPDU's with other devices. This exchange establishes which device in the network is the root or root device. If there is only one device in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after device initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

**Listening State**

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

**Learning State**

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs

**Forwarding State**

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface
• Forwards frames switched from another interface
• Learns addresses
• Receives BPDUs

### Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:
• Discards frames received on the interface
• Discards frames switched from another interface for forwarding
• Does not learn addresses
• Does not receive BPDUs

### How a Device or Port Becomes the Root Device or Root Port

If all devices in a network are enabled with default spanning-tree settings, the device with the lowest MAC address becomes the root device.

**Figure 23: Spanning-Tree Topology**

Device A is elected as the root device because the device priority of all the devices is set to the default (32768) and Device A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Device A might not be the ideal root device. By increasing the priority (lowering the numerical value) of the ideal device so that it becomes the root device, you force a spanning-tree recalculation to form a new topology with the ideal device as the root.

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.

For example, assume that one port on Device B is a Gigabit Ethernet link and that another port on Device B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.
Spanning Tree and Redundant Connectivity

You can create a redundant backbone with spanning tree by connecting two device interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds are the same, the port priority and port ID are added together, and spanning tree disables the link with the highest value.

You can also create redundant links between devices by using EtherChannel groups.

Spanning-Tree Address Management

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C2000000 to 0x0180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each device in the stack receives but does not forward packets destined for addresses between 0x0180C2000000 and 0x0180C20000F.

If spanning tree is enabled, the CPU on the device or on each device in the stack receives packets destined for 0x0180C2000000 and 0x0180C200010. If spanning tree is disabled, the device or each device in the stack forwards those packets as unknown multicast addresses.

Accelerated Aging to Retain Connectivity

The default for aging dynamic addresses is 5 minutes, the default setting of the `mac address-table aging-time` global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (spanning-tree vlan vlan-id forward-time seconds global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the device accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the device.

Spanning-Tree Modes and Protocols

The device supports these spanning-tree modes and protocols:
• PVST+—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. The PVST+ runs on each VLAN on the device up to the maximum supported, ensuring that each has a loop-free path through the network.

The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root device. This root device propagates the spanning-tree information associated with that VLAN to all other devices in the network. Because each device has the same information about the network, this process ensures that the network topology is maintained.

• Rapid PVST+—This spanning-tree mode is the same as PVST+ except that it is uses a rapid convergence based on the IEEE 802.1w standard. Beginning from 15.2(4)E release, the STP default mode is Rapid PVST+. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to re provision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

• MSTP—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a device stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

Supported Spanning-Tree Instances

In PVST+ or Rapid PVST+ mode, the device or device stack supports up to 128 spanning-tree instances.

In MSTP mode, the device or device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

Spanning-Tree Interoperability and Backward Compatibility

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ device cannot connect to multiple MST regions.

When a network contains devices running Rapid PVST+ and devices running PVST+, we recommend that the Rapid PVST+ devices and PVST+ devices be configured for different spanning-tree instances. In the Rapid PVST+ spanning-tree instances, the root device must be a Rapid PVST+ device. In the PVST+ instances, the root device must be a PVST+ device. The PVST+ devices should be at the edge of the network.

All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

**STP and IEEE 802.1Q Trunks**

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for *all* VLANs allowed on the trunks. However, in a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for *each* VLAN allowed on the trunks.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the device uses it instead of PVST+. The device combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.

Rapid PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

**VLAN-Bridge Spanning Tree**

Cisco VLAN-bridge spanning tree is used with the fallback bridging feature (bridge groups), which forwards non-IP protocols such as DECnet between two or more VLAN bridge domains or routed ports. The VLAN-bridge spanning tree allows the bridge groups to form a spanning tree on top of the individual VLAN spanning trees to prevent loops from forming if there are multiple connections among VLANs. It also prevents the individual spanning trees from the VLANs being bridged from collapsing into a single spanning tree.

To support VLAN-bridge spanning tree, some of the spanning-tree timers are increased. To use the fallback bridging feature, you must have the IP services feature set enabled on your device.

**Spanning Tree and Device Stacks**

When the device stack is operating in PVST+ or Rapid PVST+ mode:

- A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switchstack master.

- When a new device joins the stack, it sets its bridge ID to the active switchstack master bridge ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root.

- When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

- If the stack master fails or leaves the stack, the stack members elect a new stack master, and all stack members change their bridge IDs of the spanning trees to the new master bridge ID.
• If the device stack is the spanning-tree root and the stack master fails or leaves the stack, the stack members elect a new stack master, and a spanning-tree reconvergence occurs.

• If a neighboring device external to the device stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a device in the active topology.

• If a new device external to the device stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a device in the network.

</table>

Beginning in Cisco IOS Release 15.2(4)E, the default STP mode is Rapid PVST+.
How to Configure Spanning-Tree Features

Changing the Spanning-Tree Mode

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the device runs the Rapid PVST+ protocol.

If you want to enable a mode that is different from the default mode, this procedure is required.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mode {pvst | mst | rapid-pvst}
4. interface interface-id
5. spanning-tree link-type point-to-point
6. end
7. clear spanning-tree detected-protocols

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>

<tr>
<td>Device(config)# spanning-tree mode pvst</td>
<td>• Select mst to enable MSTP.</td>
</tr>
<tr>
<td></td>
<td>• Select rapid-pvst to enable rapid PVST+.</td>
</tr>
<tr>
<td>Step 4 interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port channels. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface GigabitEthernet1/0/1</td>
<td></td>
</tr>
</tbody>
</table>
Disabling Spanning Tree

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

⚠️ Caution

When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no spanning-tree vlan vlan-id`
4. `end`

<tr>
<td><code>Device# clear spanning-tree detected-protocols</code></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring the Root Device

To configure a device as the root for the specified VLAN, use the `spanning-tree vlan vlan-id root` global configuration command to modify the device priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the device priority of the root devices for each VLAN. Because of the extended system ID support, the device sets its own priority for the specified VLAN to 24576 if this value will cause this device to become the root for the specified VLAN.

Use the `diameter` keyword to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the `hello` keyword to override the automatically calculated hello time.

This procedure is optional.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree vlan vlan-id root [diameter net-diameter]`
4. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
*enable*

**Example:**

Device> `enable`

| **Step 2**
`configure terminal`

**Example:**

Device# `configure terminal`

| **Step 3**
no spanning-tree vlan vlan-id

**Example:**

Device(config)# `no spanning-tree vlan 300`

| **Step 4**
`end`

**Example:**

Device(config)# `end`
### Configuring a Secondary Root Device

When you configure a device as the secondary root, the device priority is modified from the default value (32768) to 28672. With this priority, the device is likely to become the root device for the specified VLAN if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768, and therefore, are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the `spanning-tree vlan vlan-id root primary` global configuration command.

This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree vlan vlan-id root secondary [diameter net-diameter]`
4. `end`

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>spanning-tree vlan vlan-id root primary [diameter net-diameter]</code></td>
<td>Configures a device to become the root for the specified VLAN.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config)# spanning-tree vlan 20-24 root primary diameter 4</code></td>
<td>• For <code>vlan-id</code>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For <code>diameter net-diameter</code>, specify the maximum number of devices between any two end stations. The range is 2 to 7.</td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

### What to do next

After configuring the device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the `spanning-tree vlan vlan-id hello-time`, `spanning-tree vlan vlan-id forward-time`, and the `spanning-tree vlan vlan-id max-age` global configuration commands.
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
</tbody>
</table>

**Configuring Port Priority**

*Note*

If your device is a member of a device stack, you must use the `spanning-tree [vlan vlan-id] cost cost` interface configuration command instead of the `spanning-tree [vlan vlan-id] port-priority priority` interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

**SUMMARY STEPS**

1. enable

</tbody>
</table>
Configuring Path Cost

This procedure is optional.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree cost cost`
5. `spanning-tree vlan vlan-id cost cost`
6. `end`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device&gt; enable</code></td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>interface interface-id</code></td>
<td>Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces (port-channel port-channel-number).</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config)# interface gigabitethernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>spanning-tree cost cost</code></td>
<td>Configures the cost for an interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config-if)# spanning-tree cost 250</code></td>
<td>If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission. For <code>cost</code>, the range is 1 to 200000000; the default value is derived from the media speed of the interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>spanning-tree vlan vlan-id cost cost</code></td>
<td>Configures the cost for a VLAN.</td>
</tr>
</tbody>
</table>
If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.

- For **vlan-id**, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.
- For **cost**, the range is 1 to 200000000; the default value is derived from the media speed of the interface.

### Examples:

**Step 6**

```bash
Device(config-if)# spanning-tree vlan 10,12-15,20
cost 300
```

Example:

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

The **show spanning-tree interface interface-id** privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the **show running-config** privileged EXEC command to confirm the configuration.

## Configuring the Device Priority of a VLAN

You can configure the device priority and make it more likely that a standalone device or a device in the stack will be chosen as the root device.

**Note**

Exercise care when using this command. For most situations, we recommend that you use the **spanning-tree vlan vlan-id root primary** and the **spanning-tree vlan vlan-id root secondary** global configuration commands to modify the device priority.

This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree vlan vlan-id priority priority
4. end

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for MSTP

- For two or more devices to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

- For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

- For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a device stack by manually configuring the path cost.

- For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the internal spanning tree (IST) master of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST
regions must contain the CST root, and all of the other MST regions must have a better path to the root contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the devices in the clouds.

Restrictions for MSTP

• The device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

• PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)

• All stack members must run the same version of spanning tree (all PVST+, Rapid PVST+, or MSTP).

• VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each device within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.

• Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.

• A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

• After configuring a device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the spanning-tree mst hello-time, spanning-tree mst forward-time, and the spanning-tree mst max-age global configuration commands.

Information About MSTP

MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing,
and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

---

**Note**

The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment. When the device is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.

Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same device ID.

### MSTP Configuration Guidelines

- When you enable MST by using the `spanning-tree mode mst` global configuration command, RSTP is automatically enabled.
- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.
- When the device is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

<table>
<thead>
<tr>
<th>Speed</th>
<th>Path Cost Value</th>

### Root Switch

The device maintains a spanning-tree instance for the group of VLANs mapped to it. A device ID, consisting of the device priority and the device MAC address, is associated with each instance. For a group of VLANs, the device with the lowest device ID becomes the root device.
When you configure a device as the root, you modify the device priority from the default value (32768) to a significantly lower value so that the device becomes the root device for the specified spanning-tree instance. When you enter this command, the device checks the device priorities of the root devices. Because of the extended system ID support, the device sets its own priority for the specified instance to 24576 if this value will cause this device to become the root for the specified spanning-tree instance.

If any root device for the specified instance has a device priority lower than 24576, the device sets its own priority to 4096 less than the lowest device priority. (4096 is the value of the least-significant bit of a 4-bit device priority value. For more information, select "Bridge ID, Device Priority, and Extended System ID" link in Related Topics.

If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected switches running older software.

The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Use the diameter keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the hello keyword to override the automatically calculated hello time.

### Multiple Spanning-Tree Regions

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each device belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the device for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the "Specifying the MST Region Configuration and Enabling MSTP" link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

### IST, CIST, and CST

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- An internal spanning tree (IST), which is the spanning tree that runs in an MST region.

  Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

  The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because
the MSTP BPDU carries information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root device ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- A common and internal spanning tree (CIST), which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.

The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

### Operations Within an MST Region

The IST connects all the MST switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the IST master before the implementation of the IEEE 802.1s standard). It is the device within the region with the lowest device ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MST switches at the boundary of the region is selected as the CIST regional root.

When an MSTP device initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The device also initializes all of its MST instances and claims to be the root for all of them. If the device receives superior MST root information (lower device ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

### Operations Between MST Regions

If there are multiple regions or legacy IEEE 802.1D devices within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP devices in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP devices in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual device to adjacent STP devices and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring devices and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPDU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, device priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.
IEEE 802.1s Terminology

Some MST naming conventions used in Cisco’s prestandard implementation have been changed to identify some *internal* or *regional* parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root device for the unique instance that spans the whole network, the CIST.
- The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single device for the CIST. The CIST external root path cost is the root path cost calculated between these virtual devices and devices that do not belong to any region.
- The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest device to the CIST root in the region. The CIST regional root acts as a root device for the IST.
- The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

**Illustration of MST Regions**

This figure displays three MST regions and a legacy IEEE 802.1D device (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.
Hop Count

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the `spanning-tree mst max-hops` global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root device of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a device receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDUs it generates. When the count reaches zero, the device discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.

Boundary Ports

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.
There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both devices and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

Note

If there is a legacy STP device on the segment, messages are always considered external.

The other change from the Cisco prestandard implementation is that the CIST regional root device ID field is now inserted where an RSTP or legacy IEEE 802.1Q device has the sender device ID. The whole region performs like a single virtual device by sending a consistent sender device ID to neighboring devices. In this example, device C would receive a BPDU with the same consistent sender device ID of root, whether or not A or B is designated for the segment.

IEEE 802.1s Implementation

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

Port Role Naming Change

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco’s implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special master role.

- The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the show commands identify a port as boundary in the type column of the output.
Interoperation Between Legacy and Standard Devices

Because automatic detection of prestandard devices can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard device, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a device receives a prestandard BPDU on a port that has not been configured for prestandard BPDU transmission.

Figure 26: Standard and Prestandard Device Interoperation

Assume that A is a standard device and B a prestandard device, both configured to be in the same region. A is the root device for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPDU, AY cannot detect that a prestandard device is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology changes.

Note

We recommend that you minimize the interaction between standard and prestandard MST implementations.

Detecting Unidirectional Link Failure

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

Figure 27: Detecting Unidirectional Link Failure

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Device A is the root device, and its BPDUs are lost on the link leading to device B. RSTP and MST BPDUs include the role and state of the sending port. With this information, device A can detect that device B does not react to the superior role.
BPDUs it sends and that device B is the designated, not root device. As a result, device A blocks (or keeps blocking) its port, which prevents the bridging loop.

MSTP and Device Stacks

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switchstack master.

If a device that does not support MSTP is added to a device stack that does support MSTP or the reverse, the device is put into a version mismatch state. If possible, the device is automatically upgraded or downgraded to the same version of software that is running on the device stack.

When a new device joins the stack, it sets its device ID to the device ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root. A topology change occurs if the newly added device contains a better root port for the device stack or a better designated port for the LAN connected to the stack. The newly added device causes a topology change in the network if another device connected to the newly added device changes its root port or designated ports.

When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

If the stack master fails or leaves the stack, the stack members elect a new stack master, and all stack members change their device IDs of the spanning trees to the new master device ID.

Interoperability with IEEE 802.1D STP

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device might also continue to assign a boundary role to a port when the device to which this device is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring devices), use the clear spanning-tree detected-protocols privileged EXEC command.

If all the legacy devices on the link are RSTP devices, they can process MSTP BPDUs as if they are RSTP BPDUs. Therefore, MSTP devices send either a Version 0 configuration and TCN BPDUs or Version 3 MSTP BPDUs on a boundary port. A boundary port connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.
RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).

Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the device with the highest device priority (lowest numerical priority value) as the root device. The RSTP then assigns one of these port roles to individual ports:

- Root port—Provides the best path (lowest cost) when the device forwards packets to the root device.
- Designated port—Connects to the designated device, which incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
- Alternate port—Offers an alternate path toward the root device to that provided by the current root port.
- Backup port—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a device has two or more connections to a shared LAN segment.
- Disabled port—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

Table 50: Port State Comparison

</tbody>
</table>

To be consistent with Cisco STP implementations, this guide defines the port state as blocking instead of discarding. Designated ports start in the listening state.
Rapid Convergence

The RSTP provides for rapid recovery of connectivity following the failure of a device, a device port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

- **Edge ports**—If you configure a port as an edge port on an RSTP device by using the `spanning-tree portfast` interface configuration command, the edge port immediately transitions to the forwarding state. An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.

- **Root ports**—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.

- **Point-to-point links**—If you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

*Figure 28: Proposal and Agreement Handshaking for Rapid Convergence*

Device A is connected to Device B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Device A is a smaller numerical value than the priority of Device B. Device A sends a proposal message (a configuration BPDU with the proposal flag set) to Device B, proposing itself as the designated device.

After receiving the proposal message, Device B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Device B’s agreement message, Device A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Device B blocked all of its nonedge ports and because there is a point-to-point link between Devices A and B.

When Device C is connected to Device B, a similar set of handshaking messages are exchanged. Device C selects the port connected to Device B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more device joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a device stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the device is in MST mode.

The device learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the `spanning-tree link-type` interface configuration command.
Synchronization of Port Roles

When the device receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The device is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the device is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

Figure 29: Sequence of Events During Rapid Convergence

After ensuring that all of the ports are synchronized, the device sends an agreement message to the designated device corresponding to its root port. When the devices connected by a point-to-point link are in agreement
about their port roles, the RSTP immediately transitions the port states to forwarding.

### Bridge Protocol Data Unit Format and Processing

The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

**Table 51: RSTP BPDU Flags**

<table>
<thead>
<tr>

</table>
| 2–3: | Port role:
| 00   | Unknown                                       |
| 01   | Alternate port                                |
| 10   | Root port                                     |
| 11   | Designated port                               |
| 4    | Learning                                      |
| 5    | Forwarding                                    |
| 6    | Agreement                                     |
| 7    | Topology change acknowledgement (TCA)         |

The sending device sets the proposal flag in the RSTP BPDU to propose itself as the designated device on that LAN. The port role in the proposal message is always set to the designated port.
The sending device sets the agreement flag in the RSTP BPDU to accept the previous proposal. The port role in the agreement message is always set to the root port.

The RSTP does not have a separate topology change notification (TCN) BPDU. It uses the topology change (TC) flag to show the topology changes. However, for interoperability with IEEE 802.1D devices, the RSTP device processes and generates TCN BPDUs.

The learning and forwarding flags are set according to the state of the sending port.

**Processing Superior BPDU Information**

If a port receives superior root information (lower device ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDU received is an RSTP BPDU with the proposal flag set, the device sends an agreement message after all of the other ports are synchronized. If the BPDU is an IEEE 802.1D BPDU, the device does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

**Processing Inferior BPDU Information**

If a designated port receives an inferior BPDU (such as a higher device ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.

**Topology Changes**

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- **Detection**—Unlike IEEE 802.1D in which *any* transition between the blocking and the forwarding state causes a topology change, *only* transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP device detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.

- **Notification**—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP device processes and generates TCN BPDUs.

- **Acknowledgement**—When an RSTP device receives a TCN message on a designated port from an IEEE 802.1D device, it replies with an IEEE 802.1D configuration BPDU with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D device and a configuration BPDU with the TCA bit set is received, the TC-while timer is reset.

  This behavior is only required to support IEEE 802.1D devices. The RSTP BPDUs never have the TCA bit set.

- **Propagation**—When an RSTP device receives a TC message from another device through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding
the port on which it is received). The device starts the TC-while timer for all such ports and flushes the information learned on them.

- Protocol migration—For backward compatibility with IEEE 802.1D devices, RSTP selectively sends IEEE 802.1D configuration BPDUs and TCN BPDU s on a per-port basis.

When a port is initialized, the migrate-delay timer is started (specifies the minimum time during which RSTP BPDUs are sent), and RSTP BPDUs are sent. While this timer is active, the device processes all BPDUs received on that port and ignores the protocol type.

If the device receives an IEEE 802.1D BPDU after the port migration-delay timer has expired, it assumes that it is connected to an IEEE 802.1D device and starts using only IEEE 802.1D BPDU s. However, if the RSTP device is using IEEE 802.1D BPDU s on a port and receives an RSTP BPDU after the timer has expired, it restarts the timer and starts using RSTP BPDU s on that port.

Protocol Migration Process

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDU s on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDU s because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device also might continue to assign a boundary role to a port when the device to which it is connected has joined the region.

About MST-to-PVST+ Interoperability (PVST+ Simulation)

The PVST+ simulation feature enables seamless interoperability between MST and Rapid PVST+. You can enable or disable this per port, or globally. PVST+ simulation is enabled by default.

However, you may want to control the connection between MST and Rapid PVST+ to protect against accidentally connecting an MST-enabled port to a Rapid PVST+-enabled port. Because Rapid PVST+ is the default STP mode, you may encounter many Rapid PVST+-enabled connections.

Disabling this feature causes the switch to stop the MST region from interacting with PVST+ regions. The MST-enabled port moves to a PVST peer inconsistent (blocking) state once it detects it is connected to a Rapid PVST+-enabled port. This port remains in the inconsistent state until the port stops receiving Shared Spanning Tree Protocol (SSTP) BPDUs, and then the port resumes the normal STP transition process.

You can for instance, disable PVST+ simulation, to prevent an incorrectly configured switch from connecting to a network where the STP mode is not MSTP (the default mode is PVST+).

Observe these guidelines when you configure MST switches (in the same region) to interact with PVST+ switches:

• Configure the root for all VLANs inside the MST region as shown in this example:

```
Switch# show spanning-tree mst interface gigabitethernet 1/1
GigabitEthernet1/1 of MST00 is root forwarding
    Edge port: no (trunk) port guard : none (default)
    Link type: point-to-point (auto) bpdu filter: disable (default)
    Boundary : boundary (PVST) bpdu guard : disable (default)
    Bpdus sent 10, received 310

    Instance Role Sts Cost Prio.Nbr Vlans mapped
    -------- ---- --- --------- -------- -------------------------------
    0 Root FWD 20000 128.1 1-2,4-2999,4000-4094
    3 Boun FWD 20000 128.1 3,3000-3999
```

The ports that belong to the MST switch at the boundary simulate PVST+ and send PVST+ BPDUs for all the VLANs.

If you enable loop guard on the PVST+ switches, the ports might change to a loop-inconsistent state when the MST switches change their configuration. To correct the loop-inconsistent state, you must disable and re-enable loop guard on that PVST+ switch.

• Do not locate the root for some or all of the VLANs inside the PVST+ side of the MST switch because when the MST switch at the boundary receives PVST+ BPDUs for all or some of the VLANs on its designated ports, root guard sets the port to the blocking state.

• When you connect a PVST+ switch to two different MST regions, the topology change from the PVST+ switch does not pass beyond the first MST region. In such a case, the topology changes are propagated only in the instance to which the VLAN is mapped. The topology change stays local to the first MST region, and the Cisco Access Manager (CAM) entries in the other region are not flushed. To make the...
topology change visible throughout other MST regions, you can map that VLAN to IST or connect the PVST+ switch to the two regions through access links.

- When you disable the PVST+ simulation, note that the PVST+ peer inconsistency can also occur while the port is already in other states of inconsistency. For example, the root bridge for all STP instances must all be in either the MST region or the Rapid PVST+ side. If the root bridge for all STP instances are not on one side or the other, the software moves the port into a PVST+ simulation-inconsistent state.

**Note**
We recommend that you put the root bridge for all STP instances in the MST region.

### About Detecting Unidirectional Link Failure

The dispute mechanism that detects unidirectional link failures is included in the IEEE 802.1D-2004 RSTP and IEEE 802.1Q-2005 MSTP standard, and requires no user configuration.

The switch checks the consistency of the port role and state in the BPDUs it receives, to detect unidirectional link failures that could cause bridging loops. When a designated port detects a conflict, it keeps its role, but reverts to a discarding (blocking) state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

For example, in the figure below, Switch A is the root bridge and Switch B is the designated port. BPDUs from Switch A are lost on the link leading to switch B.

**Figure 30: Detecting Unidirectional Link Failure**

Since Rapid PVST+ (802.1w) and MST BPDU includes the role and state of the sending port, Switch A detects (from the inferior BPDU), that switch B does not react to the superior BPDU it sends, because switch B has the role of a designated port and not the root bridge. As a result, switch A blocks (or keeps blocking) its port, thus preventing the bridging loop.

Note these guidelines and limitations relating to the dispute mechanism:

- It works only on switches running RSTP or MST (the dispute mechanism requires reading the role and state of the port initiating BPDU).

- It may result in loss of connectivity. For example, in the figure below, Bridge A cannot transmit on the port it elected as a root port. As a result of this situation, there is loss of connectivity (r1 and r2 are designated, a1 is root and a2 is alternate. There is only a one way connectivity between A and R).
How to Configure MSTP Features

Specifying the MST Region Configuration and Enabling MSTP

For two or more switches to be in the same MST region, they must have the same VLAN-to-instance mapping, the same configuration revision number, and the same name.

A region can have one member or multiple members with the same MST configuration; each member must be capable of processing RSTP BPDUs. There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mst configuration`
4. `instance instance-id vlan vlan-range`
5. `name name`
6. `revision version`
7. `show pending`
8. `exit`
9. `spanning-tree mode mst`
10. `end`

### DETAILED STEPS

<table>

### Configuring the Root Device

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. Step 2 in the example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.
SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mst instance-id root primary
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>

<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Configuring a Secondary Root Device

When you configure a device with the extended system ID support as the secondary root, the device priority is modified from the default value (32768) to 28672. The device is then likely to become the root device for the specified instance if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768 and therefore are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the spanning-tree mst instance-id root primary global configuration command.

This procedure is optional.
Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mst instance-id root secondary
4. end

DETAILED STEPS

<table>

</table>

Configuring Port Priority

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.
If the device is a member of a device stack, you must use the `spanning-tree mst [instance-id] cost cost` interface configuration command instead of the `spanning-tree mst [instance-id] port-priority priority` interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree mst instance-id port-priority priority
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>

<td>• For instance-id, you can specify a single instance, a range of instances separated by a hyphen, or a series</td>
</tr>
</tbody>
</table>
### Configuring Path Cost

The MSTP path cost default value is derived from the media speed of an interface. If a loop occurs, the MSTP uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree mst instance-id cost cost
5. end

The `show spanning-tree mst interface interface-id` privileged EXEC command displays information only if the port is in a link-up operative state. Otherwise, you can use the `show running-config interface` privileged EXEC command to confirm the configuration.
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces. The port-channel range is 1 to 48.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td>Step 4 spanning-tree mst instance-id cost cost</td>
<td>Configures the cost. If a loop occurs, the MSTP uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.</td>
</tr>
<tr>
<td>Example:</td>
<td>• For instance-id, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.</td>
</tr>
<tr>
<td>Device(config-if)# spanning-tree mst 0 cost 17031970</td>
<td>• For cost, the range is 1 to 200000000; the default value is derived from the media speed of the interface.</td>
</tr>
<tr>
<td>Step 5 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

The `show spanning-tree mst interface interface-id` privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the `show running-config` privileged EXEC command to confirm the configuration.

### Configuring the Device Priority

Changing the priority of a device makes it more likely to be chosen as the root device whether it is a standalone device or a device in the stack.
Exercise care when using this command. For normal network configurations, we recommend that you use the `spanning-tree mst instance-id root primary` and the `spanning-tree mst instance-id root secondary` global configuration commands to specify a device as the root or secondary root device. You should modify the device priority only in circumstances where these commands do not work.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree mst instance-id priority priority`
4. `end`

**DETAILED STEPS**

<table>
<thead>

<tr>
<td>Example: Device(config)# spanning-tree mst 0 priority 40960</td>
<td>• For instance-id, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• For priority, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device.</td>
</tr>
</tbody>
</table>
Configuring the Hello Time

The hello time is the time interval between configuration messages generated and sent by the root device. This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree mst hello-time seconds
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong> spanning-tree mst hello-time seconds</td>
<td>Configures the hello time for all MST instances. The hello time is the time interval between configuration messages generated and sent by the root device. These messages indicate that the device is alive.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# spanning-tree mst hello-time 4</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring the Forwarding-Delay Time

#### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mst forward-time seconds`
4. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst forward-time <code>seconds</code></td>
<td>Configures the forward time for all MST instances. The forwarding delay is the number of seconds a port waits before changing from its spanning-tree learning and listening states to the forwarding state. For <code>seconds</code>, the range is 4 to 30; the default is 20.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# <code>spanning-tree mst forward-time 25</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>

<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst max-age seconds</td>
<td>Configures the maximum-aging time for all MST instances.</td>
</tr>
<tr>
<td>Example:</td>
<td>The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration.</td>
</tr>
<tr>
<td>Device(config)# spanning-tree mst max-age 40</td>
<td>For seconds, the range is 6 to 40; the default is 20.</td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
Configuring the Maximum-Hop Count

This procedure is optional.

Before you begin
A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mst max-hops hop-count
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>

<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst max-hops hop-count</td>
<td>Specifies the number of hops in a region before the BPDU is discarded, and the information held for a port is aged.</td>
</tr>
<tr>
<td>Example:</td>
<td>For hop-count, the range is 1 to 255; the default is 20.</td>
</tr>
<tr>
<td>Device(config)# spanning-tree mst max-hops 25</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Specifying the Link Type to Ensure Rapid Transitions

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.
By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote device running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree link-type point-to-point
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port-channel logical interfaces. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> spanning-tree link-type point-to-point</td>
<td>Specifies that the link type of a port is point-to-point.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# spanning-tree link-type point-to-point</td>
<td></td>
</tr>
</tbody>
</table>
Designating the Neighbor Type

A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.

You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the `show` commands, even if the port is in STP compatibility mode.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree mst pre-standard`
5. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | `enable`          | Enables privileged EXEC mode.  
  * Enter your password if prompted. |
|      | Example:          |         |
|      | Device> `enable`  |         |
| 2    | `configure terminal` | Enters global configuration mode. |
|      | Example:          |         |
|      | Device# `configure terminal` |         |
| 3    | `interface interface-id` | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports. |
|      | Example:          |         |
|      | Device(config)# `interface gigabitethernet 1/0/1` |         |
**Restarting the Protocol Migration Process**

This procedure restarts the protocol migration process and forces renegotiation with neighboring devices. It reverts the device to MST mode. It is needed when the device no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Follow these steps to restart the protocol migration process (force the renegotiation with neighboring devices) on the device.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

If you want to use the interface version of the command, you must also know the MST interface used. This example uses GigabitEthernet1/0/1 as the interface because that was the interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. **enable**
2. Enter one of the following commands:
   - `clear spanning-tree detected-protocols`
   - `clear spanning-tree detected-protocols interface interface-id`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
   **Example:**  
   Device> enable  
   The device reverts to the MSTP mode, and the protocol migration process restarts.  
| **Step 2** Enter one of the following commands:  
   - `clear spanning-tree detected-protocols` |  
| **Step 4** spanning-tree mst pre-standard  
   **Example:**  
   Device(config-if)# spanning-tree mst pre-standard | Specifies that the port can send only prestandard BPDUs.  
| **Step 5** end  
   **Example:**  
   Device(config-if)# end | Returns to privileged EXEC mode. |
What to do next

This procedure may need to be repeated if the device receives more legacy IEEE 802.1D configuration BPDUs (BPDUs with the protocol version set to 0).

### Configuring PVST+ Simulation

PVST+ simulation is enabled by default. This means that all ports automatically interoperate with a connected device that is running in Rapid PVST+ mode. If you disabled the feature and want to re-configure it, refer to the following tasks.

To enable PVST+ simulation globally, perform this task:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree mst simulate pvst global
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst simulate pvst global</td>
<td>Enables PVST+ simulation globally.</td>
</tr>
<tr>
<td>Example:</td>
<td>To prevent the switch from automatically interoperating with a connecting switch that is running Rapid PVST+, enter the no version of the command.</td>
</tr>
</tbody>
</table>
## Enabling PVST+ Simulation on a Port

To enable PVST+ simulation on a port, perform this task:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree mst simulate pvst`
5. `end`
6. `show spanning-tree summary`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>

<tr>
<td></td>
<td>Example:</td>
<td>To prevent a specified interface from automatically interoperating with a connecting switch that is not running</td>
</tr>
</tbody>
</table>

Example:

```
Device(config)# spanning-tree mst simulate pvst
```

Step 4

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

Example:

```
Device(config)# end
```
Examples

Examples: PVST+ Simulation

This example shows how to prevent the switch from automatically interoperating with a connecting switch that is running Rapid PVST+:

Switch# configure terminal
Switch(config)# no spanning-tree mst simulate pvst global

This example shows how to prevent a port from automatically interoperating with a connecting device that is running Rapid PVST+:

Switch(config)# interface 1/0/1
Switch(config-if)# spanning-tree mst simulate pvst disable

The following sample output shows the system message you receive when a SSTP BPDU is received on a port and PVST+ simulation is disabled:

Message
SPANTREE_PVST_PEER_BLOCK: PVST BPDU detected on port %s [port number].

Severity
Critical

Explanation
A PVST+ peer was detected on the specified interface on the switch. PVST+ simulation feature is disabled, as a result of which the interface was moved to the spanning tree Blocking state.

Action
Identify the PVST+ switch from the network which might be configured incorrectly.

The following sample output shows the system message you receive when peer inconsistency on the interface is cleared:

Message
SPANTREE_PVST_PEER_UNBLOCK: Unblocking port %s [port number].

Severity
Critical

Explanation
The interface specified in the error message has been restored to normal spanning tree state.

Action
None.

This example shows the spanning tree status when port 1/0/1 has been configured to disable PVST+ simulation and is currently in the peer type inconsistent state:

Switch# show spanning-tree
VLAN0010

<td></td>
<td></td>
</tr>
</tbody>
</table>
This example shows the spanning tree summary when PVST+ simulation is disabled in any STP mode:

```
Switch# show spanning-tree summary
Switch is in mst mode (IEEE Standard)
Root bridge for: MST0
EtherChannel misconfig guard is enabled
Extended system ID is enabled
Portfast Default is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default is disabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is long
PVST Simulation Default is disabled

Name Blocking Listening Learning Forwarding STP Active
------------------------ -------- --------- -------- ---------- ----------
MST0 2 0 0 0 2
------------------------ -------- --------- -------- ---------- ----------
1 mst 2 0 0 0 2
```

This example shows the spanning tree summary when the switch is not in MSTP mode, that is, the switch is in PVST or Rapid-PVST mode. The output string displays the current STP mode:

```
Switch# show spanning-tree summary
Switch is in rapid-pvst mode
Root bridge for: VLAN0001, VLAN2001-VLAN2002
EtherChannel misconfig guard is enabled
Extended system ID is enabled
Portfast Default is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default is disabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is short
PVST Simulation Default is enabled but inactive in rapid-pvst mode

Name Blocking Listening Learning Forwarding STP Active
------------------------ -------- --------- -------- ---------- ----------
VLAN0001 2 0 0 0 2
VLAN2001 2 0 0 0 2
VLAN2002 2 0 0 0 2
------------------------ -------- --------- -------- ---------- ----------
3 vlans 6 0 0 0 6
```

This example shows the interface details when PVST+ simulation is globally enabled, or the default configuration:

```
Switch# show spanning-tree interface1/0/1 detail
```
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is forwarding
Port path cost 4, Port priority 128, Port Identifier 128.297.
Designated root has priority 32769, address 0013.5f20.01c0
Designated bridge has priority 32769, address 0013.5f20.01c0
Designated port id is 128.297, designated path cost 0
Timers: message age 0, forward delay 0, hold 0
Number of transitions to forwarding state: 1
Link type is point-to-point by default
PVST Simulation is enabled by default
BPDU: sent 132, received 1

This example shows the interface details when PVST+ simulation is globally disabled:

Switch# show spanning-tree interface1/0/1 detail
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is forwarding
Port path cost 4, Port priority 128, Port Identifier 128.297.
Designated root has priority 32769, address 0013.5f20.01c0
Designated bridge has priority 32769, address 0013.5f20.01c0
Designated port id is 128.297, designated path cost 0
Timers: message age 0, forward delay 0, hold 0
Number of transitions to forwarding state: 1
Link type is point-to-point by default
PVST Simulation is disabled by default
BPDU: sent 132, received 1

This example shows the interface details when PVST+ simulation is explicitly enabled on the port:

Switch# show spanning-tree interface1/0/1 detail
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is forwarding
Port path cost 4, Port priority 128, Port Identifier 128.297.
Designated root has priority 32769, address 0013.5f20.01c0
Designated bridge has priority 32769, address 0013.5f20.01c0
Designated port id is 128.297, designated path cost 0
Timers: message age 0, forward delay 0, hold 0
Number of transitions to forwarding state: 1
Link type is point-to-point by default
PVST Simulation is enabled
BPDU: sent 132, received 1

This example shows the interface details when the PVST+ simulation feature is disabled and a PVST Peer inconsistency has been detected on the port:

Switch# show spanning-tree interface1/0/1 detail
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is broken (PVST Peer Inconsistent)
Port path cost 4, Port priority 128, Port Identifier 128.297.
Designated root has priority 32769, address 0013.5f20.01c0
Designated bridge has priority 32769, address 0013.5f20.01c0
Designated port id is 128.297, designated path cost 0
Timers: message age 0, forward delay 0, hold 0
Number of transitions to forwarding state: 1
Link type is point-to-point by default
PVST Simulation is disabled
BPDU: sent 132, received 1

Examples: Detecting Unidirectional Link Failure

This example shows the spanning tree status when port 1/0/1 detail has been configured to disable PVST+ simulation and the port is currently in the peer type inconsistent state:

Switch# show spanning-tree

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restriction for Optional Spanning-Tree Features

• PortFast minimizes the time that interfaces must wait for spanning tree to converge, so it is effective only when used on interfaces connected to end stations. If you enable PortFast on an interface connecting to another switch, you risk creating a spanning-tree loop.
Information About Optional Spanning-Tree Features

PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

Figure 33: PortFast-Enabled Interfaces

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to converge.

Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.

BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast edge-enabled ports, spanning tree shuts down ports that are in a PortFast edge-operational state if any BPDU is received on them. In a valid configuration, PortFast edge-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast edge-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast edge feature, and the port receives a BPDU, it is put in the error-disabled state.

The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.
BPDU Filtering

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast edge-enabled interfaces at the global level keeps those interfaces that are in a PortFast edge-operational state from sending or receiving BPDDUs. The interfaces still send a few BPDDUs at link-up before the switch begins to filter outbound BPDDUs. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDDUs. If a BPDU is received on a PortFast edge-enabled interface, the interface loses its PortFast edge-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast edge feature keeps the interface from sending or receiving BPDDUs.

Caution

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature for the entire switch or for an interface.

UplinkFast

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one redundant link that spanning tree blocks to prevent loops.

If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.
When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

**UplinkFast** is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.

**Figure 35: UplinkFast Example Before Direct Link Failure**

This topology has no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in a blocking state.

**Figure 36: UplinkFast Example After Direct Link Failure**

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked interface on Switch C and transitions it to the forwarding state without going through the listening and learning states. This change takes approximately 1 to 5 seconds.
Cross-Stack UplinkFast

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see Related Topics.

How Cross-Stack UplinkFast Works

Cross-Stack UplinkFast (CSUF) ensures that one link in the stack is elected as the path to the root.

Figure 37: Cross-Stack UplinkFast Topology

The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.
When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.

Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate (2 * forward-delay time + max-age time).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur.
Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.
  
  If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.

- The failed link, which connects the stack root to the spanning-tree root, recovers.

- A network reconfiguration causes a new stack-root switch to be selected.

- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

  **Note**  
  The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.

- The stack-root switch, which was powered off or failed, is powered on.

- A new switch, which might become the stack root, is added to the stack.

**BackboneFast**

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches. BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDUs from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDUs for the maximum aging time (default is 20 seconds).

The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate
root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.

*Figure 38: BackboneFast Example Before Indirect Link Failure*

This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B is in the blocking state.

*Figure 39: BackboneFast Example After Indirect Link Failure*

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDUs to Switch C, identifying itself as the root. When Switch C receives the inferior BPDUs from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is
set. BackboneFast reconfigures the topology to account for the failure of link

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDUs did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDUs that indicate it is the root switch. However, the other switches ignore these inferior BPDUs, and the new switch learns that Switch B is the designated switch to Switch A, the root switch.

**EtherChannel Guard**

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel, but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.
Root Guard

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer’s network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer’s switch from becoming the root switch or being in the path to the root.

If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer’s switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

Caution
Misuse of the root guard feature can cause a loss of connectivity.

Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched
network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDU on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDU on root or alternate ports.

When the switch is operating in MST mode, BPDUs are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.

**STP PortFast Port Types**

You can configure a spanning tree port as an edge port, a network port, or a normal port. A port can be in only one of these states at a given time. The default spanning tree port type is normal. You can configure the port type either globally or per interface.

Depending on the type of device to which the interface is connected, you can configure a spanning tree port as one of these port types:

- A PortFast edge port—is connected to a Layer 2 host. This can be either an access port or an edge trunk port (portfast edge trunk). This type of port interface immediately transitions to the forwarding state, bypassing the listening and learning states. Use PortFast edge on Layer 2 access ports connected to a single workstation or server to allow those devices to connect to the network immediately, rather than waiting for spanning tree to converge.

Even if the interface receives a bridge protocol data unit (BPDU), spanning tree does not place the port into the blocking state. Spanning tree sets the port’s operating state to non-port fast even if the configured state remains port fast edge and starts participating in the topology change.

| Note | If you configure a port connected to a Layer 2 switch or bridge as an edge port, you might create a bridging loop. |

- A PortFast network port—is connected only to a Layer 2 switch or bridge. Bridge Assurance is enabled only on PortFast network ports. For more information, refer to *Bridge Assurance*.

| Note | If you configure a port that is connected to a Layer 2 host as a spanning tree network port, the port will automatically move into the blocking state. |

- A PortFast normal port—is the default type of spanning tree port.

| Note | Beginning with Cisco IOS Release 15.2(4)E, or IOS XE 3.8.0E, if you enter the spanning-tree portfast [trunk] command in the global or interface configuration mode, the system automatically saves it as spanning-tree portfast edge [trunk]. |
Bridge Assurance

You can use Bridge Assurance to help prevent looping conditions that are caused by unidirectional links (one-way traffic on a link or port), or a malfunction in a neighboring switch. Here a malfunction refers to a switch that is not able to run STP any more, while still forwarding traffic (a brain dead switch).

BPDUs are sent out on all operational network ports, including alternate and backup ports, for each hello time period. Bridge Assurance monitors the receipt of BPDUs on point-to-point links on all network ports. When a port does not receive BPDUs within the allotted hello time period, the port is put into a blocked state (the same as a port inconsistent state, which stops forwarding of frames). When the port resumes receipt of BPDUs, the port resumes normal spanning tree operations.

Note

Only Rapid PVST+ and MST spanning tree protocols support Bridge Assurance. PVST+ does not support Bridge Assurance.

The following example shows how Bridge Assurance protects your network from bridging loops.

The following figure shows a network with normal STP topology.

Figure 42: Network with Normal STP Topology

The following figure demonstrates a potential network problem when the device fails (brain dead) and Bridge Assurance is not enabled on the network.

Figure 43: Network Loop Due to a Malfunctioning Switch
The following figures show the network with Bridge Assurance enabled, and the STP topology progressing normally with bidirectional BDPUs issuing from every STP network port.

*Figure 44: Network with STP Topology Running Bridge Assurance*

The following figure shows how the potential network problem shown in figure *Network Loop Due to a Malfunctioning Switch* does not occur when you have Bridge Assurance enabled on your network.

*Figure 45: Network Problem Averted with Bridge Assurance Enabled*

The system generates syslog messages when a port is block and unblocked. The following sample output shows the log that is generated for each of these states:

**BRIDGE_ASSURANCE_BLOCK**

Sep 17 09:48:16.249 PDT: %SPANTREE-2-BRIDGE_ASSURANCE_BLOCK: Bridge Assurance blocking port GigabitEthernet1/0/1 on VLAN0001.

**BRIDGE_ASSURANCE_UNBLOCK**

Sep 17 09:48:58.426 PDT: %SPANTREE-2-BRIDGE_ASSURANCE_UNBLOCK: Bridge Assurance unblocking port GigabitEthernet1/0/1 on VLAN0001.

Follow these guidelines when enabling Bridge Assurance:

- It can only be enabled or disabled globally.
- It applies to all operational network ports, including alternate and backup ports.
• Only Rapid PVST+ and MST spanning tree protocols support Bridge Assurance. PVST+ does not support Bridge Assurance.

• For Bridge Assurance to work properly, it must be supported and configured on both ends of a point-to-point link. If the device on one side of the link has Bridge Assurance enabled and the device on the other side does not, the connecting port is blocked and in a Bridge Assurance inconsistent state. We recommend that you enable Bridge Assurance throughout your network.

• To enable Bridge Assurance on a port, BPDU filtering and BPDU Guard must be disabled.

• You can enable Bridge Assurance in conjunction with Loop Guard.

• You can enable Bridge Assurance in conjunction with Root Guard. The latter is designed to provide a way to enforce the root bridge placement in the network.

How to Configure Optional Spanning-Tree Features

Enabling PortFast

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution

Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree portfast [trunk]
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable Example:</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

**configure terminal**

**Example:**

Device# configure terminal

**Step 3**

**interface interface-id**

**Example:**

Device(config)# interface gigabitethernet 1/0/2

**Step 4**

**spanning-tree portfast [trunk]**

**Example:**

Device(config-if)# spanning-tree portfast trunk

Enables PortFast on an access port connected to a single workstation or server.

By specifying the `trunk` keyword, you can enable PortFast on a trunk port.

**Note**

To enable PortFast on trunk ports, you must use the `spanning-tree portfast trunk` interface configuration command. The `spanning-tree portfast` command will not work on trunk ports.

Make sure that there are no loops in the network between the trunk port and the workstation or server before you enable PortFast on a trunk port.

By default, PortFast is disabled on all interfaces.

**Step 5**

**end**

**Example:**

Device(config-if)# end

Returns to privileged EXEC mode.

---

**What to do next**

You can use the `spanning-tree portfast default` global configuration command to globally enable the PortFast feature on all nontrunking ports.

---

**Enabling BPDU Guard**

You can enable the BPDU guard feature if your switch is running PVST+, Rapid PVST+, or MSTP.
Configure PortFast edge only on ports that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree portfast edge
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 interface interface-id</td>
<td>Specifies the interface connected to an end station, and enters interface configuration mode.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Step 4 spanning-tree portfast edge</td>
<td>Enables the PortFast edge feature.</td>
</tr>
<tr>
<td>Example: Device(config-if)# spanning-tree portfast edge</td>
<td></td>
</tr>
<tr>
<td>Step 5 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

What to do next

To prevent the port from shutting down, you can use the `errdisable detect cause bpduguard shutdown vlan` global configuration command to shut down just the offending VLAN on the port where the violation occurred.
You also can use the `spanning-tree bpduguard enable` interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put it in the error-disabled state.

### Enabling BPDU Filtering

You can also use the `spanning-tree bpdufilter enable` interface configuration command to enable BPDU filtering on any interface without also enabling the PortFast edge feature. This command prevents the interface from sending or receiving BPDUs.

⚠️ **Caution**

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

⚠️ **Caution**

Configure PortFast edge only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree portfast edge bpdufilter default`
4. `interface interface-id`
5. `spanning-tree portfast edge`
6. `end`

<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

#### Enabling UplinkFast for Use with Redundant Links

When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable UplinkFast and CSUF.

**Before you begin**

UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the `no spanning-tree vlan vlan-id priority` global configuration command.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree uplinkfast [max-update-rate pkts-per-second]`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>

**Step 2**

configure terminal

**Example:**

Device# configure terminal

Enters global configuration mode.

**Step 3**

spanning-tree uplinkfast [max-update-rate pkts-per-second]

**Example:**

Device(config)# spanning-tree uplinkfast
max-update-rate 200

Enables UplinkFast.

(Optional) For *pkts-per-second*, the range is 0 to 32000 packets per second; the default is 150.

If you set the rate to 0, station-learning frames are not generated, and the spanning-tree topology converges more slowly after a loss of connectivity.

When you enter this command, CSUF also is enabled on all nonstack port interfaces.

**Step 4**

end

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

When UplinkFast is enabled, the switch priority of all VLANs is set to 49152. If you change the path cost to a value less than 3000 and you enable UplinkFast or UplinkFast is already enabled, the path cost of all interfaces and VLAN trunks is increased by 3000 (if you change the path cost to 3000 or above, the path cost is not altered). The changes to the switch priority and the path cost reduce the chance that a switch will become the root switch.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you enable the UplinkFast feature using these instructions, CSUF is automatically globally enabled on nonstack port interfaces.

### Disabling UplinkFast

This procedure is optional.

Follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

**Before you begin**

UplinkFast must be enabled.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no spanning-tree uplinkfast`
4. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
Example:  

Device> enable |

- Enter your password if prompted. |
| **Step 2** `configure terminal` | Enters global configuration mode.  
Example:  

Device# configure terminal |
| **Step 3** `no spanning-tree uplinkfast` | Disables UplinkFast and CSUF on the switch and all of its VLANs.  
Example:  

Device(config)# no spanning-tree uplinkfast |
| **Step 4** `end` | Returns to privileged EXEC mode.  
Example:  

Device(config)# end |

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you disable the UplinkFast feature using these instructions, CSUF is automatically globally disabled on nonstack port interfaces.

### Enabling BackboneFast

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable BackboneFast on the switch.
Before you begin
If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree backbonefast
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 spanning-tree backbonefast</td>
<td>Enables BackboneFast.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# spanning-tree backbonefast</td>
<td></td>
</tr>
<tr>
<td>Step 4 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Enabling EtherChannel Guard

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable EtherChannel Guard on the device.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree etherchannel guard misconfig
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree etherchannel guard misconfig</td>
<td>Enables EtherChannel guard.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# spanning-tree etherchannel guard misconfig</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

What to do next

You can use the **show interfaces status err-disabled** privileged EXEC command to show which device ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the **show etherchannel summary** privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the **shutdown** and **no shutdown** interface configuration commands on the port-channel interfaces that were misconfigured.

Enabling Root Guard

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.
You cannot enable both root guard and loop guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.
This procedure is optional.
Follow these steps to enable root guard on the switch.

**SUMMARY STEPS**

1. *enable*
2. *configure terminal*
3. *interface interface-id*
4. *spanning-tree guard root*
5. *end*

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>
Enabling Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

**Note**

You cannot enable both loop guard and root guard at the same time.

You can enable this feature if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional. Follow these steps to enable loop guard on the device.

**SUMMARY STEPS**

1. Enter one of the following commands:
   - `show spanning-tree active`
   - `show spanning-tree mst`
2. `configure terminal`
3. `spanning-tree loopguard default`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | Enter one of the following commands:  
  - `show spanning-tree active`
  - `show spanning-tree mst`
  **Example:**
  Device# `show spanning-tree active`
  or  
  Device# `show spanning-tree mst`
  | Verifies which interfaces are alternate or root ports. |
| **Step 2** | `configure terminal`
  **Example:**
  Device# `configure terminal`
  | Enters global configuration mode. |
| **Step 3** | `spanning-tree loopguard default`
  **Example:**
  Device(config)# `spanning-tree loopguard default`
  | Enables loop guard.  
  By default, loop guard is disabled. |
Enabling PortFast Port Types

This section describes the different steps to enable Portfast Port types.

Configuring the Default Port State Globally

To configure the default PortFast state, perform this task:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree portfast [edge | network | normal] default
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree portfast [edge</td>
<td>network</td>
</tr>
<tr>
<td>Example: Device(config)# spanning-tree portfast default</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• (Optional) edge—Configures all interfaces as edge ports. This assumes all ports are connected to hosts/servers.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) network—Configures all interfaces as spanning tree network ports. This assumes all ports are connected to switches and bridges. Bridge Assurance is enabled on all network ports by default.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) <strong>normal</strong> — Configures all interfaces normal spanning tree ports. These ports can be connected to any type of device.</td>
<td></td>
</tr>
<tr>
<td>• <strong>default</strong> — The default port type is normal.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 4

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

---

### Configuring PortFast Edge on a Specified Interface

Interfaces configured as edge ports immediately transition to the forwarding state, without passing through the blocking or learning states, on linkup.

**Note**

Because the purpose of this type of port is to minimize the time that access ports must wait for spanning tree to converge, it is most effective when used on access ports. If you enable PortFast edge on a port connecting to another switch, you risk creating a spanning tree loop.

To configure an edge port on a specified interface, perform this task:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id | port-channel port_channel_number`
4. `spanning-tree portfast edge [trunk]`
5. `end`
6. `show running interface interface-id | port-channel port_channel_number`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

**Example:**

```
Device> enable
```

Enables privileged EXEC mode.

• Enter your password if prompted.

| **Step 2**

**Example:**

```
Device# configure terminal
```

Enters global configuration mode.
### Configuring a PortFast Network Port on a Specified Interface

Ports that are connected to Layer 2 switches and bridges can be configured as network ports.

**Note**

Bridge Assurance is enabled only on PortFast network ports. For more information, refer to *Bridge Assurance*.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id | port-channel port_channel_number`
4. `spanning-tree portfast network`
5. `end`

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td>interface `interface-id</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>spanning-tree portfast edge [trunk]</code>&lt;br&gt;<code>Example:</code>&lt;br&gt;<code>Device(config-if)# spanning-tree portfast trunk</code>&lt;br&gt;Enables edge behavior on a Layer 2 access port connected to an end workstation or server.&lt;br&gt;- <em>(Optional) trunk</em>—Enables edge behavior on a trunk port. Use this keyword if the link is a trunk. Use this command only on ports that are connected to end host devices that terminate VLANs and from which the port should never receive STP BPDUs. Such end host devices include workstations, servers, and ports on routers that are not configured to support bridging.&lt;br&gt;- Use the <code>no</code> version of the command to disable PortFast edge.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>end</code>&lt;br&gt;<code>Example:</code>&lt;br&gt;<code>Device(config-if)# end</code>&lt;br&gt;Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>`show running interface interface-id</td>
</tr>
</tbody>
</table>
### Enabling Bridge Assurance

To configure the Bridge Assurance, perform the steps given below:

**Step 1**

**Command or Action:**
- `enable`

**Example:**
- Device> `enable`

**Purpose:** Enables privileged EXEC mode.
- Enter your password if prompted.

**Step 2**

**Command or Action:**
- `configure terminal`

**Example:**
- Device# `configure terminal`

**Purpose:** Enters global configuration mode.

**Step 3**

**Command or Action:**
- `interface interface-id | port-channel port_channel_number`

**Example:**
- Device(config)# `interface gigabitethernet 1/0/1 | port-channel port_channel_number`

**Purpose:** Specifies an interface to configure.

**Step 4**

**Command or Action:**
- `spanning-tree portfast network`

**Example:**
- Device(config-if)# `spanning-tree portfast network`

**Purpose:** Enables edge behavior on a Layer 2 access port connected to an end workstation or server.
- Configures the port as a network port. If you have enabled Bridge Assurance globally, it automatically runs on a spanning tree network port.
- Use the **no** version of the command to disable PortFast.

**Step 5**

**Command or Action:**
- `end`

**Example:**
- Device(config-if)# `end`

**Purpose:** Exits configuration mode.

**Step 6**

**Command or Action:**
- `show running interface interface-id | port-channel port_channel_number`

**Example:**
- Device# `show running interface gigabitethernet 1/0/1 | port-channel port_channel_number`

**Purpose:** Verifies the configuration.

---

### Examples

#### Examples: Configuring PortFast Edge on a Specified Interface

This example shows how to enable edge behavior on GigabitEthernet interface 1/0/1:
Examples: Configuring a PortFast Network Port on a Specified Interface

This example shows how to configure GigabitEthernet interface 1/0/1 as a network port:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# spanning-tree portfast network
Switch(config-if)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show running-config interface gigabitethernet1/0/1
Building configuration...  
Current configuration:
!
interface GigabitEthernet1/0/1
no ip address
switchport
switchport access vlan 200
switchport mode access
spanning-tree portfast network
end
```

This example shows how you can display that port GigabitEthernet 1/0/1 is currently in the edge state:

```
Switch# show spanning-tree vlan 200
VLAN0200
Spanning tree enabled protocol rstp
Root ID Priority 2
Address 001b.2a68.5fc0
Cost 3
Port 125 (GigabitEthernet5/9)
Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
Bridge ID Priority 2 (priority 0 sys-id-ext 2)
Address 7010.5c9c.5200
Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
Aging Time 0 sec
Interface Role Sts Cost Prio.Nbr Type
------------------- ---- --- --------- -------- --------------------------------
Gi1/0/1 Desg FWD 4 128.1 P2p Edge
```

Examples: Configuring a PortFast Network Port on a Specified Interface

This example shows how to verify the configuration:

```
Switch# show running-config interface gigabitethernet1/0/1
Building configuration...  
Current configuration:
!
interface GigabitEthernet1/0/1
no ip address
switchport
switchport access vlan 200
switchport mode access
spanning-tree portfast network
end
```

This example shows how to verify the configuration:

```
Switch# show running-config interface gigabitethernet1/0/1
Building configuration...  
Current configuration:
!
interface GigabitEthernet1/0/1
no ip address
switchport
switchport access vlan 200
switchport mode access
spanning-tree portfast network
end
```

This example shows how the output for show spanning-tree vlan
Example: Configuring Bridge Assurance

This output shows port GigabitEthernet 1/0/1 has been configured as a network port and it is currently in the Bridge Assurance inconsistent state.

The output shows the port type as network and *BA_Inc, indicating that the port is in an inconsistent state.

Example: Configuring Bridge Assurance

This output shows port GigabitEthernet 1/0/1 has been configured as a network port and it is currently in the Bridge Assurance inconsistent state.

The output shows the port type as network and *BA_Inc, indicating that the port is in an inconsistent state.
Monitoring the Spanning-Tree Status

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for EtherChannels

• Layer 3 EtherChannels are not supported if the switch is running the LAN Base feature set.

• All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.

• When the ports in an EtherChannel are configured as trunk ports, all the ports must be configured with the same mode (either Inter-Switch Link [ISL] or IEEE 802.1Q).

• Port Aggregation Protocol (PAgP) can be enabled only in single-switch EtherChannel configurations; PAgP cannot be enabled on cross-stack EtherChannels.
Information About EtherChannels

EtherChannel Overview

EtherChannel provides fault-tolerant high-speed links between switches, routers, and servers. You can use the EtherChannel to increase the bandwidth between the wiring closets and the data center, and you can deploy it anywhere in the network where bottlenecks are likely to occur. EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention.

An EtherChannel consists of individual Ethernet links bundled into a single logical link.

![Figure 46: Typical EtherChannel Configuration]

Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The LAN Base feature set supports up to 24 EtherChannels.

The IP Lite feature set supports up to 48 EtherChannels.

EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as would any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.

- When you configure an EtherChannel in the on mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the on mode; otherwise, packet loss can occur.
**EtherChannel on Devices**

You can create an EtherChannel on a device, on a single device in the stack, or on multiple devices in the stack (known as cross-stack EtherChannel).

*Figure 47: Single-Switch EtherChannel*

*Figure 48: Cross-Stack EtherChannel*

**EtherChannel Link Failover**

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.
Channel Groups and Port-Channel Interfaces

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.

Figure 49: Relationship of Physical Ports, Channel Group and Port-Channel Interface

The **channel-group** command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 48. This port-channel interface number corresponds to the one specified with the **channel-group** interface configuration command.

- With Layer 2 ports, use the **channel-group** interface configuration command to dynamically create the port-channel interface.

You also can use the **interface port-channel port-channel-number** global configuration command to manually create the port-channel interface, but then you must use the **channel-group channel-group-number** command to bind the logical interface to a physical port. The **channel-group-number** can be the same as the **port-channel-number**, or you can use a new number. If you use a new number, the **channel-group** command dynamically creates a new port channel.

Port Aggregation Protocol

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco devices and on those devices licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports.

By using PAgP, the device or device stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single device in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single device port.
PAgP Modes

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

**Table 54: EtherChannel PAgP Modes**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets. This mode is not supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel).</td>
</tr>
<tr>
<td>desirable</td>
<td>Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is not supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel).</td>
</tr>
</tbody>
</table>

Switch ports exchange PAgP packets only with partner ports configured in the **auto** or **desirable** modes. Ports configured in the **on** mode do not exchange PAgP packets.

Both the **auto** and **desirable** modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the **desirable** mode can form an EtherChannel with another port that is in the **desirable** or **auto** mode.
- A port in the **auto** mode can form an EtherChannel with another port in the **desirable** mode.

A port in the **auto** mode cannot form an EtherChannel with another port that is also in the **auto** mode because neither port starts PAgP negotiation.

**Silent Mode**

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the **non-silent** keyword. If you do not specify **non-silent** with the **auto** or **desirable** mode, silent mode is assumed.

Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

**PAgP Learn Method and Priority**

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.
When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.

PAgP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the `pagp port-priority` interface configuration command. The higher the priority, the more likely that the port will be selected.

### Note

The device supports address learning only on aggregate ports even though the `physical-port` keyword is provided in the CLI. The `pagp learn-method` command and the `pagp port-priority` command have no effect on the device hardware, but they are required for PAgP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the device is a physical learner, we recommend that you configure the device as a physical-port learner by using the `pagp learn-method physical-port` interface configuration command. Set the load-distribution method based on the source MAC address by using the `port-channel load-balance src-mac` global configuration command. The device then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the `pagp learn-method` command in this situation.

### PAgP Interaction with Virtual Switches and Dual-Active Detection

A virtual switch can be two or more core switches connected by virtual switch links (VSLs) that carry control and data traffic between them. One of the switches is in active mode. The others are in standby mode. For redundancy, remote switches are connected to the virtual switch by remote satellite links (RSLs).

If the VSL between two switches fails, one switch does not know the status of the other. Both switches could change to the active mode, causing a *dual-active situation* in the network with duplicate configurations (including duplicate IP addresses and bridge identifiers). The network might go down.

To prevent a dual-active situation, the core switches send PAgP protocol data units (PDUs) through the RSLs to the remote switches. The PAgP PDUs identify the active switch, and the remote switches forward the PDUs to core switches so that the core switches are in sync. If the active switch fails or resets, the standby switch takes over as the active switch. If the VSL goes down, one core switch knows the status of the other and does not change its state.

### PAgP Interaction with Other Features

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAgP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel.
PAgP sends and receives PAgP PDUs only from ports that are up and have PAgP enabled for the auto or desirable mode.

**Link Aggregation Control Protocol**

The LACP is defined in IEEE 802.3ad and enables Cisco devices to manage Ethernet channels between devices that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the device or device stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single device port.

The independent mode behavior of ports in a port channel is changed. With CSCtn96950, by default, standalone mode is enabled. When no response is received from an LACP peer, ports in the port channel are moved to suspended state.

**LACP Modes**

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.</td>
</tr>
<tr>
<td>passive</td>
<td>Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets.</td>
</tr>
</tbody>
</table>

Both the **active** and **passive** LACP modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the **active** mode can form an EtherChannel with another port that is in the **active** or **passive** mode.
- A port in the **passive** mode cannot form an EtherChannel with another port that is also in the **passive** mode because neither port starts LACP negotiation.

**LACP Interaction with Other Features**

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.
In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

**EtherChannel On Mode**

EtherChannel **on** mode can be used to manually configure an EtherChannel. The **on** mode forces a port to join an EtherChannel without negotiations. The **on** mode can be useful if the remote device does not support PAgP or LACP. In the **on** mode, a usable EtherChannel exists only when the devices at both ends of the link are configured in the **on** mode.

Ports that are configured in the **on** mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the **on** mode.

---

**Caution**

You should use care when using the **on** mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

---

**Load-Balancing and Forwarding Methods**

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the device.

---

**Note**

Layer 3 Equal-cost multi path (ECMP) load balancing is based on source IP address, destination IP address, source port, destination port, and layer 4 protocol. Fragmented packets will be treated on two different links based on the algorithm calculated using these parameters. Any changes in one of these parameters will result in load balancing.

You configure the load-balancing and forwarding method by using the **port-channel load-balance** global configuration command.

**MAC Address Forwarding**

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host’s MAC address of the incoming packet. Therefore,
packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular device. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

**IP Address Forwarding**

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel. Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular device. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

**Load-Balancing Advantages**

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the device in the network and the kind of traffic that needs to be load-distributed.

*Figure 50: Load Distribution and Forwarding Methods*

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the device EtherChannel ensures that the device uses all available bandwidth to the router. The router is configured for destination-based forwarding because
the large number of workstations ensures that the traffic is evenly distributed from the router EtherChannel.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

**EtherChannel Load Deferral Overview**

In an Instant Access system, the EtherChannel Load Deferral feature allows ports to be bundled into port channels, but prevents the assignment of group mask values to these ports. This prevents the traffic from being forwarded to new instant access stack members and reduce data loss following a stateful switchover (SSO).

Cisco Catalyst Instant Access creates a single network touch point and a single point of configuration across distribution and access layer switches. Instant Access enables the merging of physical distribution and access layer switches into a single logical entity with a single point of configuration, management, and troubleshooting. The following illustration represents a sample network where an Instant Access system interacts with a switch (Catalyst 2960-X Series Switches) that is connected via a port channel to stacked clients (Member 1 and Member 2).

When the EtherChannel Load Deferral feature is configured and a new Instant Access client stack member comes up, ports of this newly-joined stack member is bundled into the port channel. In the transition period, the data path is not fully established on the distribution switch (Catalyst 6000 Series Switches), and traffic originating from the access layer switch (Catalyst 2960-X Series Switches) reaches non-established ports and the traffic gets lost.

When load share deferral is enabled on a port channel, the assignment of a member port’s load share is delayed for a period that is configured globally by the `port-channel load-defer` command. During the deferral period, the load share of a deferred member port is set to 0. In this state, the deferred port is capable of receiving data and control traffic, and of sending control traffic, but the port is prevented from sending data traffic to the virtual switching system (VSS). Upon expiration of the global deferral timer, the deferred member port exits the deferral state and the port assumes its normal configured load share.
Load share deferral is applied only if at least one member port of the port channel is currently active with a nonzero load share. If a port enabled for load share deferral is the first member bringing up the EtherChannel, the deferral feature does not apply and the port will forward traffic immediately.

This feature is enabled on a per port-channel basis; however, the load deferral timer is configured globally and not per port-channel. As a result, when a new port is bundled, the timer starts only if it is not already running. If some other ports are already deferred then the new port will be deferred only for the remaining amount of time.

The load deferral is stopped as soon as a member in one of the deferred port channels is unbundled. As a result, all the ports that were deferred is assigned a group-mask in the event of an unbundling during the deferral period.

---

**Note**

When you try to enable this feature on a stack member switch, the following message is displayed:

Load share deferral is supported only on stand-alone stack.

---

### EtherChannel and Device Stacks

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active device removes the failed stack member device ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a device is added to an existing stack, the new device receives the running configuration from the active device and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAgP or LACP configuration on a winning device stack is not affected, but the PAgP or LACP configuration on the losing device stack is lost after the stack reboots.

For a mixed stack containing one or more Catalyst 2960-S switches, we recommend that you configure no more than six EtherChannels on the stack.

### Device Stack and PAgP

With PAgP, if the active device fails or leaves the stack, the standby device becomes the new active device. The new active device synchronizes the configuration of the stack members to that of the active device. The PAgP configuration is not affected after an active device change unless the EtherChannel has ports residing on the old active device.

### Switch Stacks and LACP

With LACP, the system ID uses the stack MAC address from the active switch, and if the active switch changes, the LACP system ID can change. If the LACP system ID changes, the entire EtherChannel will flap, and there will be an STP reconvergence. Use the **stack-mac persistent timer** command to control whether or not the stack MAC address changes during a active switch failover.
Default EtherChannel Configuration

The default EtherChannel configuration is described in this table.

**Table 56: Default EtherChannel Configuration**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>

<td>Load-balancing</td>
<td>Load distribution on the device is based on the source-MAC address of the incoming packet.</td>
</tr>
</tbody>
</table>

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

- Do not try to configure more than 24 EtherChannels on the device or device stack.
- In a mixed switch stack that contains one or more Catalyst 2960-S switches, do not configure more than six EtherChannels on the switch stack.
- Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
- Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
- Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
- Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the `shutdown` interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.
When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:

- Allowed-VLAN list
- Spanning-tree path cost for each VLAN
- Spanning-tree port priority for each VLAN
- Spanning-tree Port Fast setting

Do not configure a port to be a member of more than one EtherChannel group.

Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same device or on different devices in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.

Do not configure a secure port as part of an EtherChannel or the reverse.

Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.

If EtherChannels are configured on device interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a device by using the `dot1x system-auth-control` global configuration command.

For cross-stack EtherChannel configurations, ensure that all ports targeted for the EtherChannel are either configured for LACP or are manually configured to be in the channel group using the `channel-group channel-group-number mode` on interface configuration command. The PAgP protocol is not supported on cross-stack EtherChannels.

**Layer 2 EtherChannel Configuration Guidelines**

When configuring Layer 2 EtherChannels, follow these guidelines:

- Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.

- An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAgP is set to the auto or desirable mode.

- Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

**Layer 3 EtherChannel Configuration Guidelines**

- For Layer 3 EtherChannels, assign the Layer 3 address to the port-channel logical interface, not to the physical ports in the channel.
Auto-LAG

The auto-LAG feature provides the ability to auto create EtherChannels on ports connected to a switch. By default, auto-LAG is disabled globally and is enabled on all port interfaces. The auto-LAG applies to a switch only when it is enabled globally.

On enabling auto-LAG globally, the following scenarios are possible:

- All port interfaces participate in creation of auto EtherChannels provided the partner port interfaces have EtherChannel configured on them. For more information, see the "The supported auto-LAG configurations between the actor and partner devices" table below.
- Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.
- When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:

<table>
<thead>
<tr>
<th>Actor/Partner</th>
<th>Active</th>
<th>Passive</th>
<th>Auto</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Passive</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Auto</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels.

You cannot add any configurations in an existing auto created EtherChannel. To add, you should first convert it into a manual EtherChannel by executing the `port-channel<channel-number> persistent`.

Note: Auto-LAG uses the LACP protocol to create auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

Auto-LAG Configuration Guidelines

Follow these guidelines when configuring the auto-LAG feature.

- When auto-LAG is enabled globally and on the port interface, and if you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.
- A port interface will not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.
- When auto-LAG is enabled and auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.
- The auto-LAG is supported only on Layer 2 EtherChannel. It is not supported on Layer 3 interface and Layer 3 EtherChannel.
How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

Configuring Layer 2 EtherChannels

You configure Layer 2 EtherChannels by assigning ports to a channel group with the `channel-group` interface configuration command. This command automatically creates the port-channel logical interface.

If you enabled PAgP on a port in the `auto` or `desirable` mode, you must reconfigure it for either the `on` mode or the LACP mode before adding this port to a cross-stack EtherChannel. PAgP does not support cross-stack EtherChannels.

SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `switchport mode {access | trunk}`
4. `switchport access vlan vlan-id`
5. `channel-group channel-group-number mode {auto [non-silent] | desirable [non-silent] | on | active | passive}`
6. `end`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>interface interface-id</code></td>
<td>Specifies a physical port, and enters interface configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>interface gigabitethernet1/0/1</code></td>
<td>Valid interfaces are physical ports. For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group. For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Layer 2 EtherChannels

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3**

- `switchport mode {access | trunk}`

  **Example:**

  ```console
  Device(config-if)# switchport mode access
  ```

  Assigns all ports as static-access ports in the same VLAN, or configure them as trunks.

  If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.

| **Step 4**

- `switchport access vlan vlan-id`

  **Example:**

  ```console
  Device(config-if)# switchport access vlan 22
  ```

  (Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.

| **Step 5**

- `channel-group channel-group-number mode {auto [non-silent] | desirable [non-silent ] | on } | { active | passive}`

  **Example:**

  ```console
  Device(config-if)# channel-group 5 mode auto
  ```

  Assigns the port to a channel group, and specifies the PAgP or the LACP mode.

  For `channel-group-number`, the range is 1 to 48.

  For `mode`, select one of these keywords:

  - **auto** — Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack.

  - **desirable** — Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.

  - **on** — Forces the port to channel without PAgP or LACP. In the `on` mode, an EtherChannel exists only when a port group in the `on` mode is connected to another port group in the `on` mode.

  - **non-silent** — (Optional) If your device is connected to a partner that is PAgP-capable, configures the device port for nonsilent operation when the port is in the `auto` or `desirable` mode. If you do not specify `non-silent`, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

  - **active** — Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.
### Configuring Layer 3 EtherChannels

To configure Layer 3 EtherChannels, you create the port-channel logical interface and then put the Ethernet ports into the port channel as described in the next two sections.

### Creating Port-Channel Logical Interfaces

When configuring Layer 3 EtherChannels, you should first manually create the port-channel logical interface by using the `interface port-channel` global configuration command. Then put the logical interface into the channel group by using the `channel-group` interface configuration command.

#### Note

To move an IP address from a physical port to an EtherChannel, you must delete the IP address from the physical port before configuring it on the port-channel interface.

Follow these steps to create a port-channel interface for a Layer 3 EtherChannel. This procedure is required.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface port-channel port-channel-number`
4. `no switchport`
5. `ip address ip-address mask`
6. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specifies the port-channel logical interface, and enters</td>
</tr>
<tr>
<td>interface port-channel port-channel-number</td>
<td>interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>For port-channel-number, the range is 1 to 48.</td>
</tr>
<tr>
<td>Device(config)# interface port-channel 5</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Puts the interface into Layer 3 mode.</td>
</tr>
<tr>
<td>no switchport</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# no switchport</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Assigns an IP address and subnet mask to the EtherChannel.</td>
</tr>
<tr>
<td>ip address ip-address mask</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ip address 172.10.20.10 255.255.255.0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to create the logical port channel 5 and assign 172.10.20.10 as its IP address:

```
Switch# configure terminal
Switch(config)# interface port-channel 5
Switch(config-if)# no switchport
Switch(config-if)# ip address 172.10.20.10 255.255.255.0
Switch(config-if)# end
```

**Configuring the Physical Interfaces**

Follow these steps to assign an Ethernet port to a Layer 3 EtherChannel. This procedure is required.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. no ip address
5. no switchport
6. channel-group channel-group-number mode { auto [non-silent] | desirable [non-silent] | on } [ active | passive ]
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
<td>Enables privileged EXEC mode.&lt;br&gt;• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>interface interface-id</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# interface gigabitethernet 1/0/2</td>
<td>Specifies a physical port, and enters interface configuration mode.&lt;br&gt;Valid interfaces include physical ports.&lt;br&gt;For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group.&lt;br&gt;For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>no ip address</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# no ip address</td>
<td>Ensures that there is no IP address assigned to the physical port.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>no switchport</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# no switchport</td>
<td>Puts the port into Layer 3 mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>`channel-group channel-group-number mode { auto [ non-silent ]</td>
<td>desirable [ non-silent ]</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>desirable</strong>—Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.</td>
<td></td>
</tr>
<tr>
<td>• <strong>on</strong>—Forces the port to channel without PAgP or LACP. In the <strong>on</strong> mode, an EtherChannel exists only when a port group in the <strong>on</strong> mode is connected to another port group in the <strong>on</strong> mode.</td>
<td></td>
</tr>
<tr>
<td>• <strong>non-silent</strong>—(Optional) If your device is connected to a partner that is PAgP capable, configures the device port for nonsilent operation when the port is in the <strong>auto</strong> or <strong>desirable</strong> mode. If you do not specify <strong>non-silent</strong>, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.</td>
<td></td>
</tr>
<tr>
<td>• <strong>active</strong>—Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.</td>
<td></td>
</tr>
<tr>
<td>• <strong>passive</strong>—Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 7

**Example:**

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

---

### Configuring EtherChannel Load-Balancing

You can configure EtherChannel load-balancing by using source-based or destination-based forwarding methods.

This task is optional.

### SUMMARY STEPS

1. `configure terminal`
2. `port-channel load-balance { dst-ip | dst-mac | src-dst-ip | src-dst-mac | src-ip | src-mac }`
3. `end`
### DETAILED STEPS

### Configuring Port Channel Load Deferral

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `port-channel load-defer seconds`
4. `interface type number`
5. `port-channel load-defer`
6. `end`
7. `show etherchannel channel-group port-channel`
8. `show platform pm group-masks`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `enable` | Enables privileged EXEC mode.  
  **Example:**  
  Switch> enable |
| Step 2 | `configure terminal` | Enters global configuration mode.  
  **Example:**  
  Switch# configure terminal |
| Step 3 | `port-channel load-defer seconds` | Configures the port load share deferral interval for all port channels.  
  **Example:**  
  Switch(config)# port-channel load-defer 60  
  • `seconds`—The time interval during which load sharing is initially 0 for deferred port channels. The range is 1 to 1800 seconds; the default is 120 seconds |
| Step 4 | `interface type number` | Configures a port channel interface and enters interface configuration mode.  
  **Example:**  
  Switch(config)# interface port-channel 10 |
| Step 5 | `port-channel load-defer` | Enables port load share deferral on the port channel.  
  **Example:**  
  Switch(config-if)# port-channel load-defer |
| Step 6 | `end` | Exits interface configuration mode and returns to privileged EXEC mode.  
  **Example:**  
  Switch(config-if)# end |
| Step 7 | `show etherchannel channel-group port-channel` | Displays port channel information.  
  **Example:**  
  Switch# show etherchannel 1 port-channel |
| Step 8 | `show platform pm group-masks` | Display EtherChannel group masks information.  
  **Example:**  
  Switch# show platform pm group-masks |

**Example**

The following is sample output from the `show etherchannel channel-group port-channel` command.  
If the `channel-group` argument is not specified; the command displays information about all channel groups are displayed.

```
Switch# show etherchannel 1 port-channel

Port-channels in the group:
--------------------------
```
Port-channel: Po1
------------
Age of the Port-channel = 0d:00h:37m:08s
Logical slot/port = 9/1 Number of ports = 0
GC = 0x00000000 HotStandBy port = null
Port state = Port-channel Ag-Not-Inuse
Protocol = -
Port security = Disabled
Load share deferral = Enabled defer period = 120 sec time left = 0 sec

The following is sample output from the show platform pm group-masks command. Deferred ports have the group mask of 0xFFFF, when the defer timer is running.

Switch# show platform pm group-masks

<table>
<thead>

Configuring the PAgP Learn Method and Priority

This task is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. pagp learn-method physical-port
4. pagp port-priority priority
5. end
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>interface interface-id</td>
<td>Specifies the port for transmission, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>pagp learn-method physical-port</td>
<td>Selects the PAgP learning method.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# pagp learn-method physical port</td>
<td>By default, <strong>aggregation-port learning</strong> is selected, which means the device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Selects <strong>physical-port</strong> to connect with another device that is a physical learner.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Make sure to configure the <strong>port-channel load-balance</strong> global configuration command to <strong>src-mac</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The learning method must be configured the same at both ends of the link.</td>
</tr>
<tr>
<td>Step 4</td>
<td>pagp port-priority priority</td>
<td>Assigns a priority so that the selected port is chosen for packet transmission.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# pagp port-priority 200</td>
<td>For <strong>priority</strong>, the range is 0 to 255. The default is 128. The higher the priority, the more likely that the port will be used for PAgP transmission.</td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring LACP Hot-Standby Ports

When enabled, LACP tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time. The software places any additional links in a hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.
If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the device MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

### Configuring the LACP System Priority

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the `lacp system-priority` global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Follow these steps to configure the LACP system priority. This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `lacp system-priority priority`
4. `end`

**DETAILED STEPS**

<table>

</table>

---

Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)

Layer 2/3
Configuring the LACP Port Priority

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

**Note**

If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Follow these steps to configure the LACP port priority. This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `lacp port-priority priority`
5. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>
Configuring the LACP Port Channel Min-Links Feature

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

To configure the minimum number of links that are required for a port channel. Perform the following tasks.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface port-channel channel-number`
4. `port-channel min-links min-links-number`
5. `end`

**Configuring LACP Fast Rate Timer**

You can change the LACP timer rate to modify the duration of the LACP timeout. Use the **lACP rate** command to set the rate at which LACP control packets are received by an LACP-supported interface. You can change the timeout rate from the default rate (30 seconds) to the fast rate (1 second). This command is supported only on LACP-enabled interfaces.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface {fastethernet | gigabitethernet | tengigabitethernet} slot/port
4. lACP rate {normal | fast}
5. end
6. show lacp internal

<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
</tbody>
</table>

### Step 2

**configure terminal**

**Example:**

Device# `configure terminal`

**Step 3**

**interface interface-id**

**Example:**

Device(config)# `interface gigabitethernet 1/0/1`

### Step 4

(No) `channel-group auto`

**Example:**

Device(config-if)# `channel-group auto`

### Step 5

`end`

**Example:**

Device(config-if)# `end`

### Step 6

`show etherchannel auto`

**Example:**

Device# `show etherchannel auto`

---

### What to do next

**Configuring Persistence with Auto-LAG**

You use the persistence command to convert the auto created EtherChannel into a manual one and allow you to add configuration on the existing EtherChannel.

### SUMMARY STEPS

1. `enable`
2. `port-channel channel-number persistent`
3. `show etherchannel summary`

Configuration Examples for Configuring EtherChannels

Configuring Layer 2 EtherChannels: Examples

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAgP mode desirable:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode desirable non-silent
Device(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode active:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
```

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode passive
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# switchport mode access
Device(config-if)# switchport access vlan 10
Device(config-if)# channel-group 5 mode passive
Device(config-if)# exit
```

PoE or LACP negotiation errors may occur if you configure two ports from switch to the access point (AP). This scenario can be avoided if the port channel configuration is on the switch side. For more details, see the following example:

```
interface Port-channel1
    switchport access vlan 20
    switchport mode access
    switchport nonegotiate
    no port-channel standalone-disable
    spanning-tree portfast
```
If the port reports LACP errors on port flap, you should include the following command as well:

```
no errdisable
detect cause pagp-flap
```

### Configuring Port-Channel Logical Interfaces: Example

This example shows how to create the logical port channel 5 and assign 172.10.20.10 as its IP address:

```
Device# configure terminal
Device(config)# interface port-channel 5
Device(config-if)# no switchport
Device(config-if)# ip address 172.10.20.10 255.255.255.0
Device(config-if)# end
```

### Configuring EtherChannel Physical Interfaces: Examples

This example shows how to configure an EtherChannel. It assigns two ports to channel 5 with the LACP mode `active`:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
```

This example shows how to configure a cross-stack EtherChannel. It assigns two ports on stack member 2 and one port on stack member 3 to channel 7 using LACP active mode:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 7 mode active
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# no ip address
Device(config-if)# no switchport
Device(config-if)# channel-group 7 mode active
Device(config-if)# exit
```
Example: Configuring Port Channel Load Deferral

Switch# configure terminal
Switch(config)# port-channel load-defer 60
Switch(config)# interface port-channel 10
Switch(config-if)# port-channel load-defer
Switch(config-if)# end

Configuring Auto LAG: Examples

This example shows how to configure Auto-LAG on a switch

device> enable
device# configure terminal
device (config)# port-channel auto
device (config-if)# end
device# show etherchannel auto

The following example shows the summary of EtherChannel that was created automatically.

device# show etherchannel auto
Flags: D - down    P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3    S - Layer2
U - in use    f - failed to allocate aggregator
M - not in use, minimum links not met
u - unsuitable for bundling
w - waiting to be aggregated
d - default port
A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators: 1

Group   Port-channel   Protocol   Ports
---------------------------------------------
1       Po1(SUA)       LACP       Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)

The following example shows the summary of auto EtherChannel after executing the port-channel 1 persistent command.

device# port-channel 1 persistent
device# show etherchannel summary

Switch# show etherchannel summary
Flags: D - down    P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3    S - Layer2
U - in use    f - failed to allocate aggregator
M - not in use, minimum links not met
u - unsuitable for bundling
w - waiting to be aggregated
d - default port
A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators: 1
Configuring LACP Port Channel Min-Links: Examples

This example shows how to configure LACP port-channel min-links:

```
device > enable
device# configure terminal
device(config)# interface port-channel 5
device(config-if)# port-channel min-links 3
device# show etherchannel 25 summary
device# end
```

When the minimum links requirement is not met in standalone switches, the port-channel is flagged and assigned SM/SN or RM/RN state.

```
device# show etherchannel 5 summary
```

Flags: D - down P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3 S - Layer2
U - in use N= not in use, no aggregation
f - failed to allocate aggregator
M - not in use, no aggregation due to minimum links not met
m - not in use, port not aggregated due to minimum links not met
u - unsuitable for bundling
w - waiting to be aggregated
d - default port
Number of channel-groups in use: 6
Number of aggregators: 6

```

```

Example: Configuring LACP Fast Rate Timer

This example shows you how to configure the LACP rate:

```
device> enable
device# configure terminal
device(config)# interface gigabitEthernet 2/1
device(config-if)# lacp rate fast
device(config-if)# exit
device(config)# end
device# show lacp internal
device# show lacp counters
```

The following is sample output from the `show lacp internal` command:

```
device# show lacp internal
Flags: S - Device is requesting Slow LACPDUs
F - Device is requesting Fast LACPDUs
A - Device is in Active mode P - Device is in Passive mode
Channel group 25
LACP port Admin Oper Port Port
Port Flags State Priority Key Key Number State
```
The following is sample output from the `show lacp counters` command:

device# show lacp counters

LACPDU Marker Marker Response LACPDU
Sent Recv Sent Recv Sent Recv Pkts Err
=====================================================================
Channel group: 24
Te1/1/27 2 2 0 0 0 0 0
Te2/1/25 2 2 0 0 0 0 0

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring Link-State Tracking

• You can configure only two link-state groups per switch.

• An interface cannot be a member of more than one link-state group.

• An interface that is defined as an upstream interface in a link-state group cannot also be defined as a downstream interface in the link-state group.

• Do not enable link-state tracking on individual interfaces that will part of a downstream EtherChannel interface.
Understanding Link-State Tracking

Link-state tracking, also known as trunk failover, binds the link state of multiple interfaces. Link-state tracking can be with server NIC adapter teaming to provide redundancy in the network. When the server NIC adapters are configured in a primary or secondary relationship, and the link is lost on the primary interface, network connectivity is transparently changed to the secondary interface.

Note

An interface can be an aggregation of ports (an EtherChannel) or a single physical port in either access or trunk mode.

The configuration in this figure ensures that the network traffic flow is balanced.

Figure 51: Typical Link-State Tracking Configuration

- For links to switches and other network devices
  - Server 1 and server 2 use switch A for primary links and switch B for secondary links.
  - Server 3 and server 4 use switch B for primary links and switch A for secondary links.

- Link-state group 1 on switch A
• Switch A provides primary links to server 1 and server 2 through link-state group 1. Port 1 is connected to server 1, and port 2 is connected to server 2. Port 1 and port 2 are the downstream interfaces in link-state group 1.

• Port 5 and port 6 are connected to distribution switch 1 through link-state group 1. Port 5 and port 6 are the upstream interfaces in link-state group 1.

• Link-state group 2 on switch A

• Switch A provides secondary links to server 3 and server 4 through link-state group 2. Port 3 is connected to server 3, and port 4 is connected to server 4. Port 3 and port 4 are the downstream interfaces in link-state group 2.

• Port 7 and port 8 are connected to distribution switch 2 through link-state group 2. Port 7 and port 8 are the upstream interfaces in link-state group 2.

• Link-state group 2 on switch B

• Switch B provides primary links to server 3 and server 4 through link-state group 2. Port 3 is connected to server 3, and port 4 is connected to server 4. Port 3 and port 4 are the downstream interfaces in link-state group 2.

• Port 5 and port 6 are connected to distribution switch 2 through link-state group 2. Port 5 and port 6 are the upstream interfaces in link-state group 2.

• Link-state group 1 on switch B

• Switch B provides secondary links to server 1 and server 2 through link-state group 1. Port 1 is connected to server 1, and port 2 is connected to server 2. Port 1 and port 2 are the downstream interfaces in link-state group 1.

• Port 7 and port 8 are connected to distribution switch 1 through link-state group 1. Port 7 and port 8 are the upstream interfaces in link-state group 1.

In a link-state group, the upstream ports can become unavailable or lose connectivity because the distribution switch or router fails, the cables are disconnected, or the link is lost. These are the interactions between the downstream and upstream interfaces when link-state tracking is enabled:

• If any of the upstream interfaces are in the link-up state, the downstream interfaces can change to or remain in the link-up state.

• If all of the upstream interfaces become unavailable, link-state tracking automatically puts the downstream interfaces in the error-disabled state. Connectivity to and from the servers is automatically changed from the primary server interface to the secondary server interface. For example, in the previous figure, if the upstream link for port 6 is lost, the link states of downstream ports 1 and 2 do not change. However, if the link for upstream port 5 is also lost, the link state of the downstream ports changes to the link-down state. Connectivity to server 1 and server 2 is then changed from link-state group 1 to link-state group 2. The downstream ports 3 and 4 do not change state because they are in link-group 2.

• If the link-state group is configured, link-state tracking is disabled, and the upstream interfaces lose connectivity, the link states of the downstream interfaces remain unchanged. The server does not recognize that upstream connectivity has been lost and does not failover to the secondary interface.

You can recover a downstream interface link-down condition by removing the failed downstream port from the link-state group. To recover multiple downstream interfaces, disable the link-state group.
How to Configure Link-State Tracking

To enable link-state tracking, create a link-state group and specify the interfaces that are assigned to the group. This task is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `link state track number`
3. `interface interface-id`
4. `link state group [number]{upstream | downstream}`
5. `end`

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring Flex Links and MAC Address-Table Move Update

- Flex Links are supported only on Layer 2 ports and port channels.
- You can configure up to 16 backup links.
- You can configure only one Flex Links backup link for any active link, and it must be a different interface from the active interface.
An interface can belong to only one Flex Links pair. An interface can be a backup link for only one active link. An active link cannot belong to another Flex Links pair.

Neither of the links can be a port that belongs to an EtherChannel. However, you can configure two port channels (EtherChannel logical interfaces) as Flex Links, and you can configure a port channel and a physical interface as Flex Links, with either the port channel or the physical interface as the active link.

A backup link does not have to be the same type (Gigabit Ethernet or port channel) as the active link. However, you should configure both Flex Links with similar characteristics so that there are no loops or changes in behavior if the standby link begins to forward traffic.

STP is disabled on Flex Links ports. A Flex Links port does not participate in STP, even if the VLANs present on the port are configured for STP. When STP is not enabled, be sure that there are no loops in the configured topology.

### Information About Flex Links and MAC Address-Table Move Update

#### Flex Links

Flex Links are a pair of a Layer 2 interfaces (device ports or port channels) where one interface is configured to act as a backup to the other. The feature provides an alternative solution to the Spanning Tree Protocol (STP). Users can disable STP and still retain basic link redundancy. Flex Links are typically configured in service provider or enterprise networks where customers do not want to run STP on the device. If the device is running STP, Flex Links are not necessary because STP already provides link-level redundancy or backup.

You configure Flex Links on one Layer 2 interface (the active link) by assigning another Layer 2 interface as the Flex Links or backup link. On devices, the Flex Links can be on the same device or on another device in the stack. When one of the links is up and forwarding traffic, the other link is in standby mode, ready to begin forwarding traffic if the other link shuts down. At any given time, only one of the interfaces is in the linkup state and forwarding traffic. If the primary link shuts down, the standby link starts forwarding traffic. When the active link comes back up, it goes into standby mode and does not forward traffic. STP is disabled on Flex Links interfaces.

#### Flex Links Configuration

In the following figure, ports 1 and 2 on device A are connected to uplink switches B and C. Because they are configured as Flex Links, only one of the interfaces is forwarding traffic; the other is in standby mode. If port 1 is the active link, it begins forwarding traffic between port 1 and switch B; the link between port 2 (the backup link) and switch C is not forwarding traffic. If port 1 goes down, port 2 comes up and starts forwarding traffic to switch C. When port 1 comes back up, it goes into standby mode and does not forward traffic; port 2 continues forwarding traffic.

You can also configure a preemption function, specifying the preferred port for forwarding traffic. For example, you can configure the Flex Links pair with preemption mode. In the scenario shown, when port 1 comes back up and has more bandwidth than port 2, port 1 begins forwarding traffic after 60 seconds. Port 2 becomes the standby port. You do this by entering the `switchport backup interface preemption mode bandwidth` and `switchport backup interface preemption delay` interface configuration commands.
If a primary (forwarding) link goes down, a trap notifies the network management stations. If the standby link goes down, a trap notifies the users.

Flex Links are supported only on Layer 2 ports and port channels, not on VLANs or on Layer 3 ports.

**VLAN Flex Links Load Balancing and Support**

VLAN Flex Links load balancing allows users to configure a Flex Links pair so that both ports simultaneously forward the traffic for some mutually exclusive VLANs. For example, if Flex Links ports are configured for 1 to 100 VLANs, the traffic of the first 50 VLANs can be forwarded on one port and the rest on the other port. If one of the ports fail, the other active port forwards all the traffic. When the failed port comes back up, it resumes forwarding traffic in the preferred VLANs. In addition to providing the redundancy, this Flex Links pair can be used for load balancing. Flex Links VLAN load balancing does not impose any restrictions on uplink devices.

**Multicast Fast Convergence with Flex Links Failover**

Multicast fast convergence reduces the multicast traffic convergence time after a Flex Links failure. Multicast fast convergence is implemented by a combination of learning the backup link as an mrouter port, generating IGMP reports, and leaking IGMP reports.

**Learning the Other Flex Links Port as the mrouter Port**

In a typical multicast network, there is a querier for each VLAN. A device deployed at the edge of a network has one of its Flex Links ports receiving queries. Flex Links ports are also always forwarding at any given time.

A port that receives queries is added as an mrouter port on the device. An mrouter port is part of all the multicast groups learned by the device. After a changeover, queries are received by the other Flex Links port.
The other Flex Links port is then learned as the mrouter port. After changeover, multicast traffic then flows through the other Flex Links port. To achieve faster convergence of traffic, both Flex Links ports are learned as mrouter ports whenever either Flex Links port is learned as the mrouter port. Both Flex Links ports are always part of multicast groups.

Although both Flex Links ports are part of the groups in normal operation mode, all traffic on the backup port is blocked. The normal multicast data flow is not affected by the addition of the backup port as an mrouter port. When the changeover happens, the backup port is unblocked, allowing the traffic to flow. In this case, the upstream multicast data flows as soon as the backup port is unblocked.

Generating IGMP Reports

When the backup link comes up after the changeover, the upstream new distribution device does not start forwarding multicast data, because the port on the upstream router, which is connected to the blocked Flex Links port, is not part of any multicast group. The reports for the multicast groups were not forwarded by the downstream device because the backup link is blocked. The data does not flow on this port, until it learns the multicast groups, which occurs only after it receives reports.

The reports are sent by hosts when a general query is received, and a general query is sent within 60 seconds in normal scenarios. When the backup link starts forwarding, to achieve faster convergence of multicast data, the downstream device immediately sends proxy reports for all the learned groups on this port without waiting for a general query.

Leaking IGMP Reports

To achieve multicast traffic convergence with minimal loss, a redundant data path must be set up before the Flex Links active link goes down. This can be achieved by leaking only IGMP report packets on the Flex Links backup link. These leaked IGMP report messages are processed by upstream distribution routers, so multicast data traffic gets forwarded to the backup interface. Because all incoming traffic on the backup interface is dropped at the ingress of the access device, no duplicate multicast traffic is received by the host. When the Flex Links active link fails, the access device starts accepting traffic from the backup link immediately. The only disadvantage of this scheme is that it consumes bandwidth on the link between the distribution devices and on the backup link between the distribution and access devices. This feature is disabled by default and can be configured by using the `switchport backup interface interface-id multicast fast-convergence` command.

When this feature has been enabled at changeover, the device does not generate the proxy reports on the backup port, which became the forwarding port.

MAC Address-Table Move Update

The MAC address-table move update feature allows the device to provide rapid bidirectional convergence when a primary (forwarding) link goes down and the standby link begins forwarding traffic.

Figure 54: MAC Address-Table Move Update Example

In the following figure, switch A is an access switch, and ports 1 and 2 on switch A are connected to uplink devices B and D through a Flex Links pair. Port 1 is forwarding traffic, and port 2 is in the backup state. Traffic from the PC to the server is forwarded from port 1 to port 3. The MAC address of the PC has been
learned on port 3 of device C. Traffic from the server to the PC is forwarded from port 3 to port 1.

If the MAC address-table move update feature is not configured and port 1 goes down, port 2 starts forwarding traffic. However, for a short time, device C keeps forwarding traffic from the server to the PC through port 3, and the PC does not get the traffic because port 1 is down. If device C removes the MAC address of the PC on port 3 and relearns it on port 4, traffic can then be forwarded from the server to the PC through port 2.

If the MAC address-table move update feature is configured and enabled on the devices, and port 1 goes down, port 2 starts forwarding traffic from the PC to the server. The device sends a MAC address-table move update packet from port 2. Device C gets this packet on port 4 and immediately learns the MAC address of the PC on port 4, which reduces the reconvergence time.

You can configure the access device, device A, to send MAC address-table move update messages. You can also configure the uplink devices B, C, and D to get and process the MAC address-table move update messages. When device C gets a MAC address-table move update message from device A, device C learns the MAC address of the PC on port 4. Device C updates the MAC address table, including the forwarding table entry for the PC.

Device A does not need to wait for the MAC address-table update. The device detects a failure on port 1 and immediately starts forwarding server traffic from port 2, the new forwarding port. This change occurs in less than 100 milliseconds (ms). The PC is directly connected to device A, and the connection status does not change. Device A does not need to update the PC entry in the MAC address table.
Flex Links VLAN Load Balancing Configuration Guidelines

- For Flex Links VLAN load balancing, you must choose the preferred VLANs on the backup interface.
- You cannot configure a preemption mechanism and VLAN load balancing for the same Flex Links pair.

MAC Address-Table Move Update Configuration Guidelines

- You can enable and configure this feature on the access device to send the MAC address-table move updates.
- You can enable and configure this feature on the uplink devices to get the MAC address-table move updates.

Default Flex Links and MAC Address-Table Move Update Configuration

- Flex Links is not configured, and there are no backup interfaces defined.
- The preemption mode is off.
- The preemption delay is 35 seconds.
- The MAC address-table move update feature is not configured on the device.

How to Configure Flex Links and the MAC Address-Table Move Update Feature

Configuring Flex Links

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. switchport backup interface interface-id
4. end

### Configuration Examples for Flex Links

#### Configuring Flex Links: Examples

This example shows how to verify the configuration after you configure an interface with a backup interface:

```
Device# show interface switchport backup
Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----------------------------------------------
GigabitEthernet1/0/1 GigabitEthernet1/0/2 Active Up/Backup Standby
```

This example shows how to verify the configuration after you configure the preemption mode as forced for a backup interface pair:

```
Device# show interface switchport backup detail
Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----------------------------------------------
GigabitEthernet1/0/2/11 GigabitEthernet1/0/2/2 Active Up/Backup Standby
Interface Pair : Gi1/0/1, Gi1/0/2
Preemption Mode : forced
Preemption Delay : 50 seconds
Bandwidth : 100000 Kbit (Gi1/0/1), 100000 Kbit (Gi1/0/2)
Mac Address Move Update Vlan : auto
```

#### Configuring VLAN Load Balancing on Flex Links: Examples

In the following example, VLANs 1 to 50, 60, and 100 to 120 are configured on the device:

```
Device(config)# interface gigabitethernet 2/0/6
Device(config-if)# switchport backup interface gigabitethernet 2/0/8 prefer vlan 60,100-120
```

When both interfaces are up, Gi2/0/8 forwards traffic for VLANs 60 and 100 to 120 and Gi2/0/6 forwards traffic for VLANs 1 to 50.

```
Device# show interfaces switchport backup
Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----------------------------------------------
```
When a Flex Links interface goes down (LINK_DOWN), VLANs preferred on this interface are moved to the peer interface of the Flex Links pair. In this example, if interface Gi2/0/6 goes down, Gi2/0/8 carries all VLANs of the Flex Links pair.

Device# show interfaces switchport backup

Switch Backup Interface Pairs:

<table>
<thead>
<tr>
<th>Active Interface</th>
<th>Backup Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>GigabitEthernet2/0/6</td>
<td>GigabitEthernet2/0/8</td>
<td>Active Down/Backup Up</td>
</tr>
</tbody>
</table>

Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120

When a Flex Links interface comes up, VLANs preferred on this interface are blocked on the peer interface and moved to the forwarding state on the interface that has just come up. In this example, if interface Gi2/0/6 comes up, VLANs preferred on this interface are blocked on the peer interface Gi2/0/8 and forwarded on Gi2/0/6.

Device# show interfaces switchport backup

Switch Backup Interface Pairs:

<table>
<thead>
<tr>
<th>Active Interface</th>
<th>Backup Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>GigabitEthernet2/0/6</td>
<td>GigabitEthernet2/0/8</td>
<td>Active Up/Backup Standby</td>
</tr>
</tbody>
</table>

Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120

Device# show interfaces switchport backup detail

Switch Backup Interface Pairs:

<table>
<thead>
<tr>
<th>Active Interface</th>
<th>Backup Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>FastEthernet1/0/3</td>
<td>FastEthernet1/0/4</td>
<td>Active Down/Backup Up</td>
</tr>
</tbody>
</table>

Vlans Preferred on Active Interface: 1-2, 5-4094
Vlans Preferred on Backup Interface: 3-4
Preemption Mode : off
Bandwidth : 10000 Kbit (Fa1/0/3), 100000 Kbit (Fa1/0/4)
Mac Address Move Update Vlan : auto

Configuring the MAC Address-Table Move Update: Examples

This example shows how to verify the configuration after you configure an access device to send MAC address-table move updates:

Device# show mac address-table move update
Configuring Multicast Fast Convergence with Flex Links Failover: Examples

These are configuration examples for learning the other Flex Links port as the mrouter port when Flex Links is configured on GigabitEthernet1/0/11 and GigabitEthernet1/0/12, and output for the `show interfaces switchport backup` command:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface GigabitEthernet1/0/11
Device(config-if)# switchport trunk encapsulation dot1q
Device(config-if)# switchport mode trunk
Device(config-if)# switchport backup interface GigabitEthernet1/0/12
Device(config-if)# exit
Device(config)# interface GigabitEthernet1/0/12
Device(config-if)# switchport trunk encapsulation dot1q
Device(config-if)# switchport mode trunk
Device(config-if)# end
```

This output shows a querier for VLANs 1 and 401, with their queries reaching the device through GigabitEthernet1/0/11:

```
Device# show ip igmp snooping querier
Vlan IP Address IGMP Version Port
-----------------------------------------------
1 1.1.1.1 v2 Gi1/0/11
401 41.41.41.1 v2 Gi1/0/11
```
This example is output for the `show ip igmp snooping mrouter` command for VLANs 1 and 401:

```
Device# show ip igmp snooping mrouter
Vlan ports
---- -----
1    Gi1/0/11(dynamic), Gi1/0/12(dynamic)
401  Gi1/0/11(dynamic), Gi1/0/12(dynamic)
```

Similarly, both Flex Links ports are part of learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Device# show ip igmp snooping groups
Vlan Group Type Version Port List
-----------------------------------------------
1    228.1.5.1 igmp v2 Gi1/0/11, Gi1/0/12, Gi2/0/11
1    228.1.5.2 igmp v2 Gi1/0/11, Gi1/0/12, Gi2/0/11
```

When a host responds to the general query, the device forwards this report on all the mrouter ports. In this example, when a host sends a report for the group 228.1.5.1, it is forwarded only on GigabitEthernet1/0/11, because the backup port GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding.

As soon as this port starts forwarding, the device sends proxy reports for the groups 228.1.5.1 and 228.1.5.2 on behalf of the host. The upstream router learns the groups and starts forwarding multicast data. This is the default behavior of Flex Links. This behavior changes when the user configures fast convergence using the `switchport backup interface gigabitEthernet 1/0/12 multicast fast-convergence` command. This example shows turning on this feature:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface gigabitEthernet 1/0/11
Device(config-if)# switchport backup interface gigabitEthernet 1/0/12 multicast fast-convergence
Device(config-if)# exit
Device# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----------------------------------------------
GigabitEthernet1/0/11 GigabitEthernet1/0/12 Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : On
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLAN 1 and 401 with their queries reaching the device through GigabitEthernet1/0/11:

```
Device# show ip igmp snooping querier
Vlan IP Address IGMP Version Port
--------------------------------
1    1.1.1.1   v2   Gi1/0/11
```
This is output for the `show ip igmp snooping mrouter` command for VLAN 1 and 401:

```
Device# show ip igmp snooping mrouter
Vlan ports
----- ----- 
1    Gi1/0/11(dynamic), Gi1/0/12(dynamic)
401  Gi1/0/11(dynamic), Gi1/0/12(dynamic)
```

Similarly, both the Flex Links ports are a part of the learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Device# show ip igmp snooping groups
Vlan Group Type Version Port List
-----------------------------------------------------------------------
1  228.1.5.1  igmp v2  Gi1/0/11, Gi1/0/12, Gi2/0/11
1  228.1.5.2  igmp v2  Gi1/0/11, Gi1/0/12, Gi2/0/11
```

Whenever a host responds to the general query, the device forwards this report on all the mrouter ports. When you turn on this feature through the command-line port, and when a report is forwarded by the device on GigabitEthernet1/0/11, it is also leaked to the backup port GigabitEthernet1/0/12. The upstream router learns the groups and starts forwarding multicast data, which is dropped at the ingress because GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding. You do not need to send any proxy reports as the multicast data is already being forwarded by the upstream router. By leaking reports to the backup port, a redundant multicast path has been set up, and the time taken for the multicast traffic convergence is very minimal.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another device.

- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

⚠️ Caution
Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.
Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

Modes of Operation

UDLD two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

• On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
• On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
• One of the fiber strands in the cable is disconnected.

In these cases, UDLD disables the affected port.
In a point-to-point link, UDLD hello packets can be considered as a heartbeat whose presence guarantees the health of the link. Conversely, the loss of the heartbeat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

**Methods to Detect Unidirectional Links**

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

**Neighbor Database Maintenance**

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the device receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the device receives a new hello message before an older cache entry ages, the device replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the device is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

**Event-Driven Detection and Echoing**

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

**UDLD Reset Options**

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The `udld reset` interface configuration command.
- The `shutdown` interface configuration command followed by the `no shutdown` interface configuration command restarts the disabled port.
- The `no udld {aggressive | enable}` global configuration command followed by the `udld {aggressive | enable}` global configuration command reenables the disabled ports.
• The `no udld port` interface configuration command followed by the `udld port [aggressive]` interface configuration command reenables the disabled fiber-optic port.

• The `errdisable recovery cause udld` global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the `errdisable recovery interval interval` global configuration command specifies the time to recover from the UDLD error-disabled state.

### How to Configure UDLD

#### Enabling UDLD Globally

Follow these steps to enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic ports on the device.

**SUMMARY STEPS**

1. `configure terminal`
2. `udld {aggressive | enable | message time message-timer-interval}`
3. `end`

**DETAILED STEPS**

<td>- <code>aggressive</code>—Enables UDLD in aggressive mode on all fiber-optic ports.</td>
</tr>
</tbody>
</table>
Purpose
Command or Action

Device(config)# udld enable
message time 10

• enable—Enables UDLD in normal mode on all fiber-optic ports on the device. UDLD is disabled by default.

   An individual interface configuration overrides the setting of the udld enable global configuration command.

• message time message-timer-interval—Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are detected to be bidirectional. The range is from 1 to 90 seconds; the default value is 15.

   Note
   This command affects fiber-optic ports only. Use the udld interface configuration command to enable UDLD on other port types.

   Use the no form of this command, to disable UDLD.

Step 3
end
Example:
Device(config)# end

Returns to privileged EXEC mode.

Enabling UDLD on an Interface

Follow these steps either to enable UDLD in the aggressive or normal mode or to disable UDLD on a port.

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. udld port [aggressive]
4. end

### Purpose

**Command or Action**

**Step 2**

interface interface-id

**Example:**

Device(config)# interface gigabitethernet 1/0/1

**Purpose**

Specifies the port to be enabled for UDLD, and enters interface configuration mode.

**Step 3**

udld port [aggressive]

**Example:**

Device(config-if)# udld port aggressive

**Purpose**

UDLD is disabled by default.

- **udld port**—Enables UDLD in normal mode on the specified port.
- **udld port aggressive**—(Optional) Enables UDLD in aggressive mode on the specified port.

**Note**

Use the **no udld port** interface configuration command to disable UDLD on a specified fiber-optic port.

**Step 4**

end

**Example:**

Device(config-if)# end

**Purpose**

Returns to privileged EXEC mode.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Overview of Resilient Ethernet Protocol

Resilient Ethernet Protocol (REP) is a Cisco-proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

A REP segment is a chain of ports connected to each other and configured with a segment ID. Each segment consists of standard (nonedge) segment ports and two user-configured edge ports. A device can have no more than two ports that belong to the same segment, and each segment port can have only one external neighbor. A segment can go through a shared medium, but on any link, only two ports can belong to the same segment. REP is supported only on Trunk Ethernet Flow Point (EFP) interfaces.

The following figure shows an example of a segment consisting of six ports spread across four switches. Ports E1 and E2 are configured as edge ports. When all the ports are operational (as in the segment on the left), a single port is blocked, as shown by the diagonal line. When there is a failure in the network, the blocked port returns to the forwarding state to minimize network disruption.
The segment shown in the figure above is an open segment; there is no connectivity between the two edge ports. The REP segment cannot cause a bridging loop, and you can safely connect the segment edges to any network. All the hosts connected to devices inside the segment have two possible connections to the rest of the network through the edge ports, but only one connection is accessible at any time. If a failure occurs on any segment or on any port on a REP segment, REP unblocks all the ports to ensure that connectivity is available through the other gateway.

The segment shown in the following figure is a ring segment, with both the edge ports located on the same device. With this configuration, you can create a redundant connection between any two devices in the segment.

REP segments have the following characteristics:

- If all the ports in a segment are operational, one port (referred to as the alternate port) is in the blocked state for each VLAN. If VLAN load balancing is configured, two ports in the segment control the blocked state of VLANs.

- If one or more ports in a segment is not operational, and cause a link failure, all the ports forward traffic on all the VLANs to ensure connectivity.

- In case of a link failure, alternate ports are unblocked as quickly as possible. When the failed link is up, a logically blocked port per VLAN is selected with minimal disruption to the network.

You can construct almost any type of network based on REP segments. REP also supports VLAN load balancing, which is controlled by the primary edge port (any port in the segment).

In access ring-topologies, the neighboring switch might not support REP as shown in the following figure. In this scenario, you can configure the non-REP-facing ports (E1 and E2) as edge no-neighbor ports. These ports inherit all the properties of edge ports, and you can configure them the same as any edge port, including...
configuring them to send STP or REP topology change notices to the aggregation switch. In this scenario, the STP topology change notice (TCN) that is sent is a multiple spanning-tree (MST) STP message.

Figure 57: Edge No-Neighbor Ports

REP has these limitations:

- You must configure each segment port; an incorrect configuration might cause forwarding loops in the networks.
- REP can manage only a single failed port within the segment; multiple port failures within the REP segment cause loss of network connectivity.
- You should configure REP only in networks with redundancy. Configuring REP in a network without redundancy causes loss of connectivity.

**Link Integrity**

REP does not use an end-to-end polling function between edge ports to verify link integrity. It implements local link failure detection. The REP Link Status Layer (LSL) detects its REP-aware neighbor and establishes connectivity within the segment. All the VLANs are blocked on an interface until the neighbor is detected. After the neighbor is identified, REP determines which neighbor port should become the alternate port and which ports should forward traffic.

Each port in a segment has a unique port ID. The port ID format is similar to that used by the spanning tree algorithm: a port number (unique on the bridge) associated to a MAC address (unique in the network). When a segment port is coming up, its LSL starts sending packets that include the segment ID and the port ID. The port is declared as operational after it performs a three-way handshake with a neighbor in the same segment.

A segment port does not become operational if:

- No neighbor has the same segment ID.
- More than one neighbor has the same segment ID.
- A neighbor does not acknowledge a local port as a peer.

Each port creates an adjacency with its immediate neighbor. After the neighbor adjacencies are created, the ports negotiate with each other to determine the blocked port for the segment, which will function as the alternate port. All the other ports become unblocked. By default, REP packets are sent to a bridge protocol.
data unit-class MAC address. The packets can also be sent to a Cisco multicast address, which is used only to send blocked port advertisement (BPA) messages when there is a failure in the segment. The packets are dropped by the devices not running REP.

**Fast Convergence**

REP runs on a physical link basis and not on a per-VLAN basis. Only one hello message is required for all the VLANs, and this reduces the load on the protocol. We recommend that you create VLANs consistently on all the switches in a given segment and configure the same allowed VLANs on the REP trunk ports. To avoid the delay introduced by relaying messages in software, REP also allows some packets to be flooded to a regular multicast address. These messages operate at the hardware flood layer (HFL) and are flooded to the entire network, not just the REP segment. Switches that do not belong to the segment treat them as data traffic. You can control flooding of these messages by configuring an administrative VLAN for the entire domain or for a particular segment.

The estimated convergence recovery time on fiber interfaces is between 50 ms and 200 ms for the local segment with 200 VLANs configured. Convergence for VLAN load balancing is 300 ms or less.

**VLAN Load Balancing**

One edge port in the REP segment acts as the primary edge port; and another as the secondary edge port. It is the primary edge port that always participates in VLAN load balancing in the segment. REP VLAN balancing is achieved by blocking some VLANs at a configured alternate port and all the other VLANs at the primary edge port. When you configure VLAN load balancing, you can specify the alternate port in one of three ways:

- By entering the port ID of the interface. To identify the port ID of a port in the segment, enter the show interface rep detail interface configuration command for the port.
- By entering the preferred keyword to select the port that you previously configured as the preferred alternate port with the rep segment segment-id preferred interface configuration command.
- By entering the neighbor offset number of a port in the segment, which identifies the downstream neighbor port of an edge port. The neighbor offset number range is –256 to +256; a value of 0 is invalid. The primary edge port has an offset number of 1; positive numbers above 1 identify downstream neighbors of the primary edge port. Negative numbers indicate the secondary edge port (offset number -1) and its downstream neighbors.

**Note**

Configure offset numbers on the primary edge port by identifying a port’s downstream position from the primary (or secondary) edge port. Never enter an offset value of 1 because that is the offset number of the primary edge port.

The following figure shows neighbor offset numbers for a segment, where E1 is the primary edge port and E2 is the secondary edge port. The red numbers inside the ring are offset numbers from the primary edge port; the black numbers outside of the ring show the offset numbers from the secondary edge port. Note that you can identify all the ports (except the primary edge port) by either a positive offset number (downstream position from the primary edge port) or a negative offset number (downstream position from the secondary edge port). If E2 became the primary edge port, its offset number would then be 1 and E1 would be -1.
When the REP segment is complete, all the VLANs are blocked. When you configure VLAN load balancing, you must also configure triggers in one of two ways:

- Manually trigger VLAN load balancing at any time by entering the `rep preempt segment segment-id` privileged EXEC command on the switch that has the primary edge port.
- Configure a preempt delay time by entering the `reppreempt delay seconds` interface configuration command. After a link failure and recovery, VLAN load balancing begins after the configured preemption time period elapses. Note that the delay timer restarts if another port fails before the time has elapsed.

When VLAN load balancing is configured, it does not start working until triggered by either manual intervention or a link failure and recovery.

When VLAN load balancing is triggered, the primary edge port sends out a message to alert all the interfaces in the segment about the preemption. When the secondary port receives the message, the message is sent to the network to notify the alternate port to block the set of VLANs specified in the message and to notify the primary edge port to block the remaining VLANs.

You can also configure a particular port in the segment to block all the VLANs. Only the primary edge port initiates VLAN load balancing, which is not possible if the segment is not terminated by an edge port on each end. The primary edge port determines the local VLAN load-balancing configuration.

Reconfigure the primary edge port to reconfigure load balancing. When you change the load-balancing configuration, the primary edge port waits for the `reppreempt segment` command or for the configured preempt delay period after a port failure and recovery, before executing the new configuration. If you change an edge port to a regular segment port, the existing VLAN load-balancing status does not change. Configuring a new edge port might cause a new topology configuration.

**Spanning Tree Interaction**

REP does not interact with the STP or the Flex Link feature, but can coexist with both. A port that belongs to a segment is removed from spanning tree control, and STP BPUDs are not accepted or sent from segment ports. Therefore, STP cannot run on a segment.

To migrate from an STP ring configuration to an REP segment configuration, begin by configuring a single port in the ring as part of the segment and continue by configuring contiguous ports to minimize the number of segments. Since each segment always contains a blocked port, multiple segments means multiple blocked
ports and a potential loss of connectivity. After the segment is configured in both directions up to the location of the edge ports, configure the edge ports.

**REP Ports**

REP segments consist of Failed, Open, or Alternate ports:

- A port configured as a regular segment port starts as a failed port.
- After the neighbor adjacencies are determined, the port transitions to alternate port state, blocking all the VLANs on the interface. Blocked-port negotiations occur, and when the segment settles, one blocked port remains in the alternate role and all the other ports become open ports.
- When a failure occurs in a link, all the ports move to the Failed state. When the Alternate port receives the failure notification, it changes to the Open state, forwarding all the VLANs.

A regular segment port converted to an edge port, or an edge port converted to a regular segment port, does not always result in a topology change. If you convert an edge port into a regular segment port, VLAN load balancing is not implemented unless it has been configured. For VLAN load balancing, you must configure two edge ports in the segment.

A segment port that is reconfigured as a spanning tree port restarts according to the spanning tree configuration. By default, this is a designated blocking port. If PortFast is configured or if STP is disabled, the port goes into the forwarding state.

**How to Configure Resilient Ethernet Protocol**

A segment is a collection of ports connected to one another in a chain and configured with a segment ID. To configure REP segments, configure the REP administrative VLAN (or use the default VLAN 1) and then add the ports to the segment, using interface configuration mode. You should configure two edge ports in a segment, with one of them being the primary edge port and the other the secondary edge port by default. A segment should have only one primary edge port. If you configure two ports in a segment as primary edge ports, for example, ports on different switches, the REP selects one of them to serve as the segment's primary edge port. If required, you can configure the location to which segment topology change notices (STCNs) and VLAN load balancing are to be sent.

**Default REP Configuration**

REP is disabled on all the interfaces. When enabled, the interface is a regular segment port unless it is configured as an edge port.

When REP is enabled, the task of sending segment topology change notices (STCNs) is disabled, all the VLANs are blocked, and the administrative VLAN is VLAN 1.

When VLAN load balancing is enabled, the default is manual preemption with the delay timer disabled. If VLAN load balancing is not configured, the default after manual preemption is to block all the VLANs in the primary edge port.

**REP Configuration Guidelines**

Follow these guidelines when configuring REP:
• We recommend that you begin by configuring one port and then configure contiguous ports to minimize the number of segments and the number of blocked ports.

• If more than two ports in a segment fail when no external neighbors are configured, one port goes into a forwarding state for the data path to help maintain connectivity during configuration. In the `show rep interface` command output, the Port Role for this port is displayed as **Fail Logical Open**; the Port Role for the other failed port is displayed as **Fail No Ext Neighbor**. When the external neighbors for the failed ports are configured, the ports go through the alternate port transitions and eventually go to an open state, or remain as the alternate port, based on the alternate port selection mechanism.

• **REP ports** must be Layer 2 IEEE 802.1Q or Trunk ports.

• We recommend that you configure all the trunk ports in a segment with the same set of allowed VLANs.

• Be careful when configuring REP through a Telnet connection because REP blocks all the VLANs until another REP interface sends a message to unblock it. You might lose connectivity to the router if you enable REP in a Telnet session that accesses the router through the same interface.

• You cannot run REP and STP or REP and Flex Links on the same segment or interface.

• If you connect an STP network to an REP segment, be sure that the connection is at the segment edge. An STP connection that is not at the edge might cause a bridging loop because STP does not run on REP segments. All the STP BPDUs are dropped at REP interfaces.

• You must configure all the trunk ports in a segment with the same set of allowed VLANs. If this is not done, misconfiguration occurs.

• If REP is enabled on two ports on a switch, both the ports must be either regular segment ports or edge ports. REP ports follow these rules:
  
  • There is no limit to the number of REP ports on a switch. However, only two ports on a switch can belong to the same REP segment.

  • If only one port on a switch is configured in a segment, the port should be an edge port.

  • If two ports on a switch belong to the same segment, they must both be edge ports, regular segment ports, or one regular port and one edge no-neighbor port. An edge port and regular segment port on a switch cannot belong to the same segment.

  • If two ports on a switch belong to the same segment, and one is configured as an edge port and one as a regular segment port (a misconfiguration), the edge port is treated as a regular segment port.

• REP interfaces come up in a blocked state and remain in a blocked state until they are safe to be unblocked. You must, therefore, be aware of the status of REP interfaces to avoid sudden connection losses.

• REP sends all the LSL PDUs in the untagged frames to the native VLAN. The BPA message sent to a Cisco multicast address is sent to the administration VLAN, which is VLAN 1 by default.

• You can configure the duration for which a REP interface remains up without receiving a hello from a neighbor. Use the `rep lsl-age-timer` value interface configuration command to set the time from 120 ms to 10000 ms. The LSL hello timer is then set to the age-timer value divided by 3. In normal operation, three LSL hellos are sent before the age timer on the peer switch expires and checks for hello messages.

  • EtherChannel port channel interfaces do not support LSL age-timer values less than 1000 ms. If you try to configure a value less than 1000 ms on a port channel, you receive an error message and the command is rejected.
• REP ports cannot be configured as one of the following port types:
  • Switched Port Analyzer (SPAN) destination port
  • Tunnel port
  • Access port

• REP is supported on EtherChannels, but not on an individual port that belongs to an EtherChannel.
• There can be a maximum of 64 REP segments per switch.

Configuring REP Administrative VLAN

To avoid the delay created by link-failure messages, and VLAN-blocking notifications during load balancing, REP floods packets to a regular multicast address at the hardware flood layer (HFL). These messages are flooded to the whole network, and not just the REP segment. You can control the flooding of these messages by configuring an administrative VLAN.

Follow these guidelines when configuring the REP administrative VLAN:

  • If you do not configure an administrative VLAN, the default is VLAN 1.
  • You can configure one admin VLAN on the switch for all segments.
  • The administrative VLAN cannot be the RSPAN VLAN.

To configure the REP administrative VLAN, follow these steps, beginning in privileged EXEC mode:

SUMMARY STEPS

1. configure terminal
2. rep admin vlan vlan-id
3. end
4. show interface [interface-id] rep detail
5. copy running-config startup config

DETAILED STEPS

</table>
Configuring a REP Interface

To configure REP, enable REP on each segment interface and identify the segment ID. This task is mandatory, and must be done before other REP configurations. You must also configure a primary and secondary edge port on each segment. All the other steps are optional.

Follow these steps to enable and configure REP on an interface:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. switchport mode trunk
5. rep segment segment-id [edge [no-neighbor] [primary]] [preferred]
6. rep stcn {interface interface id | segment id-list | stp}
7. rep block port {id port-id | neighbor-offset | preferred} vlan {vlan-list | all}
8. rep preempt delay seconds
9. rep isl-age-timer value
10. end
11. show interface [interface-id] rep [detail]
12. copy running-config startup-config

### Configuring a REP Interface

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code>&lt;br&gt;<code>Example:</code>&lt;br&gt;Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>interface interface-id</code>&lt;br&gt;<code>Example:</code>&lt;br&gt;Device# interface gigabitethernet1/1</td>
<td>Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface).</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>switchport mode trunk</code>&lt;br&gt;<code>Example:</code>&lt;br&gt;Device# switchport mode trunk</td>
<td>Configures the interface as a Layer 2 trunk port.</td>
</tr>
</tbody>
</table>
| **Step 5** | `rep segment segment-id [edge [no-neighbor] [primary]] [preferred]`<br>`Example:`<br>Device# rep segment 1 edge no-neighbor primary | Enables REP on the interface and identifies a segment number. The segment ID range is from 1 to 1024.  
**Note** You must configure two edge ports, including one primary edge port, for each segment.  
These optional keywords are available:  
• (Optional) `edge`—Configures the port as an edge port. Each segment has only two edge ports. Entering the keyword `edge` without the keyword `primary` configures the port as the secondary edge port.  
• (Optional) `primary`—Configures the port as the primary edge port, the port on which you can configure VLAN load balancing.  
• (Optional) `no-neighbor`—Configures a port with no external REP neighbors as an edge port. The port inherits all the properties of an edge port, and you can configure the properties the same way you would for an edge port.  
**Note** Although each segment can have only one primary edge port, if you configure edge ports on two different switches and enter the keyword `primary` on both the switches, the configuration is valid. However, REP selects only one of these ports as the segment primary edge port. You can identify the primary edge port for a segment by entering the `show rep topology` privileged EXEC command.  
• (Optional) `preferred`—Indicates that the port is the preferred alternate port or the preferred port for VLAN load balancing. |
Purpose
Configuring a port as preferred does not guarantee that it becomes the alternate port; it merely gives the port a slight edge over equal contenders. The alternate port is usually a previously failed port.

**Note**
(Optional) Configures the edge port to send segment topology change notices (STCNs).

- `interface interface-id`—Designates a physical interface or port channel to receive STCNs.
- `segment id-list`—Identifies one or more segments to receive STCNs. The range is from 1 to 1024.
- `stp`—Sends STCNs to STP networks.

**Step 6**
```
rep stcn {interface interface-id | segment id-list | stp}
```

**Example:**
```
Device# rep stcn segment 25-50
```

- `interface interface-id`—Designates a physical interface or port channel to receive STCNs.
- `segment id-list`—Identifies one or more segments to receive STCNs. The range is from 1 to 1024.
- `stp`—Sends STCNs to STP networks.

**Note**
Spanning Tree (MST) mode is required on edge no-neighbor nodes when `rep stcn stp` command is configured for sending STCNs to STP networks.

**Step 7**
```
rep block port {id port-id | neighbor-offset | preferred} vlan {vlan-list | all}
```

**Example:**
```
Device# rep block port id 0009001818D68700 vlan 1-100
```

- `id port-id`—Identifies the alternate port by port ID. The port ID is automatically generated for each port in the segment. You can view interface port IDs by entering the `show interface type number rep [detail]` privileged EXEC command.
- `neighbor-offset`—Number to identify the alternate port as a downstream neighbor from an edge port. The range is from -256 to 256, with negative numbers indicating the downstream neighbor from the secondary edge port. A value of 0 is invalid. Enter `-1` to identify the secondary edge port as the alternate port.

**Note**
Because you enter the `rep block port` command at the primary edge port (offset number 1), you cannot enter an offset value of 1 to identify an alternate port.

- `preferred`—Selects the regular segment port previously identified as the preferred alternate port for VLAN load balancing.
- `vlan vlan-list`—Blocks one VLAN or a range of VLANs.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 8</strong> <strong>rep preempt delay</strong> <em>seconds</em></td>
<td><em>(Optional) Configures a preempt time delay.</em></td>
</tr>
</tbody>
</table>
| **Example:** Device# *rep preempt delay 100* | • Use this command if you want VLAN load balancing to be automatically triggered after a link failure and recovery.  
• The time delay range is between 15 to 300 seconds. The default is manual preemption with no time delay. |
| **Step 9** **rep lsl-age-timer** *value* | *(Optional) Configures a time (in milliseconds) for which the REP interface remains up without receiving a hello from a neighbor.* |
| **Example:** Device# *rep lsl-age-timer 2000* | The range is from 120 to 10000 ms in 40-ms increments. The default is 5000 ms (5 seconds). |
| **Step 10** **end** | Exits global configuration mode and returns to privileged EXEC mode. |
| **Example:** Device(config)# *end* | |
| **Step 11** **show interface** *[interface-id] rep [detail]* | *(Optional) Displays the REP interface configuration.* |
| **Example:** Device(config)# *show interface gigabitethernet1/1 rep detail* | |
| **Step 12** **copy running-config startup-config** | *(Optional) Saves your entries in the router startup configuration file.* |
| **Example:** Device(config)# *copy running-config startup-config* | |
Setting Manual Preemption for VLAN Load Balancing

If you do not enter the `rep preempt delay seconds` interface configuration command on the primary edge port to configure a preemption time delay, the default is to manually trigger VLAN load balancing on the segment. Be sure that all the other segment configurations have been completed before manually preemption VLAN load balancing. When you enter the `rep preempt delay segment segment-id` command, a confirmation message is displayed before the command is executed because preemption might cause network disruption.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `rep preempt segment segment-id`
4. `show rep topology segment segment-id`
5. `end`

**DETAILED STEPS**

<table>

   SVT_3400_2 Gi10/3 Open
   10.64.106.68 Gi40/2 Open

   • (Optional) **archive**—Displays the last stable topology.

   **Note** An archive topology is not retained when the switch reloads.

   • (Optional) **detail**—Displays detailed archived information.
### Configuration Examples for Resilient Ethernet Protocol

This section provides the following configuration examples:

#### Example: Configuring the REP Administrative VLAN

This example shows how to configure the administrative VLAN as VLAN 100, and verify the configuration by entering the `show interface rep detail` command on one of the REP interfaces:

Device# configure terminal
Device(config)# rep admin vlan 100
Device(config)# end
Device# show interface gigabitethernet1/1 rep detail

GigabitEthernet1/1 REP enabled
Segment-id: 2 (Edge)
PortID: 00010019E7144680
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 0002001121A2D5800E4D
Port Role: Open
Blocked Vlan: <empty>
Admin-vlan: 100
Preempt Delay Timer: disabled
LSL Ageout Timer: 5000 ms
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 3322, tx: 1722
HFL PDU rx: 32, tx: 5
BPA TLV rx: 16849, tx: 508
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 118, tx: 118
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 4214, tx: 4190

The following example shows how to create an administrative VLAN per segment. Here, VLAN 2 is configured as the administrative VLAN only for REP segment 2. All the remaining segments that are not configured have VLAN 1 as the administrative VLAN by default.

Device# configure terminal
Device(config)# rep admin vlan 2 segment 2
Device(config)# end

#### Example: Configuring a REP Interface

This example shows how to configure an interface as the primary edge port for segment 1, to send STCNs to segments 2 through 5, and to configure the alternate port as the port with port ID 0009001818D68700 to block...
all the VLANs after a preemption delay of 60 seconds after a segment port failure and recovery. The interface is configured to remain up for 6000 ms without receiving a hello from a neighbor.

Switch# configure terminal
Switch (conf)# interface gigabitethernet1/1
Switch (conf-if)# rep segment 1 edge primary
Switch (conf-if)# rep stcn segment 2-5
Switch (conf-if)# rep block port 0009001818D68700 vlan all
Switch (conf-if)# rep preempt delay 60
Switch (conf-if)# rep lsl-age-timer 6000
Switch (conf-if)# end

This example shows how to configure the same configuration when the interface has no external REP neighbor:

Switch# configure terminal
Switch (conf)# interface gigabitethernet1/1
Switch (conf-if)# rep segment 1 edge no-neighbor primary
Switch (conf-if)# rep stcn segment 2-5
Switch (conf-if)# rep block port 0009001818D68700 vlan all
Switch (conf-if)# rep preempt delay 60
Switch (conf-if)# rep lsl-age-timer 6000
Switch (conf-if)# end

This example shows how to configure the VLAN blocking configuration shown in the Figure 5. The alternate port is the neighbor with neighbor offset number 4. After manual preemption, VLANs 100 to 200 are blocked at this port, and all the other VLANs are blocked at the primary edge port E1 (Gigabit Ethernet port 1/1).

Figure 59: Example of VLAN Blocking
CHAPTER 33

Configuring the PPPoE Intermediate Agent

- Restrictions for PPPoE Intermediate Agent, on page 573
- Information about PPPoE Intermediate Agent, on page 573
- How to Configure PPPoE IA, on page 574
- Configuration Examples for PPPoE IA, on page 583
- Displaying Configuration Parameters, on page 585
- Clearing Packet Counters, on page 587
- Debugging PPPoE Intermediate Agent, on page 587
- Troubleshooting Tips, on page 588
- Feature Information for Configuring the PPPoE Intermediate Agent, on page 589

Restrictions for PPPoE Intermediate Agent

PPPoE Intermediate Agent is not supported on routed interfaces.

Information about PPPoE Intermediate Agent

PPPoE Intermediate Agent (PPPoE IA) is placed between a subscriber and BRAS to help the service provider BRAS distinguish between end hosts connected over Ethernet to an access switch. On the access switch, PPPoE IA enables Subscriber Line Identification by appropriately tagging Ethernet frames of different users. (The tag contains specific information such as which subscriber is connected to the switch and VLAN.) PPPoE IA acts as mini security firewall between host and BRAS by intercepting all PPPoE Active Discovery (PAD) messages on a per-port per-VLAN basis. It provides specific security feature such as verifying the intercepted PAD message from untrusted port, performing per-port PAD message rate limiting, inserting and removing VSA Tags into and from PAD messages, respectively.

DSL Forum TR-101 [1] offers a means by which the PPPoE Discovery packets are tagged at the service provider's access switch with subscriber line specific information. The mechanism specifies using VSA of the PPPoE Discovery packets to add the line specific information at the switch. Even though you can perform Subscriber Line Identification (SLI) in another way (recreating virtual paths and circuits using stacked VLAN tags), DSL Forum 2004-071 [4] recommends the PPPoE Intermediate Agent mechanism. It cites lower provisioning costs and simpler co-ordination between OSS systems in charge of access switch and BRAS. PPPoE Intermediate Agent helps the service provider, BRAS, distinguish between end hosts connected over Ethernet to an access switch.
How to Configure PPPoE IA

Enabling PPPoE IA on a Switch

By default, PPPoE IA is disabled globally.

Note
Follow these steps to enable or disable PPPoE IA globally on the switch:

SUMMARY STEPS
1. `enable`
2. `configure terminal`
3. `pppoe intermediate-agent`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# config t</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>pppoe intermediate-agent</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# pppoe intermediate-agent</td>
</tr>
</tbody>
</table>

Configuring the Access Node Identifier for PPPoE IA on a Switch

Follow these steps to set the Access Node Identifier of the switch.

Note
By default, access-node-id is not set.

SUMMARY STEPS
1. `enable`
2. `configure terminal`
3. `pppoe intermediate-agent format-type access-node-id string word`
### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  - `enable`
  - **Example:**
    - Device> enable |
    - Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
  - `configure terminal`
  - **Example:**
    - Device# config terminal |
  - Enters the global configuration mode. |
| **Step 3**
  - `pppoe intermediate-agent format-type access-node-id string word`
  - **Example:**
    - Device(config)# pppoe intermediate-agent format-type access-node-id string abcd |
  - Sets the access node identifier. |
  - • access-node-identifier string word – ASCII string literal value for the access-node-identifier. |

### Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch

This functionality overrides the default automatic generation of circuit-id by the system.

The options available are sp, sv, pv and spv denoting slot:port, slot-vlan, port-vlan, and slot-port-vlan combinations, respectively. Valid delimiters are #, ., ; space.

The no form of this command without WORD, options, and delimiters, reverts to the default automatic generation of circuit-id.

This command does not affect the circuit ID configured explicitly per-interface or per-interface per-VLAN with the `pppoe intermediate-agent format-type circuit-id`.

Follow these steps to set an identifier string word with option spv delimited by “:”

### Summary Steps

1. `enable`
2. `configure terminal`
3. `pppoe intermediate-agent format-type identifier-string string word{sp | sv | pv | spv} delimiter{, | . | ; | / | #}`

### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  - `enable`
  - **Example:**
    - Device> enable |
    - Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
  - `configure terminal`
  - **Example:**
    - Device# config t |
    - Enters the global configuration mode. |
### Configuring the Generic Error Message for PPPoE IA on a Switch

Follow these steps to configure a generic message of `packet_length>1484`:

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `pppoe intermediate-agent format-type generic-error-message string` *string*

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# config terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>pppoe intermediate-agent format-type generic-error-message string</code></td>
<td>Sets the generic error message.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config)# pppoe intermediate-agent format-type generic-error-message string packet_length&gt;1484</code></td>
<td><code>string</code> – ASCII string literal value for the generic-error-message.</td>
</tr>
</tbody>
</table>

### Enabling PPPoE IA on an Interface

Follow these steps to enable PPPoE IA on FastEthernet 3/1:
Before you begin

Enabling PPPoE IA on an interface does not ensure that incoming packets are tagged. For this to happen PPPoE IA must be enabled globally, and at least one interface that connects the switch to PPPoE server has a trusted PPPoE IA setting. Refer to the following section for details.

Note

This functionality enables the PPPoE IA feature on an interface. The `pppoe intermediate-agent` command has an effect only if the PPPoE IA feature was enabled globally with this command. (You need to enable globally to activate PPPoE IA static ACL and on an interface for PPPoE IA processing of PPPoE discovery packets received on that interface.)

This setting applies to all frames passing through this interface, regardless of the VLAN they belong to. By default the PPPoE IA feature is disabled on all interfaces. You need to run this command on every interface that requires this feature.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `pppoe intermediate-agent`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# config terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>interface interface-id</code></td>
<td>Enter interface configuration mode and the physical interface identification.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config)interface FastEthernet 3/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>pppoe intermediate-agent</code></td>
<td>Enables PPPoE IA on the interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device(config-if) pppoe intermediate-agent</code></td>
<td></td>
</tr>
</tbody>
</table>
Configuring the PPPoE IA Trust Setting on an Interface

Note

Interfaces that connect the switch to PPPoE server are configured as trusted. Interfaces that connect the switch to users (PPPoE clients) are untrusted.

Follow these steps to set FastEthernet interface 3/2 as trusted:

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. pppoe intermediate-agent trust

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# config terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Enter interface configuration mode and the physical interface identification.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)interface FastEthernet 3/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> pppoe intermediate-agent trust</td>
<td>Sets the trust configuration of an interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)pppoe intermediate-agent trust</td>
<td></td>
</tr>
</tbody>
</table>

Configuring PPPoE Intermediate Agent Rate Limiting Setting on an Interface

Note

The parameter for rate limiting is the number of packets per second. If the incoming packet rate exceeds this value, the port shuts down.

Follow these steps to set a rate limit on an interface:

SUMMARY STEPS

1. enable
2. `configure terminal`
3. `interface interface-id`
4. `pppoe intermediate-agent limit rate number`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Device# config terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enters interface configuration mode and the physical interface identification.</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td>Device(config)interface FastEthernet 3/1</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Limits the rate of the PPPoE Discovery packets arriving on an interface.</td>
</tr>
<tr>
<td><code>pppoe intermediate-agent limit rate number</code></td>
<td>Device(config-if)pppoe intermediate-agent limit rate 30</td>
</tr>
</tbody>
</table>

**Configuring PPPoE IA Vendor-tag Stripping on an Interface**

*Note* Generally, you would configure vendor-tag stripping on an interfaces connected to the PPPoE server. If you configure stripping, incoming packets are stripped of their VSAs (which carry subscriber and line identification information). For this to happen, the PPPoE Intermediate agent must be enabled to make the `pppoe intermediate-agent vendor-tag strip` command effective, and the interface must be set to trust. In isolation, the command has no effect.

*Note* BRAS automatically strips the vendor-specific tag off of the PPPoE discovery packets before sending them downstream to the access switch. To operate with older BRAS which does not possess this capability, use the `pppoe intermediate-agent vendor-tag strip` command on the interface connecting the access switch to BRAS.

Follow these steps to enable vendor-tag stripping:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `pppoe intermediate-agent vendor-tag strip`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

## Configuring PPPoE Intermediate Agent Circuit-ID and Remote-ID on an Interface

The `no pppoe intermediate-agent format-type circuit-id` command sets the circuit ID on an interface and overrides the automatic generation of circuit ID by the switch. Without this command, one default tag (for example, Ethernet x/y/z on the PPPoE to which the user is connected) inserted by an intermediate-agent.

The `no pppoe intermediate-agent format-type remote-id` command sets the remote ID on an interface.

This functionality causes tagging of PADI, PADR, and PADT packets (belonging to PPPoE Discovery stage) received on this physical interface with circuit ID or remote ID. This happens regardless s of their VLAN if PPPoE IA is not enabled for that VLAN.

You should use remote ID instead of circuit ID for subscriber line identification. You should configure this setting on every interface where you enabled PPPoE IA because it is not set by default. The default value for remote-id is the switch MAC address (for all physical interfaces).

Follow these steps to configure the circuit ID as root and the remote ID as granite:

## SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. pppoe intermediate-agent format-type {circuit-id | remote-id} string
Enable privileged EXEC mode. Enter your password if prompted.

Example:

Step 1
Device> enable

Enters the global configuration mode.

Example:

Step 2
Device# config terminal

Enters interface configuration mode and the physical interface identification.

Example:

Step 3
Device(config)# interface FastEthernet 3/1

Sets circuit-id or remote-id for an interface.

• circuit-id string string – ASCII string literal value for circuit-id.

• remote-id string string – ASCII string literal value for remote-id.

Step 4

Enable PPPoE IA for a Specific VLAN on an Interface

The pppoe intermediate-agent command in the vlan-range mode is not dependent on the same command in interface mode. The pppoe intermediate-agent command will take effect independently of the command in the interface mode. To make this happen, PPPoE IA must be enabled globally and at least one interface is connected to the PPPoE server.

Follow these steps to enable PPPoE IA on a specific VLAN:

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. vlan-range {vlan-id|vlan-list|vlan-range}
5. pppoe intermediate-agent

Device(config-if-vlan-range)pppoe intermediate-agent
```

---

### Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface

**Note**

The circuit-id and remote-id configurations in vlan-range mode are affected only if PPPoE IA is enabled globally and in vlan-range mode.

**Note**

The vlan-range mode commands configure PPPoE IA for either a specific VLAN, multiple VLANs, or VLAN range, depending on what you specify in the syntax.

In this section you set the circuit ID and remote ID for a specific VLAN on an interface. The command overrides the circuit ID and remote ID specified for this physical interface and the switch uses the WORD value to tag packets received on this VLAN. This parameter is unset by default.

The default value of remote-id is the switch MAC address (for all VLANs). You would set this parameter to encode subscriber-specific information.

Follow these steps to set the circuit-id and the remote-id:

**SUMMARY STEPS**

1. `interface interface-id`
2. `vlan-range vlan-range`
3. `pppoe intermediate-agent`
4. `pppoe intermediate-agent format-type {circuit-id | remote-id} stringstring`
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

  **interface interface-id**
  **Example:**
  Device(config)# int g3/7

  Enters interface configuration mode and the physical interface identification.

| **Step 2**

  **vlan-range vlan-range**
  **Example:**
  Device(config-if)# vlan-range 5

  Enters the vlan-range mode.

| **Step 3**

  **pppoe intermediate-agent**
  **Example:**
  Device(config-if)# pppoe intermediate-agent

  Enables PPPoE IA on the specified interfaces.

| **Step 4**

  **pppoe intermediate-agent format-type {circuit-id | remote-id} string**
  **Example:**
  Device(config-if)# pppoe intermediate-agent format-type circuit-id string root

  Sets circuit-id or remote-id for an interface.
  - circuit-id string string – ASCII string literal value for circuit-id.
  - remote-id string string – ASCII string literal value for remote-id.

---

**Configuration Examples for PPPoE IA**

**Example: Enabling PPPoE Intermediate Agent on a Switch**

This example shows how to enable or disable PPPoE IA globally on the switch:

Device> enable
Device# configure terminal
Device(config)# pppoe intermediate-agent

**Example: Configuring the Access Node Identifier for PPPoE IA on a Switch**

This example shows how to set an access node identifier of abcd:

Device> enable
Device# configure terminal
Device(config)# pppoe intermediate-agent format-type access-node-id string abcd

**Example: Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch**

This example shows how to set an identifier string word with option spv delimited by “;”:

Device> enable
Device# configure terminal
Example: Configuring the Generic Error Message for PPPoE IA on a Switch

This example shows how to configure a generic message of packet_length>1484:

```
Device> enable
Device# configure terminal
Device(config)#pppoe intermediate-agent format-type generic-error-message string packet_length>1484
```

Example: Enabling PPPoE IA on an Interface

This example shows how to enable PPPoE IA on FastEthernet 3/1:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/1
Device(config-if)pppoe intermediate-agent
```

Example: Configuring the PPPoE Intermediate Agent Trust Setting on an Interface

The following example shows how to set FastEthernet interface 3/2 as trusted:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/2
Device(config-if)pppoe intermediate-agent trust
```

Example: Configuring PPPoE Intermediate Agent Rate Limiting Setting on an Interface

This example shows how to set a rate limit of 30 at FastEthernet 3/1:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/1
Device(config-if)pppoe intermediate-agent limit rate 30
```

Example: Configuring PPPoE IA Vendor-tag Stripping on an Interface

The following example shows how to enable stripping on FastEthernet 3/2:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/2
Device(config-if)pppoe intermediate-agent vendor-tag strip
```
Example: Configuring PPPoE IA Circuit-ID and Remote-ID on an Interface

The following example shows how to configure the circuit ID as root and the remote ID as granite:

Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/1
Device(config-if)pppoe intermediate-agent format-type circuit-id string root
Device(config-if)pppoe intermediate-agent format-type remote-id string granite

Example: Enabling PPPoE IA for a Specific VLAN on an Interface

The following example shows how to enable PPPOE IA on a specific VLAN:

Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5
Switch(config-if-vlan-range)# pppoe intermediate-agent

The following examples show how to enable PPPoE IA on a comma-separated VLAN list

Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5,6
Switch(config-if-vlan-range)# pppoe intermediate-agent

The following example shows how to enable PPPoE IA on a VLAN-range such as “x-y.”

Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5-9
Switch(config-if-vlan-range)# pppoe intermediate-agent

Example: Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface

The following example shows how to set the circuit-id to aaa and the remote-id as ccc on interface g3/7:

Switch(config)# int g3/7
Switch(config-if)# vlan-range 5
Switch(config-if)# pppoe intermediate-agent
Switch(config-if-vlan-range)# pppoe intermediate-agent format-type circuit-id string aaa
Switch(config-if-vlan-range)# pppoe intermediate-agent format-type remote-id string ccc

Displaying Configuration Parameters

The show pppoe intermediate-agent [ info | statistics][interface{interface}] command displays the various configuration parameters, statistics, and counters stored for PPPoE.

The info keyword appears if the PPPoE Intermediate Agent is enabled globally on an interface or on a VLAN (in an interface). It also informs you about the access node ID and generic error message of the switch, as well as the identifier string options, delimiter values configured globally, global circuit id and remote id configuration by using the following command:

Switch(config)# pppoe intermediate-agent format-type ?
access-node-id Access Node Identifier
circuit-id Circuit Id
The `info` keyword also displays the circuit ID, remote ID, trust and rate limit configurations, and vendor tag strip setting for all interfaces and for all VLANs pertaining to those interfaces. If any of these parameters are not set, they are not displayed.

The `statistics` option displays the number of PADI/PADR/PADT packets received, and the time the last packet was received on all interfaces and on all VLANs pertaining to those interfaces.

If `interface` is specified, information or statistics applicable only to that physical interface and pertaining VLANs is displayed.

Although PPoE IA is supported on PVLANs, be aware that no PVLAN association (primary and secondary VLAN mapping) information is displayed.

The PPoE IA show commands such as `show pppoe intermediate-agent info`, `show pppoe intermediate-agent info interface g3/7`, or `show pppoe intermediate-agent statistics` do not provide information about private VLAN association (primary and secondary VLAN mapping).

However, they do provide information about VLANs regardless of private or normal VLANs, as the following example illustrate:

```
Switch# show pppoe intermediate-agent info
  Switch PPPOE Intermediate-Agent is enabled
  PPPOE Intermediate-Agent trust/rate is configured on the following Interfaces:

  Interface IA Trusted Vsa Strip Rate limit (pps)
  ----------------------- -------- ------- --------- ----------------
  GigabitEthernet3/4 no yes yes unlimited PPPOE

  Intermediate-Agent is configured on following VLANs:
  2-3

  GigabitEthernet3/7 no no no unlimited oE Intermediate-Agent

  is configured on following VLANs:
  -3

Switch# show pppoe intermediate-agent info interface g3/7
  Interface IA Trusted Vsa Strip Rate limit (pps)
  ----------------------- -------- ------- --------- ----------------
  GigabitEthernet3/7 yes no no unlimited oE Intermediate-Agent

  is configured on following VLANs:
  -3

Switch# show pppoe intermediate-agent statistics
  PPPOE IA Per-Port Statistics
  ---- ----------------
  Interface : GigabitEthernet3/7 Packets received
  All = 0
  PADI = 0 PADO = 0
  PADR = 0 PADS = 0
  PADT = 0
  Packets dropped:
  Rate-limit exceeded = 0
  Server responses from untrusted ports = 0
  Client requests towards untrusted ports = 0
  Malformed PPoE Discovery packets = 0
```
The following statistics will be displayed when PPPoE IA feature is enabled on every VLAN interface and the PAD packet counters have a non-zero value.

```
switch# sh run int gi2/0/1
Building configuration...
Current configuration : 135 bytes
!
interface GigabitEthernet2/0/1
switchport mode trunk
pppoe intermediate-agent
vlan-range 200-201
pppoe intermediate-agent
end
```

Switch# show pppoe intermediate-agent statistics interface gi2/0/3
Interface: GigabitEthernet2/0/3
Packets received
All = 0
PADI = 0 PADO = 0
PADR = 0 PADS = 0
PADT = 0
Packets dropped:
Rate-limit exceeded = 0
Server responses from untrusted ports = 0
Client requests towards untrusted ports = 0
Malformed PPPoE Discovery packets = 0

Switch# show pppoe intermediate-agent statistics interface gi2/0/3
Interface: GigabitEthernet2/0/1
Packets received
All = 50
PADI = 20 PADO = 0
PADR = 20 PADS = 0
PADT = 10
Packets dropped: Rate-limit exceeded = 0
Server responses from untrusted ports = 0
Client requests towards untrusted ports = 0
Malformed PPPoE Discovery packets = 0
Vlan 200: Packets received PADI = 2 PADO = 0 PADR = 2 PADS = 0 PADT = 1
Vlan 201: Packets received PADI = 2 PADO = 0 PADR = 2 PADS = 0 PADT = 1

### Clearing Packet Counters

This section illustrates how to clear packet counters on all interfaces (per-port and per-port-per-VLAN).

The following example illustrates how to do this:

Switch# clear pppoe intermediate-agent statistics
Issuing of the above command clears the counters for all PPPoE discovery packets (PADI, PADO, PADR, PADS, PADT) received on DUT.

### Debugging PPPoE Intermediate Agent

The `debug pppoe intermediate-agent [packet | event | all]` command enables you to display useful PPPoE information that assists in debugging. This command is disabled by default.

The `packet` option of the command displays the contents of a packet received in the software: source and destination MAC address of Ethernet frame, code, version and type of PPPoE Discovery packet and a list of TAGs present.
The **event** option of the command echoes important messages (interface state change to errdisable due to PPPoE discovery packets entering at a rate exceeding the configured limit). It is the only event shown by the `debug pppoe intermediate-agent event` command.

The **all** option enables both package and event options.

The following example illustrates how to enter the debug command with the packet option:

```
Switch# debug pppoe intermediate-agent packet
PPPOE IA Packet debugging is on
*Sep 2 06:12:56.133: PPPOE_IA: Process new PPPOE packet, Message type: PADI, input interface:
Gi3/7, vlan : 2 MAC da: ffff.ffff.ffff, MAC sa: aabb.cc00.0000
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/4)
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/8)
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPOE packet, Message type: PADO, input interface:
Gi3/7, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: aabb.cc00.0000
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPOE packet, Message type: PADO, input interface:
Gi3/4, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: 001d.e64c.6512
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/8)
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPOE packet, Message type: PADO, input interface:
Gi3/8, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: aabb.cc80.0000
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/8)
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPOE packet, Message type: PADR, input interface:
Gi3/7, vlan : 2 MAC da: 001d.e64c.6512, MAC sa: aabb.cc00.0000
*Sep 2 06:12:56.145: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/4)
*Sep 2 06:12:56.145: PPPOE_IA: Process new PPPOE packet, Message type: PAD, input interface:
Gi3/4, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: 001d.e64c.6512
```

The following example illustrates how to enter the debug command with the event option:

```
Switch# PPPOE IA
*Jul 30 19:00:10.254: %PPPOE_IA-4-PPPOE_IA_ERRDISABLE_WARNING: PPPOE IA received 5 PPPOE packets on interface Gi3/7
*Jul 30 19:00:10.254: %PPPOE_IA-4-PPPOE_IA_RATE_LIMIT_EXCEEDED: The interface Gi3/7 is receiving more than the threshold set
*Jul 30 19:00:10.394: %PM-4-ERR_DISABLE: detected on Gi3/7, putting Gi3/7 in err-disable stat
```

**Troubleshooting Tips**

When the `radius-server attribute 31 remote-id` global configuration command is entered in the PPPoE Agent Remote-ID Tag and DSL Line Characteristics feature configuration on the BRAS, the `debug radius` privileged EXEC command can be used to generate a report that includes information about the incoming access interface, where discovery frames are received, and about the session being established in PPPoE extended NAS-Port format (format d)

Configuring Cisco IOS Configuration Engine

- Prerequisites for Configuring the Configuration Engine, on page 593
- Restrictions for Configuring the Configuration Engine, on page 593
- Information About Configuring the Configuration Engine, on page 594
- How to Configure the Configuration Engine, on page 599
- Monitoring CNS Configurations, on page 611
- Additional References, on page 611
- Feature History and Information for the Configuration Engine, on page 612

Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.
- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured device.
- All devices configured with the `cns config partial` global configuration command must access the event bus. The DeviceID, as originated on the device, must match the DeviceID of the corresponding device definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured devices can share the same value for ConfigID.
- Within the scope of a single instance of the event bus, no two configured devices can share the same value for DeviceID.
Information About Configuring the Configuration Engine

Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (devices and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
  - Web server
  - File manager
  - Namespace mapping server

- Event service (event gateway)
- Data service directory (data models and schema)

Note
Support for Cisco Configuration Engine will be deprecated in future releases. Use the configuration described in Cisco Plug and Play Feature Guide.

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.
Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the device. The Configuration Service delivers device and service configurations to the device for initial configuration and mass reconfiguration by logical groups. Devices receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the device and facilitates the communication between the device and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.
NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, cisco.cns.config.load. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured device. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term ConfigID is the unique identifier for a device. Within the scope of the event bus namespace, the term DeviceID is the CNS unique identifier for a device.

ConfigID

Each configured device has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of device CLI attributes. The ConfigID defined on the device must match the ConfigID for the corresponding device definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the device hostname is reconfigured.

DeviceID

Each configured device participating on the event bus has a unique DeviceID, which is analogous to the device source address so that the device can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the device. However, the DeviceID variable and its usage reside within the event gateway adjacent to the device.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the device. The event gateway represents the device and its corresponding DeviceID to the event bus.

The device declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the device.
Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the device hostname is reconfigured.

When changing the device hostname on the device, the only way to refresh the DeviceID is to break the connection between the device and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the device sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

Caution

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the device acquires after, not before, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a device, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the cn=<value> of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the device.

These and other associated attributes (tag value pairs) are set when you run Setup on the Cisco Configuration Engine.

Cisco IOS CNS Agents

The CNS event agent feature allows the device to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the device Cisco IOS software, allow the device to be connected and automatically configured.

Initial Configuration

When the device first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution device acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new device and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the device.

The device automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the device loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the device.
The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

*Figure 61: Initial Configuration*

---

**Incremental (Partial) Configuration**

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the device. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the device to initiate a pull operation.

The device can check the syntax of the configuration before applying it. If the syntax is correct, the device applies the incremental configuration and publishes an event that signals success to the configuration server. If the device does not apply the incremental configuration, it publishes an event showing an error status. When the device has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

**Synchronized Configuration**

When the device receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the device not to save the updated configuration into its NVRAM. The device uses the updated configuration as its running configuration. This ensures that the device configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

**Automated CNS Configuration**

To enable automated CNS configuration of the device, you must first complete the prerequisites listed in this topic. When you complete them, power on the device. At the *setup* prompt, do nothing; the device begins the initial configuration. When the full configuration file is loaded on your device, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

**Table 62: Prerequisites for Enabling Automatic Configuration**

<table>
<thead>
<tr>
<th>Device</th>
<th>Required Configuration</th>

<tbody>
<tr>
<td>Access device</td>
<td>Factory default (no configuration file)</td>
</tr>
</tbody>
</table>
### How to Configure the Configuration Engine

#### Enabling the CNS Event Agent

**Note**
You must enable the CNS event agent on the device before you enable the CNS configuration agent.

Follow these steps to enable the CNS event agent on the device.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `cns event {hostname | ip-address} [port-number] [keepalive seconds retry-count] [failover-time seconds] [reconnect-time time] | backup]`
4. `end`
5. `show running-config`

---

2 A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.
6. copy running-config startup-config

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>configure terminal</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><strong>cns event</strong> `{hostname</td>
<td>ip-address} [port-number] [keepalive seconds retry-count] [failover-time seconds] [reconnect-time time]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# cns event 10.180.1.27 keepalive 120 10</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>end</strong></td>
<td>Returns to privileged EXEC mode.</td>

<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

### Note

Though visible in the command-line help string, the `encrypt` and the `clock-timeout` time keywords are not supported.
### Enabling the Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent on the device.

**Before you begin**

You must enable the CNS event agent on the device before you enable this agent.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. cns config initial \{hostname | ip-address\} \{port-number\}
4. cns config partial \{hostname | ip-address\} \{port-number\}
5. end
6. show running-config
7. copy running-config startup-config
8. Start the Cisco IOS CNS agent on the device.

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> cns config initial `{hostname</td>
<td>ip-address} [port-number]`</td>
</tr>
<tr>
<td>Example: Device(config)# cns config initial 10.180.1.27 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> cns config partial `{hostname</td>
<td>ip-address} [port-number]`</td>
</tr>
</tbody>
</table>
| Example: Device(config)# cns config partial 10.180.1.27 10 | - For `{hostname | ip-address}`, enter either the hostname or the IP address of the configuration server.  
- (Optional) For `port number`, enter the port number for the configuration server. |
| **Step 5** end | Returns to privileged EXEC mode. |
| Example: Device(config)# end | |
| **Step 6** show running-config | Verifies your entries. |
| Example: Device# show running-config | |
| **Step 7** copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| Example: Device# copy running-config startup-config | |
| **Step 8** Start the Cisco IOS CNS agent on the device. | |
What to do next

You can now use the Cisco Configuration Engine to remotely send incremental configurations to the device.

Enabling an Initial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the CNS configuration agent and initiate an initial configuration on the device.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `cns template connect name`
4. `cli config-text`
5. Repeat Steps 3 to 4 to configure another CNS connect template.
6. `exit`
7. `cns connect name [retries number] [retry-interval seconds] [sleep seconds] [timeout seconds]`
8. `discover {controller controller-type | dlci [subinterface subinterface-number] | interface [interface-type] | line line-type}`
9. `template name [... name]`
10. Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile.
11. `exit`
12. `hostname name`
13. `ip route network-number`
14. `cns id interface num {dns-reverse | ipaddress | mac-address} [event] [image]`
15. `cns id {hardware-serial | hostname | string string | udi} [event] [image]`
16. `cns config initial {hostname | ip-address} [port-number] [event] [no-persist] [page page] [source ip-address] [syntax-check]`
17. `end`
18. `show running-config`
19. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>

<tr>
<td>------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Step 3**
  cns template connect *name*
  
  Example:
  
  Device(config)# cns template connect template-dhcp |
| Enters CNS template connect configuration mode, and specifies the name of the CNS connect template. |
| **Step 4**
  cli config-text
  
  Example:
  
  Device(config-tmpl-conn)# cli ip address dhcp |
| Enters a command line for the CNS connect template. Repeat this step for each command line in the template. |
| **Step 5**
  Repeat Steps 3 to 4 to configure another CNS connect template. |
| **Step 6**
  exit
  
  Example:
  
  Device(config)# exit |
| Returns to global configuration mode. |
| **Step 7**
  cns connect *name* [retries *number*] [retry-interval *seconds*] [sleep *seconds*] [timeout *seconds*]
  
  Example:
  
  Device(config)# cns connect dhcp |
| Enters CNS connect configuration mode, specifies the name of the CNS connect profile, and defines the profile parameters. The device uses the CNS connect profile to connect to the Configuration Engine. |
| • Enter the *name* of the CNS connect profile. |
| • (Optional) For retries *number*, enter the number of connection retries. The range is 1 to 30. The default is 3. |
| • (Optional) For retry-interval *seconds*, enter the interval between successive connection attempts to the Configuration Engine. The range is 1 to 40 seconds. The default is 10 seconds. |
| • (Optional) For sleep *seconds*, enter the amount of time before which the first connection attempt occurs. The range is 0 to 250 seconds. The default is 0. |
| • (Optional) For timeout *seconds*, enter the amount of time after which the connection attempts end. The range is 10 to 2000 seconds. The default is 120. |
| **Step 8**
  discover {controller controller-type | dlcI [subinterface subinterface-number] | interface [interface-type] | line line-type}
  
  Example:
  
  Device(config-cns-conn)# discover interface gigabitethernet |
<p>| Specifies the interface parameters in the CNS connect profile. |
| • For controller controller-type, enter the controller type. |
| • For dlcI, enter the active data-link connection identifiers (DLCIs). |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| (Optional) For `subinterface subinterface-number`, specify the point-to-point subinterface number that is used to search for active DLCIs.  
- For `interface [interface-type]`, enter the type of interface.  
- For `line line-type`, enter the line type. |

**Step 9**
```
template name [... name]  
Example:  
Device(config-cns-conn)# template template-dhcp  
```
Specifies the list of CNS connect templates in the CNS connect profile to be applied to the device configuration. You can specify more than one template.

**Step 10**
Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile.

**Step 11**
```
exit  
Example:  
Device(config-cns-conn)# exit
```
Returns to global configuration mode.

**Step 12**
```
hostname name  
Example:  
Device(config)# hostname device1
```
Enters the hostname for the device.

**Step 13**
```
ip route network-number  
Example:  
RemoteDevice(config)# ip route 172.28.129.22 255.255.255.255 11.11.11.1
```
(Optional) Establishes a static route to the Configuration Engine whose IP address is `network-number`.

**Step 14**
```
cns id interface num {dns-reverse | ipaddress | mac-address} [event] [image]  
Example:  
RemoteDevice(config)# cns id GigabitEthernet0/1 ipaddress
```
(Optional) Sets the unique EventID or ConfigID used by the Configuration Engine. If you enter this command, do not enter the `cns id {hardware-serial | hostname | string string | udi} [event] [image]` command.

- For `interface num`, enter the type of interface. For example, ethernet, group-async, loopback, or virtual-template. This setting specifies from which interface the IP or MAC address should be retrieved to define the unique ID.
- For `{dns-reverse | ipaddress | mac-address}`, enter `dns-reverse` to retrieve the hostname and assign it as the unique ID, enter `ipaddress` to use the IP address, or enter `mac-address` to use the MAC address as the unique ID.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 15**       | **cns id {hardware-serial | hostname | string string | udi} [event] [image]**
| Example:          | (Optional) Sets the unique EventID or ConfigID used by the Configuration Engine. If you enter this command, do not enter the **cns id interface num {dns-reverse | ipaddress | mac-address} [event] [image]** command.
| RemoteDevice(config)# cns id hostname | • For { hardware-serial | hostname | string string | udi }, enter **hardware-serial** to set the device serial number as the unique ID, enter **hostname** (the default) to select the device hostname as the unique ID, enter an arbitrary text string for **string** as the unique ID, or enter **udi** to set the unique device identifier (UDI) as the unique ID. |

| **Step 16**       | **cns config initial {hostname | ip-address} [port-number] [event] [no-persist] [page page] [source ip-address] [syntax-check]**
| Example:          | Enables the Cisco IOS agent, and initiates an initial configuration.
<p>| RemoteDevice(config)# cns config initial 10.1.1.1 no-persist | • For {hostname | ip-address}, enter the hostname or the IP address of the configuration server. |
|                   | • (Optional) For <strong>port-number</strong>, enter the port number of the configuration server. The default port number is 80. |
|                   | • (Optional) Enable <strong>event</strong> for configuration success, failure, or warning messages when the configuration is finished. |
|                   | • (Optional) Enable <strong>no-persist</strong> to suppress the automatic writing to NVRAM of the configuration pulled as a result of entering the <strong>cns config initial</strong> global configuration command. If the <strong>no-persist</strong> keyword is not entered, using the <strong>cns config initial</strong> command causes the resultant configuration to be automatically written to NVRAM. |
|                   | • (Optional) For <strong>page page</strong>, enter the web page of the initial configuration. The default is /Config/config/asp. |
|                   | • (Optional) Enter <strong>source ip-address</strong> to use for source IP address. |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) Enable <strong>syntax-check</strong> to check the syntax when this parameter is entered.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Though visible in the command-line help string, the <strong>encrypt</strong>, <strong>status url</strong>, and <strong>inventory</strong> keywords are not supported.</td>
</tr>
</tbody>
</table>

**Step 17**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 18**

**Example:**

```
Device# show running-config
```

Verifies your entries.

**Step 19**

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

**What to do next**

To verify information about the configuration agent, use the **show cns config connections** command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the **no cns config initial** { ip-address | hostname } global configuration command.

**Refreshing DeviceIDs**

Follow these steps to refresh a DeviceID when changing the hostname on the device.

**SUMMARY STEPS**

1. enable
2. show cns config connections
3. Make sure that the CNS event agent is properly connected to the event gateway.
4. show cns event connections
5. Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.
6. configure terminal
7. no cns event ip-address port-number
8. cns event ip-address port-number
9. end
10. Make sure that you have reestablished the connection between the device and the event connection by examining the output from `show cnseventconnections`.
11. `show running-config`
12. `copy running-config startup-config`

### DETAILED STEPS

<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>configure terminal</th>
<th>Enters global configuration mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| Step 3 | cns config partial \{ip-address | hostname\} [port-number] [source ip-address] | Enables the configuration agent, and initiates a partial configuration. |
|---------|----------------------------------|---------------------|
| Example: | Device(config)# cns config partial 172.28.129.22 2013 | • For \{ip-address | hostname\}, enter the IP address or the hostname of the configuration server. |
|         | | • (Optional) For port-number, enter the port number of the configuration server. The default port number is 80. |
|         | | • (Optional) Enter source ip-address to use for the source IP address. |
| **Note** | Though visible in the command-line help string, the encrypt keyword is not supported. |

<table>
<thead>
<tr>
<th>Step 4</th>
<th>end</th>
<th>Returns to privileged EXEC mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 5</th>
<th>show running-config</th>
<th>Verifies your entries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# show running-config</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 6</th>
<th>copy running-config startup-config</th>
<th>(Optional) Saves your entries in the configuration file.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

To verify information about the configuration agent, use either the `show cns config stats` or the `show cns config outstanding` command in privileged EXEC mode.

To disable the Cisco IOS agent, use the `no cns config partial \{ip-address | hostname\}` global configuration command. To cancel a partial configuration, use the `cns config cancel` global configuration command.
## Monitoring CNS Configurations

### Table 63: CNS show Commands

<table>
<thead>
<tr>
<th>Command</th>

Cisco Discovery Protocol is a Layer 2, media-independent, and network-independent protocol that runs on Cisco devices and enables networking applications to learn about directly connected devices nearby. This protocol facilitates the management of Cisco devices by discovering these devices, determining how they are configured, and allowing systems using different network-layer protocols to learn about each other.

This module describes Cisco Discovery Protocol Version 2 and how it functions with SNMP.

- Information About CDP, on page 613
- How to Configure CDP, on page 614
- Monitoring and Maintaining Cisco Discovery Protocol, on page 621
- Additional References, on page 622
- Feature History and Information for Cisco Discovery Protocol, on page 623

Information About CDP

Cisco Discovery Protocol Overview

Cisco Discovery Protocol is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With Cisco Discovery Protocol, network management applications can learn the device type and the SNMP agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

Cisco Discovery Protocol runs on all media that support Subnetwork Access Protocol (SNAP). Because Cisco Discovery Protocol runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each Cisco Discovery Protocol-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information, which is the length of time a receiving device holds Cisco Discovery Protocol information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.

On the device, Cisco Discovery Protocol enables Network Assistant to display a graphical view of the network. The device uses Cisco Discovery Protocol to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command device by default.
• Cisco Discovery Protocol identifies connected endpoints that communicate directly with the device.
• To prevent duplicate reports of neighboring devices, only one wired device reports the location information.
• The wired device and the endpoints both send and receive location information.

**CDP and Stacks**

A device stack appears as a single device in the network. Therefore, CDP discovers the device stack, not the individual stack members. The device stack sends CDP messages to neighboring network devices when there are changes to the device stack membership, such as stack members being added or removed.

**Default Cisco Discovery Protocol Configuration**

This table shows the default Cisco Discovery Protocol configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco Discovery Protocol global state</td>
<td>Enabled</td>
</tr>
<tr>
<td>Cisco Discovery Protocol interface state</td>
<td>Enabled</td>
</tr>
<tr>
<td>Cisco Discovery Protocol timer (packet update frequency)</td>
<td>60 seconds</td>
</tr>
<tr>
<td>Cisco Discovery Protocol holdtime (before discarding)</td>
<td>180 seconds</td>
</tr>
<tr>
<td>Cisco Discovery Protocol Version-2 advertisements</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**How to Configure CDP**

**Configuring Cisco Discovery Protocol Characteristics**

You can configure these Cisco Discovery Protocol characteristics:

• Frequency of Cisco Discovery Protocol updates
• Amount of time to hold the information before discarding it
• Whether or not to send Version 2 advertisements

**Note**

Steps 3 through 5 are all optional and can be performed in any order.

Follow these steps to configure the Cisco Discovery Protocol characteristics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `cdp timer seconds`
4. `cdp holdtime seconds`
5. `cdp advertise-v2`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

---

**What to do next**

You must reenable Cisco Discovery Protocol to use it.

---

## Enabling Cisco Discovery Protocol

Cisco Discovery Protocol is enabled by default.

---

**Note**

Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Follow these steps to enable Cisco Discovery Protocol when it has been disabled.

**Before you begin**

Cisco Discovery Protocol must be disabled, or it cannot be enabled.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. cdp run
4. end
5. show running-config
6. copy running-config startup-config
**Disabling Cisco Discovery Protocol on an Interface**

Cisco Discovery Protocol is enabled by default on all supported interfaces to send and to receive Cisco Discovery Protocol information.

**What to do next**

Use the `show run all` command to show that Cisco Discovery Protocol has been enabled. If you enter only `show run`, the enabling of Cisco Discovery Protocol may not be displayed.

**Disabling Cisco Discovery Protocol on an Interface**

Cisco Discovery Protocol is enabled by default on all supported interfaces to send and to receive Cisco Discovery Protocol information.
Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Note

Cisco Discovery Protocol bypass is not supported and may cause a port go into err-disabled state.

Follow these steps to disable Cisco Discovery Protocol on a port.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. no cdp enable
5. end
6. show running-config
7. copy running-config startup-config

Prerequisites for SNMP

Supported SNMP Versions

This software release supports the following SNMP versions:

- SNMPv1—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- SNMPv2C replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:
  - SNMPv2C—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- SNMPv3—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
  - Message integrity—Ensures that a packet was not tampered with in transit.
  - Authentication—Determines that the message is from a valid source.
Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

To select encryption, enter the `priv` keyword.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent’s MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

<table>

</tbody>
</table>

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.

### Restrictions for SNMP

**Version Restrictions**

- SNMPv1 does not support informs.

### Information About SNMP

#### SNMP Overview

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information
base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime Infrastructure. The agent and MIB reside on the device. To configure SNMP on the device, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager's requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

### SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

**Table 66: SNMP Operations**

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get-request</td>
<td>Retrieves a value from a specific variable.</td>
</tr>
<tr>
<td>get-next-request</td>
<td>Retrieves a value from a variable within a table.</td>
</tr>
<tr>
<td>get-bulk-request</td>
<td>Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data.</td>
</tr>
<tr>
<td>get-response</td>
<td>Replies to a get-request, get-next-request, and set-request sent by an NMS.</td>
</tr>
<tr>
<td>set-request</td>
<td>Stores a value in a specific variable.</td>
</tr>
<tr>
<td>trap</td>
<td>An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.</td>
</tr>
</tbody>
</table>

With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

The get-bulk command only works with SNMPv2 or later.

### SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- Get a MIB variable—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.
- Set a MIB variable—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.
SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the device, the community string definitions on the NMS must match at least one of the three community string definitions on the device.

A community string can have one of the following attributes:

- Read-only (RO)—Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.

- Read-write (RW)—Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.

- When a cluster is created, the command device manages the exchange of messages among member devices and the SNMP application. The Network Assistant software appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device and propagates them to the member devices.

SNMP MIB Variables Access

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure software uses the device MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in get-request, get-next-request, and set-request format.

Figure 62: SNMP Network

SNMP Notifications

SNMP allows the device to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps or informs, or both. Use the snmp-server host command to specify whether to send SNMP notifications as traps or informs.

Note

SNMPv1 does not support informs.
Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the device and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the device is a concern and notification is not required, use traps.

### SNMP ifIndex MIB Object Values

In an NMS, the IF-MIB generates and assigns an interface index (ifIndex) object value that is a unique number greater than zero to identify a physical or a logical interface. When the device reboots or the device software is upgraded, the device uses this same value for the interface. For example, if the device assigns a port 2 an ifIndex value of 10003, this value is the same after the device reboots.

The device uses one of the values in the following table to assign an ifIndex value to an interface:

**Table 67: ifIndex Values**

<table>
<thead>
<tr>
<th>Interface Type</th>
<th>ifIndex Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVI(^5)</td>
<td>1–4999</td>
</tr>
<tr>

SNMP Configuration Guidelines

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMPv3 authentication</td>
<td>If no keyword is entered, the default is the <strong>noauth</strong> (noAuthNoPriv) security level.</td>
</tr>
<tr>
<td>SNMP notification type</td>
<td>If no type is specified, all notifications are sent.</td>
</tr>
</tbody>
</table>

This is the default when the device starts and the startup configuration does not have any `snmp-server` global configuration commands.

SNMP Configuration Guidelines

If the device starts and the device startup configuration has at least one `snmp-server` global configuration command, the SNMP agent is enabled.

An SNMP group is a table that maps SNMP users to SNMP views. An SNMP user is a member of an SNMP group. An SNMP host is the recipient of an SNMP trap operation. An SNMP engine ID is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The `snmp-server host` global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.
- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the `snmp-server engineID` global configuration command with the `remote` option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.
- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.
- If a local user is not associated with a remote host, the device does not send informs for the **auth** (authNoPriv) and the **priv** (authPriv) authentication levels.
- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the `snmp-server user username` global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.
How to Configure SNMP

Disabling the SNMP Agent

The `no snmp-server` global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenable all versions of the SNMP agent by the first `snmp-server` global configuration command that you enter. There is no Cisco IOS command specifically designated for enabling SNMP.

Follow these steps to disable the SNMP agent.

**Before you begin**

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first `snmp-server` global configuration command entered on the device.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no snmp-server`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | `configure terminal` | Enters global configuration mode. |
| **Example:**      | Device# `configure terminal` | |

| **Step 3**        | `no snmp-server` | Disables the SNMP agent operation. |
| **Example:**      | Device(config)# `no snmp-server` | |

| **Step 4**        | `end` | Returns to privileged EXEC mode. |
| **Example:**      | Device(config)# `end` | |
Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the device. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

Follow these steps to configure a community string on the device.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. snmp-server community string [view view-name] [ro | rw] [access-list-number]
4. access-list access-list-number {deny | permit} source [source-wildcard]
5. end
6. show running-config
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<tr>
<td><strong>Note</strong></td>
<td>The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</td>
</tr>
<tr>
<td></td>
<td>• For string, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings of any length.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For view, specify the view record accessible to the community.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Specify either read-only (ro) if you want authorized management stations to retrieve MIB objects, or specify read-write (rw) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For access-list-number, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.</td>
</tr>
<tr>
<td><strong>Step 4</strong> access-list access-list-number {deny</td>
<td>permit} source [source-wildcard]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# access-list 4 deny any</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For access-list-number, enter the access list number specified in Step 3.</td>
</tr>
<tr>
<td></td>
<td>• The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched.</td>
</tr>
<tr>
<td></td>
<td>• For source, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</td>
</tr>
<tr>
<td></td>
<td>Recall that the access list is always terminated by an implicit deny statement for everything.</td>
</tr>
</tbody>
</table>
**Purpose**

**Command or Action**

**Step 5**

end

Example:

Device(config)# end

- Returns to privileged EXEC mode.

**Step 6**

show running-config

Example:

Device# show running-config

- Verifies your entries.

**Step 7**

copy running-config startup-config

Example:

Device# copy running-config startup-config

- (Optional) Saves your entries in the configuration file.

---

**What to do next**

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the `no snmp-server` community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

**Configuring SNMP Groups and Users**

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Follow these steps to configure SNMP groups and users on the device.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. snmp-server engineID {local engineid-string | remote ip-address [udp-port port-number] engineid-string}
4. snmp-server group group-name {v1 | v2c | v3 [auth | noauth | priv]} [read readview] [write writeview] [notify notifyview] [access access-list]
5. snmp-server user username group-name {remote host [udp-port port] } {v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password] | [priv {des | 3des | aes {128 | 192 | 256}}] priv-password}
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> `snmp-server engineID {local engineid-string</td>
<td>remote ip-address [udp-port port-number] engineid-string}`</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp-server engineID local 1234</td>
<td>- The <code>engineid-string</code> is a 24-character ID string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. The Step Example configures an engine ID of 123400000000000000000000.</td>
</tr>
<tr>
<td><strong>Step 4</strong> `snmp-server group group-name {v1</td>
<td>v2c</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp-server group public v2c access lmnop</td>
<td>For <code>group-name</code>, specify the name of the group. Specify one of the following security models:</td>
</tr>
<tr>
<td></td>
<td>- <code>v1</code> is the least secure of the possible security models.</td>
</tr>
<tr>
<td></td>
<td>- <code>v2c</code> is the second least secure model. It allows transmission of informs and integers twice the normal width.</td>
</tr>
<tr>
<td></td>
<td>- <code>v3</code>, the most secure, requires you to select one of the following authentication levels:</td>
</tr>
<tr>
<td></td>
<td>- <code>auth</code>—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.</td>
</tr>
</tbody>
</table>
**Step 5**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>noauth—Enables the noAuthNoPriv security level. This is the default if no keyword is specified.</td>
<td></td>
</tr>
<tr>
<td>priv—Enables Data Encryption Standard (DES) packet encryption (also called privacy).</td>
<td></td>
</tr>
<tr>
<td>(Optional) Enter <code>read readview</code> with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.</td>
<td></td>
</tr>
<tr>
<td>(Optional) Enter <code>write writeview</code> with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.</td>
<td></td>
</tr>
<tr>
<td>(Optional) Enter <code>notify notifyview</code> with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.</td>
<td></td>
</tr>
<tr>
<td>(Optional) Enter <code>access access-list</code> with a string (not to exceed 64 characters) that is the name of the access list.</td>
<td></td>
</tr>
</tbody>
</table>

`snmp-server user username group-name {remote host [udp-port port]} {v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password] } [priv {des | 3des | aes {128 | 192 | 256}} priv-password]`

Example:

```
Device(config)# snmp-server user Pat public v2c
```

Adds a new user for an SNMP group.

The `username` is the name of the user on the host that connects to the agent.

The `group-name` is the name of the group to which the user is associated.

Enter `remote` to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.

Enter the SNMP version number (`v1`, `v2c`, or `v3`). If you enter `v3`, you have these additional options:

- `encrypted` specifies that the password appears in encrypted format. This keyword is available only when the `v3` keyword is specified.

- `auth` is an authentication level setting session that can be either the HMAC-MD5-96 (`md5`) or the HMAC-SHA-96 (`sha`) authentication level and requires a password string `auth-password` (not to exceed 64 characters).

If you enter `v3` you can also configure a private (`priv`) encryption algorithm and password string `priv-password` using the following keywords (not to exceed 64 characters):

- `priv` specifies the User-based Security Model (USM).

- `des` specifies the use of the 56-bit DES algorithm.

- `3des` specifies the use of the 168-bit DES algorithm.
PurposeCommand or Action

aes specifies the use of the DES algorithm. You must select either 128-bit, 192-bit, or 256-bit encryption.

(Optional) Enter `access access-list` with a string (not to exceed 64 characters) that is the name of the access list.

### Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the device generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Devices running this Cisco IOS release can have an unlimited number of trap managers.

Note

Many commands use the word `traps` in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword `traps` refers to traps, informs, or both. Use the `snmp-server host` global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the `snmp-server host` global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

<table>
<thead>
<tr>
<th>Table 68: Device Notification Types</th>
</tr>
</thead>

</tbody>
</table>
| port-security            | Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.  

**Note** When you configure a trap by using the notification type `port-security`, configure the port security trap first, and then configure the port security trap rate:

1. `snmp-server enable traps port-security`
2. `snmp-server enable traps port-security trap-rate rate`

| rtr                       | Generates a trap for the SNMP Response Time Reporter (RTR). |
| snmp                     | Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down. |
### Configuring SNMP Notifications

**Notification Type Keyword** | **Description**
--- | ---
storm-control | Generates a trap for SNMP storm-control. You can also set a maximum trap rate per minute. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence).
stpx | Generates SNMP STP Extended MIB traps.
syslog | Generates SNMP syslog traps.
tty | Generates a trap for TCP connections. This trap is enabled by default.
vlan-membership | Generates a trap for SNMP VLAN membership changes.
vlancreate | Generates SNMP VLAN created traps.
vlandelete | Generates SNMP VLAN deleted traps.
vtp | Generates a trap for VLAN Trunking Protocol (VTP) changes.

Follow these steps to configure the device to send traps or informs to a host.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. snmp-server engineID remote ip-address engineid-string
4. snmp-server user username group-name { remote host [udp-port port] } [v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password]
5. snmp-server group group-name {v1 | v2c | v3 [auth | noauth | priv]} {read readview} {write writeview} {notify notifyview} {access access-list}
6. snmp-server host host-addr [informs | traps] [version {1 | 2c | 3 [auth | noauth | priv]}] community-string [notification-type]
7. snmp-server enable traps notification-types
8. snmp-server trap-source interface-id
9. snmp-server queue-length length
10. snmp-server trap-timeout seconds
11. end
12. show running-config
13. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> snmp-server engineID remote ip-address engineid-string</td>
<td>Specifies the engine ID for the remote host.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> snmp-server user username group-name { remote host [ udp-port port] } { v1 [ access access-list ]</td>
<td>v2c [ access access-list ]</td>
</tr>
<tr>
<td><strong>Note</strong> You cannot configure a remote user for an address without first configuring the engine ID for the remote host. Otherwise, you receive an error message, and the command is not executed.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp-server user Pat public v2c</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> snmp-server group group-name { v1</td>
<td>v2c</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp-server group public v2c access lmnop</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> snmp-server host host-addr [ informs</td>
<td>traps ] [ version { 1</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp-server host 203.0.113.1 comaccess snmp</td>
<td>For host-addr, specify the name or Internet address of the host (the targeted recipient).</td>
</tr>
<tr>
<td>(Optional) Specify traps (the default) to send SNMP traps to the host.</td>
<td></td>
</tr>
<tr>
<td>(Optional) Specify informs to send SNMP informs to the host.</td>
<td></td>
</tr>
<tr>
<td>(Optional) Specify the SNMP version (1, 2c, or 3). SNMPv1 does not support informs.</td>
<td></td>
</tr>
<tr>
<td>(Optional) For Version 3, select authentication level auth, noauth, or priv.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong> The priv keyword is available only when the cryptographic software image is installed.</td>
<td></td>
</tr>
<tr>
<td>For community-string, when version 1 or version 2c is specified, enter the password-like community string sent with the notification operation. When version 3 is specified, enter the SNMPv3 username.</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

#### Purpose

The `@` symbol is used for delimiting the context information. Avoid using the `@` symbol as part of the SNMP community string when configuring this command.

(Optional) For notification-type, use the keywords listed in the table above. If no type is specified, all notifications are sent.

#### Step 7

**snmp-server enable traps** notification-types

**Example:**

```
Device(config)# snmp-server enable traps snmp
```

Enables the device to send traps or informs and specifies the type of notifications to be sent. For a list of notification types, see the table above, or enter `snmp-server enable traps`?

To enable multiple types of traps, you must enter a separate `snmp-server enable traps` command for each trap type.

**Note** When you configure a trap by using the notification type `port-security`, configure the port security trap first, and then configure the port security trap rate:

1. `snmp-server enable traps port-security`
2. `snmp-server enable traps port-security trap-rate rate`

#### Step 8

**snmp-server trap-source** interface-id

**Example:**

```
Device(config)# snmp-server trap-source gigabitethernet 1/0/1
```

(Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs.

#### Step 9

**snmp-server queue-length** length

**Example:**

```
Device(config)# snmp-server queue-length 20
```

(Optional) Establishes the message queue length for each trap host. The range is 1 to 5000; the default is 10.

#### Step 10

**snmp-server trap-timeout** seconds

**Example:**

```
Device(config)# snmp-server trap-timeout 60
```

(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.

#### Step 11

**end**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

#### Step 12

**show running-config**

**Example:**

```
Device# show running-config
```

Verifies your entries.
### Setting the Agent Contact and Location Information

Follow these steps to set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `snmp-server contact text`
4. `snmp-server location text`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

<td></td>
</tr>
</tbody>
</table>

**Limiting TFTP Servers Used Through SNMP**

Follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. snmp-server tftp-server-list *access-list-number*
4. access-list *access-list-number* [deny | permit] source [source-wildcard]
5. end
6. show running-config
7. copy running-config startup-config

---

**Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)**
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable | Enables privileged EXEC mode.  
Example:  
Device> enable |
| |  | • Enter your password if prompted. |
| Step 2 | configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal |
| Step 3 | snmp-server tftp-server-list access-list-number | Limits the TFTP servers used for configuration file copies through SNMP to the servers in the access list.  
Example:  
Device(config)# snmp-server tftp-server-list 44 |
| | | For access-list-number, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999. |
| Step 4 | access-list access-list-number { deny | permit } source [ source-wildcard ] | Creates a standard access list, repeating the command as many times as necessary.  
Example:  
Device(config)# access-list 44 permit 10.1.1.2 |
| | | For access-list-number, enter the access list number specified in Step 3.  
The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched.  
For source, enter the IP address of the TFTP servers that can access the device.  
(Optional) For source-wildcard, enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore.  
The access list is always terminated by an implicit deny statement for everything. |
| Step 5 | end | Returns to privileged EXEC mode.  
Example:  
Device(config)# end |
| Step 6 | show running-config | Verifies your entries.  
Example:  
Device# show running-config |
Monitoring SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the `show snmp` privileged EXEC command. You also can use the other privileged EXEC commands listed in the table to display SNMP information.

**Table 69: Commands for Displaying SNMP Information**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show snmp</code></td>
<td>Displays SNMP statistics.</td>
</tr>
<tr>
<td><code>show snmp group</code></td>
<td>Displays information on each SNMP group on the network.</td>
</tr>
<tr>
<td><code>show snmp pending</code></td>
<td>Displays information on pending SNMP requests.</td>
</tr>
<tr>
<td><code>show snmp sessions</code></td>
<td>Displays information on the current SNMP sessions.</td>
</tr>
<tr>
<td><code>show snmp user</code></td>
<td>Displays information on each SNMP user name in the SNMP users table.</td>
</tr>
</tbody>
</table>

**Note**  You must use this command to display SNMPv3 configuration information for `auth | noauth | priv` mode. This information is not displayed in the `show running-config` output.

**SNMP Examples**

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string `public`. This configuration does not cause the device to send any traps.

```
Device(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string `public`. The device also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33.
using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string `public` is sent with the traps.

```bash
Device(config)# snmp-server community public
Device(config)# snmp-server enable traps vtp
Device(config)# snmp-server host 192.180.1.27 version 2c public
Device(config)# snmp-server host 192.180.1.111 version 1 public
Device(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the `comaccess` community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host `cisco.com` using the community string `public`.

```bash
Device(config)# snmp-server community comaccess ro 4
Device(config)# snmp-server enable traps snmp authentication
Device(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host `cisco.com`. The community string is restricted. The first line enables the device to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous `snmp-server host` commands for the host `cisco.com`.

```bash
Device(config)# snmp-server enable traps entity
Device(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the device to send all traps to the host `myhost.cisco.com` using the community string `public`:

```bash
Device(config)# snmp-server enable traps
Device(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send `auth` (authNoPriv) authentication-level informs when the user enters global configuration mode:

```bash
Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Device(config)# snmp-server group authgroup v3 auth
Device(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Device(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Device(config)# snmp-server enable traps
Device(config)# snmp-server inform retries 0
```

Configuring SPAN and RSPAN

Prerequisites for SPAN and RSPAN

**SPAN**

- You can limit SPAN traffic to specific VLANs by using the `filter vlan` keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

**RSPAN**

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.

Restrictions for SPAN and RSPAN

**SPAN**

The restrictions for SPAN are as follows:

- On each device, you can configure 66 sessions. A maximum of 7 source sessions can be configured and the remaining sessions can be configured as RSPAN destinations sessions. A source session is either a local SPAN session or an RSPAN source session.

- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.
• The destination port cannot be a source port; a source port cannot be a destination port.

• You cannot have two SPAN sessions using the same destination port.

• When you configure a device port as a SPAN destination port, it is no longer a normal device port; only monitored traffic passes through the SPAN destination port.

• Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the **no monitor session {session_number | all | local | remote}** global configuration command to delete configured SPAN parameters.

• For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the **encapsulation replicate** keywords are specified. If the keywords are not specified, the packets are sent in native form.

• You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.

• You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

• Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.

• Wireshark does not capture egress packets when egress span is active.

• You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.

• You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.

• You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.

• SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.

• When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.

• You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

• The device does not support a combination of local SPAN and RSPAN in a single session.

• An RSPAN source session cannot have a local destination port.

• An RSPAN destination session cannot have a local source port.

• An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.
RSPAN

The restrictions for RSPAN are as follows:

- RSPAN does not support BPDU packet monitoring or other Layer 2 device protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating devices.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the device does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the device.
- CDP packets are not forwarded in RSPAN configured VLAN due to limitation in hardware. The workaround is to disable CDP on all the interfaces carrying RSPAN VLAN on the devices connected to the switch.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- To use RSPAN, the switch must be running the LAN Base image.

Information About SPAN and RSPAN

SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the device or on another device that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

Local SPAN

Local SPAN supports a SPAN session entirely within one device; all source ports or source VLANs and destination ports are in the same device or device stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.
Remote SPAN

Remote SPAN supports source ports, source VLANs, and destination ports on different devices (or different device stacks), enabling remote monitoring of multiple devices across your network.

Figure 65: Example of RSPAN Configuration

The figure below shows source ports on Device A and Device B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating devices.
The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source device must have either ports or VLANs as RSPAN sources. The destination is always a physical port, as shown on Device C in the figure.

**SPAN and RSPAN Concepts and Terminology**

**SPAN Sessions**

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination device.
An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

More than one source session and more than one destination session can be active in the same RSPAN VLAN. Intermediate devices also can separate the RSPAN source and destination sessions. These devices are unable to run RSPAN, but they must respond to the requirements of the RSPAN VLAN.

Traffic monitoring in a SPAN session has these restrictions:

• Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.

• You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.

• You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.

• You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.

• SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.

• When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.

• You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

• The device does not support a combination of local SPAN and RSPAN in a single session.
  • An RSPAN source session cannot have a local destination port.
  • An RSPAN destination session cannot have a local source port.
  • An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

Monitored Traffic

SPAN sessions can monitor these traffic types:

• Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the device. A copy of each packet received by the source is sent to the destination port for that SPAN session.

Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.
- Transmit (Tx) SPAN—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the device. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

  - Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

  - Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- Both—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

The default configuration for local SPAN session ports is to send all packets untagged. SPAN also does not normally monitor bridge protocol data unit (BPDU) packets and Layer 2 protocols, such as Cisco Discovery Protocol (CDP), VLAN Trunk Protocol (VTP), Dynamic Trunking Protocol (DTP), Spanning Tree Protocol (STP), and Port Aggregation Protocol (PAgP). However, when you enter the encapsulation replicate keywords when configuring a destination port, these changes occur:

  - Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.

  - Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Device congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

  - A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.

  - An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.

  - An egress packet dropped because of device congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the device through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

**Source Ports**

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis.

In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions.

The device supports any number of source ports (up to the maximum number of available ports on the device) and any number of source VLANs (up to the maximum number of VLANs supported).
However, the device supports a maximum of (local or RSPAN) with source ports or VLANs. You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.
- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.

Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.
Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same device or device stack as the source port. For an RSPAN session, it is located on the device containing the RSPAN destination session. There is no destination port on a device or device stack running only an RSPAN source session.

- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.

  **Note** When QoS is configured on the SPAN destination port, QoS takes effect immediately.

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.

- It can be any Ethernet physical port.

- It cannot be a secure port.

- It cannot be a source port.

- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).

- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session.Incoming traffic is never learned or forwarded on a destination port.

- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.

- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).

- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.

- The maximum number of destination ports in a device or device stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

- For local SPAN, if the **encapsulation replicate** keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with **encapsulation replicate** enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.

- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.
RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the `remote-span` VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate devices.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

- Routing—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the device, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the device routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.
- STP—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.
- CDP—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.
- VTP—You can use VTP to prune an RSPAN VLAN between devices.
- VLAN and trunking—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.
- EtherChannel—You can configure an EtherChannel group as a source port a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored.

If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.
A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

- Multicast traffic can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.
- A private-VLAN port cannot be a SPAN destination port.
- A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

### SPAN and RSPAN and Device Stacks

Because the stack of devices represents one logical device, local SPAN source ports and destination ports can be in different devices in the stack. Therefore, the addition or deletion of devices in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a device is removed from the stack or an inactive session can become active when a device is added to the stack.

### Flow-Based SPAN

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session. The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.
You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL—Filters only IPv4 packets.
- IPv6 FSPAN ACL—Filters only IPv6 packets.
- MAC FSPAN ACL—Filters only non-IP packets.

The security ACLs have higher priority than the FSPAN ACLs on a device. If FSPAN ACLs are applied, and you later add more security ACLs that cannot fit in the hardware memory, the FSPAN ACLs that you applied are removed from memory to allow space for the security ACLs. A system message notifies you of this action, which is called unloading. When there is again space for the FSPAN ACLs to reside in memory, they are added to the hardware memory on the device. A system message notifies you of this action, which is called reloading. The IPv4, IPv6 and MAC FSPAN ACLs can be unloaded or reloaded independently.

If a VLAN-based FSPAN session configured on a stack cannot fit in the hardware memory on one or more devices, it is treated as unloaded on those devices, and traffic meant for the FSPAN ACL and sourcing on that device is not copied to the SPAN destination ports. The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the devices where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

IPv4 and MAC FSPAN ACLs are supported on all feature sets. IPv6 FSPAN ACLs are supported only in the advanced IP Services feature set.

### Default SPAN and RSPAN Configuration

#### Table 70: Default SPAN and RSPAN Configuration

</tr>
</tbody>
</table>

### Configuration Guidelines

#### SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session** command. For example, to remove a source interface:

  ```text
  no monitor session session_number source interface interface-id
  ```

  To remove a VLAN:

  ```text
  no monitor session session_number source vlan vlan-id
  ```
monitor session session_number destination interface interface-id global configuration command. For destination interfaces, the encapsulation options are ignored with the no form of the command.

- To monitor all VLANs on the trunk port, use the no monitor session session_number filter global configuration command.

**RSPAN Configuration Guidelines**

- All the SPAN configuration guidelines apply to RSPAN.
- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.
- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source devices.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple devices in your network.
- Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.
- You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
  - The same RSPAN VLAN is used for an RSPAN session in all the devices.
  - All participating devices support RSPAN.

**FSPAN and FRSPAN Configuration Guidelines**

- When at least one FSPAN ACL is attached, FSPAN is enabled.
- When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

**How to Configure SPAN and RSPAN**

**Creating a Local SPAN Session**

Follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no monitor session {session_number | all | local | remote}
4. monitor session session_number source {interface interface-id | vlan vlan-id} [, -] [both | rx | tx]
5. monitor session session_number destination {interface interface-id [, -] [encapsulation replicate]}
Creating a Local SPAN Session

6. end
7. show running-config
8. copy running-config startup-config

<tr>
<td></td>
<td>Device(config)# monitor session 1 source interface gigabitethernet1/0/1</td>
<td>• For interface-id, specify the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel port-channel-number). Valid port-channel numbers are 1 to 6.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For vlan-id, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) [ , - ] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.</td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) <strong>both</strong></td>
</tr>
<tr>
<td>• <strong>both</strong> — Monitors both received and sent traffic.</td>
</tr>
<tr>
<td>• <strong>rx</strong> — Monitors received traffic.</td>
</tr>
<tr>
<td>• <strong>tx</strong> — Monitors sent traffic.</td>
</tr>
</tbody>
</table>

### Step 5

<table>
<thead>
<tr>
<th><strong>monitor session</strong></th>
<th><strong>session_number</strong></th>
<th><strong>destination</strong></th>
<th><strong>{interface interface-id [ [, ] [-] [encapsulation replicate]}</strong></th>
</tr>
</thead>
</table>

**Example:**

```
Device(config)# monitor session 1 destination interface gigabitethernet1/0/2 encapsulation replicate
```

**Specifies the SPAN session and the destination port (monitoring port). The port LED changes to amber when the configuration changes take effect. The LED returns to its original state (green) only after removing the SPAN destination configuration.**

**Note**

For local SPAN, you must use the same session number for the source and destination interfaces.

| • For **session_number**, specify the session number entered in step 4. |
| • For **interface-id**, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. |
| • (Optional) **[ [, ] [-]** Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. |

(Optional) **encapsulation replicate** specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).

**Note**

You can use **monitor session** | **session_number** | **destination** command multiple times to configure multiple destination ports.

### Step 6

<table>
<thead>
<tr>
<th><strong>end</strong></th>
</tr>
</thead>
</table>

**Example:**

```
Device(config)# end
```

**Returns to privileged EXEC mode.**
Creating a Local SPAN Session and Configuring Incoming Traffic

Follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [., -] [both | rx | tx]`
5. `monitor session session_number destination {interface interface-id[,] [-] [encapsulation replicate[ingress {dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id}]]}
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** `enable` | Enables privileged EXEC mode.  
  
  • Enter your password if prompted. |
| Example: `Device> enable` | |
| **Step 2** `configure terminal` | Enters global configuration mode. |
| Example: `Device# configure terminal` | |
| **Step 3** `no monitor session {session_number | all | local | remote}` | Removes any existing SPAN configuration for the session. |
### Command or Action

**Example:**

Device(config)# no monitor session all

**Purpose**

- For session_number, the range is 1 to 4.
- all—Removes all SPAN sessions.
- local—Removes all local sessions.
- remote—Removes all remote SPAN sessions.

### Step 4

**monitor session session_number source {interface interface-id | vlan vlan-id} [[,]|[-] [both | rx | tx]}

**Example:**

Device(config)# monitor session 2 source gigabitethernet0/1 rx

Specifies the SPAN session and the source port (monitored port).

### Step 5

**monitor session session_number destination {interface interface-id [[,]|[-] [encapsulation replicate[ingress {dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id]]]}

**Example:**

Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6

Specifies the SPAN session, the destination port, the packet encapsulation, and the ingress VLAN and encapsulation.

- For session_number, specify the session number entered in Step 4.
- For interface-id, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.
- (Optional) [[,]|[-]—Specifies a series or range of interfaces. Enter a space before and after the comma or hyphen.
- (Optional) encapsulation replicate—Specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).
- ingress—Enables forwarding of incoming traffic on the destination port and to specify the encapsulation type.
  - dot1q vlan vlan-id—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN.
  - untagged vlan vlan-id or vlan vlan-id—Accepts incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.

### Step 6

**end

**Example:**

Device(config)# end

Returns to privileged EXEC mode.
Specifying VLANs to Filter

Follow these steps to limit SPAN source traffic to specific VLANs.

SUMMARY STEPS

1. enable
2. configure terminal
3. no monitor session {session_number | all | local | remote}
4. monitor session session_number source interface interface-id
5. monitor session session_number filter vlan vlan-id [, | -]
6. monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate]}
7. end
8. show running-config
9. copy running-config startup-config

DETAILED STEPS

<table>
<thead>

<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Device(config)# no monitor session all** | **Purpose**
| • all—Removes all SPAN sessions.  
| • local—Removes all local sessions.  
| • remote—Removes all remote SPAN sessions. |

**Step 4**

**monitor session session_number source interface interface-id**  
**Example:**

Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx

Specifies the characteristics of the source port (monitored port) and SPAN session.  
• For `session_number`, the range is 1 to 66.  
• For `interface-id`, specify the source port to monitor. The interface specified must already be configured as a trunk port.

**Step 5**

**monitor session session_number filter vlan vlan-id [, | -]**  
**Example:**

Device(config)# monitor session 2 filter vlan 1 - 5 , 9

Limits the SPAN source traffic to specific VLANs.  
• For `session_number`, enter the session number specified in Step 4.  
• For `vlan-id`, the range is 1 to 4094.  
• (Optional) Use a comma (,) to specify a series of VLANs, or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.

**Step 6**

**monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate]}**  
**Example:**

Device(config)# monitor session 2 destination interface gigabitethernet1/0/1

Specifies the SPAN session and the destination port (monitoring port).  
• For `session_number`, specify the session number entered in Step 4.  
• For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.  
• (Optional) [, | -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.  
• (Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).

**Step 7**

**Example:**

Device(config)# end

Returns to privileged EXEC mode.
## Configuring a VLAN as an RSPAN VLAN

Follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `vlan vlan-id`
4. `remote-span`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>

</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs).

**Step 4**
**remote-span**
**Example:**
```
Device(config-vlan)# remote-span
```
Configures the VLAN as an RSPAN VLAN.

**Step 5**
**end**
**Example:**
```
Device(config-vlan)# end
```
Returns to privileged EXEC mode.

**Step 6**
**show running-config**
**Example:**
```
Device# show running-config
```
Verifies your entries.

**Step 7**
**copy running-config startup-config**
**Example:**
```
Device# copy running-config startup-config
```
(Optional) Saves your entries in the configuration file.

---

**What to do next**

You must create the RSPAN VLAN in all devices that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one device, and VTP propagates it to the other devices in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination devices and any intermediate devices.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the `no remote-span` VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the `no monitor session session_number source {interface interface-id | vlan vlan-id}` global configuration command. To remove the RSPAN VLAN from the session, use the `no monitor session session_number destination remote vlan vlan-id`.

---

**Creating an RSPAN Source Session**

Follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.
**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]`
5. `monitor session session_number destination remote vlan vlan-id`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | `enable`          | Enables privileged EXEC mode.  
|      | Example:          | • Enter your password if prompted.  
|      | `Device> enable`  |         |
| 2    | `configure terminal` | Enters global configuration mode.  
|      | Example:          |         |
|      | `Device# configure terminal` |         |
| 3    | `no monitor session {session_number | all | local | remote}` | Removes any existing SPAN configuration for the session.  
|      | Example:          | • For `session_number`, the range is 1 to 66.  
|      | `Device(config)# no monitor session 1` | • `all`—Removes all SPAN sessions.  
|      |                     | • `local`—Removes all local sessions.  
|      |                     | • `remote`—Removes all remote SPAN sessions.  |
| 4    | `monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]` | Specifies the RSPAN session and the source port (monitored port).  
|      | Example:          | • For `session_number`, the range is 1 to 66.  
|      | `Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx` | • Enter a source port or source VLAN for the RSPAN session:  
|      |                     | • For `interface-id`, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces `(port-channel port-channel-number)`. Valid port-channel numbers are 1 to 48.  
|      |                     | • For `vlan-id`, specifies the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).  |
### Purpose

A single session can include multiple sources (ports or VLANs), defined in a series of commands, but you cannot combine source ports and source VLANs in one session.

- (Optional) `[|]`—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.

- (Optional) `both | rx | tx`—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic.
  - `both`—Monitors both received and sent traffic.
  - `rx`—Monitors received traffic.
  - `tx`—Monitors sent traffic.

### Command or Action | Purpose
--- | ---

| Step 5 | **monitor session** *session_number* **destination remote vlan** *vlan-id*  
**Example:**  
Device(config)# monitor session 1 destination remote vlan 100  
**Purpose:** Specifies the RSPAN session, the destination RSPAN VLAN, and the destination-port group.  
- For *session_number*, enter the number defined in Step 4.  
- For *vlan-id*, specify the source RSPAN VLAN to monitor. |
| --- | --- |

| Step 6 | **end**  
**Example:**  
Device(config)# end  
**Purpose:** Returns to privileged EXEC mode. |
| --- | --- |

| Step 7 | **show running-config**  
**Example:**  
Device# show running-config  
**Purpose:** Verifies your entries. |
| --- | --- |

| Step 8 | **copy running-config startup-config**  
**Example:**  
Device# copy running-config startup-config  
**Purpose:** (Optional) Saves your entries in the configuration file. |
Specifying VLANs to Filter

Follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source interface interface-id`
5. `monitor session session_number filter vlan vlan-id [, | -]`
6. `monitor session session_number destination remote vlan vlan-id`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

### Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different device or device stack; that is, not the device or device stack on which the source session was configured.

Follow these steps to define the RSPAN VLAN on that device, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. vlan vlan-id
Creating an RSPAN Destination Session

4. remote-span
5. exit
6. no monitor session {session_number | all | local | remote}
7. monitor session session_number source remote vlan vlan-id
8. monitor session session_number destination interface interface-id
9. end
10. show running-config
11. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>

<td>Device# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>vlan vlan-id</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# vlan 901</td>
</tr>
<tr>
<td></td>
<td>Specifies the VLAN ID of the RSPAN VLAN created from the source device, and enters VLAN configuration mode.</td>
</tr>
<tr>
<td></td>
<td>If both devices are participating in VTP and the RSPAN VLAN ID is from 2 to 1005, Steps 3 through 5 are not required because the RSPAN VLAN ID is propagated through the VTP network.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>remote-span</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-vlan)# remote-span</td>
</tr>
<tr>
<td></td>
<td>Identifies the VLAN as the RSPAN VLAN.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>exit</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-vlan)# exit</td>
</tr>
<tr>
<td></td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>no monitor session {session_number</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# no monitor session 1</td>
</tr>
<tr>
<td></td>
<td>Removes any existing SPAN configuration for the session.</td>
</tr>
<tr>
<td></td>
<td>• For session_number, the range is 1 to 66.</td>
</tr>
<tr>
<td></td>
<td>• all—Removes all SPAN sessions.</td>
</tr>
<tr>
<td></td>
<td>• local—Removes all local sessions.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>remote</strong></td>
<td>Removes all remote SPAN sessions.</td>
</tr>
</tbody>
</table>

**Step 7**

`monitor session session_number source remote vlan vlan-id`

**Example:**

```
Device(config)# monitor session 1 source remote vlan 901
```

Specifies the RSPAN session and the source RSPAN VLAN.

- For `session_number`, the range is 1 to 66.
- For `vlan-id`, specify the source RSPAN VLAN to monitor.

**Step 8**

`monitor session session_number destination interface interface-id`

**Example:**

```
Device(config)# monitor session 1 destination interface gigabitethernet2/0/1
```

Specifies the RSPAN session and the destination interface.

- For `session_number`, enter the number defined in Step 7.

  In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port.

- For `interface-id`, specify the destination interface. The destination interface must be a physical interface.

- Though visible in the command-line help string, `encapsulation replicate` is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged.

**Step 9**

`end`

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 10**

`show running-config`

**Example:**

```
Device# show running-config
```

Verifies your entries.

**Step 11**

`copy running-config startup-config`

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
Creating an RSPAN Destination Session and Configuring Incoming Traffic

Follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source remote vlan vlan-id`
5. `monitor session session_number destination {interface interface-id [ , - ] [ingress] {dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id}}`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

Configuring an FSPAN Session

Follow these steps to create a SPAN session, specify the source (monitored) ports or VLANs and the destination (monitoring) ports, and configure FSPAN for the session.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]`
5. `monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate]}`
6. `monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

DETAILED STEPS

<table>

<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
</tbody>
</table>
| Device(config)# monitor session 2 source interface gigabitethernet1/0/1 | - For interface-id, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel port-channel-number). Valid port-channel numbers are 1 to 48. 
- For vlan-id, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). Note A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session. 
- (Optional) [, | -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. 
- (Optional) [both | rx | tx]—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic. 
  - both—Monitors both sent and received traffic. This is the default. 
  - rx—Monitors received traffic. 
  - tx—Monitors sent traffic. Note You can use the monitor session session_number source command multiple times to configure multiple source ports. |

**Step 5**

**monitor session session_number destination [interface interface-id [, | -] [encapsulation replicate]]**

**Example:**

Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate

Specifies the SPAN session and the destination port (monitoring port).

- For session_number, specify the session number entered in Step 4. 
- For destination, specify the following parameters: 
  - For interface-id, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. 
  - (Optional) [, | -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.
## Configuring an FRSPAN Session

Follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) <strong>encapsulation replicate</strong> specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>For local SPAN, you must use the same session number for the source and destination interfaces. You can use <code>monitor session session_number destination</code> command multiple times to configure multiple destination ports.</td>
</tr>
</tbody>
</table>
| **Step 6** monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name} | Specifies the SPAN session, the types of packets to filter, and the ACLs to use in an FSPAN session.  
  - For `session_number`, specify the session number entered in Step 4.  
  - For `access-list-number`, specify the ACL number that you want to use to filter traffic.  
  - For `name`, specify the ACL name that you want to use to filter traffic. |
| Example: | Device(config)# monitor session 2 filter ipv6 access-group 4 |
| **Step 7** end | Returns to privileged EXEC mode. |
| Example: | Device(config)# end |
| **Step 8** show running-config | Verifies your entries. |
| Example: | Device# show running-config |
| **Step 9** copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| Example: | Device# copy running-config startup-config |
SUMMARY STEPS

1. enable
2. configure terminal
3. no monitor session {session_number | all | local | remote}
4. monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]
5. monitor session session_number destination remote vlan vlan-id
6. vlan vlan-id
7. remote-span
8. exit
9. monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}
10. end
11. show running-config
12. copy running-config startup-config

</tr>
</tbody>
</table>

**Step 5**

```bash
monitor session session_number destination remote vlan vlan-id
```

Example:

```bash
Device(config)# monitor session 2 destination remote vlan 5
```

Specifies the RSPAN session and the destination RSPAN VLAN.

• For `session_number`, enter the number defined in Step 4.
• For `vlan-id`, specify the destination RSPAN VLAN to monitor.

**Step 6**

```bash
vlan vlan-id
```

Example:

```bash
Device(config)# vlan 10
```

Enters the VLAN configuration mode. For `vlan-id`, specify the source RSPAN VLAN to monitor.

**Step 7**

```bash
remote-span
```

Example:

```bash
Device(config-vlan)# remote-span
```

Specifies that the VLAN you specified in Step 5 is part of the RSPAN VLAN.

**Step 8**

```bash
exit
```

Example:

```bash

```

Returns to global configuration mode.
### Purpose

Command or Action | Purpose
--- | ---
```
Device(config-vlan)# exit
```

**Step 9**

```text
monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}
```

**Example:**
```
Device(config)# monitor session 2 filter ip access-group 7
```

Specifies the RSPAN session, the types of packets to filter, and the ACLs to use in an FRSPAN session.

- For `session_number`, specify the session number entered in Step 4.
- For `access-list-number`, specify the ACL number that you want to use to filter traffic.
- For `name`, specify the ACL name that you want to use to filter traffic.

**Step 10**

```text
end
```

**Example:**
```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 11**

```text
show running-config
```

**Example:**
```
Device# show running-config
```

Verifies your entries.

**Step 12**

```text
copy running-config startup-config
```

**Example:**
```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

### Monitoring SPAN and RSPAN Operations

The following table describes the command used to display SPAN and RSPAN operations configuration and results to monitor operations:

**Table 71: Monitoring SPAN and RSPAN Operations**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show monitor</td>
<td>Displays the current SPAN, RSPAN, FSPAN, or FRSPAN configuration.</td>
</tr>
</tbody>
</table>
SPAN and RSPAN Configuration Examples

Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1
Device(config)# monitor session 1 destination interface gigabitethernet1/0/2
    encapsulation replicate
Device(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1
Device(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source vlan 1 - 3 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2
Device(config)# monitor session 2 source vlan 10
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with VLAN 6 as the default ingress VLAN:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source gigabitethernet0/1 rx
```
Device(config)# monitor session 2 destination interface gigabitethernet0/2 encapsulation replicate ingress vlan 6
Device(config)#

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination interface gigabitethernet1/0/1
Device(config)#

Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

Device> enable
Device# configure terminal
Device(config)# vlan 901
Device(config-vlan)# remote span
Device(config-vlan)#

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Device(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 1 source interface port-channel 2
Device(config)# monitor session 1 destination remote vlan 901
Device(config)#

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination remote vlan 902
Device(config)#

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

Device> enable
Device# configure terminal
Device(config)# monitor session 1 source remote vlan 901

- Feature Information for Flexible NetFlow, on page 718

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Flexible NetFlow

- Flexible NetFlow is supported on the Catalyst 2960-X Switch and the Catalyst 2960-XR Switch with a Cisco ONE for Access license. Catalyst 2960-XR is not stackable with the Catalyst 2960-X platform.

- One of the following must be enabled on your device and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding or distributed Cisco Express Forwarding.

- The targets for attaching a NetFlow monitor are the following:
  - Port—Monitor attachment is only supported on physical interfaces and not on logical interfaces, such as EtherChannels. The physical interface could be a routed port or a switched port.
  - VLAN—Monitor attachment is supported on VLAN interfaces only (SVI) and not on a Layer 2 VLAN.
• You are familiar with the Flexible NetFlow key fields as they are defined in the following commands:
  • **match datalink**—Datalink (layer2) fields
  • **match ipv4**—IPv4 fields
  • **match ipv6**—IPv6 fields
  • **match transport**—Transport layer fields

• You are familiar with the Flexible NetFlow non key fields as they are defined in the following commands:
  • **collect counter**—Counter fields
  • **collect flow**—Flow identifying fields
  • **collect interface**—Interface fields
  • **collect timestamp**—Timestamp fields
  • **collect transport**—Transport layer fields

---

### Restrictions for Flexible NetFlow

The following restrictions apply to Flexible NetFlow and Flexible NetFlow Lite:

#### General Restrictions:
- InterSwitch Link (ISL) is not supported.
- Policy-based NetFlow is not supported.
- Cisco TrustSec monitoring is not supported.
- Access control lists (ACL)-based NetFlow is not supported.
- Only NetFlow Version 9 is supported for Flexible NetFlow exporter using the `export-protocol` command option.
- NetFlow Version 5 is not supported.

#### Flow Record Restrictions:
- When a flow monitor has configured the `collect interface output` command as the collect field in the flow record, the field will return a value of **NULL** when a flow gets created for any of the following addresses:
  - L2 broadcast and multicast
  - L3 broadcast and multicast
  - L2 unknown destination.

When a flow monitor has the collect interface output configured as the collect field in the flow record, the output interface is detected based on the destination IP address on the device. For the different flow monitors, you must configure the following commands:
• IPv4 flow monitor--Configure the **match ip destination address** command.
• IPv6 flow monitor--Configure the **match ipv6 destination address** command.
• Datalink flow monitor--Configure the **match datalink mac output** command.

• Predefined flow records are not supported.

Monitor Restrictions:
• Monitor attachment is only supported in the ingress direction.
• One monitor per interface is supported, although multiple exporters per interface are supported.
• Only permanent and normal cache is supported for the monitor; immediate cache is not supported.
• Changing any monitor parameter will not be supported when it is applied on any of the interfaces or VLANs.
• When both the port and VLANs have monitors attached, then VLAN monitor will overwrite the port monitor for traffic coming on the port.
• Flow monitor type and traffic type (type means IPv4, IPv6, and data link) should be same for the flows to be created.
• You cannot attach an IP and a port-based monitor to an interface. A 48-port device supports a maximum of 48 monitors (IP or port-based) and for 256 SVIs, you can configure up to 256 monitors (IP or port-based).
• When running the **show flow monitor flow_name cache** command, the device displays cache information from an earlier switch software version (Catalyst 2960-S) with all fields entered as zero. Ignore these fields, as they are inapplicable to the switch.

Sampler Restrictions:
• For both port and VLANS, a total of only 4 samplers (random or deterministic) are supported on the device.
• The sampling minimum rate for both modes is 1 out of 32 flows, and the sampling maximum rate for both modes is 1 out of 1022 flows.
• Use the **ip flow monitor monitor_name sampler sampler_name input** command to associate a sample with a monitor while attaching it to an interface.
• When you attach a monitor using a deterministic sampler, every attachment with the same sampler uses one new free sampler from the switch (hardware) out of the 4 available samplers. You are not allowed to attach a monitor with any sampler, beyond 4 attachments.

When you attach a monitor using a random sampler, only the first attachment uses a new sampler from the switch (hardware). The remainder of all of the attachments using the same sampler, share the same sampler.

Because of this behavior, when using a deterministic sampler, you can always make sure that the correct number of flows are sampled by comparing the sampling rate and what the device sends. If the same random sampler is used with multiple interfaces, flows from any interface can always be sampled, and flows from other interfaces can always be skipped.

Stacking Restrictions:
• Each device in a stack (hardware) can support the creation of a maximum of 16,000 flows at any time. But as the flows are periodically pushed to the software cache, the software cache can hold a much larger amount of flows (1048 Kb flows). From the hardware flow cache, every 20 seconds (termed as poll timer), 200 flows (termed as poll entries) are pushed to software.

  • Use the `remote command all show platform hulc-fnf poll` command to report on the current NetFlow polling parameters of each switch.

  • Use the `show platform hulc-fnf poll` command to report on the current NetFlow polling parameters of the master switch.

  • Network flows and statistics are collected at the line rate.

Information About Flexible Netflow

Flexible NetFlow Overview

Flexible NetFlow uses flows to provide statistics for accounting, network monitoring, and network planning. A flow is a unidirectional stream of packets that arrives on a source interface and has the same values for the keys. A key is an identified value for a field within the packet. You create a flow using a flow record to define the unique keys for your flow.

The device supports the Flexible NetFlow feature that enables enhanced network anomalies and security detection. Flexible NetFlow allows you to define an optimal flow record for a particular application by selecting the keys from a large collection of predefined fields.

All key values must match for the packet to count in a given flow. A flow might gather other fields of interest, depending on the export record version that you configure. Flows are stored in the Flexible NetFlow cache.

You can export the data that Flexible NetFlow gathers for your flow by using an exporter and export this data to a remote system such as a Flexible NetFlow collector. The Flexible NetFlow collector can use an IPv4 address.

You define the size of the data that you want to collect for a flow using a monitor. The monitor combines the flow record and exporter with the Flexible NetFlow cache information.

Original NetFlow and Benefits of Flexible NetFlow

Flexible NetFlow allows the flow to be user defined. The benefits of Flexible NetFlow include:

  • High-capacity flow recognition, including scalability and aggregation of flow information.

  • Enhanced flow infrastructure for security monitoring and dDoS detection and identification.

  • New information from packets to adapt flow information to a particular service or operation in the network. The flow information available will be customizable by Flexible NetFlow users.

  • Extensive use of Cisco’s flexible and extensible NetFlow Version 9.

  • A comprehensive IP accounting feature that can be used to replace many accounting features, such as IP accounting, Border Gateway Protocol (BGP) Policy Accounting, and persistent caches.
Flexible NetFlow allows you to understand network behavior with more efficiency, with specific flow information tailored for various services used in the network. The following are some example applications for a Flexible NetFlow feature:

- Flexible NetFlow enhances Cisco NetFlow as a security monitoring tool. For instance, new flow keys can be defined for packet length or MAC address, allowing users to search for a specific type of attack in the network.

- Flexible NetFlow allows you to quickly identify how much application traffic is being sent between hosts by specifically tracking TCP or UDP applications by the class of service (CoS) in the packets.

- The accounting of traffic entering a Multiprotocol Label Switching (MPLS) or IP core network and its destination for each next hop per class of service. This capability allows the building of an edge-to-edge traffic matrix.

The figure below is an example of how Flexible NetFlow might be deployed in a network.

*Figure 66: Typical Deployment for Flexible NetFlow*

Flexible NetFlow Components

Flexible NetFlow consists of components that can be used together in several variations to perform traffic analysis and data export. The user-defined flow records and the component structure of Flexible NetFlow facilitates the creation of various configurations for traffic analysis and data export on a networking device with a minimum number of configuration commands. Each flow monitor can have a unique combination of flow record, flow exporter, and cache type. If you change a parameter such as the destination IP address for a flow exporter, it is automatically changed for all the flow monitors that use the flow exporter. The same flow monitor can be used in conjunction with different flow samplers to sample the same type of network traffic at different rates on different interfaces. The following sections provide more information on Flexible NetFlow components:

Flow Records

In Flexible NetFlow a combination of key and nonkey fields is called a record. Flexible NetFlow records are assigned to Flexible NetFlow flow monitors to define the cache that is used for storing flow data.

A flow record defines the keys that Flexible NetFlow uses to identify packets in the flow, as well as other fields of interest that Flexible NetFlow gathers for the flow. You can define a flow record with any combination...
of keys and fields of interest. The device supports a rich set of keys. A flow record also defines the types of counters gathered per flow. You can configure 64-bit packet or byte counters. The device enables the following match fields as the defaults when you create a flow record:

- match data-link — Layer 2 attributes
- match ipv4 — IPv4 attributes
- match ipv6 — IPv6 attributes
- match transport — Transport layer fields
- match wireless — Wireless fields

User-Defined Records

Flexible NetFlow enables you to define your own records for a Flexible NetFlow flow monitor cache by specifying the key and nonkey fields to customize the data collection to your specific requirements. When you define your own records for a Flexible NetFlow flow monitor cache, they are referred to as user-defined records. The values in nonkey fields are added to flows to provide additional information about the traffic in the flows. A change in the value of a nonkey field does not create a new flow. In most cases the values for nonkey fields are taken from only the first packet in the flow. Flexible NetFlow enables you to capture counter values such as the number of bytes and packets in a flow as nonkey fields.

Flexible NetFlow adds a new Version 9 export format field type for the header and packet section types. Flexible NetFlow will communicate to the NetFlow collector the configured section sizes in the corresponding Version 9 export template fields. The payload sections will have a corresponding length field that can be used to collect the actual size of the collected section.

Flow Exporters

Flow exporters export the data in the flow monitor cache to a remote system, such as a server running NetFlow collector, for analysis and storage. Flow exporters are created as separate entities in the configuration. Flow exporters are assigned to flow monitors to provide data export capability for the flow monitors. You can create several flow exporters and assign them to one or more flow monitors to provide several export destinations. You can create one flow exporter and apply it to several flow monitors.

NetFlow Data Export Format Version 9

The basic output of NetFlow is a flow record. Several different formats for flow records have evolved as NetFlow has matured. The most recent evolution of the NetFlow export format is known as Version 9. The distinguishing feature of the NetFlow Version 9 export format is that it is template-based. Templates provide an extensible design to the record format, a feature that should allow future enhancements to NetFlow services without requiring concurrent changes to the basic flow-record format. Using templates provides several key benefits:

- Third-party business partners who produce applications that provide collector or display services for NetFlow do not have to recompile their applications each time a new NetFlow feature is added. Instead, they should be able to use an external data file that documents the known template formats.
- New features can be added to NetFlow quickly without breaking current implementations.
- NetFlow is “future-proofed” against new or developing protocols because the Version 9 format can be adapted to provide support for them.
The Version 9 export format consists of a packet header followed by one or more template flow or data flow sets. A template flow set provides a description of the fields that will be present in future data flow sets. These data flow sets may occur later within the same export packet or in subsequent export packets. Template flow and data flow sets can be intermingled within a single export packet, as illustrated in the figure below.

Figure 67: Version 9 Export Packet

NetFlow Version 9 will periodically export the template data so the NetFlow collector will understand what data is to be sent and also export the data flow set for the template. The key advantage to Flexible NetFlow is that the user configures a flow record, which is effectively converted to a Version 9 template and then forwarded to the collector. The figure below is a detailed example of the NetFlow Version 9 export format, including the header, template flow, and data flow sets.

Figure 68: Detailed Example of the NetFlow Version 9 Export Format

Flow Monitors

Flow monitors are the Flexible NetFlow component that is applied to interfaces to perform network traffic monitoring.
Flow data is collected from the network traffic and added to the flow monitor cache during the monitoring process based on the key and nonkey fields in the flow record.

Flexible NetFlow can be used to perform different types of analysis on the same traffic. In the figure below, packet 1 is analyzed using a record designed for standard traffic analysis on the input interface and a record designed for security analysis on the output interface.

*Figure 69: Example of Using Two Flow Monitors to Analyze the Same Traffic*

The figure below shows a more complex example of how you can apply different types of flow monitors with custom records.

*Figure 70: Complex Example of Using Multiple Types of Flow Monitors with Custom Records*
Normal

The default cache type is “normal”. In this mode, the entries in the cache are aged out according to the timeout active and timeout inactive settings. When a cache entry is aged out, it is removed from the cache and exported via any exporters configured.

Flow Samplers

Flow samplers are created as separate components in a router’s configuration. Flow samplers are used to reduce the load on the device that is running Flexible NetFlow by limiting the number of packets that are selected for analysis.

Samplers use random sampling techniques (modes); that is, a randomly selected sampling position is used each time a sample is taken.

Flow sampling exchanges monitoring accuracy for router performance. When you apply a sampler to a flow monitor, the overhead load on the router of running the flow monitor is reduced because the number of packets that the flow monitor must analyze is reduced. The reduction in the number of packets that are analyzed by the flow monitor causes a corresponding reduction in the accuracy of the information stored in the flow monitor’s cache.

Samplers are combined with flow monitors when they are applied to an interface with the `ip flow monitor` command.

Supported Flexible NetFlow Fields

The following tables provide a consolidated list of supported fields in Flexible NetFlow (FNF) for various traffic types and traffic direction.

<table>
<thead>
<tr>
<th>Field</th>
<th>Layer 2 In</th>
<th>Layer 2 Out</th>
<th>IPv4 In</th>
<th>IPv4 Out</th>
<th>IPv6 In</th>
<th>IPv6 Out</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key or Collect</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Fields</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Interface input</td>
<td>Yes</td>
<td>—</td>
<td>Yes</td>
<td>—</td>
<td>Yes</td>
<td>—</td>
<td>If you apply a flow monitor in the input direction:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Use the <code>match</code> keyword and use the input interface as a key field.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Use the <code>collect</code> keyword and use the output interface as a collect field. This field will be present in the exported records but with a value of 0.</td>
</tr>
</tbody>
</table>
If you apply a flow monitor in the output direction:

- Use the `match` keyword and use the output interface as a key field.
- Use the `collect` keyword and use the input interface as a collect field. This field will be present in the exported records but with a value of 0.

### Default Settings

The following table lists the Flexible NetFlow default settings for the device.

**Table 72: Default Flexible NetFlow Settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow active timeout</td>
<td>1800 seconds</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>The default value for this setting may be too high for your specific Flexible NetFlow configuration. You may want to consider changing it to a lower value of 180 or 300 seconds.</td>
</tr>
<tr>
<td>Flow timeout inactive</td>
<td>Enabled, 30 seconds</td>
</tr>
<tr>
<td>Flow update timeout</td>
<td>1800 seconds</td>
</tr>
<tr>
<td>Default cache size</td>
<td>16640 bits</td>
</tr>
</tbody>
</table>
In Cisco IOS Release 15.2(5)E1, Flexible NetFlow polling was changed from 200 entries every 20 seconds to 2000 entries every 5 seconds. Based on this change, the current flow count will reflect the actual hardware flow count, and continuously active flows will experience active timeout. All flows will be exported as per the configured timeout values.

**How to Configure Flexible Netflow**

To configure Flexible Netflow, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.
2. Create an optional flow exporter by specifying the protocol and transport destination port, destination, and other parameters.
3. Create a flow monitor based on the flow record and flow exporter.
4. Create an optional sampler.
5. Apply the flow monitor to a Layer 2 port, Layer 3 port, or VLAN.

**Creating a Flow Record**

Perform this task to configure a customized flow record.

Customized flow records are used to analyze traffic data for a specific purpose. A customized flow record must have at least one **match** criterion for use as the key field and typically has at least one **collect** criterion for use as a nonkey field.

There are hundreds of possible permutations of customized flow records. This task shows the steps that are used to create one of the possible permutations. Modify the steps in this task as appropriate to create a customized flow record for your requirements.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `flow record record-name`
4. `description description`
5. `match {ip | ipv6} {destination | source} address`
6. Repeat Step 5 as required to configure additional key fields for the record.
7. `• collect counter {bytes [exported | long] | flows [exported] | packets [exported | long]`
   `• or`
   `collect timestamp sysuptime {first | last}`
8. Repeat the above step as required to configure additional nonkey fields for the record.
9. `end`
10. `show flow record record-name`
11. `show running-config flow record record-name`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Example:** | Device> enable |
| **Step 2** | configure terminal | Enters global configuration mode. |
| **Example:** | Device# configure terminal |
| **Step 3** | flow record record-name | Creates a flow record and enters Flexible NetFlow flow record configuration mode.  
  • This command also allows you to modify an existing flow record. |
| **Example:** | Device(config)# flow record FLOW-RECORD-1 |
| **Step 4** | description description | (Optional) Creates a description for the flow record. |
| **Example:** | Device(config-flow-record)# description Used for basic traffic analysis |
| **Step 5** | match {ip | ipv6} {destination | source} address | Note  
  This example configures the IPv4 destination address as a key field for the record. For information about the other key fields available for the match ipv4 command, and the other match commands that are available to configure key fields. |
| **Example:** | Device(config-flow-record)# match ipv4 destination address |
| **Step 6** | Repeat Step 5 as required to configure additional key fields for the record. | — |
| **Step 7** | • collect counter {bytes [exported | long] | flows [exported] | packets} [ exported | long]  
  • or  
  collect timestamp sysuptime {first | last} | Configures the input interface as a nonkey field for the record.  
  Note  
  This example configures the input interface as a nonkey field for the record. |
| **Example:** | Device(config-flow-record)# collect counter bytes |
| **Step 8** | Repeat the above step as required to configure additional nonkey fields for the record. | — |
| **Step 9** | end | Exits Flexible NetFlow flow record configuration mode and returns to privileged EXEC mode. |
| **Example:** | — |
Creating a Flow Exporter

You can create a flow export to define the export parameters for a flow.

Note
Each flow exporter supports only one destination. If you want to export the data to multiple destinations, you must configure multiple flow exporters and assign them to the flow monitor.

You can export to a destination using IPv4 address.

Summary Steps

1. configure terminal
2. flow exporter name
3. description string
4. destination {ipv4-address} [vrf vrf-name]
5. dscp value
6. source {source type}
7. transport udp number
8. ttl seconds
9. export-protocol {netflow-v9}
10. end
11. show flow exporter [name record-name]
12. copy running-config startup-config

Detailed Steps

<table>

</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><strong>ttl seconds</strong></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-flow-exporter)# ttl 210</td>
<td>(Optional) Configures the time-to-live (TTL) value for datagrams sent by the exporter. The range is from 1 to 255 seconds. The default is 255.</td>
</tr>
</tbody>
</table>
### Creating a Flow Monitor

Perform this required task to create a customized flow monitor.

Each flow monitor has a separate cache assigned to it. Each flow monitor requires a record to define the contents and layout of its cache entries. These record formats can be a user-defined format. An advanced user can create a customized format using the `flow record` command.

#### Before you begin

If you want to use a customized record, you must create the customized record before you can perform this task. If you want to add a flow exporter to the flow monitor for data export, you must create the exporter before you can complete this task.

#### Note

You must use the `no ip flow monitor` command to remove a flow monitor from all of the interfaces to which you have applied it before you can modify the parameters for the `record` command on the flow monitor.
SUMMARY STEPS

1. enable
2. configure terminal
3. flow monitor monitor-name
4. description description
5. record {record-name}
6. cache {entries number | timeout {active | inactive | update} seconds | { normal }}
7. Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.
8. exporter exporter-name
9. end
10. show flow monitor [[name] monitor-name [cache [format {csv | record | table}] ]]
11. show running-config flow monitor monitor-name
12. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable                  | Enables privileged EXEC mode.  
| Example:                           |         |
| Device> enable                     | • Enter your password if prompted. |
| **Step 2** configure terminal      | Enters global configuration mode. |
| Example:                           |         |
| Device# configure terminal         |         |
| **Step 3** flow monitor monitor-name | Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode.  
| Example:                           | • This command also allows you to modify an existing flow monitor. |
| Device(config)# flow monitor FLOW-MONITOR-1 |         |
| **Step 4** description description | (Optional) Creates a description for the flow monitor. |
| Example:                           |         |
| Device(config-flow-monitor)# description Used for basic ipv4 traffic analysis |         |
| **Step 5** record {record-name}    | Specifies the record for the flow monitor. |
| Example:                           |         |
| Device(config-flow-monitor)# record FLOW-RECORD-1 |         |
| **Step 6** cache {entries number | timeout {active | inactive | update} seconds | { normal } | (Optional) Modifies the flow monitor cache parameters such as timeout values, number of cache entries, and the cache type. |
| Example:                           |         |
### Creating a Sampler

You can create a sampler to define the NetFlow sampling rate for a flow.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>timeout active seconds</strong>  — Configure the active flow timeout. This defines the granularity of the traffic analysis. The range is from 1 to 604800 seconds. The default is 1800. Typical values are 60 or 300 seconds. See the Configuring Data Export for Cisco IOS Flexible NetFlow with Flow Exporters document for recommended values.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong>  — Although visible in the command line help, the entries keyword and inactive and update timeouts are not supported.</td>
<td></td>
</tr>
<tr>
<td>Step 7  — Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.</td>
<td></td>
</tr>
<tr>
<td><strong>exporter exporter-name</strong>  — (Optional) Specifies the name of an exporter that was created previously.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-flow-monitor)# exporter EXPORTER-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong>  — Exits Flexible NetFlow flow monitor configuration mode and returns to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-flow-monitor)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong>  — (Optional) Displays the status for a Flexible NetFlow flow monitor.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show flow monitor FLOW-MONITOR-2 cache</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong>  — (Optional) Displays the configuration of the specified flow monitor.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show running-config flow monitor FLOW_MONITOR-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong>  — (Optional) Saves your entries in the configuration file.</td>

<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>sampler name</td>
</tr>
<tr>
<td>Example:</td>
<td>Creates a sampler and enters flow sampler configuration mode.</td>
</tr>
<tr>
<td>Device(config)# sampler SampleTest</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>description string</td>
</tr>
<tr>
<td>Example:</td>
<td>(Optional) Describes this flow record as a maximum 63-character string.</td>
</tr>
<tr>
<td>Device(config-flow-sampler)# description samples</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>mode {deterministic {m - n}</td>
</tr>
<tr>
<td>Example:</td>
<td>Defines the random sample mode.</td>
</tr>
<tr>
<td>Device(config-flow-sampler)# mode random 1 out-of 1022</td>
<td>You can configure either a random or deterministic sampler to an interface. Select $m$ packets out of an $n$ packet window. The window size to select packets from ranges from 32 to 1022. Note the following when configuring a sampler to an interface:</td>
</tr>
<tr>
<td></td>
<td>• When you attach a monitor using deterministic sampler (for example, s1), every attachment with same sampler s1 uses one new free sampler from the device (hardware) out of 4 available samplers. Therefore, beyond 4 attachments, you are not allowed to attach a monitor with any sampler.</td>
</tr>
<tr>
<td></td>
<td>• In contrast, when you attach a monitor using random sampler (for example-again, s1), only the first attachment uses a new sampler from the device</td>
</tr>
</tbody>
</table>
Applying a Flow to an Interface

You can apply a flow monitor and an optional sampler to an interface.

SUMMARY STEPS

1. configure terminal
2. interface type
3. {ip flow monitor | ipv6 flow monitor}name [sampler name] {input | output}
4. end
5. show flow interface [interface-type number]
6. copy running-config startup-config

What to do next

Apply the flow monitor to a source interface or a VLAN.

Step 5

end

Example:

Device(config-flow-sampler)# end

Returns to privileged EXEC mode.

Step 6

show sampler [name]

Example:

Device show sample SampleTest

(Optional) Displays information about NetFlow samplers.

Step 7

copy running-config startup-config

Example:

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | **configure terminal**  
**Example:**  
Device# configure terminal | Enters global configuration mode. |
| Step 2 | **interface type**  
**Example:**  
Device(config)# interface GigabitEthernet1/0/1 | Enters interface configuration mode and configures an interface.  
Command parameters for the interface configuration include:  
Flexible Net Flow is supported only on the service module 1-Gigabit or 10-Gigabit Ethernet interfaces.  
You cannot attach a NetFlow monitor to a port channel interface. If both service module interfaces are part of an EtherChannel, you should attach the monitor to both physical interfaces. |
| Step 3 | {ip flow monitor | ipv6 flow monitor}name [sampler name] | Associate an IPv4 or an IPv6 flow monitor, and an optional sampler to the interface for input or output packets.  
You can associate multiple monitors to an interface in both input and output directions.  
To monitor datalink L2 traffic flows, you would use **datalink flow monitor name sampler sampler-name {input}** interface command. This specific command associates a datalink L2 flow monitor and required sampler to the interface for input packets. When a datalink flow monitor is assigned to an interface or VLAN record, it only creates flows for non-IPv6 or non-IPv4 traffic. |
| Step 4 | **end**  
**Example:**  
Device(config-flow-monitor)# end | Returns to privileged EXEC mode. |
| Step 5 | **show flow interface** [interface-type number]  
**Example:**  
Device# show flow interface | (Optional) Displays information about NetFlow on an interface. |
| Step 6 | **copy running-config startup-config**  
**Example:**  
Device# copy running-config | (Optional) Saves your entries in the configuration file. |
Configuring a Bridged NetFlow on a VLAN

You can apply a flow monitor and an optional sampler to a VLAN.

SUMMARY STEPS

1. configure terminal
2. vlan [configuration] vlan-id
3. ip flow monitor monitor name [sampler sampler name] {input}
4. copy running-config startup-config

Configuring Layer 2 NetFlow

You can define Layer 2 keys in Flexible NetFlow records that you can use to capture flows in Layer 2 interfaces.

SUMMARY STEPS

1. configure terminal
2. flow record name
3. match datalink {ethertype | mac {destination {address input} | source {address input}}}
4. match { ipv4 {destination | protocol | source | tos} | ipv6 {destination | flow-label | protocol | source | traffic-class} | transport {destination-port | source-port}}
5. end
6. show flow record [name]
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>show sampler [broker</td>
<td>name</td>
</tr>
<tr>
<td>show wlan wlan-name</td>
<td>Displays the WLAN configured on the device.</td>
</tr>
</tbody>
</table>
Configuration Examples for Flexible NetFlow

Example: Configuring a Flow

This example shows how to create a flow and apply it to an interface:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Device(config)# flow export export1
Device(config-flow-exporter)# destination 10.0.101.254
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# exit

Device(config)# flow record record1
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match ipv4 protocol
Device(config-flow-record)# match transport source-port
Device(config-flow-record)# match transport destination-port
Device(config-flow-record)# collect counter byte long
Device(config-flow-record)# collect counter packet long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit

Device(config)# flow monitor monitor1
Device(config-flow-monitor)# record record1
Device(config-flow-monitor)# exporter export1
Device(config-flow-monitor)# exit
Device(config)# interface tenGigabitEthernet 1/0/1
Device(config-if)# ip flow monitor monitor1 input
Device(config-if)# end
```

Feature Information for Flexible NetFlow

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for OpenFlow

The Prerequisites for OpenFlow are as follows:

- A Cisco device and its corresponding operating system that supports the installation of OpenFlow.

  Refer to the corresponding release notes for information about which operating system release supports the features and necessary infrastructure.

  Note: Release notes for Cisco Catalyst 2960X/XR Series Switches

- A controller installed on a connected server.
Table 75: Controller Support

<table>
<thead>
<tr>
<th>OpenFlow Version</th>

</tr>
</thead>
<tbody>
<tr>
<td>OpenFlow 1.0</td>
<td>Extensible Network Controller (XNC) 1.0, POX, Cisco Open SDN Controller, or Ixia controllers</td>
</tr>
<tr>
<td>OpenFlow 1.3</td>
<td>Ixia, Cisco Open SDN Controller, or OpenDaylight</td>
</tr>
</tbody>
</table>

Restrictions for OpenFlow

The Restrictions for OpenFlow are as listed below:

- OpenFlow supports only a subset of OpenFlow 1.3 functions. For more information, see the Cisco OpenFlow Feature Support section.

- You cannot configure more than one OpenFlow logical switch. The logical switch ID has a value of 1.

- OpenFlow hybrid model (ships-in-the-night) is supported. VLANs configured for OpenFlow logical switch ports should not overlap with regular device interfaces.

- The OpenFlow logical switch ports must not be configured in a mode other than trunk port.

- You cannot configure a bridge domain, Virtual LANs, virtual routing and forwarding (VRF) or port-channel interfaces on an OpenFlow logical switch. You can only configure physical interfaces.

- You cannot make additional configurations to an interface configured as a port of OpenFlow Logical Switch without removing the configuration as a port of OpenFlow Logical Switch.

- In stack scenarios, consisting of master / member switches, whenever the master switch goes down, all current configuration will exist in newly elected master switch. However, the flows have to program again from the controller.

- MIBs and XMLs are not supported.

- Cisco Catalyst 2960X/XR switch supports 1000 L2 flows with EtherType, 200 L2 flows without EtherType, and 500 L3 flows.

- A maximum of 48 ports can be assigned for Openflow operation.

- In general, the maximum sustained flow programming rate from the controller should not exceed 50 (added or deleted) flows per second. For flows that have more than 1 match criteria (more than input port + 1 match), the sustained controller programming rate should not exceed 40 flows per second.

- The maximum burst flow programming rate from the controller should not exceed 1000 flows, spaced by 30-second time intervals. A minimum of 30-second time interval should be maintained between addition or deletion of flows.

- The rate of PACKET_IN messages sent to the controller should be rate-limited to 300 packets per second, using configuration.
Information About Open Flow

Overview of OpenFlow

OpenFlow is a standard communications interface defined between the control and forwarding plane for direct access to and manipulation of the forwarding plane of network devices such as switches and routers from multiple vendors.

OpenFlow Switch Specification Version 1.0.1 (Wire Protocol 0x01), referred to as OpenFlow 1.0, and OpenFlow Switch Specification Version 1.3.0 (Wire Protocol 0x04), referred to as OpenFlow 1.3, are based on the concept of an Ethernet switch with an internal flow table and standardized interface to allow traffic flows on a device to be added or removed. OpenFlow 1.3 defines the communication channel between OpenFlow and controllers.

A generic OpenFlow controller will interact with an specialized OpenFlow agent that translates the OpenFlow configuration into IOS configurations and configures the data plane.

Support of OpenFlow on catalyst 2960X/XR is limited to only software forwarding (due to ASIC limitations). The software forwarding of flows will happen at the OpenFlow agent with support of 12 tuples matches consisting of single table with both L2 and L3 fields together. The match criteria can be match on all 12 tuple fields or any of the 12 tuple fields.

The corresponding actions to the matching criteria can be:

- Push / Pop of Vlan
- Output the packet to port
- Drop the packet
- Set/Decrement IP TTL value
- Modify of L2/L3/L4 fields of Ethernet frame

The Physical ports can be configured as OpenFlow ports or as normal port. The flows in the flow table will be installed based on the priority of the flow.

---

**Note**

Priority 0 flows are not supported.

Cisco supports a subset of OpenFlow 1.0 and OpenFlow 1.3 functions. A controller can be Extensible Network Controller (XNC) 1.0, or any controller compliant with OpenFlow 1.3.

OpenFlow Controller Operation

OpenFlow controller (referred to as controller) controls the switch and inserts flows with a subset of OpenFlow 1.3 and 1.0 match and action criteria through OpenFlow logical switch.
Cisco OpenFlow Feature Support

The following is a subset of OpenFlow 1.3 and OpenFlow 1.0 functions that are supported by OpenFlow.

**Table 76: Cisco OpenFlow Feature Support**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration of physical interfaces as OpenFlow logical switch ports</td>

<tr>
<td>Connection to controllers</td>
<td>You can connect up to eight controllers. Connection to the controller through a management interface or a switched virtual interface (SVI) is supported. Connection via TCP and TLS is supported.</td>
</tr>
</tbody>
</table>
If multiple actions are associated with a flow, they are processed in the order specified. The output action should be the last action in the action list. Any action after the output action is not supported, and can cause the flow to fail and return an error to the controller.

Flows defined on the controller must follow these guidelines:

- The flow can have only one output action.
- Some action combinations which are not supported may be rejected at flow programming time.
- The flow should not have an output-to-controller action in combination with other rewrite actions.

### Supported OpenFlow counters

<table>
<thead>
<tr>
<th>Feature</th>

### Configuring OpenFlow

To configure OpenFlow logical switch and the IP address of a controller, perform this task:

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `feature openflow`
4. `openflow`
5. `switch logical-switch-id pipeline logical-id`
6. `controller [ipv4 ip-address ] [ port tcp-port ] [ vrf vrf-name ] [ security {none | tls} ]`
7. `of-port interface interface-name`
8. `default-miss action-for-unmatched-flows`
9. `protocol-version {1.1 | 1.3 | negotiate}`
10. `shutdown`
11. `datapath-id datapath-id`
12. `tls trust-point local local-trust-point remote remote-trust-point`
13. `probe-interval probe-interval`
14. `rate-limit packet_in controller-packet-rate burst maximum-packets-to-controller`
15. `max-backoff backoff-timer`
16. `logging flow-mod`
17. `statistics collection-interval interval`
18. `end`
19. `copy running-config startup-config`

#### DETAILED STEPS

**Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)**

730
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Device(config-ofa-switch)# default-miss**  
**continue-controller** | • forward the packets to the controller  
• drop the packets  
The default option is to forward the packets using the normal routing tables. |

**Step 9**  
**protocol-version {1.1 | 1.3 | negotiate}**  
**Example:**  
**Device(config-ofa-switch)# protocol-version negotiate**  
Configures the protocol version. Supported values are:  
• 1.0—Configures device to connect to 1.0 controllers only.  
• 1.3—Configures device to connect to 1.3 controllers only.  
• negotiate—Negotiates the protocol version with the controller. Device uses 1.3 for negotiation.  
The default value is 1.0. |

**Step 10**  
**shutdown**  
**Example:**  
**Device(config-ofa-switch)# shutdown**  
Disables a logical switch, bringing down the tcp/ip connection and removing flows from the dataplane. |

**Step 11**  
**datapath-id datapath-id**  
**Example:**  
**Device(config-ofa-switch)# datapath-id 0x222**  
Configures a unique datapath ID for the switch.  
This step is mandatory for a logical switch configuration. Enter a 64-bit hexadecimal value. |

**Step 12**  
**tls trust-point local local-trust-point remote remote-trust-point**  
**Example:**  
**Device(config-ofa-switch)# tls trust-point local myCA remote myCA**  
(Optional) Specifies the local and remote TLS trustpoints to be used for the controller connection. |

**Step 13**  
**probe-interval probe-interval**  
**Example:**  
**Device(config-ofa-switch)# probe-interval 7**  
(Optional) Configures the interval (in seconds) at which the controller is probed.  
After the configured interval of time passes, if the switch has not received any messages from the controller, the switch sends an echo request (echo_request) to the controller. It should normally receive an echo reply (echo_reply). If no message is seen for the duration of another probe interval, the switch presumes that the controller is down and disconnects the controller connection. The switch tries to reconnect periodically.  
The default value is 5 seconds; the range is from 5 to 65535 seconds.
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td><code>rate-limit packet_in controller-packet-rate burst maximum-packets-to-controller</code></td>
<td>(Optional) Configures the maximum packet rate sent to the controller and the maximum packets burst sent to the controller in a second. The default value is zero, that is, an indefinite packet rate and packet burst is permitted. This rate limit is for OpenFlow. It is not related to the rate limit of the device (data plane) configured by COPP.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config-ofa-switch)# <code>rate-limit packet_in 300 burst 50</code></td>
</tr>
<tr>
<td>15</td>
<td><code>max-backoff backoff-timer</code></td>
<td>(Optional) Configures the duration (in seconds) for which the device must wait before attempting to initiate a connection with the controller. The device initially tries to initiate connection frequently, as the number of unsuccessful attempts increases, the device tries less frequently, that is, the waiting period between attempts also increases. The backoff timer configures the maximum period that the device waits in-between each retry. The default value is 8 seconds; the range is from 1 to 65535 seconds.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config-ofa-switch)# <code>max-backoff 8</code></td>
</tr>
<tr>
<td>16</td>
<td><code>logging flow-mod</code></td>
<td>(Optional) Enables logging of flow changes, including addition, deletion, and modification of flows. Logging of flow changes is a CPU intensive activity and should not be enabled for a large number of flows. Logging of flow changes is disabled by default. Flow changes are logged in syslog and can be viewed using the <code>show logging</code> command.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config-ofa-switch)# <code>logging flow-mod</code></td>
</tr>
</tbody>
</table>
| 17   | `statistics collection-interval interval` | Configures the statistics collection interval (in seconds) for all configured flows of OpenFlow. Observe these guidelines: 
  - The default interval value is 7 seconds. 
  - The minimum interval is 7 seconds; the maximum is 82 seconds. 
  - You can also specify a value of 0, this disables statistics collection. 
  - Flows with an idle timeout value less than 2 * interval are rejected. Configured interval value is displayed in the output of the `show openflow switch 1` command. |
|      | Example: | Device(config-ofa-switch)# `statistics collection-interval 7` |
| 18   | `end` | Returns to privileged EXEC mode. |
Monitoring OpenFlow

You can monitor OpenFlow parameters using the following commands:

<table>
<thead>
<tr>
<th>Commands</th>

- Feature History and Information for QoS, on page 839

**Finding Feature Information**

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

**Prerequisites for QoS**

Before configuring standard QoS, you must have a thorough understanding of these items:

- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?
- Bandwidth requirements and speed of the network.
- Location of congestion points in the network.
You can configure QoS on physical ports and on switch virtual interfaces (SVIs). Other than to apply policy maps, you configure the QoS settings, such as classification, queueing, and scheduling, the same way on physical ports and SVIs. When configuring QoS on a physical port, you apply a nonhierarchical policy map. When configuring QoS on an SVI, you apply a nonhierarchical or a hierarchical policy map.

QoS ACL Guidelines

Follow these guidelines when configuring QoS with access control lists (ACLs):

- It is not possible to match IP fragments against configured IP extended ACLs to enforce QoS. IP fragments are sent as best-effort. IP fragments are denoted by fields in the IP header.

- Only one ACL per class map and only one match class-map configuration command per class map are supported. The ACL can have multiple ACEs, which match fields against the contents of the packet.

- A trust statement in a policy map requires multiple hardware entries per ACL line. If an input service policy map contains a trust statement in an ACL, the access list might be too large to fit into the available QoS hardware memory, and an error can occur when you apply the policy map to a port. Whenever possible, you should minimize the number of lines is a QoS ACL.

Applying QoS on Interfaces Guidelines

These are the guidelines for configuring QoS on physical ports and SVIs (Layer 3 VLAN interfaces):

- You can configure QoS on physical ports and SVIs. When configuring QoS on physical ports, you create and apply nonhierarchical policy maps. When configuring QoS on SVIs, you can create and apply nonhierarchical and hierarchical policy maps.

- Incoming traffic is classified, policed, and marked down (if configured) regardless of whether the traffic is bridged, routed, or sent to the CPU. It is possible for bridged frames to be dropped or to have their DSCP and CoS values modified.

- Follow these guidelines when configuring policy maps on physical ports or SVIs:
  - You cannot apply the same policy map to a physical port and to an SVI.
  - If VLAN-based QoS is configured on a physical port, the switch removes all the port-based policy maps on the port. The traffic on this physical port is now affected by the policy map attached to the SVI to which the physical port belongs.
  - In a hierarchical policy map attached to an SVI, you can only configure an individual policer at the interface level on a physical port to specify the bandwidth limits for the traffic on the port. The ingress port must be configured as a trunk or as a static-access port. You cannot configure policers at the VLAN level of the hierarchical policy map.
  - The switch does not support aggregate policers in hierarchical policy maps.
  - After the hierarchical policy map is attached to an SVI, the interface-level policy map cannot be modified or removed from the hierarchical policy map. A new interface-level policy map also cannot be added to the hierarchical policy map. If you want these changes to occur, the hierarchical policy map must first be removed from the SVI. You also cannot add or remove a class map specified in the hierarchical policy map.
Policing Guidelines

- The port ASIC device, which controls more than one physical port, supports 256 policers (255 user-configurable policers plus 1 policer reserved for system internal use). The maximum number of user-configurable policers supported per port is 63. Policers are allocated on demand by the software and are constrained by the hardware and ASIC boundaries.

For example, you could configure 32 policers on a Gigabit Ethernet port and 7 policers on a 10-Gigabit Ethernet port, or you could configure 64 policers on a Gigabit Ethernet port and 4 policers on a 10-Gigabit Ethernet port. Policers are allocated on demand by the software and are constrained by the hardware and ASIC boundaries.

You cannot reserve policers per port; there is no guarantee that a port will be assigned to any policer.

- Only one policer is applied to a packet on an ingress port. Only the average rate and committed burst parameters are configurable.

- You can create an aggregate policer that is shared by multiple traffic classes within the same nonhierarchical policy map. However, you cannot use the aggregate policer across different policy maps.

- On a port configured for QoS, all traffic received through the port is classified, policed, and marked according to the policy map attached to the port. On a trunk port configured for QoS, traffic in all VLANs received through the port is classified, policed, and marked according to the policy map attached to the port.

- If you have EtherChannel ports configured on your switch, you must configure QoS classification, policing, mapping, and queuing on the individual physical ports that comprise the EtherChannel. You must decide whether the QoS configuration should match on all ports in the EtherChannel.

- If you need to modify a policy map of an existing QoS policy, first remove the policy map from all interfaces, and then modify or copy the policy map. After you finish the modification, apply the modified policy map to the interfaces. If you do not first remove the policy map from all interfaces, high CPU usage can occur, which, in turn, can cause the console to pause for a very long time.

General QoS Guidelines

- Control traffic (such as spanning-tree bridge protocol data units [BPDUs] and routing update packets) received by the switch are subject to all ingress QoS processing.

- You are likely to lose data when you change queue settings; therefore, try to make changes when traffic is at a minimum.

- A switch that is running the IP services feature set supports QoS DSCP and IP precedence matching in policy-based routing (PBR) route maps with these limitations:
  - You cannot apply QoS DSCP mutation maps and PBR route maps to the same interface.
  - You cannot configure DSCP transparency and PBR DSCP route maps on the same switch.

Restrictions for QoS

The following are the restrictions for QoS:
• Ingress queuing and scheduling are not supported on the switch.
• IPv6 QoS is not supported on switches running the LAN base feature set.
• IPv6 ACLs are not supported on switches running the LAN base feature set.
• The switch supports 3 templates: default, vlan, and IPv4. Both the default and vlan templates support IPv6. The IPv4 template does not support IPv6.
• You can configure only individual policers on an SVI.
• For the `class-map [match-all | match-any] class-map-name` global configuration command, because only one `match` command per class map is supported, the `match-all` and `match-any` keywords function the same.

**Information About QoS**

**QoS Implementation**

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (`class`) information. Classification can also be carried in the Layer 2 frame.
Layer 2 Frame Prioritization Bits

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.
End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

QoS Basic Model

To implement QoS, the switch must distinguish packets or flows from one another (classify), assign a label to indicate the given quality of service as the packets move through the switch, make the packets comply with the configured resource usage limits (police and mark), and provide different treatment (queue and schedule) in all situations where resource contention exists. The switch also needs to ensure that traffic sent from it meets a specific traffic profile (shape).

**Figure 72: QoS Basic Model**

**Actions at Ingress Port**

Actions at the ingress port include classifying traffic, policing, marking, and scheduling:

- Classifying a distinct path for a packet by associating it with a QoS label. The switch maps the CoS or DSCP in the packet to a QoS label to distinguish one kind of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.

- Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, marking down the QoS label in the packet, or dropping the packet).

**Note**
Queueing and scheduling are only supported at egress and not at ingress on the switch.

### Actions at Egress Port

Actions at the egress port include queueing and scheduling:

- Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the four egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, WTD differentiates traffic classes and subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.

- Scheduling services the four egress queues based on their configured SRR shared or shaped weights. One of the queues (queue 1) can be the expedited queue, which is serviced until empty before the other queues are serviced.

### Classification Overview

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is globally enabled on the switch. By default, QoS is globally disabled, so no classification occurs.

During classification, the switch performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.

The QoS label is based on the DSCP or the CoS value in the packet and decides the queuing and scheduling actions to perform on the packet. The label is mapped according to the trust setting and the packet type as shown in the Classification Flowchart.

You specify which fields in the frame or packet that you want to use to classify incoming traffic.

### Non-IP Traffic Classification

The following table describes the non-IP traffic classification options for your QoS configuration.

**Table 78: Non-IP Traffic Classifications**

<table>
<thead>
<tr>
<th>Non-IP Traffic Classification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trust the CoS value</td>
<td>Trust the CoS value in the incoming frame (configure the port to trust CoS), and then use the configurable CoS-to-DSCP map to generate a DSCP value for the packet. Layer 2 ISL frame headers carry the CoS value in the 3 least-significant bits of the 1-byte User field. Layer 2 802.1Q frame headers carry the CoS value in the 3 most-significant bits of the Tag Control Information field. CoS values range from 0 for low priority to 7 for high priority.</td>
</tr>
</tbody>
</table>
Non-IP Traffic Classification

<table>
<thead>
<tr>
<th>Description</th>
<th>Trust the DSCP or trust IP precedence value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Trust the DSCP or trust IP precedence value in the incoming frame. These configurations are meaningless for non-IP traffic. If you configure a port with either of these options and non-IP traffic is received, the switch assigns a CoS value and generates an internal DSCP value from the CoS-to-DSCP map. The switch uses the internal DSCP value to generate a CoS value representing the priority of the traffic.</td>
</tr>
<tr>
<td></td>
<td>Perform classification based on configured Layer 2 MAC ACL</td>
</tr>
<tr>
<td></td>
<td>Perform the classification based on a configured Layer 2 MAC access control list (ACL), which can examine the MAC source address, the MAC destination address, and other fields. If no ACL is configured, the packet is assigned 0 as the DSCP and CoS values, which means best-effort traffic. Otherwise, the policy-map action specifies a DSCP or CoS value to assign to the incoming frame.</td>
</tr>
</tbody>
</table>

After classification, the packet is sent to the policing and marking stages.

**IP Traffic Classification**

The following table describes the IP traffic classification options for your QoS configuration.

### Table 79: IP Traffic Classifications

<table>
<thead>
<tr>
<th>IP Traffic Classification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trust the DSCP value</td>
<td>Trust the DSCP value in the incoming packet (configure the port to trust DSCP), and assign the same DSCP value to the packet. The IETF defines the 6 most-significant bits of the 1-byte ToS field as the DSCP. The priority represented by a particular DSCP value is configurable. DSCP values range from 0 to 63. You can also classify IP traffic based on IPv6 DSCP. For ports that are on the boundary between two QoS administrative domains, you can modify the DSCP to another value by using the configurable DSCP-to-DSCP-mutation map.</td>
</tr>
<tr>
<td>Trust the IP precedence value</td>
<td>Trust the IP precedence value in the incoming packet (configure the port to trust IP precedence), and generate a DSCP value for the packet by using the configurable IP-precedence-to-DSCP map. The IP Version 4 specification defines the 3 most-significant bits of the 1-byte ToS field as the IP precedence. IP precedence values range from 0 for low priority to 7 for high priority. You can also classify IP traffic based on IPv6 precedence.</td>
</tr>
<tr>
<td>Trust the CoS value</td>
<td>Trust the CoS value (if present) in the incoming packet, and generate a DSCP value for the packet by using the CoS-to-DSCP map. If the CoS value is not present, use the default port CoS value.</td>
</tr>
</tbody>
</table>
### IP Traffic Classification

<table>
<thead>
<tr>
<th>IP Traffic Classification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP standard or an extended ACL</td>
<td>Perform the classification based on a configured IP standard or an extended ACL, which examines various fields in the IP header. If no ACL is configured, the packet is assigned 0 as the DSCP and CoS values, which means best-effort traffic. Otherwise, the policy-map action specifies a DSCP or CoS value to assign to the incoming frame.</td>
</tr>
<tr>
<td>Override configured CoS</td>
<td>Override the configured CoS of incoming packets, and apply the default port CoS value to them. For IPv6 packets, the DSCP value is rewritten by using the CoS-to-DSCP map and by using the default CoS of the port. You can do this for both IPv4 and IPv6 traffic.</td>
</tr>
</tbody>
</table>

After classification, the packet is sent to the policing and marking stages.
Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:
• If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.

• If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.

**Note**  Deny action is supported in Cisco IOS Release 3.7.4E and later releases.

• If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the offers best-effort service to the packet.

• If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

**Note**  When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate-limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the `access-list` global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the `mac access-list extended` global configuration command.

### Classification Based on Class Maps and Policy Maps

A class map is a mechanism that you use to name a specific traffic flow (or class) and to isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

A policy map specifies which traffic class to act on. Actions can include trusting the CoS, DSCP, or IP precedence values in the traffic class; setting a specific DSCP or IP precedence value in the traffic class; or specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile. Before a policy map can be effective, you must attach it to a port.

You create a class map by using the `class-map` global configuration command or the `class` policy-map configuration command. You should use the `class-map` command when the map is shared among many ports. When you enter the `class-map` command, the switch enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the `match` class-map configuration command.

You can configure a default class by using the `class class-default` policy-map configuration command. Unclassified traffic (traffic specified in the other traffic classes configured on the policy-map) is treated as default traffic.
You create and name a policy map by using the `policy-map` global configuration command. When you enter this command, the switch enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the `class`, `trust`, or `set` policy-map configuration and policy-map class configuration commands.

The policy map can contain the `police` and `police aggregate` policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded.

To enable the policy map, you attach it to a port by using the `service-policy` interface configuration command.

You can apply a nonhierarchical policy map to a physical port or an SVI. However, a hierarchical policy map can only be applied to an SVI. A hierarchical policy map contains two levels. The first level, the VLAN level, specifies the actions to be taken against a traffic flow on the SVI. The second level, the interface level, specifies the actions to be taken against the traffic on the physical ports that belong to the SVI. The interface-level actions are specified in the interface-level policy map.

### Policing and Marking Overview

After a packet is classified and has a DSCP-based or CoS-based QoS label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP of the packet and allowing the packet to pass through. The configurable policed-DSCP map provides the packet with a new DSCP-based QoS label. Marked-down packets use the same queues as the original QoS label to prevent packets in a flow from getting out of order.

---

**Note**

All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can configure policing (either individual or aggregate policers) on a physical port or an SVI. When configuring policy maps on an SVI, you can create a hierarchical policy map and can define an individual policer only in the secondary interface-level policy map.

After you configure the policy map and policing actions, attach the policy to an ingress port or SVI by using the `service-policy` interface configuration command.

### Physical Port Policing

In policy maps on physical ports, you can create the following types of policers:

- **Individual**—QoS applies the bandwidth limits specified in the policer separately to each matched traffic class. You configure this type of policer within a policy map by using the `police` policy-map class configuration command.

- **Aggregate**—QoS applies the bandwidth limits specified in an aggregate policer cumulatively to all matched traffic flows. You configure this type of policer by specifying the aggregate policer name within a policy map by using the `police aggregate` policy-map class configuration command. You specify the bandwidth limits of the policer by using the `mls qos aggregate-policer` global configuration command. In this way, the aggregate policer is shared by multiple classes of traffic within a policy map.
You can configure only individual policers on an SVI.

Policing uses a token.bucket algorithm. As each frame is received by the switch, a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the switch verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).

How quickly the bucket fills is a function of the bucket depth (burst-byte), the rate at which the tokens are removed (rate-bps), and the duration of the burst above the average rate. The size of the bucket imposes an upper limit on the burst length and limits the number of frames that can be transmitted back-to-back. If the burst is short, the bucket does not overflow, and no action is taken against the traffic flow. However, if a burst is long and at a higher rate, the bucket overflows, and the policing actions are taken against the frames in that burst.

You configure the bucket depth (the maximum burst that is tolerated before the bucket overflows) by using the burst-byte option of the `police` policy-map class configuration command or the `mls qos aggregate-policer` global configuration command. You configure how fast (the average rate) that the tokens are removed from the bucket by using the rate-bps option of the `police` policy-map class configuration command or the `mls qos aggregate-policer` global configuration command.

*Figure 74: Policing and Marking Flowchart on Physical Ports*

The following figure shows the policing and marking process when these types of policy maps are configured:

- A nonhierarchical policy map on a physical port.
- The interface level of a hierarchical policy map attached to an SVI. The physical ports are specified in this secondary policy map.
Before configuring a hierarchical policy map with individual policers on an SVI, you must enable VLAN-based QoS on the physical ports that belong to the SVI. Though a policy map is attached to the SVI, the individual policers only affect traffic on the physical ports specified in the secondary interface level of the hierarchical policy map.

A hierarchical policy map has two levels. The first level, the VLAN level, specifies the actions to be taken against a traffic flow on an SVI. The second level, the interface level, specifies the actions to be taken against the traffic on the physical ports that belong to the SVI and are specified in the interface-level policy map.

When configuring policing on an SVI, you can create and configure a hierarchical policy map with these two levels:

- **VLAN level**—Create this primary level by configuring class maps and classes that specify the port trust state or set a new DSCP or IP precedence value in the packet. The VLAN-level policy map applies only to the VLAN in an SVI and does not support policers.

- **Interface level**—Create this secondary level by configuring class maps and classes that specify the individual policers on physical ports the belong to the SVI. The interface-level policy map only supports
individual policers and does not support aggregate policers. You can configure different interface-level policy maps for each class defined in the VLAN-level policy map.

**Figure 75: Policing and Marking Flowchart on SVIs**

The following figure shows the policing and marking process when hierarchical policy maps on an SVI.

---

**Mapping Tables Overview**

During QoS processing, the switch represents the priority of all traffic (including non-IP traffic) with a QoS label based on the DSCP or CoS value from the classification stage.
The following table describes QoS processing and mapping tables.

**Table 80: QoS Processing and Mapping Tables**

<table>
<thead>
<tr>
<th>QoS Processing Stage</th>
<th>Mapping Table Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Classification</strong></td>
<td>During the classification stage, QoS uses configurable mapping tables to derive a corresponding DSCP or CoS value from a received CoS, DSCP, or IP precedence value. These maps include the CoS-to-DSCP map and the IP-precedence-to-DSCP map. You configure these maps by using the <code>mls qos map cos-dscp</code> and the <code>mls qos map ip-prec-dscp</code> global configuration commands. On an ingress port configured in the DSCP-trusted state, if the DSCP values are different between the QoS domains, you can apply the configurable DSCP-to-DSCP-mutation map to the port that is on the boundary between the two QoS domains. You configure this map by using the <code>mls qos map dscp-mutation</code> global configuration command.</td>
</tr>
<tr>
<td><strong>Policing</strong></td>
<td>During policing stage, QoS can assign another DSCP value to an IP or a non-IP packet (if the packet is out of profile and the policer specifies a marked-down value). This configurable map is called the policed-DSCP map. You configure this map by using the <code>mls qos map policed-dscp</code> global configuration command.</td>
</tr>
<tr>
<td><strong>Pre-scheduling</strong></td>
<td>Before the traffic reaches the scheduling stage, QoS stores the packet in an egress queue according to the QoS label. The QoS label is based on the DSCP or the CoS value in the packet and selects the queue through the DSCP output queue threshold maps or through the CoS output queue threshold maps. In addition to an egress queue, the QOS label also identifies the WTD threshold value. You configure these maps by using the <code>mls qos srr-queue { output } dscp-map</code> and the <code>mls qos srr-queue { output } cos-map</code> global configuration commands.</td>
</tr>
</tbody>
</table>

The CoS-to-DSCP, DSCP-to-CoS, and the IP-precedence-to-DSCP maps have default values that might or might not be appropriate for your network.

The default DSCP-to-DSCP-mutation map and the default policed-DSCP map are null maps; they map an incoming DSCP value to the same DSCP value. The DSCP-to-DSCP-mutation map is the only map you apply to a specific port. All other maps apply to the entire switch.

**Queueing and Scheduling Overview**

The switch has queues at specific points to help prevent congestion.
The switch supports 4 egress queues by default and there is an option to enable a total of 8 egress queues. The 8 egress queue configuration is only supported on a standalone switch.

**Weighted Tail Drop**

As a frame is enqueued to a particular queue, WTD uses the frame’s assigned QoS label to subject it to different thresholds. If the threshold is exceeded for that QoS label (the space available in the destination queue is less than the size of the frame), the switch drops the frame.

Each queue has three threshold values. The QoS label determines which of the three threshold values is subjected to the frame. Of the three thresholds, two are configurable (explicit) and one is not (implicit).

**Figure 77: WTD and Queue Operation**

The following figure shows an example of WTD operating on a queue whose size is 1000 frames. Three drop percentages are configured: 40 percent (400 frames), 60 percent (600 frames), and 100 percent (1000 frames). These percentages indicate that up to 400 frames can be queued at the 40-percent threshold, up to 600 frames at the 60-percent threshold, and up to 1000 frames at the 100-percent threshold.

In the example, CoS values 6 and 7 have a greater importance than the other CoS values, and they are assigned to the 100-percent drop threshold (queue-full state). CoS values 4 and 5 are assigned to the 60-percent threshold, and CoS values 0 to 3 are assigned to the 40-percent threshold.

Suppose the queue is already filled with 600 frames, and a new frame arrives. It contains CoS values 4 and 5 and is subjected to the 60-percent threshold. If this frame is added to the queue, the threshold will be exceeded, so the switch drops it.
SRR Shaping and Sharing

You can configure SRR on egress queues for sharing or for shaping.

In shaped mode, the egress queues are guaranteed a percentage of the bandwidth, and they are rate-limited to that amount. Shaped traffic does not use more than the allocated bandwidth even if the link is idle. Shaping provides a more even flow of traffic over time and reduces the peaks and valleys of bursty traffic. With shaping, the absolute value of each weight is used to compute the bandwidth available for the queues.

In shared mode, the queues share the bandwidth among them according to the configured weights. The bandwidth is guaranteed at this level but not limited to it. For example, if a queue is empty and no longer requires a share of the link, the remaining queues can expand into the unused bandwidth and share it among them. With sharing, the ratio of the weights controls the frequency of dequeuing; the absolute values are meaningless. Shaping and sharing is configured per interface. Each interface can be uniquely configured.

Queueing and Scheduling on Egress Queues

The following figure shows queueing and scheduling flowcharts for egress ports on the switch.
If the expedite queue is enabled, SRR services it until it is empty before servicing the other three queues.

**Egress Expedite Queue**

Each port supports four egress queues, one of which (queue 1) can be the egress expedite queue. These queues are assigned to a queue-set. All traffic exiting the switch flows through one of these four queues and is subjected to a threshold based on the QoS label assigned to the packet.
If the expedite queue is enabled, SRR services it until it is empty before servicing the other three queues.

**Egress Queue Buffer Allocation**

The following figure shows the egress queue buffer.

*Figure 79: Egress Queue Buffer Allocation*

The buffer space is divided between the common pool and the reserved pool. The switch uses a buffer allocation scheme to reserve a minimum amount of buffers for each egress queue, to prevent any queue or port from consuming all the buffers and depriving other queues, and to control whether to grant buffer space to a requesting queue. The switch detects whether the target queue has not consumed more buffers than its reserved amount (under-limit), whether it has consumed all of its maximum buffers (over limit), and whether the common pool is empty (no free buffers) or not empty (free buffers). If the queue is not over-limit, the switch can allocate buffer space from the reserved pool or from the common pool (if it is not empty). If there are no free buffers in the common pool or if the queue is over-limit, the switch drops the frame.

**Buffer and Memory Allocation**

You guarantee the availability of buffers, set drop thresholds, and configure the maximum memory allocation for a queue-set by using the `mls qos queue-set output qset-id threshold queue-id drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold` global configuration command. Each threshold value is a percentage of the queue’s allocated memory, which you specify by using the `mls qos queue-set output qset-id buffers allocation1 ... allocation4` global configuration command. The sum of all the allocated buffers represents the reserved pool, and the remaining buffers are part of the common pool.

Through buffer allocation, you can ensure that high-priority traffic is buffered. For example, if the buffer space is 400, you can allocate 70 percent of it to queue 1 and 10 percent to queues 2 through 4. Queue 1 then has 280 buffers allocated to it, and queues 2 through 4 each have 40 buffers allocated to them.

You can guarantee that the allocated buffers are reserved for a specific queue in a queue-set. For example, if there are 100 buffers for a queue, you can reserve 50 percent (50 buffers). The switch returns the remaining 50 buffers to the common pool. You also can enable a queue in the full condition to obtain more buffers than are reserved for it by setting a maximum threshold. The switch can allocate the needed buffers from the common pool if the common pool is not empty.
Queues and WTD Thresholds

You can assign each packet that flows through the switch to a queue and to a threshold. Specifically, you map DSCP or CoS values to an egress queue and map DSCP or CoS values to a threshold ID. You use the `mls qos srr-queue output dscp-map queue-id {dscp1...dscp8 | threshold threshold-id dscp1...dscp8}` or the `mls qos srr-queue output cos-map queue-id {cos1...cos8 | threshold threshold-id cos1...cos8}` global configuration command. You can display the DSCP output queue threshold map and the CoS output queue threshold map by using the `show mls qos maps` privileged EXEC command.

The queues use WTD to support distinct drop percentages for different traffic classes. Each queue has three drop thresholds: two configurable (explicit) WTD thresholds and one nonconfigurable (implicit) threshold preset to the queue-full state. You assign the two WTD threshold percentages for threshold ID 1 and ID 2. The drop threshold for threshold ID 3 is preset to the queue-full state, and you cannot modify it. You map a port to queue-set by using the `queue-set qset-id` interface configuration command. Modify the queue-set configuration to change the WTD threshold percentages.

Shaped or Shared Mode

SRR services each queue-set in shared or shaped mode. You map a port to a queue-set by using the `queue-set qset-id` interface configuration command.

You assign shared or shaped weights to the port by using the `srr-queue bandwidth share weight1 weight2 weight3 weight4` or the `srr-queue bandwidth shape weight1 weight2 weight3 weight4` interface configuration command.

The buffer allocation together with the SRR weight ratios control how much data can be buffered and sent before packets are dropped. The weight ratio is the ratio of the frequency in which the SRR scheduler sends packets from each queue.

All four queues participate in the SRR unless the expedite queue is enabled, in which case the first bandwidth weight is ignored and is not used in the ratio calculation. The expedite queue is a priority queue, and it is serviced until empty before the other queues are serviced. You enable the expedite queue by using the `priority-queue out` interface configuration command.

You can combine the commands described in this section to prioritize traffic by placing packets with particular DSCPs or CoSs into certain queues, by allocating a large queue size or by servicing the queue more frequently, and by adjusting queue thresholds so that packets with lower priorities are dropped.

---

**Note**

The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

---

Packet Modification

A packet is classified, policed, and queued to provide QoS. The following packet modifications can occur during the process to provide QoS:

- For IP and non-IP packets, classification involves assigning a QoS label to a packet based on the DSCP or CoS of the received packet. However, the packet is not modified at this stage; only an indication of the assigned DSCP or CoS value is carried along.

- During policing, IP and non-IP packets can have another DSCP assigned to them (if they are out of profile and the policer specifies a markdown DSCP). Once again, the DSCP in the packet is not modified, but an indication of the marked-down value is carried along. For IP packets, the packet modification occurs...
at a later stage; for non-IP packets the DSCP is converted to CoS and used for queueing and scheduling decisions.

- Depending on the QoS label assigned to a frame and the mutation chosen, the DSCP and CoS values of the frame are rewritten. If you do not configure a table map and if you configure the port to trust the DSCP of the incoming frame, the DSCP value in the frame is not changed, but the CoS is rewritten according to the DSCP-to-CoS map. If you configure the port to trust the CoS of the incoming frame and it is an IP packet, the CoS value in the frame is not changed, but the DSCP might be changed according to the CoS-to-DSCP map.

The input mutation causes the DSCP to be rewritten depending on the new value of DSCP chosen. The set action in a policy map also causes the DSCP to be rewritten.

**Standard QoS Default Configuration**

Standard QoS is disabled by default.

When QoS is disabled, there is no concept of trusted or untrusted ports because the packets are not modified. The CoS, DSCP, and IP precedence values in the packet are not changed.

Traffic is switched in pass-through mode. The packets are switched without any rewrites and classified as best effort without any policing.

When QoS is enabled using the `mls qos` global configuration command and all other QoS settings are at their defaults, traffic is classified as best effort (the DSCP and CoS value is set to 0) without any policing. No policy maps are configured. The default port trust state on all ports is untrusted.

---

**Note**

Starting Cisco IOS Release 15.2(1)E, IPv6 QoS is supported on switches running the LAN base license with lanbase-routing template.

**Default Egress Queue Configuration**

The following tables describe the default egress queue configurations.

The following table shows the default egress queue configuration for each queue-set when QoS is enabled. All ports are mapped to queue-set 1. The port bandwidth limit is set to 100 percent and rate unlimited. Note that for the SRR shaped weights (absolute) feature, a shaped weight of zero indicates that the queue is operating in shared mode. Note that for the SRR shared weights feature, one quarter of the bandwidth is allocated to each queue.

**Table 81: Default Egress Queue Configuration**

**Default Mapping Table Configuration**

The default DSCP-to-DSCP-mutation map is a null map, which maps an incoming DSCP value to the same DSCP value.

The default policed-DSCP map is a null map, which maps an incoming DSCP value to the same DSCP value (no markdown).
DSCP Maps

Default CoS-to-DSCP Map

When DSCP transparency mode is disabled, the DSCP values are derived from CoS as per the following table. If these values are not appropriate for your network, you need to modify them.

Note: The DSCP transparency mode is disabled by default. If it is enabled (no mls qos rewrite ip dscp interface configuration command), DSCP rewrite will not happen.

Table 84: Default CoS-to-DSCP Map

<table>
<thead>
<tr>
<th>CoS Value</th>
<th>DSCP Value</th>

</tbody>
</table>

Default IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default IP-precedence-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

Table 85: Default IP-Precedence-to-DSCP Map

How to Configure QoS

Enabling QoS Globally

By default, QoS is disabled on the switch.

The following procedure to enable QoS globally is required.

SUMMARY STEPS

1. configure terminal
2. mls qos
3. end
4. show mls qos
5. copy running-config startup-config
Enabling VLAN-Based QoS on Physical Ports

By default, VLAN-based QoS is disabled on all physical switch ports. The switch applies QoS, including class maps and policy maps, only on a physical-port basis. You can enable VLAN-based QoS on a switch port.

The following procedure is required on physical ports that are specified in the interface level of a hierarchical policy map on a Switch Virtual Interface (SVI).

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. mls qos vlan-based
4. end
5. show mls qos interface interface-id
6. copy running-config startup-config

| Step 1 | configure terminal  
Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface-id  
Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the physical port, and enter interface configuration mode. |
| Step 3 | mls qos vlan-based  
Example: Device(config-if)# mls qos vlan-based | Enables VLAN-based QoS on the port.  
**Note** Use the no mls qos vlan-based interface configuration command to disable VLAN-based QoS on the physical port. |
| Step 4 | end  
Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface interface-id  
Example: Device# show mls qos interface gigabitethernet 1/0/1 | Verifies if VLAN-based QoS is enabled on the physical port. |
| Step 6 | copy running-config startup-config  
Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

**Configuring Classification Using Port Trust States**

These sections describe how to classify incoming traffic by using port trust states.
Depending on your network configuration, you must perform one or more of these tasks in this module or one or more of the tasks in the Configuring a QoS Policy.

### Configuring the Trust State on Ports Within the QoS Domain

Packets entering a QoS domain are classified at the edge of the QoS domain. When the packets are classified at the edge, the switch port within the QoS domain can be configured to one of the trusted states because there is no need to classify the packets at every switch within the QoS domain.

*Figure 80: Port Trusted States on Ports Within the QoS Domain*

#### SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. mls qos trust [cos | dscp | ip-precedence]
4. end
5. show mls qos interface
6. copy running-config startup-config
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | configure terminal  
Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface-id  
Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies the port to be trusted, and enters interface configuration mode. Valid interfaces are physical ports. |
| Step 3 | mls qos trust [cos | dscp | ip-precedence]  
Example: Device(config-if)# mls qos trust cos | Configures the port trust state. By default, the port is not trusted. If no keyword is specified, the default is `dscp`. The keywords have these meanings:  
  • `cos`—Classifies an ingress packet by using the packet CoS value. For an untagged packet, the port default CoS value is used. The default port CoS value is 0.  
  • `dscp`—Classifies an ingress packet by using the packet DSCP value. For a non-IP packet, the packet CoS value is used if the packet is tagged; for an untagged packet, the default port CoS is used. Internally, the switch maps the CoS value to a DSCP value by using the CoS-to-DSCP map.  
  • `ip-precedence`—Classifies an ingress packet by using the packet IP-precedence value. For a non-IP packet, the packet CoS value is used if the packet is tagged; for an untagged packet, the default port CoS is used. Internally, the switch maps the CoS value to a DSCP value by using the CoS-to-DSCP map.  
To return a port to its untrusted state, use the `no mls qos trust` interface configuration command. |
| Step 4 | end  
Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface  
Example: | Verifies your entries. |
Configuring the CoS Value for an Interface

QoS assigns the CoS value specified with the `mls qos cos` interface configuration command to untagged frames received on trusted and untrusted ports.

Beginning in privileged EXEC mode, follow these steps to define the default CoS value of a port or to assign the default CoS to all incoming packets on the port.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. mls qos cos {default-cos | override}
4. end
5. show mls qos interface
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>

</tr>
<tr>
<td>mls qos cos {default-cos</td>
<td>override}</td>
</tr>
<tr>
<td>Example:</td>
<td>- For <code>default-cos</code>, specify a default CoS value to be assigned to a port. If the packet is untagged, the default CoS value becomes the packet CoS value. The CoS range is 0 to 7. The default is 0.</td>
</tr>
<tr>
<td>Device(config-if)# mls qos</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>override</td>
<td>• Use the override keyword to override the previously configured trust state of the incoming packet and to apply the default port CoS value to the port on all incoming packets. By default, CoS override is disabled. Use the override keyword when all incoming packets on specified ports deserve higher or lower priority than packets entering from other ports. Even if a port was previously set to trust DSCP, CoS, or IP precedence, this command overrides the previously configured trust state, and all the incoming CoS values are assigned the default CoS value configured with this command. If an incoming packet is tagged, the CoS value of the packet is modified with the default CoS of the port at the ingress port.</td>
</tr>
</tbody>
</table>

**Note** To return to the default setting, use the no mls qos cos {default-cos | override} interface configuration command.

**Step 4**
end

**Example:**
Device(config-if)# end

**Step 5**
show mls qos interface

**Example:**
Device# show mls qos interface

copy running-config startup-config

**Example:**
Device# copy running-config startup-config

---

**Configuring a Trusted Boundary to Ensure Port Security**

In a typical network, you connect a Cisco IP Phone to a port and cascade devices that generate data packets from the back of the telephone. The Cisco IP Phone guarantees the voice quality through a shared data link by marking the CoS level of the voice packets as high priority (CoS = 5) and by marking the data packets as low priority (CoS = 0). Traffic sent from the telephone to the is typically marked with a tag that uses the 802.1Q header. The header contains the VLAN information and the class of service (CoS) 3-bit field, which is the priority of the packet.

For most Cisco IP Phone configurations, the traffic sent from the telephone to the should be trusted to ensure that voice traffic is properly prioritized over other types of traffic in the network. By using the mls qos trust
cos interface configuration command, you configure the port to which the telephone is connected to trust the CoS labels of all traffic received on that port. Use the `mls qos trust dscp` interface configuration command to configure a routed port to which the telephone is connected to trust the DSCP labels of all traffic received on that port.

With the trusted setting, you also can use the trusted boundary feature to prevent misuse of a high-priority queue if a user bypasses the telephone and connects the PC directly to the . Without trusted boundary, the CoS labels generated by the PC are trusted by the (because of the trusted CoS setting). By contrast, trusted boundary uses CDP to detect the presence of a Cisco IP Phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the port and prevents misuse of a high-priority queue. Note that the trusted boundary feature is not effective if the PC and Cisco IP Phone are connected to a hub that is connected to the .

In some situations, you can prevent a PC connected to the Cisco IP Phone from taking advantage of a high-priority data queue. You can use the `switchport priority extend cos` interface configuration command to configure the telephone through the CLI to override the priority of the traffic received from the PC.

**SUMMARY STEPS**

1. `configure terminal`
2. `cdp run`
3. `interface interface-id`
4. `cdp enable`
5. Use one of the following:
   - `mls qos trust cos`
   - `mls qos trust dscp`
6. `mls qos trust device cisco-phone`
7. `end`
8. `show mls qos interface`
9. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>

### Command or Action

<table>
<thead>
<tr>
<th><strong>Purpose</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables CDP on the port. By default, CDP is enabled.</td>
</tr>
</tbody>
</table>

**Step 4**

```
Device(config)# interface gigabitethernet 2/1/1
```

**Example:**

```
Device(config-if)# cdp enable
```

**Step 5**

Use one of the following:

- `mls qos trust cos`
- `mls qos trust dscp`

**Example:**

```
Device(config-if)# mls qos trust cos
```

**Configure the port to trust the CoS value in traffic received from the Cisco IP Phone.**

**or**

**Configure the routed port to trust the DSCP value in traffic received from the Cisco IP Phone.**

By default, the port is not trusted.

**Step 6**

```
mls qos trust device cisco-phone
```

**Example:**

```
Device(config-if)# mls qos trust device cisco-phone
```

Specifies that the Cisco IP Phone is a trusted device.

**Note** To disable the trusted boundary feature, use the `no mls qos trust device` interface configuration command.

**Step 7**

```
end
```

**Example:**

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

**Step 8**

```
show mls qos interface
```

**Example:**

```
Device# show mls qos interface
```

Verifies your entries.

**Step 9**

```
copy running-config startup-config
```

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
Enabling DSCP Transparency Mode

The switch supports the DSCP transparency feature. It affects only the DSCP field of a packet at egress. By default, DSCP transparency is disabled. The switch modifies the DSCP field in an incoming packet, and the DSCP field in the outgoing packet is based on the quality of service (QoS) configuration, including the port trust setting, policing and marking, and the DSCP-to-DSCP mutation map.

If DSCP transparency is enabled by using the `no mls qos rewrite ip dscp` command, the switch does not modify the DSCP field in the incoming packet, and the DSCP field in the outgoing packet is the same as that in the incoming packet.

Regardless of the DSCP transparency configuration, the switch modifies the internal DSCP value of the packet, which the switch uses to generate a class of service (CoS) value that represents the priority of the traffic. The switch also uses the internal DSCP value to select an egress queue and threshold.

**SUMMARY STEPS**

1. configure terminal
2. mls qos
3. no mls qos rewrite ip dscp
4. end
5. show mls qos interface [interface-id]
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
</tbody>
</table>
DSCP Transparency Mode

To configure the switch to modify the DSCP value based on the trust setting or on an ACL by disabling DSCP transparency, use the `mls qos rewrite ip dscp` global configuration command.

If you disable QoS by using the `no mls qos` global configuration command, the CoS and DSCP values are not changed (the default QoS setting).

If you enter the `no mls qos rewrite ip dscp` global configuration command to enable DSCP transparency and then enter the `mls qos trust [cos | dscp]` interface configuration command, DSCP transparency is still enabled.

Note

For Catalyst 2960-L switches, DSCP transparency is enabled by default.

Configuring the DSCP Trust State on a Port Bordering Another QoS Domain

If you are administering two separate QoS domains between which you want to implement QoS features for IP traffic, you can configure the ports bordering the domains to a DSCP-trusted state. The receiving port accepts the DSCP-trusted value and avoids the classification stage of QoS. If the two domains use different DSCP values, you can configure the DSCP-to-DSCP-mutation map to translate a set of DSCP values to match the definition in the other domain.
Beginning in privileged EXEC mode, follow these steps to configure the DSCP-trusted state on a port and modify the DSCP-to-DSCP-mutation map. To ensure a consistent mapping strategy across both QoS domains, you must perform this procedure on the ports in both domains.

### SUMMARY STEPS

1. configure terminal  
2. mls qos map dscp-mutation dscp-mutation-name in-dscp to out-dscp  
3. interface interface-id  
4. mls qos trust dscp  
5. mls qos dscp-mutation dscp-mutation-name  
6. end  
7. show mls qos maps dscp-mutation  
8. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
 configure terminal  
 Example:  
 Device# configure terminal                                                                 | Enters global configuration mode.                                         |
| **Step 2**  
 mls qos map dscp-mutation dscp-mutation-name in-dscp to out-dscp  
 Example:  
 Device(config)# mls qos map dscp-mutation gigabitethernet1/0/2-mutation 10 11 12 13 to 30 | Modifies the DSCP-to-DSCP-mutation map.  
 The default DSCP-to-DSCP-mutation map is a null map, which maps an incoming DSCP value to the same DSCP value.  
 • For dscp-mutation-name, enter the mutation map name.  
 You can create more than one map by specifying a new name. |
### Purpose

**Command or Action**

- For `in-dscp`, enter up to eight DSCP values separated by spaces. Then enter the `to` keyword.
- For `out-dscp`, enter a single DSCP value.

The DSCP range is 0 to 63.

### Step 3

**interface interface-id**

**Example:**

```
Device(config)# interface gigabitethernet1/0/2
```

Specifies the port to be trusted, and enter interface configuration mode.

Valid interfaces include physical ports.

### Step 4

**mls qos trust dscp**

**Example:**

```
Device(config-if)# mls qos trust dscp
```

**Note** To return a port to its non-trusted state, use the **no mls qos trust** interface configuration command.

### Step 5

**mls qos dscp-mutation dscp-mutation-name**

**Example:**

```
Device(config-if)# mls qos dscp-mutation gigabitethernet1/0/2-mutation
```

Applies the map to the specified ingress DSCP-trusted port.

For `dscp-mutation-name`, specify the mutation map name created in Step 2.

You can configure multiple DSCP-to-DSCP-mutation maps on an ingress port.

**Note** To return to the default DSCP-to-DSCP-mutation map values, use the **no mls qos map dscp-mutation dscp-mutation-name** global configuration command.

### Step 6

**end**

**Example:**

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

### Step 7

**show mls qos maps dscp-mutation**

**Example:**

```
Device# show mls qos maps dscp-mutation
```

Verifies your entries.

### Step 8

**copy running-config startup-config**

**Example:**

(Optional) Saves your entries in the configuration file.
Configuring a QoS Policy

Configuring a QoS policy typically requires the following tasks:

- Classifying traffic into classes
- Configuring policies applied to those traffic classes
- Attaching policies to ports

These sections describe how to classify, police, and mark traffic. Depending on your network configuration, you must perform one or more of the modules in this section.

Classifying Traffic by Using ACLs

You can classify IP traffic by using IPv4 standard ACLs, IPv4 extended ACLs, or IPv6 ACLs.

You can classify non-IP traffic by using Layer 2 MAC ACLs.

Creating an IP Standard ACL for IPv4 Traffic

Before you begin

Before you perform this task, determine which access lists you will be using for your QoS configuration.

**SUMMARY STEPS**

1. configure terminal
2. access-list access-list-number {deny | permit} source [source-wildcard]
3. end
4. show access-lists
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

| Step 2 | `access-list access-list-number {deny | permit} source [source-wildcard]` |
|---------|---------------------------------------------------------------------|

**Example:**

```bash
Device(config)# access-list 1
permit 192.2.255.0 1.1.1.255
```

**Purpose**

Creates an IP standard ACL, repeating the command as many times as necessary.

- For `access-list-number`, enter the access list number. The range is 1 to 99 and 1300 to 1999.
- Use the `permit` keyword to permit a certain type of traffic if the conditions are matched. Use the `deny` keyword to deny a certain type of traffic if conditions are matched.
- For `source`, enter the network or host from which the packet is being sent. You can use the `any` keyword as an abbreviation for 0.0.0.0-255.255.255.255.
- (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

When you create an access list, remember that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

**Note** To delete an access list, use the `no access-list access-list-number` global configuration command.

<table>
<thead>
<tr>
<th>Step 3</th>
<th><code>end</code></th>
</tr>
</thead>
</table>

**Example:**

```bash
Device(config)# end
```

**Purpose**

Returns to privileged EXEC mode.

<table>
<thead>
<tr>
<th>Step 4</th>
<th><code>show access-lists</code></th>
</tr>
</thead>
</table>

**Example:**

```bash
Device# show access-lists
```

**Purpose**

Verifies your entries.

<table>
<thead>
<tr>
<th>Step 5</th>
<th><code>copy running-config startup-config</code></th>
</tr>
</thead>
</table>

**Example:**

```bash
Device# copy running-config startup-config
```

**Purpose**

(Optional) Saves your entries in the configuration file.
Creating an IP Extended ACL for IPv4 Traffic

Before you begin

Before you perform this task, determine which access lists you will be using for your QoS configuration.

SUMMARY STEPS

1. `configure terminal`
2. `access-list access-list-number {deny | permit} protocol source source-wildcard destination destination-wildcard`
3. `end`
4. `show access-lists`
5. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | configure terminal  
Example:  
Device# configure terminal | Enters global configuration mode. |
| Step 2 | `access-list access-list-number {deny | permit} protocol source source-wildcard destination destination-wildcard`  
Example:  
Device(config)# access-list 100 permit ip any any dscp 32 | Creates an IP extended ACL, repeating the command as many times as necessary. |

- For `access-list-number`, enter the access list number. The range is 100 to 199 and 2000 to 2699.
- Use the `permit` keyword to permit a certain type of traffic if the conditions are matched. Use the `deny` keyword to deny a certain type of traffic if conditions are matched.
- For `protocol`, enter the name or number of an IP protocol. Use the question mark (?) to see a list of available protocol keywords.
- For `source`, enter the network or host from which the packet is being sent. You specify this by using dotted decimal notation, by using the `any` keyword as an abbreviation for `source 0.0.0.0 source-wildcard 255.255.255.255`, or by using the `host` keyword for `source 0.0.0.0`.
- For `source-wildcard`, enter the wildcard bits by placing ones in the bit positions that you want to ignore. You specify the wildcard by using dotted decimal notation, by using the `any` keyword as an abbreviation for `source 0.0.0.0 source-wildcard 255.255.255.255`, or by using the `host` keyword for `source 0.0.0.0`. |
### Creating an IPv6 ACL for IPv6 Traffic

**Before you begin**

Before you perform this task, determine which access lists you will be using for your QoS configuration.

**SUMMARY STEPS**

1. `configure terminal`
2. `ipv6 access-list access-list-name`
3. `{deny | permit} protocol {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dscp value] [fragments] [log] [log-input] [routing] [sequence value] [time-range name]`
4. `end`
5. `show ipv6 access-list`
6. `copy running-config startup-config`
## Creating an IPv6 ACL for IPv6 Traffic

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** | Creates an IPv6 ACL and enters IPv6 access-list configuration mode. |
| ipv6 access-list access-list-name | |
| **Example:** | |
| Device(config)# ipv6 access-list ipv6_Name_ACL | |

**Note** To delete an access list, use the `no ipv6 access-list access-list-number` global configuration command.

| **Step 3** | Enters `deny` or `permit` to specify whether to deny or permit the packet if conditions are matched. These are the conditions: |
| {deny | permit} protocol {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/ prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dscp value] [fragments] [log] [log-input] [routing] [sequence number] [time-range name] | |
| **Example:** | |
| Device(config-ipv6-acl)# permit ip host 10::1 host 11::2 host | |

For `protocol`, enter the name or number of an Internet protocol: `ahp`, `esp`, `icmp`, `ipv6`, `pcp`, `stcp`, `tcp`, or `udp`, or an integer in the range 0 to 255 representing an IPv6 protocol number.

- The `source-ipv6-prefix/prefix-length` or `destination-ipv6-prefix/ prefix-length` is the source or destination IPv6 network or class of networks for which to set deny or permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373).

- Enter `any` as an abbreviation for the IPv6 prefix `::/0`.

- For `host source-ipv6-address` or `destination-ipv6-address`, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons.

- (Optional) For `operator`, specify an operand that compares the source or destination ports of the specified protocol. Operands are `lt` (less than), `gt` (greater than), `eq` (equal), `neq` (not equal), and `range`.

If the operator follows the `source-ipv6-prefix/prefix-length` argument, it must match the source port. If the operator follows the `destination-ipv6-prefix/prefix-length` argument, it must match the destination port.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is IPv6.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter log to cause a logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter routing to specify that IPv6 packets be routed.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

End

Example:

```
Device(config-ipv6-acl)# end
```

Returns to privileged EXEC mode.

**Step 5**

show ipv6 access-list

Example:

```
Device# show ipv6 access-list
```

Verifies the access list configuration.

**Step 6**

copy running-config startup-config

Example:

```
Device# copy-running-config startup-config
```

(Optional) Saves your entries in the configuration file.
Creating a Layer 2 MAC ACL for Non-IP Traffic

Before you begin
Before you perform this task, determine that Layer 2 MAC access lists are required for your QoS configuration.

SUMMARY STEPS
1. configure terminal
2. mac access-list extended name
3. {permit | deny} {host src-MAC-addr mask | any} host dst-MAC-addr | dst-MAC-addr mask} [type mask]
4. end
5. show access-lists [access-list-number | access-list-name]
6. copy running-config startup-config

</table>
### Classifying Traffic by Using Class Maps

You use the `class-map` global configuration command to name and to isolate a specific traffic flow (or class) from all other traffic. The class map defines the criteria to use to match against a specific traffic flow to further classify it. Match statements can include criteria such as an ACL, IP precedence values, or DSCP values. The match criterion is defined with one match statement entered within the class-map configuration mode.

Classifying Traffic by Using Class Maps and Filtering IPv6 Traffic

To apply the primary match criteria to only IPv4 traffic, use the `match protocol` command with the `ip` keyword. To apply the primary match criteria to only IPv6 traffic, use the `match protocol` command with the `ipv6` keyword.

**SUMMARY STEPS**

1. `configure terminal`
2. `class-map {match-all} class-map-name`
3. `match protocol [ip | ipv6]`
4. `match {ip dscp dscp-list | ip precedence ip-precedence-list}`
5. `end`
6. `show class-map`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>

<td></td>
</tr>
<tr>
<td>(Optional) Saves your entries in the configuration file.</td>
<td></td>
</tr>
<tr>
<td>Example: Device# <code>copy-running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

Verifies your entries.

Verifies your entries.
### Purpose

- For `class-map-name`, specify the name of the class map.

If neither the `match-all` or `match-any` keyword is specified, the default is `match-all`.

### Note

To delete an existing class map, use the **no** class-map `[match-all | match-any]` global configuration command.

---

**Step 3**

**match protocol** `[ip | ipv6]`

*(Optional)* Specifies the IP protocol to which the class map applies:

- Use the argument `ip` to specify IPv4 traffic and `ipv6` to specify IPv6 traffic.
- When you use the `match protocol` command, only the `match-all` keyword is supported for the `class-map` command.

**Example:**

```
Device(config-cmap)# match protocol ip
```

**Step 4**

**match** `{ip dscp dscp-list | ip precedence ip-precedence-list}`

Defines the match criterion to classify traffic.

By default, no match criterion is defined.

- For `ip dscp dscp-list`, enter a list of up to eight IP DSCP values to match against incoming packets. Separate each value with a space. The range is 0 to 63.
- For `ip precedence ip-precedence-list`, enter a list of up to eight IP-precedence values to match against incoming packets. Separate each value with a space. The range is 0 to 7.

**Note** To remove a match criterion, use the no match `{access-group acl-index-or-name | ip dscp | ip precedence}` class-map configuration command.

**Example:**

```
Device(config-cmap)# match ip dscp 10
```

---

**Step 5**

**end**

Returns to privileged EXEC mode.

**Example:**

```
Device(config-cmap)# end
```

---

**Step 6**

**show class-map**

Verifies your entries.

**Example:**

```
Device# show class-map
```
Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps

You can configure a policy map on a physical port that specifies which traffic class to act on. Actions can include trusting the CoS, DSCP, or IP precedence values in the traffic class; setting a specific DSCP or IP precedence value in the traffic class; and specifying the traffic bandwidth limitations for each matched traffic class (policer) and the action to take when the traffic is out of profile (marking).

A policy map also has these characteristics:

- A policy map can contain multiple class statements, each with different match criteria and policers.
- A policy map can contain a predefined default traffic class explicitly placed at the end of the map.
- A separate policy-map class can exist for each type of traffic received through a port.

Follow these guidelines when configuring policy maps on physical ports:

- You can attach only one policy map per ingress port.
- If you configure the IP-precedence-to-DSCP map by using the `mls qos map ip-prec-dscp dscp1...dscp8` global configuration command, the settings only affect packets on ingress interfaces that are configured to trust the IP precedence value. In a policy map, if you set the packet IP precedence value to a new value by using the `set ip precedence new-precedence` policy-map class configuration command, the egress DSCP value is not affected by the IP-precedence-to-DSCP map. If you want the egress DSCP value to be different than the ingress value, use the `set dscp new-dscp` policy-map class configuration command.

- If you enter or have used the `set ip dscp` command, the changes this command to `set dscp` in its configuration.

- You can use the `set ip precedence` or the `set precedence` policy-map class configuration command to change the packet IP precedence value. This setting appears as set ip precedence in the configuration.

- You can configure a separate second-level policy map for each class defined for the port. The second-level policy map specifies the police action to take for each traffic class.

- A policy-map and a port trust state can both run on a physical interface. The policy-map is applied before the port trust state.

- When you configure a default traffic class by using the `class class-default` policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (class-default).

**SUMMARY STEPS**

1. `configure terminal`
2. `class-map [match-all | match-any] class-map-name`
3. `policy-map policy-map-name`
### Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps

4. `class [class-map-name | class-default]`
5. `trust [cos | dscp | ip-precedence]`
6. `set {dscp new-dscp | ip precedence new-precedence}`
7. `police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}]`
8. `exit`
9. `exit`
10. `interface interface-id`
11. `service-policy input policy-map-name`
12. `end`
13. `show policy-map [policy-map-name [class class-map-name]]`
14. `copy running-config startup-config`

#### Detailed Steps

<tr>
<td></td>
<td>• (Optional) Use the <code>match-all</code> keyword to perform a logical-AND of all matching statements under this class map. All match criteria in the class map must be matched.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• (Optional) Use the <code>match-any</code> keyword to perform a logical-OR of all matching statements under this class map. One or more match criteria must be matched.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For <code>class-map-name</code>, specify the name of the class map. If neither the <code>match-all</code> or <code>match-any</code> keyword is specified, the default is <code>match-all</code>.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><code>policy-map policy-map-name</code></td>
<td>Creates a policy map by entering the policy map name, and enters policy-map configuration mode. By default, no policy maps are defined.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device(config-cmap)# policy-map flowit</code></td>
<td>The default behavior of a policy map is to set the DSCP to 0 if the packet is an IP packet and to set the CoS to 0 if the packet is tagged. No policing is performed.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong> To delete an existing policy map, use the no <code>policy-map policy-map-name</code> global configuration command.</td>
<td></td>
</tr>
</tbody>
</table>

#### Step 4

**class** `[class-map-name | class-default]`<br>
**Example:**<br>
Device(config-pmap)# `class ipclass1`<br>

Defines a traffic classification, and enters policy-map class configuration mode.<br>
By default, no policy map class-maps are defined.<br>
If a traffic class has already been defined by using the `class-map` global configuration command, specify its name for `class-map-name` in this command.<br>
A `class-default` traffic class is pre-defined and can be added to any policy. It is always placed at the end of a policy map. With an implied `match any` included in the `class-default` class, all packets that have not already matched the other traffic classes will match `class-default`.<br>
**Note** To delete an existing class map, use the no class `class-map-name` policy-map configuration command.

#### Step 5

**trust** `[cos | dscp | ip-precedence]`<br>
**Example:**<br>
Device(config-pmap-c)# `trust dscp`<br>

Configures the trust state, which QoS uses to generate a CoS-based or DSCP-based QoS label.<br>
This command is mutually exclusive with the `set` command within the same policy map. If you enter the `trust` command, go to Step 6.<br>
By default, the port is not trusted. If no keyword is specified when the command is entered, the default is `dscp`.<br>
The keywords have these meanings:<br>
- **cos**—QoS derives the DSCP value by using the received or default port CoS value and the CoS-to-DSCP map.<br>
- **dscp**—QoS derives the DSCP value by using the DSCP value from the ingress packet. For non-IP packets that are tagged, QoS derives the DSCP value by using the received CoS value; for non-IP packets that are untagged, QoS derives the DSCP value by using the default port CoS value. In either case, the DSCP value is derived from the CoS-to-DSCP map.<br>
- **ip-precedence**—QoS derives the DSCP value by using the IP precedence value from the ingress packet and the IP-precedence-to-DSCP map. For non-IP packets that are tagged, QoS derives the DSCP value by using the received CoS value; for non-IP packets that are untagged, QoS derives the DSCP value by
### Purpose

Command or Action | Purpose
---|---
using the default port CoS value. In either case, the DSCP value is derived from the CoS-to-DSCP map.

Note To return to the untrusted state, use the **no trust** policy-map configuration command.

### Step 6

**set {dscp new-dscp | ip precedence new-precedence}**

**Example:**

Device(config-pmap-c)# set dscp 45

Classifies IP traffic by setting a new value in the packet.

- For **dscp new-dscp**, enter a new DSCP value to be assigned to the classified traffic. The range is 0 to 63.
- For **ip precedence new-precedence**, enter a new IP-precedence value to be assigned to the classified traffic. The range is 0 to 7.

Note To remove an assigned DSCP or IP precedence value, use the **no set {dscp new-dscp | ip precedence new-precedence}** policy-map configuration command.

### Step 7

**police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}]**

**Example:**

Device(config-pmap-c)# police 100000 80000 drop

Defines a policer for the classified traffic.

By default, no policer is defined.

- For **rate-bps**, specify average traffic rate in bits per second (b/s). The range is 8000 to 10000000000.
- For **burst-byte**, specify the normal burst size in bytes. The range is 8000 to 1000000.
- (Optional) Specifies the action to take when the rates are exceeded. Use the **exceed-action drop** keywords to drop the packet. Use the **exceed-action policed-dscp-transmit** keywords to mark down the DSCP value (by using the policed-DSCP map) and to send the packet.

Note To remove an existing policer, use the **no police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}]** policy-map configuration command.

### Step 8

**exit**

**Example:**

Device(config-pmap-c)# exit

Returns to policy map configuration mode.

### Step 9

**exit**

**Example:**

Returns to global configuration mode.
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>device(config-pmap)# exit</code></td>
<td>Specifies the port to attach to the policy map, and enters interface configuration mode. Valid interfaces include physical ports.</td>
</tr>
</tbody>
</table>

#### Step 10

**interface interface-id**

Example:

```plaintext
device(config)# interface gigabitethernet 2/0/1
```

#### Step 11

**service-policy input policy-map-name**

Example:

```plaintext
device(config-if)# service-policy input flowit
```

#### Step 12

**end**

Example:

```plaintext
device(config-if)# end
```

#### Step 13

**show policy-map [policy-map-name [class class-map-name]]**

Example:

```plaintext
device# show policy-map
```

#### Step 14

**copy running-config startup-config**

Example:

```plaintext
device# copy-running-config startup-config
```

### Classifying, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps

You can configure hierarchical policy maps on SVIs, but not on other types of interfaces. Hierarchical policing combines the VLAN- and interface-level policy maps to create a single policy map.

You can configure hierarchical policy maps on SVIs, but not on other types of interfaces. Hierarchical policing combines the VLAN- and interface-level policy maps to create a single policy map.

On an SVI, the VLAN-level policy map specifies which traffic class to act on. Actions can include trusting the CoS, DSCP, or IP precedence values or setting a specific DSCP or IP precedence value in the traffic class. Use the interface-level policy map to specify the physical ports that are affected by individual policers.
You can configure hierarchical policy maps that filter IPv4 and IPv6 traffic.

Follow these guidelines when configuring hierarchical policy maps:

- Before configuring a hierarchical policy map, you must enable VLAN-based QoS on the physical ports that are to be specified at the interface level of the policy map.
- You can attach only one policy map per ingress port or SVI.
- A policy map can contain multiple class statements, each with different match criteria and actions.
- A separate policy-map class can exist for each type of traffic received on the SVI.
- In a switch stack, you cannot use the `match input-interface` class-map configuration command to specify interfaces across stack members in a policy-map class.
- A policy-map and a port trust state can both run on a physical interface. The policy-map is applied before the port trust state.
- If you configure the IP-precedence-to-DSCP map by using the `mls qos map ip-prec-dscp dscp1...dscp8` global configuration command, the settings only affect packets on ingress interfaces that are configured to trust the IP precedence value. In a policy map, if you set the packet IP precedence value to a new value by using the `set ip precedence new-precedence` policy-map class configuration command, the egress DSCP value is not affected by the IP-precedence-to-DSCP map. If you want the egress DSCP value to be different than the ingress value, use the `set dscp new-dscp` policy-map class configuration command.
- If you enter or have used the `set ip dscp` command, the switch changes this command to `set dscp` in its configuration. If you enter the `set ip dscp` command, this setting appears as `set dscp` in the switch configuration.
- You can use the `set ip precedence` or the `set precedence` policy-map class configuration command to change the packet IP precedence value. This setting appears as `set ip precedence` in the switch configuration.
- If VLAN-based QoS is enabled, the hierarchical policy map supersedes the previously configured port-based policy map.
- The hierarchical policy map is attached to the SVI and affects all traffic in the VLAN. The actions specified in the VLAN-level policy map affect the traffic belonging to the SVI. The police action on the port-level policy map affects the ingress traffic on the affected physical interfaces.
- When configuring a hierarchical policy map on trunk ports, the VLAN ranges must not overlap. If the ranges overlap, the actions specified in the policy map affect the incoming and outgoing traffic on the overlapped VLANs.
- Aggregate policers are not supported in hierarchical policy maps.
- When VLAN-based QoS is enabled, the switch supports VLAN-based features, such as the VLAN map.
- You can configure a hierarchical policy map only on the primary VLAN of a private VLAN.
- When you enable VLAN-based QoS and configure a hierarchical policy map in a switch stack, these automatic actions occur when the stack configuration changes:
  - When a new stack master is selected, the stack master reenables and reconfigures these features on all applicable interfaces on the stack master.
  - When a stack member is added, the stack master reenables and reconfigures these features on all applicable ports on the stack member.
• When you merge switch stacks, the new stack master reenables and reconfigures these features on the switches in the new stack.

• When the switch stack divides into two or more switch stacks, the stack master in each switch stack re-enables and reconfigures these features on all applicable interfaces on the stack members, including the stack master.

• When you configure a default traffic class by using the `class class-default` policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as default traffic class (`class-default`).

SUMMARY STEPS

1. configure terminal
2. class-map [match-all | match-any] class-map-name
3. match {access-group acl-index-or-name | ip dscp dscp-list | ip precedence ip-precedence-list}
4. match protocol [ip | ipv6]
5. exit
6. exit
7. class-map [match-all | match-any] class-map-name
8. match input-interface interface-id-list
9. exit
10. exit
11. policy-map policy-map-name
12. class-map class-map-name
13. police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}]
14. exit
15. exit
16. policy-map policy-map-name
17. class [class-map-name | class-default]
18. trust [cos | dscp | ip-precedence]
19. set {dscp new-dscp | ip precedence new-precedence}
20. service-policy policy-map-name
21. exit
22. exit
23. interface interface-id
24. service-policy input policy-map-name
25. end
26. show policy-map [policy-map-name [class class-map-name]] or show mls qos vlan-based
27. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
# Classifying, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps

## Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Creates a VLAN-level class map, and enters class-map configuration mode.</td>
</tr>
</tbody>
</table>

### Step 2

```bash
class-map [match-all | match-any] class-map-name
```

**Example:**

```bash
Device(config)# class-map cm-1
```

By default, no class maps are defined.

- (Optional) Use the `match-all` keyword to perform a logical-AND of all matching statements under this class map. All match criteria in the class map must be matched.

- (Optional) Use the `match-any` keyword to perform a logical-OR of all matching statements under this class map. One or more match criteria must be matched.

- For `class-map-name`, specify the name of the class map.

If neither the `match-all` or `match-any` keyword is specified, the default is `match-all`.

Because only one `match` command per class map is supported, the `match-all` and `match-any` keywords function the same.

### Step 3

```bash
match {access-group acl-index-or-name | ip dscp dscp-list | ip precedence ip-precedence-list}
```

**Example:**

```bash
Device(config-cmap)# match ip dscp 10
```

Defines the match criterion to classify traffic.

By default, no match criterion is defined.

Only one match criterion per class map is supported, and only one ACL per class map is supported.

- For `access-group acl-index-or-name`, specify the number or name of the ACL.

- For `ip dscp dscp-list`, enter a list of up to eight IP DSCP values to match against incoming packets. Separate each value with a space. The range is 0 to 63.

- For `ip precedence ip-precedence-list`, enter a list of up to eight IP-precedence values to match against incoming packets. Separate each value with a space. The range is 0 to 7.

### Step 4

```bash
match protocol [ip | ipv6]
```

**Example:**

```bash
Device(config-cmap)# match protocol ipv6
```

(Optional) Specifies the IP protocol to which the class map applies.

- Use the argument `ip` to specify IPv4 traffic, and `ipv6` to specify IPv6 traffic.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• When you use the <strong>match protocol</strong> command, only the <strong>match-all</strong> keyword is supported for the first level class map. You can use the <strong>match protocol</strong> command with the <strong>match ip dscp</strong> or <strong>match precedence</strong> commands, but not with the <strong>match access-group</strong> command.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**
**exit**
**Example:**
Device(config-cmap)# **exit**

**Step 6**
**exit**
**Example:**
Device(config)# **exit**

**Step 7**
**class-map [match-all | match-any] class-map-name**
**Example:**
Device(config)# **class-map match-all cm-2**

Creates an interface-level class map, and enters class-map configuration mode.

By default, no class maps are defined.

• (Optional) Use the **match-all** keyword to perform a logical-AND of all matching statements under this class map. All match criteria in the class map must be matched.

• (Optional) Use the **match-any** keyword to perform a logical-OR of all matching statements under this class map. One or more match criteria must be matched.

• For **class-map-name**, specify the name of the class map.

If neither the **match-all** or **match-any** keyword is specified, the default is **match-all**.

Because only one **match** command per class map is supported, the **match-all** and **match-any** keywords function the same.

**Step 8**
**match input-interface interface-id-list**
**Example:**
Device(config-cmap)# **match input-interface gigabitethernet 3/0/1-3/0/2**

Specifies the physical ports on which the interface-level class map acts. You can specify up to six ports as follows:

• A single port (counts as one entry)

• A list of ports separated by a space (each port counts as an entry)
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• A range of ports separated by a hyphen (counts as two entries)</td>
<td>This command can only be used in the child-level policy map and must be the only match condition in the child-level policy map.</td>
</tr>
</tbody>
</table>

**Step 9**

exit

Example:

Device(config-cmap)# exit

Returns to class-map configuration mode.

**Step 10**

exit

Example:

Device(config)# exit

Returns to global configuration mode.

**Step 11**

policy-map policy-map-name

Example:

Device(config)# policy-map port-plcmap

Creates an interface-level policy map by entering the policy-map name, and enters policy-map configuration mode.

By default, no policy maps are defined, and no policing is performed.

To delete an existing policy map, use the `no policy-map policy-map-name` global configuration command. To delete an existing class map, use the `no class class-map-name` policy-map configuration command.

To return to the untrusted state in a policy map, use the `no trust` policy-map configuration command. To remove an assigned DSCP or IP precedence value, use the `no set {dscp new-dscp | ip precedence new-precedence}` policy-map configuration command.

**Step 12**

class-map class-map-name

Example:

Device(config-pmap)# class cm-interface-1

Defines an interface-level traffic classification, and enters policy-map configuration mode.

By default, no policy-map class-maps are defined.

If a traffic class has already been defined by using the `class-map` global configuration command, specify its name for `class-map-name` in this command.

**Step 13**

police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}]}

Example:

Device(config-pmap-c)# police 900000 9000 exceed-action

Defines an individual policer for the classified traffic.

By default, no policer is defined.

• For `rate-bps`, specify average traffic rate in bits per second (b/s). The range is 8000 to 1000000000.

---

**Classification, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps**

Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)
### Classifying, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>policed-dscp-transmit</td>
<td>• For burst-byte, specify the normal burst size in bytes. The range is 8000 to 1000000.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Specifies the action to take when the rates are exceeded. Use the exceed-action drop keywords to drop the packet. Use the exceed-action policed-dscp-transmit keywords to mark down the DSCP value (by using the policed-DSCP map) and to send the packet.</td>
</tr>
</tbody>
</table>

To remove an existing policer in an interface-level policy map, use the no police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}] policy-map configuration command. To remove the hierarchical policy map and port associations, use the no service-policy input policy-map-name interface configuration command.

**Step 14**

**exit**

**Example:**

Device(config-pmap-c)# exit

**Step 15**

**exit**

**Example:**

Device(config-pmap)# exit

**Step 16**

**policy-map** policy-map-name

**Example:**

Device(config)# policy-map 

vlan-plcmap

Creates a VLAN-level policy map by entering the policy-map name, and enters policy-map configuration mode.

By default, no policy maps are defined.

The default behavior of a policy map is to set the DSCP to 0 if the packet is an IP packet and to set the CoS to 0 if the packet is tagged. No policing is performed.

**Step 17**

**class** [class-map-name | class-default]

**Example:**

Device(config-pmap)# class cm-1

Defines a VLAN-level traffic classification, and enters policy-map class configuration mode.

By default, no policy-map class-maps are defined.

If a traffic class has already been defined by using the class-map global configuration command, specify its name for class-map-name in this command.

A class-default traffic class is pre-defined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any included in the class-default class, all packets that have not already matched the other traffic classes will match class-default.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 18** | **trust** [cos | dscp | ip-precedence]  
  Example:  
  Device(config-pmap-c) # trust dscp | Configures the trust state, which QoS uses to generate a CoS-based or DSCP-based QoS label.  
  This command is mutually exclusive with the **set** command within the same policy map. If you enter the **trust** command, omit Step 18.  
  By default, the port is not trusted. If no keyword is specified when the command is entered, the default is **dscp**.  
  The keywords have these meanings:  
  - **cos**—QoS derives the DSCP value by using the received or default port CoS value and the CoS-to-DSCP map.  
  - **dscp**—QoS derives the DSCP value by using the DSCP value from the ingress packet. For non-IP packets that are tagged, QoS derives the DSCP value by using the received CoS value; for non-IP packets that are untagged, QoS derives the DSCP value by using the default port CoS value. In either case, the DSCP value is derived from the CoS-to-DSCP map.  
  - **ip-precedence**—QoS derives the DSCP value by using the IP precedence value from the ingress packet and the IP-precedence-to-DSCP map. For non-IP packets that are tagged, QoS derives the DSCP value by using the received CoS value; for non-IP packets that are untagged, QoS derives the DSCP value by using the default port CoS value. In either case, the DSCP value is derived from the CoS-to-DSCP map. |
| **Step 19** | **set** {dscp new-dscp | ip precedence new-precedence}  
  Example:  
  Device(config-pmap-c) # set dscp 10 | Classifies IP traffic by setting a new value in the packet.  
  - For **dscp** new-dscp, enter a new DSCP value to be assigned to the classified traffic. The range is 0 to 63.  
  - For **ip precedence** new-precedence, enter a new IP-precedence value to be assigned to the classified traffic. The range is 0 to 7. |
| **Step 20** | **service-policy** policy-map-name  
  Example:  
  Device(config-pmap-c) # service-policy port-plcmap-1 | Specifies the interface-level policy-map name (from Step 10) and associate it with the VLAN-level policy map.  
  If the VLAN-level policy map specifies more than one class, each class can have a different **service-policy** policy-map-name command. |
| **Step 21** | **exit**  
  Example: | Returns to policy-map configuration mode. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-pmap-c)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 22**

**Example:**

Device(config-pmap-c)# exit

**Step 23**

**Example:**

Device(config)# interface vlan 10

**Step 24**

**Example:**

Device(config-if)# service-policy input vlan-plcmap

**Note**

To remove the hierarchical policy map and port associations, use the **no service-policy input policy-map-name** interface configuration command.

**Step 25**

**Example:**

Device(config-if)# end

**Step 26**

**Example:**

Device# show mls qos vlan-based

**Step 27**

**Example:**

Device# copy-running-config startup-config

(Optional) Saves your entries in the configuration file.
Classifying, Policing, and Marking Traffic by Using Aggregate Policers

By using an aggregate policer, you can create a policer that is shared by multiple traffic classes within the same policy map. However, you cannot use the aggregate policer across different policy maps or ports. You can configure aggregate policers only in nonhierarchical policy maps on physical ports.

**SUMMARY STEPS**

1. configure terminal
2. mls qos aggregate-policer aggregate-policer-name rate-bps burst-byte exceed-action {drop | policed-dscp-transmit}
3. class-map [match-all | match-any] class-map-name
4. policy-map policy-map-name
5. class [class-map-name | class-default]
6. police aggregate aggregate-policer-name
7. exit
8. interface interface-id
9. service-policy input policy-map-name
10. end
11. show mls qos aggregate-policer [aggregate-policer-name]
12. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> mls qos aggregate-policer aggregate-policer-name rate-bps burst-byte exceed-action {drop</td>
<td>policed-dscp-transmit}</td>
</tr>
<tr>
<td>Example: Device(config)# mls qos aggregate-police transmitt1 48000 8000 exceed-action policed-dscp-transmit</td>
<td>• For aggregate-policer-name, specify the name of the aggregate policer. • For rate-bps, specify average traffic rate in bits per second (b/s). The range is 8000 to 1000000000. • For burst-byte, specify the normal burst size in bytes. The range is 8000 to 1000000. • Specifies the action to take when the rates are exceeded. Use the exceed-action drop keywords to drop the packet. Use the exceed-action policed-dscp-transmit keywords to mark down the DSCP value (by using the policed-DSCP map) and to send the packet.</td>
</tr>
<tr>
<td>Step 3</td>
<td>**class-map [match-all</td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>

<td>Device(config)# class-map ipclass1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 4</th>
<th><strong>policy-map policy-map-name</strong></th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-cmap)# policy-map aggflow1</td>
<td>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</td>
</tr>
</tbody>
</table>

| Step 5 | **class [class-name | class-default]**  | Purpose |
|--------|-------------------------------------------------|---------|
| Example: | Device(config-cmap-p)# class ipclass1 | Defines a traffic classification, and enters policy-map class configuration mode. |

<table>
<thead>
<tr>
<th>Step 6</th>
<th><strong>police aggregate aggregate-policer-name</strong></th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Example: | Device(configure-cmap-p)# police aggregate transmit1 | Applies an aggregate policer to multiple classes in the same policy map. 
For aggregate-policer-name, enter the name specified in Step 2. 
To remove the specified aggregate policer from a policy map, use the no police aggregate aggregate-policer-name policy map configuration command. 
To delete an aggregate policer and its parameters, use the no mls qos aggregate-policer aggregate-policer-name global configuration command. |

<table>
<thead>
<tr>
<th>Step 7</th>
<th><strong>exit</strong></th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(configure-cmap-p)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 8</th>
<th><strong>interface interface-id</strong></th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Example: | Device(config)# interface gigabitethernet 2/0/1 | Specifies the port to attach to the policy map, and enters interface configuration mode. 
Valid interfaces include physical ports. |

<table>
<thead>
<tr>
<th>Step 9</th>
<th><strong>service-policy input policy-map-name</strong></th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Example: | Device(config-if)# service-policy input aggflow1 | Specifies the policy-map name, and applies it to an ingress port. 
Only one policy map per ingress port is supported. |
### Configuring DSCP Maps

#### Configuring the CoS-to-DSCP Map

You use the CoS-to-DSCP map to map CoS values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic.

Beginning in privileged EXEC mode, follow these steps to modify the CoS-to-DSCP map. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. mls qos map cos-dscp dscp1...dscp8
3. end
4. show mls qos maps cos-dscp
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device(configure-if)# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> mls qos map cos-dscp dscp1...dscp8</td>
<td>Modifies the CoS-to-DSCP map.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring the IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic.

Beginning in privileged EXEC mode, follow these steps to modify the IP-precedence-to-DSCP map. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. mls qos map ip-prec-dscp dscp1...dscp8
3. end
4. show mls qos maps ip-prec-dscp
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>mls qos map ip-prec-dscp dscp1...dscp8</td>
<td>For dscp1...dscp8, enter eight DSCP values that correspond to CoS values 0 to 7. Separate each DSCP value with a space. The DSCP range is 0 to 63.</td>
</tr>
<tr>
<td>end</td>
<td>To return to the default map, use the no mls qos cos-dscp global configuration command.</td>
</tr>
<tr>
<td>show mls qos maps cos-dscp</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
### Configuring the Policed-DSCP Map

You use the policed-DSCP map to mark down a DSCP value to a new value as the result of a policing and marking action.

The default policed-DSCP map is a null map, which maps an incoming DSCP value to the same DSCP value. Beginning in privileged EXEC mode, follow these steps to modify the policed-DSCP map. This procedure is optional.

#### SUMMARY STEPS

1. `configure terminal`
2. `mls qos map policed-dscp dscp-list to mark-down-dscp`
3. `end`
4. `show mls qos maps policed-dscp`
5. `copy running-config startup-config`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code>&lt;br&gt;<strong>Example:</strong> &lt;br&gt;Device# <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
| Step 2 | `mls qos map policed-dscp dscp-list to mark-down-dscp`<br>**Example:** <br>Device(config)# `mls qos map policed-dscp 50 51 52 53 54 55 56 57 to 0` | Modifies the policed-DSCP map.  
  - For `dscp-list`, enter up to eight DSCP values separated by spaces. Then enter the `to` keyword.  
  - For `mark-down-dscp`, enter the corresponding policed (marked down) DSCP value.  
  **Note** To return to the default map, use the `no mls qos policed-dscp` global configuration command. |
| Step 3 | `end`<br>**Example:**<br>Device(config)# `end` | Returns to privileged EXEC mode. |
| Step 4 | `show mls qos maps policed-dscp`<br>**Example:** <br>Device(config)# `show mls qos maps policed-dscp` | Verifies your entries. |
| Step 5 | `copy running-config startup-config`<br>**Example:** <br>Device# | (Optional) Saves your entries in the configuration file. |

### Configuring the DSCP-to-CoS Map

You use the DSCP-to-CoS map to generate a CoS value, which is used to select one of the four egress queues. Beginning in privileged EXEC mode, follow these steps to modify the DSCP-to-CoS map. This procedure is optional.

### SUMMARY STEPS

1. `configure terminal`  
2. `mls qos map dscp-cos dscp-list to cos`  
3. `end`
4. `show mls qos maps dscp-to-cos`
5. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

**Configuring the DSCP-to-DSCP-Mutation Map**

If two QoS domains have different DSCP definitions, use the DSCP-to-DSCP-mutation map to translate one set of DSCP values to match the definition of another domain. You apply the DSCP-to-DSCP-mutation map to the receiving port (ingress mutation) at the boundary of a QoS administrative domain.
With ingress mutation, the new DSCP value overwrites the one in the packet, and QoS applies the new value to the packet. The sends the packet out the port with the new DSCP value. You can configure multiple DSCP-to-DSCP-mutation maps on an ingress port. The default DSCP-to-DSCP-mutation map is a null map, which maps an incoming DSCP value to the same DSCP value. Beginning in privileged EXEC mode, follow these steps to modify the DSCP-to-DSCP-mutation map. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. mls qos map dscp-mutation dscp-mutation-name in-dscp to out-dscp
3. interface interface-id
4. mls qos trust dscp
5. mls qos dscp-mutation dscp-mutation-name
6. end
7. show mls qos maps dscp-mutation
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> mls qos map dscp-mutation dscp-mutation-name in-dscp to out-dscp</td>
<td>Modifies the DSCP-to-DSCP-mutation map.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mls qos map dscp-mutation mutation1 1 2 3 4 5 6 7 to 0</td>
<td>• For dscp-mutation-name, enter the mutation map name. You can create more than one map by specifying a new name. • For in-dscp, enter up to eight DSCP values separated by spaces. Then enter the to keyword. • For out-dscp, enter a single DSCP value. The DSCP range is 0 to 63.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To return to the default map, use the no mls qos dscp-mutation dscp-mutation-name global configuration command.</td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the port to which to attach the map, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Valid interfaces include physical ports.</td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet1/0/1</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Ingress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you might need to perform all of the tasks in the next modules. You need to make decisions about these characteristics:

- Which packets are assigned (by DSCP or CoS value) to each queue?
- What drop percentage thresholds apply to each queue, and which CoS or DSCP values map to each threshold?
- How much of the available buffer space is allocated between the queues?
- How much of the available bandwidth is allocated between the queues?
- Is there traffic (such as voice) that should be given high priority?

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configures the ingress port as a DSCP-trusted port. By default, the port is not trusted.</td>
<td>mls qos trust dscp</td>
</tr>
<tr>
<td>Applies the map to the specified ingress DSCP-trusted port. For <code>dscp-mutation-name</code>, enter the mutation map name specified in Step 2.</td>
<td>mls qos dscp-mutation <code>dscp-mutation-name</code></td>
</tr>
<tr>
<td>Returns to privileged EXEC mode.</td>
<td><code>end</code></td>
</tr>
<tr>
<td>Verifies your entries.</td>
<td><code>show mls qos maps dscp-mutation</code></td>
</tr>
<tr>
<td>(Optional) Saves your entries in the configuration file.</td>
<td><code>copy running-config startup-config</code></td>
</tr>
</tbody>
</table>
Configuration Guidelines

Follow these guidelines when the expedite queue is enabled or the egress queues are serviced based on their SRR weights:

- If the egress expedite queue is enabled, it overrides the SRR shaped and shared weights for queue 1.
- If the egress expedite queue is disabled and the SRR shaped and shared weights are configured, the shaped mode overrides the shared mode for queue 1, and SRR services this queue in shaped mode.
- If the egress expedite queue is disabled and the SRR shaped weights are not configured, SRR services this queue in shared mode.

Mapping DSCP or CoS Values to an Ingress Queue and Setting WTD Thresholds

You can prioritize traffic by placing packets with particular DSCPs or CoSs into certain queues and adjusting the queue thresholds so that packets with lower priorities are dropped.

Beginning in privileged EXEC mode, follow these steps to map DSCP or CoS values to an ingress queue and to set WTD thresholds. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. Use one of the following:
   - `mls qos srr-queue input dscp-map queue queue-id threshold threshold-id dscp1...dscp8`
   - `mls qos srr-queue input cos-map queue queue-id threshold threshold-id cos1...cos8`
3. `mls qos srr-queue input threshold queue-id threshold-percentage1 threshold-percentage2`
4. `end`
5. `show mls qos maps`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Maps DSCP or CoS values to an ingress queue and to a threshold ID.</td>
</tr>
<tr>
<td>Use one of the following:</td>
<td>By default, DSCP values 0–39 and 48–63 are mapped to queue 1 and threshold 1. DSCP values 40–47 are mapped to queue 2 and threshold 1. By default, CoS values 0–4, 6, and 7 are mapped to queue 1 and threshold 1. CoS value 5 is mapped to queue 2 and threshold 1.</td>
</tr>
<tr>
<td><code>mls qos srr-queue input dscp-map queue queue-id threshold threshold-id dscp1...dscp8</code></td>
<td></td>
</tr>
<tr>
<td><code>mls qos srr-queue input cos-map queue queue-id threshold threshold-id cos1...cos8</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# mls qos srr-queue input</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>dscp-map queue 1 threshold 2 20 21 22 23 24 25 26</td>
</tr>
<tr>
<td>mls qos srr-queue input threshold queue-id threshold-percentage1 threshold-percentage2</td>
</tr>
<tr>
<td>end</td>
</tr>
<tr>
<td>show mls qos maps</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

### Purpose

- For `queue-id`, the range is 1 to 2.
- For `threshold-id`, the range is 1 to 3. The drop-threshold percentage for threshold 3 is predefined. It is set to the queue-full state.
- For `dscp1...dscp8`, enter up to eight values, and separate each value with a space. The range is 0 to 63.
- For `cos1...cos8`, enter up to eight values, and separate each value with a space. The range is 0 to 7.
- Assigns the two WTD threshold percentages for (threshold 1 and 2) to an ingress queue. The default, both thresholds are set to 100 percent.
- For `queue-id`, the range is 1 to 2.
- For `threshold-percentage1 threshold-percentage2`, the range is 1 to 100. Separate each value with a space.
- Returns to privileged EXEC mode.
- Verifies your entries.
- The DSCP input queue threshold map appears as a matrix. The d1 column specifies the most-significant digit of the DSCP number; the d2 row specifies the least-significant digit in the DSCP number. The intersection of the d1 and the d2 values provides the queue ID and threshold ID; for example, queue 2 and threshold 1 (02-01).
- The CoS input queue threshold map shows the CoS value in the top row and the corresponding queue ID and threshold ID in the second row; for example, queue 2 and threshold 2 (2-2).

### Step 3

Assigns the two WTD threshold percentages for (threshold 1 and 2) to an ingress queue. The default, both thresholds are set to 100 percent.

**Example:**

```
Device(config)# mls qos srr-queue input threshold 1 50 70
```

### Step 4

**Example:**

```
Device(config)# end
```

### Step 5

Verifies your entries.

**Example:**

```
Device# show mls qos maps
```

### Step 6

(Optional) Saves your entries in the configuration file.

**Example:**

```
Device# copy running-config startup-config
```

To return to the default CoS input queue threshold map or the default DSCP input queue threshold map, use the `no mls qos srr-queue input cos-map` or the `no mls qos srr-queue input dscp-map` global configuration command. To return to the default WTD threshold percentages, use the `no mls qos srr-queue input threshold queue-id` global configuration command.
Allocating Buffer Space Between the Ingress Queues

You define the ratio (allocate the amount of space) with which to divide the ingress buffers between the two queues. The buffer and the bandwidth allocation control how much data can be buffered before packets are dropped.

Beginning in privileged EXEC mode, follow these steps to allocate the buffers between the ingress queues. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. mls qos srr-queue input buffers percentage1 percentage2
3. end
4. Use one of the following:
   - show mls qos interface buffer
   - show mls qos input-queue
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** | Allocates the buffers between the ingress queues |
| mls qos srr-queue input buffers percentage1 percentage2 | By default 90 percent of the buffers are allocated to queue 1, and 10 percent of the buffers are allocated to queue 2. |
| Example: | For percentage1 percentage2, the range is 0 to 100. Separate each value with a space. |
| Device(config)# mls qos srr-queue input buffers 60 40 | You should allocate the buffers so that the queues can handle any incoming bursty traffic. |

| **Step 3** | Returns to privileged EXEC mode. |
| end | |
| Example: | |
| Device(config)# end | |

| **Step 4** | Verifies your entries. |
| Use one of the following: | |
| - show mls qos interface buffer | |
| - show mls qos input-queue | |
| Example: | |
Purpose

Command or Action

Device# show mls qos interface buffer
or
Device# show mls qos input-queue

(Optional) Saves your entries in the configuration file.

Step 5

Example:

Device# copy-running-config startup-config

To return to the default setting, use the no mls qos srr-queue input buffers global configuration command.

Allocating Bandwidth Between the Ingress Queues

You need to specify how much of the available bandwidth is allocated between the ingress queues. The ratio of the weights is the ratio of the frequency in which the SRR scheduler sends packets from each queue. The bandwidth and the buffer allocation control how much data can be buffered before packets are dropped. On ingress queues, SRR operates only in shared mode.

Note

SRR bandwidth limit works in both mls qos enabled and disabled states.

Beginning in privileged EXEC mode, follow these steps to allocate bandwidth between the ingress queues. This procedure is optional.

SUMMARY STEPS

1. configure terminal
2. mls qos srr-queue input bandwidth weight1 weight2
3. end
4. Use one of the following:
   • show mls qos interface queueing
   • show mls qos input-queue
5. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 mls qos srr-queue input bandwidth weight1 weight2</td>
<td>Assigns shared round robin weights to the ingress queues.</td>
</tr>
</tbody>
</table>
**Command or Action**

**Example:**

Device(config)# mls qos srr-queue input bandwidth 25 75

**Purpose**

The default setting for weight1 and weight2 is 4 (1/2 of the bandwidth is equally shared between the two queues).

For weight1 and weight2, the range is 1 to 100. Separate each value with a space.

SRR services the priority queue for its configured weight as specified by the bandwidth keyword in the mls qos srr-queue input priority-queue queue-id bandwidth weight global configuration command. Then, SRR shares the remaining bandwidth with both ingress queues and services them as specified by the weights configured with the mls qos srr-queue input bandwidth weight1 weight2 global configuration command.

**Step 3**

**end**

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 4**

Use one of the following:

- show mls qos interface queueing
- show mls qos input-queue

**Example:**

Device# show mls qos interface queueing

or

Device# show mls qos input-queue

Verifies your entries.

**Step 5**

**copy running-config startup-config**

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

To return to the default setting, use the **no mls qos srr-queue input bandwidth weight1 weight2** global configuration command.

---

**Configuring Egress Queue Characteristics**

Depending on the complexity of your network and your QoS solution, you might need to perform all of the tasks in the following modules. You need to make decisions about these characteristics:

- Which packets are mapped by DSCP or CoS value to each queue and threshold ID?
- What drop percentage thresholds apply to the queue-set (four egress queues per port), and how much reserved and maximum memory is needed for the traffic type?
- How much of the fixed buffer space is allocated to the queue-set?
• Does the bandwidth of the port need to be rate limited?
• How often should the egress queues be serviced and which technique (shaped, shared, or both) should be used?

Configuration Guidelines

Follow these guidelines when the expedite queue is enabled or the egress queues are serviced based on their SRR weights:

• If the egress expedite queue is enabled, it overrides the SRR shaped and shared weights for queue 1.
• If the egress expedite queue is disabled and the SRR shaped and shared weights are configured, the shaped mode overrides the shared mode for queue 1, and SRR services this queue in shaped mode.
• If the egress expedite queue is disabled and the SRR shaped weights are not configured, SRR services this queue in shared mode.

Allocating Buffer Space to and Setting WTD Thresholds for an Egress Queue Set

You can guarantee the availability of buffers, set WTD thresholds, and configure the maximum allocation for a queue set by using the `mls qos queue-set output qset-id threshold queue-id drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold` global configuration command.

Each threshold value is a percentage of the queue’s allocated buffers, which you specify by using the `mls qos queue-set output qset-id buffers allocation1 ... allocation4` global configuration command. The queues use WTD to support distinct drop percentages for different traffic classes.

Note

The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to configure the memory allocation and to drop thresholds for a queue set. This procedure is optional.

SUMMARY STEPS

1. `configure terminal`
2. `mls qos srr-queue output queues 8`
3. `mls qos queue-set output qset-id buffers allocation1 ... allocation8`
4. `mls qos queue-set output qset-id threshold queue-id drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold`
5. `interface interface-id`
6. `queue-set qset-id`
7. `end`
8. `show mls qos interface [interface-id] buffers`
9. `copy running-config startup-config`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> mls qos srr-queue output queues 8</td>
<td>(Optional) The switch supports 4 egress queues by default, although you can enable a total of 8 egress queues. Use the optional <code>mls qos srr-queue output queues 8</code> command to enable the additional 4 egress queues.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mls qos srr-queue output queues 8</td>
<td>Once 8 queue support is enabled, you can then proceed to configure the additional 4 queues. Any existing egress queue configuration commands are then modified to support the additional queue parameters.</td>
</tr>
<tr>
<td><strong>Step 3</strong> mls qos queue-set output qset-id buffers allocation1 ... allocation8</td>
<td>Allocates buffers to a queue set.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mls qos queue-set output 2 buffers 40 20 20 20 10 10 10 10</td>
<td>By default, all allocation values are equally mapped among the four queues (25, 25, 25, 25). Each queue has 1/4 of the buffer space. When eight egress queues are configured, then by default 30 percent of the total buffer space is allocated to queue 2 and 10 percent (each) to queues 1,3,4,5,6,7, and 8. If you enabled 8 egress queues as described in Step 2 above, then the following applies:</td>
</tr>
<tr>
<td></td>
<td>• For <code>qset-id</code>, enter the ID of the queue set. The range is 1 to 2. Each port belongs to a queue set, which defines all the characteristics of the four egress queues per port.</td>
</tr>
<tr>
<td></td>
<td>• For <code>allocation1</code> ... <code>allocation8</code>, specify eight percentages, one for each queue in the queue set. For <code>allocation1</code>, <code>allocation3</code>, and <code>allocation4</code> to <code>allocation8</code>, the range is 0 to 99. For <code>allocation2</code>, the range is 1 to 100 (including the CPU buffer).</td>
</tr>
<tr>
<td></td>
<td>Allocate buffers according to the importance of the traffic; for example, give a large percentage of the buffer to the queue with the highest-priority traffic.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> To return to the default setting, use the <code>no mls qos queue-set output qset-id buffers</code> global configuration command.</td>
</tr>
</tbody>
</table>
### Allocating Buffer Space to and Setting WTD Thresholds for an Egress Queue Set

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
|        | mls qos queue-set output qset-id threshold queue-id drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold | Configures the WTD thresholds, guarantees the availability of buffers, and configures the maximum memory allocation for the queue set (four egress queues per port). By default, the WTD thresholds for queues 1, 3, and 4 are set to 100 percent. The thresholds for queue 2 are set to 200 percent. The reserved thresholds for queues 1, 2, 3, and 4 are set to 50 percent. The maximum thresholds for all queues are set to 400 percent by default. If you enabled 8 egress queues as described in Step 2 above, then the following applies:  
- For *qset-id*, enter the ID of the queue set specified in Step 3. The range is 1 to 2.  
- For *queue-id*, enter the specific queue in the queue set on which the command is performed. The queue-id range is 1-4 by default and 1-8 when 8 queues are enabled.  
- For *drop-threshold1* *drop-threshold2*, specify the two WTD thresholds expressed as a percentage of the queue’s allocated memory. The range is 1 to 3200 percent.  
- For *reserved-threshold*, enter the amount of memory to be guaranteed (reserved) for the queue expressed as a percentage of the allocated memory. The range is 1 to 100 percent.  
- For *maximum-threshold*, enable a queue in the full condition to obtain more buffers than are reserved for it. This is the maximum memory the queue can have before the packets are dropped if the common pool is not empty. The range is 1 to 3200 percent. |

**Example:**
Device(config)# mls qos queue-set output 2 threshold 2 40 60 80 200

### Step 5

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>interface interface-id</td>
<td>Specifies the port of the outbound traffic, and enters interface configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**
Device(config)# interface gigabitethernet1/0/1

### Step 6

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| queue-set qset-id | Maps the port to a queue set.  
For *qset-id*, enter the ID of the queue set specified in Step 2. The range is 1 to 2. The default is 1. |

**Example:**

---

**Note:** To return to the default WTD threshold percentages, use the `no mls qos queue-set output qset-id threshold [queue-id]` global configuration command.
Mapping DSCP or CoS Values to an Egress Queue and to a Threshold ID

You can prioritize traffic by placing packets with particular DSCPs or costs of service into certain queues and adjusting the queue thresholds so that packets with lower priorities are dropped.

### Note

The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to map DSCP or CoS values to an egress queue and to a threshold ID. This procedure is optional.

### SUMMARY STEPS

1. configure terminal
2. Use one of the following:
   - `mls qos srr-queue output dscp-map queue queue-id threshold threshold-id dscp1...dscp8`
   - `mls qos srr-queue output cos-map queue queue-id threshold threshold-id cos1...cos8`
3. `mls qos srr-queue output cos-map queue queue-id threshold threshold-id cos1...cos8`
4. end
5. show mls qos maps
6. copy running-config startup-config
## DETAILED STEPS

<table>
<thead>

<tr>
<td>• mls qos srr-queue output dscp-map queue queue-id threshold threshold-id dscp1...dscp8</td>
<td>By default, DSCP values 0–15 are mapped to queue 2 and threshold 1. DSCP values 16–31 are mapped to queue 3 and threshold 1. DSCP values 32–39 and 48–63 are mapped to queue 4 and threshold 1. DSCP values 40–47 are mapped to queue 1 and threshold 1.</td>
</tr>
<tr>
<td>• mls qos srr-queue output cos-map queue queue-id threshold threshold-id cos1...cos8</td>
<td>By default, CoS values 0 and 1 are mapped to queue 2 and threshold 1. CoS values 2 and 3 are mapped to queue 3 and threshold 1. CoS values 4, 6, and 7 are mapped to queue 4 and threshold 1. CoS value 5 is mapped to queue 1 and threshold 1.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mls qos srr-queue output dscp-map queue 1 threshold 2 10 11</td>
<td>- For queue-id, the range is 1 to 4.</td>
</tr>
<tr>
<td></td>
<td>- For threshold-id, the range is 1 to 3. The drop-threshold percentage for threshold 3 is predefined. It is set to the queue-full state.</td>
</tr>
<tr>
<td></td>
<td>- For dscp1...dscp8, enter up to eight values, and separate each value with a space. The range is 0 to 63.</td>
</tr>
<tr>
<td></td>
<td>- For cos1...cos8, enter up to eight values, and separate each value with a space. The range is 0 to 7.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td>mls qos srr-queue output cos-map queue queue-id threshold threshold-id cos1...cos8</td>
<td>Maps CoS values to an egress queue and to a threshold ID.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mls qos srr-queue output cos-map queue 3 threshold 1 2 3</td>
<td>- For queue-id, the range is 1 to 4.</td>
</tr>
<tr>
<td></td>
<td>- For threshold-id, the range is 1 to 3. The drop-threshold percentage for threshold 3 is predefined. It is set to the queue-full state.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>- For cos1...cos8, enter up to eight values, and separate each value with a space. The range is 0 to 7.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To return to the default CoS output queue threshold map, use the <code>no mls qos srr-queue output cos-map</code> global configuration command.</td>
</tr>
</tbody>
</table>

#### Step 4

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

#### Step 5

**Example:**

```
Device# show mls qos maps
```

Verifies your entries.

- The DSCP output queue threshold map appears as a matrix. The d1 column specifies the most-significant digit of the DSCP number; the d2 row specifies the least-significant digit in the DSCP number. The intersection of the d1 and the d2 values provides the queue ID and threshold ID; for example, queue 2 and threshold 1 (02-01).
- The CoS output queue threshold map shows the CoS value in the top row and the corresponding queue ID and threshold ID in the second row; for example, queue 2 and threshold 2 (2-2).

#### Step 6

**Example:**

```
Device# copy-running-config startup-config
```

(Optional) Saves your entries in the configuration file.

To return to the default DSCP output queue threshold map or the default CoS output queue threshold map, use the `no mls qos srr-queue output dscp-map` or the `no mls qos srr-queue output cos-map` global configuration command.

---

### Configuring SRR Shaped Weights on Egress Queues

You can specify how much of the available bandwidth is allocated to each queue. The ratio of the weights is the ratio of frequency in which the SRR scheduler sends packets from each queue.

You can configure the egress queues for shaped or shared weights, or both. Use shaping to smooth bursty traffic or to provide a smoother output over time.

Beginning in privileged EXEC mode, follow these steps to assign the shaped weights and to enable bandwidth shaping on the four egress queues mapped to a port. This procedure is optional.

#### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `srr-queue bandwidth shape weight1 weight2 weight3 weight4`
4. `end`

---
5. `show mls qos interface interface-id queueing`
6. `copy running-config startup-config`

## DETAILED STEPS

<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring SRR Shared Weights on Egress Queues

In shared mode, the queues share the bandwidth among them according to the configured weights. The bandwidth is guaranteed at this level but not limited to it. For example, if a queue empties and does not require a share of the link, the remaining queues can expand into the unused bandwidth and share it among them. With sharing, the ratio of the weights controls the frequency of dequeuing; the absolute values are meaningless.

#### Note

The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to assign the shared weights and to enable bandwidth sharing on the four egress queues mapped to a port. This procedure is optional.

#### SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. srr-queue bandwidth share weight1 weight2 weight3 weight4
4. end
5. show mls qos interface interface-id queuing
6. copy running-config startup-config

<tr>
<td>Device# copy running-config startup-config</td>
<td>To disable the egress expedite queue, use the no priority-queue out interface configuration command.</td>
</tr>
</tbody>
</table>

### Summary of Steps

**Limiting the Bandwidth on an Egress Interface**

You can limit the bandwidth on an egress port. For example, if a customer pays only for a small percentage of a high-speed link, you can limit the bandwidth to that amount.

**Note**

The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to limit the bandwidth on an egress port. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. srr-queue bandwidth limit weight1
4. end
5. show mls qos interface [interface-id] queueing
6. copy running-config startup-config

</tbody>
</table>

| **Step 2** | Specifies the port to be rate-limited, and enters interface configuration mode. |
| interface interface-id |         |
| Example: |         |
| Device(config)# interface gigabitethernet2/0/1 |         |

| **Step 3** | Specifies the percentage of the port speed to which the port should be limited. The range is 10 to 90. By default, the port is not rate-limited and is set to 100 percent. |
| srr-queue bandwidth limit weight1 |         |
| Example: |         |
| Device(config-if)# srr-queue |         |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bandwidth limit 80</code></td>
<td>Note: To return to the default setting, use the <code>no srr-queue bandwidth limit</code> interface configuration command.</td>
</tr>
</tbody>
</table>

### Step 4

**Example:**

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

### Step 5

**Example:**

```
Device# show mls qos interface [interface-id] queueing
```

Verifies your entries.

### Step 6

**Example:**

```
Device# copy-running-config startup-config
```

(Optional) Saves your entries in the configuration file. To return to the default setting, use the `no srr-queue bandwidth limit` interface configuration command.

---

## Monitoring Standard QoS

### Table 87: Commands for Monitoring Standard QoS on the Switch

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show class-map [class-map-name]</code></td>
<td>Displays QoS class maps, which define the match criteria to classify traffic.</td>
</tr>
<tr>
<td><code>show mls qos</code></td>
<td>Displays global QoS configuration information.</td>
</tr>
<tr>
<td><code>show mls qos aggregate-policer [aggregate-policer-name]</code></td>
<td>Displays the aggregate policer configuration.</td>
</tr>
<tr>
<td>`show mls qos interface [interface-id] [buffers</td>
<td>policers</td>
</tr>
<tr>
<td><code>show mls qos queue-set [qset-id]</code></td>
<td>Displays QoS settings for the egress queues.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>show mls qos vlan vlan-id</td>
<td>Displays the policy maps attached to the specified SVI.</td>
</tr>
<tr>
<td>show policy-map [policy-map-name [class class-map-name]]</td>
<td>Displays QoS policy maps, which define classification criteria for incoming traffic. Do not use the <code>show policy-map interface</code> privileged EXEC command to display classification information for incoming traffic. The <code>control-plane</code> and <code>interface</code> keywords are not supported, and the statistics shown in the display should be ignored.</td>
</tr>
<tr>
<td>show running-config</td>
<td>Displays the DSCP transparency setting.</td>
</tr>
</tbody>
</table>

**Configuration Examples for QoS**

**Example: Configuring Port to the DSCP- Trusted State and Modifying the DSCP-to-DSCP-Mutation Map**

This example shows how to configure a port to the DSCP-trusted state and to modify the DSCP-to-DSCP-mutation map (named `gi1/0/2-mutation`) so that incoming DSCP values 10 to 13 are mapped to DSCP 30:

```
Device(config)# mls qos map dscp-mutation gigabitethernet1/0/2-mutation 10 11 12 13 to 30
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# mls qos trust dscp
Device(config-if)# mls qos dscp-mutation gigabitethernet1/0/2-mutation
Device(config-if)# end
```

**Examples: Classifying Traffic by Using ACLs**

This example shows how to allow access for only those hosts on the three specified networks. The wildcard bits apply to the host portions of the network addresses. Any host with a source address that does not match the access list statements is rejected.

```
Device(config)# access-list 1 permit 192.5.255.0 0.0.0.255
Device(config)# access-list 1 permit 128.88.0.0 0.0.255.255
Device(config)# access-list 1 permit 36.0.0.0 0.0.0.255
  ! (Note: all other access implicitly denied)
```

This example shows how to create an ACL that permits IP traffic from any source to any destination that has the DSCP value set to 32:

```
Device(config)# access-list 100 permit ip any any dscp 32
```
This example shows how to create an ACL that permits IP traffic from a source host at 10.1.1.1 to a destination host at 10.1.1.2 with a precedence value of 5:

```
Device(config)# access-list 100 permit ip host 10.1.1.1 host 10.1.1.2 precedence 5
```

This example shows how to create an ACL that permits PIM traffic from any source to a destination group address of 224.0.0.2 with a DSCP set to 32:

```
Device(config)# access-list 102 permit pim any 224.0.0.2 dscp 32
```

This example shows how to create an ACL that permits IPv6 traffic from any source to any destination that has the DSCP value set to 32:

```
Device(config)# ipv6 access-list 100 permit ip any any dscp 32
```

This example shows how to create an ACL that permits IPv6 traffic from a source host at 10.1.1.1 to a destination host at 10.1.1.2 with a precedence value of 5:

```
Device(config)# ipv6 access-list ipv6_Name_ACL permit ip host 10::1 host 10.1.1.2 precedence 5
```

This example shows how to create a Layer 2 MAC ACL with two permit statements. The first statement allows traffic from the host with MAC address 0001.0000.0001 to the host with MAC address 0002.0000.0001. The second statement allows only Ethertype XNS-IDP traffic from the host with MAC address 0001.0000.0002 to the host with MAC address 0002.0000.0002.

```
Device(config)# mac access-list extended maclist1
Device(config-ext-macl)# permit 0001.0000.0001 0.0.0 0002.0000.0001 0.0.0
Device(config-ext-macl)# permit 0001.0000.0002 0.0.0 0002.0000.0002 0.0.0 xns-idp
! (Note: all other access implicitly denied)
```

### Examples: Classifying Traffic by Using Class Maps

This example shows how to configure the class map called `class1`. The `class1` has one match criterion, which is access list 103. It permits traffic from any host to any destination that matches a DSCP value of 10.

```
Device(config)# access-list 103 permit ip any any dscp 10
Device(config)# class-map class1
Device(config-cmap)# match access-group 103
Device(config-cmap)# end
Device#
```

This example shows how to create a class map called `class2`, which matches incoming traffic with DSCP values of 10, 11, and 12.

```
Device(config)# class-map class2
Device(config-cmap)# match ip dscp 10 11 12
Device(config-cmap)# end
Device#
```
This example shows how to create a class map called `class3`, which matches incoming traffic with IP-precedence values of 5, 6, and 7:

```
Device(config)# class-map class3
Device(config-cmap)# match ip precedence 5 6 7
Device(config-cmap)# end
Device#
```

This example shows how to configure a class map to match IP DSCP and IPv6:

```
Device(config)# Class-map cm-1
Device(config-cmap)# match ip dscp 10
Device(config-cmap)# match protocol ipv6
Device(config-cmap)# exit
Device(config)# Class-map cm-2
Device(config-cmap)# match ip dscp 20
Device(config-cmap)# match protocol ip
Device(config-cmap)# exit
Device(config)# Policy-map pm1
Device(config-pmap)# class cm-1
Device(config-pmap-c)# set dscp 4
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-2
Device(config-pmap-c)# set dscp 6
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface G1/0/1
Device(config-if)# service-policy input pm1
```

This example shows how to configure a class map that applies to both IPv4 and IPv6 traffic:

```
Device(config)# ip access-list 101 permit ip any any
Device(config)# ipv6 access-list ipv6-any permit ip any any
Device(config)# Class-map cm-1
Device(config-cmap)# match access-group 101
Device(config-cmap)# exit
Device(config)# class-map cm-2
Device(config-cmap)# match access-group name ipv6-any
Device(config-cmap)# exit
Device(config)# Policy-map pm1
Device(config-pmap)# class cm-1
Device(config-pmap-c)# set dscp 4
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-2
Device(config-pmap-c)# set dscp 6
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface G0/1
Device(config-if)# switch mode access
Device(config-if)# service-policy input pm1
```
Examples: Classifying, Policing, and Marking Traffic on Physical Ports Using Policy Maps

This example shows how to create a policy map and attach it to an ingress port. In the configuration, the IP standard ACL permits traffic from network 10.1.0.0. For traffic matching this classification, the DSCP value in the incoming packet is trusted. If the matched traffic exceeds an average traffic rate of 48000 b/s and a normal burst size of 8000 bytes, its DSCP is marked down (based on the policed-DSCP map) and sent:

Device(config)# access-list 1 permit 10.1.0.0 0.0.255.255
Device(config)# class-map ipclass1
Device(config-cmap)# match access-group 1
Device(config-cmap)# exit
Device(config)# policy-map flow1t
Device(config-pmap)# class ipclass1
Device(config-pmap-c)# trust dscp
Device(config-pmap-c)# police 1000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# service-policy input flow1t

This example shows how to create a Layer 2 MAC ACL with two permit statements and attach it to an ingress port. The first permit statement allows traffic from the host with MAC address 0001.0000.0001 destined for the host with MAC address 0002.0000.0001. The second permit statement allows only Ethertype XNS-IDP traffic from the host with MAC address 0001.0000.0002 destined for the host with MAC address 0002.0000.0002.

Device(config)# mac access-list extended maclist1
Device(config-ext-mac)# permit 0001.0000.0001 0.0.0 0002.0000.0001 0.0.0
Device(config-ext-mac)# permit 0001.0000.0002 0.0.0 0002.0000.0002 0.0.0 xns-idp
Device(config-ext-mac)# exit
Device(config)# mac access-list extended maclist2
Device(config-ext-mac)# permit 0001.0000.0003 0.0.0 0002.0000.0003 0.0.0
Device(config-ext-mac)# permit 0001.0000.0004 0.0.0 0002.0000.0004 0.0.0 aarp
Device(config-ext-mac)# exit
Device(config)# class-map macclass1
Device(config-cmap)# match access-group maclist1
Device(config-cmap)# exit
Device(config)# policy-map macpolicy1
Device(config-pmap)# class macclass1
Device(config-pmap-c)# set dscp 63
Device(config-pmap-c)# exit
Device(config)# class-map macclass2 maclist2
Device(config-pmap-c)# set dscp 45
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# mls qos trust cos
Device(config-if)# service-policy input macpolicy1

This example shows how to create a class map that applies to both IPv4 and IPv6 traffic with the default class applied to unclassified traffic:

Device(config)# ip access-list 101 permit ip any any
Device(config)# ipv6 access-list ipv6-any permit ip any any
Examples: Classifying, Policing, and Marking Traffic on SVIs by Using Hierarchical Policy Maps

This example shows how to create a hierarchical policy map:

Switch> enable
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# access-list 101 permit ip any any
Device(config)# class-map cm-1
Device(config-cmap)# match access 101
Device(config-cmap)# exit
Device(config)# exit

This example shows how to attach the new map to an SVI:

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# class-map cm-interface-1
Device(config-cmap)# match input gigabitethernet3/0/1 - gigabitethernet3/0/2
Device(config-cmap)# exit
Device(config)# policy-map port-plcmap
Device(config-pmap)# class cm-interface-1
Device(config-pmap-c)# police 900000 9000 exc policed-dscp-transmit
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-1
Device(config-pmap-c)# set dscp 7
Device(config-pmap-c)# service-policy port-plcmap-1
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-2
Device(config-pmap-c)# service-policy port-plcmap-1
Device(config-pmap-c)# set dscp 10

Device(config-pmap-c)# service-policy input pm1
This example shows that when a child-level policy map is attached below a class, an action must be specified for the class:

```
Device(config)# policy-map vlan-plcmap
Device(config-pmap)# class cm-5
Device(config-pmap-c)# set dscp 7
Device(config-pmap-c)# service-policy port-plcmap-1
```

This example shows how to configure a class map to match IP DSCP and IPv6:

```
Device(config)# class-map cm-1
Device(config-cmap)# match ip dscp 10
Device(config-cmap)# match protocol ipv6
Device(config-cmap)# exit
Device(config)# class-map cm-2
Device(config-cmap)# match ip dscp 20
Device(config-cmap)# match protocol ip
Device(config-cmap)# exit
Device(config)# policy-map pm1
Device(config-pmap)# class cm-1
Device(config-pmap-c)# set dscp 4
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-2
Device(config-pmap-c)# set dscp 6
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface G1/0/1
Device(config-if)# service-policy input pm1
```

This example shows how to configure default traffic class to a policy map:

```
Device# configure terminal
Device(config)# class-map cm-3
Device(config-cmap)# match ip dscp 30
Device(config-cmap)# match protocol ipv6
Device(config-cmap)# exit
Device(config)# class-map cm-4
Device(config-cmap)# match ip dscp 40
Device(config-cmap)# match protocol ip
Device(config-cmap)# exit
Device(config)# policy-map pm3
Device(config-pmap)# class class-default
Device(config-pmap)# set dscp 10
Device(config-pmap-c)# exit
```
Device(config-pmap)# class cm-3
Device(config-pmap-c) set dscp 4
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-4
Device(config-pmap-c)# trust cos
Device(config-pmap-c)# exit
Device(config-pmap)# exit

This example shows how the default traffic class is automatically placed at the end of policy-map pm3 even though class-default was configured first:

Device# show policy-map pm3
Policy Map pm3
  Class cm-3
    set dscp 4
  Class cm-4
  trust cos
  Class class-default
    police 8000 80000 exceed-action drop
Device#

Examples: Classifying, Policing, and Marking Traffic by Using Aggregate Policers

This example shows how to create an aggregate policer and attach it to multiple classes within a policy map. In the configuration, the IP ACLs permit traffic from network 10.1.0.0 and from host 11.3.1.1. For traffic coming from network 10.1.0.0, the DSCP in the incoming packets is trusted. For traffic coming from host 11.3.1.1, the DSCP in the packet is changed to 56. The traffic rate from the 10.1.0.0 network and from host 11.3.1.1 is policed. If the traffic exceeds an average rate of 48000 b/s and a normal burst size of 8000 bytes, its DSCP is marked down (based on the policed-DSCP map) and sent. The policy map is attached to an ingress port.

Device(config)# access-list 1 permit 10.1.0.0 0.0.255.255
Device(config)# access-list 2 permit 11.3.1.1
Device(config)# mls qos aggregate-police transmit1 48000 8000 exceed-action policed-dscp-transmit
Device(config)# class-map ipclass1
Device(config-cmap)# match access-group 1
Device(config-cmap)# exit
Device(config)# class-map ipclass2
Device(config-cmap)# match access-group 2
Device(config-cmap)# exit
Device(config)# policy-map aggflow1
Device(config-pmap)# class ipclass1
Device(config-pmap-c)# trust dscp
Device(config-pmap-c)# police aggregate transmit1
Device(config-pmap-c)# exit
Device(config-pmap-c)# class ipclass2
Device(config-pmap-c)# set dscp 56
Device(config-pmap-c)# police aggregate transmit1
Device(config-pmap-c)# exit
Device(config-pmap-c)# class class-default
Device(config-pmap-c)# set dscp 10
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# service-policy input aggflow1
Device(config-if)# exit

Examples: Configuring DSCP Maps

This example shows how to modify and display the CoS-to-DSCP map:

Device(config)# mls qos map cos-dscp 10 15 20 25 30 35 40 45
Device(config)# end
Device# show mls qos maps cos-dscp
Cos-dscp map:
  cos: 0 1 2 3 4 5 6 7
  -------------------------------
  dscp: 10 15 20 25 30 35 40 45

This example shows how to modify and display the IP-precedence-to-DSCP map:

Device(config)# mls qos map ip-prec-dscp 10 15 20 25 30 35 40 45
Device(config)# end
Device# show mls qos maps ip-prec-dscp
IpPrecedence-dscp map:
  ipprec: 0 1 2 3 4 5 6 7
  -------------------------------------
  dscp: 10 15 20 25 30 35 40 45

This example shows how to map DSCP 50 to 57 to a marked-down DSCP value of 0:

Device(config)# mls qos map policed-dscp 50 51 52 53 54 55 56 57 to 0
Device(config)# end
Device# show mls qos maps policed-dscp
Policed-dscp map:
  d1 : d2 0 1 2 3 4 5 6 7 8 9
  -------------------------------
  0 : 00 01 02 03 04 05 06 07 08 09
  1 : 10 11 12 13 14 15 16 17 18 19
  2 : 20 21 22 23 24 25 26 27 28 29
  3 : 30 31 32 33 34 35 36 37 38 39
  4 : 40 41 42 43 44 45 46 47 48 49
  5 : 00 00 00 00 00 00 00 00 00 58
  6 : 60 61 62 63

In this policed-DSCP map, the marked-down DSCP values are shown in the body of the matrix. The d1 column specifies the most-significant digit of the original DSCP; the d2 row specifies the least-significant digit of the original DSCP. The intersection of the d1 and d2 values provides the marked-down value. For example, an original DSCP value of 53 corresponds to a marked-down DSCP value of 0.

This example shows how to map DSCP values 0, 8, 16, 24, 32, 40, 48, and 50 to CoS value 0 and to display the map:
### Note

In the above DSCP-to-CoS map, the CoS values are shown in the body of the matrix. The d1 column specifies the most-significant digit of the DSCP; the d2 row specifies the least-significant digit of the DSCP. The intersection of the d1 and d2 values provides the CoS value. For example, in the DSCP-to-CoS map, a DSCP value of 08 corresponds to a CoS value of 0.

This example shows how to define the DSCP-to-DSCP-mutation map. All the entries that are not explicitly configured are not modified (remains as specified in the null map):

```plaintext
Device(config)# mls qos map dscp-mutation mutation1 1 2 3 4 5 6 7 to 0
Device(config)# mls qos map dscp-mutation mutation1 8 9 10 11 12 13 to 10
Device(config)# mls qos map dscp-mutation mutation1 20 21 22 to 20
Device(config)# mls qos map dscp-mutation mutation1 30 31 32 33 34 to 30
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# mls qos trust dscp
Device(config-if)# mls qos dscp-mutation mutation1
Device(config-if)# end
Device# show mls qos maps dscp-mutation mutation1
Dscp-dscp mutation map:
mutation1:
 d1 : d2 0 1 2 3 4 5 6 7 8 9
 ---------------------------------------
 0 : 00 00 00 00 00 00 00 00 10 10
 1 : 10 10 10 10 14 15 16 17 18 19
 2 : 20 20 20 23 24 25 26 27 28 29
 3 : 30 30 30 30 30 36 37 38 39
 4 : 40 41 42 43 44 45 46 47 48 49
 5 : 50 51 52 53 54 55 56 57 58 59
 6 : 60 61 62 63
```

### Note

In the above DSCP-to-DSCP-mutation map, the mutated values are shown in the body of the matrix. The d1 column specifies the most-significant digit of the original DSCP; the d2 row specifies the least-significant digit of the original DSCP. The intersection of the d1 and d2 values provides the mutated value. For example, a DSCP value of 12 corresponds to a mutated value of 10.
Examples: Configuring Egress Queue Characteristics

This example shows how to map DSCP values 10 and 11 to egress queue 1 and to threshold 2:

Device(config)# mls qos srr-queue output dscp-map queue 1 threshold 2 10 11

This example shows how to configure bandwidth shaping on queue 1. Because the weight ratios for queues 2, 3, and 4 are set to 0, these queues operate in shared mode. The bandwidth weight for queue 1 is 1/8, which is 12.5 percent:

Device(config)# interface gigabitethernet2/0/1
Device(config-if)# srr-queue bandwidth shape 8 0 0 0

This example shows how to configure the weight ratio of the SRR scheduler running on an egress port. Four queues are used, and the bandwidth ratio allocated for each queue in shared mode is 1/(1+2+3+4), 2/(1+2+3+4), 3/(1+2+3+4), and 4/(1+2+3+4), which is 10 percent, 20 percent, 30 percent, and 40 percent for queues 1, 2, 3, and 4. This means that queue 4 has four times the bandwidth of queue 1, twice the bandwidth of queue 2, and one-and-a-third times the bandwidth of queue 3:

Device(config)# interface gigabitethernet2/0/1
Device(config-if)# srr-queue bandwidth share 1 2 3 4

This example shows how to enable the egress expedite queue when the SRR weights are configured. The egress expedite queue overrides the configured SRR weights.

Device(config)# interface gigabitethernet1/0/1
Device(config-if)# srr-queue bandwidth shape 25 0 0 0
Device(config-if)# srr-queue bandwidth share 30 20 25 25
Device(config-if)# priority-queue out
Device(config-if)# end

This example shows how to limit the bandwidth on a port to 80 percent:

Device(config)# interface gigabitethernet2/0/1
Device(config-if)# srr-queue bandwidth limit 80

When you configure this command to 80 percent, the port is idle 20 percent of the time. The line rate drops to 80 percent of the connected speed, which is 800 Mb/s. These values are not exact because the hardware adjusts the line rate in increments of six.

Where to Go Next

Review the auto-QoS documentation to see if you can use these automated capabilities for your QoS configuration.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Auto-QoS

Before configuring standard QoS or auto-QoS, you must have a thorough understanding of these items:

• The types of applications used and the traffic patterns on your network.

• Traffic characteristics and needs of your network. Is the traffic bursty? Do you need to reserve bandwidth for voice and video streams?

• Bandwidth requirements and speed of the network.

• Location of congestion points in the network.
Auto-QoS VoIP Considerations

Before configuring auto-QoS for VoIP, you should be aware of this information:

- Auto-QoS configures the switch for VoIP with Cisco IP Phones on nonrouted and routed ports. Auto-QoS also configures the switch for VoIP with devices running the Cisco SoftPhone application.

  Note When a device running Cisco SoftPhone is connected to a nonrouted or routed port, the switch supports only one Cisco SoftPhone application per port.

- When enabling auto-QoS with a Cisco IP Phone on a routed port, you must assign a static IP address to the IP phone.
- This release supports only Cisco IP SoftPhone Version 1.3(3) or later.
- Connected devices must use Cisco Call Manager Version 4 or later.
- Auto-Qos VoIP uses the priority-queue interface configuration command for an egress interface. You can also configure a policy-map and trust device on the same interface for Cisco IP phones.

Auto-QoS Enhanced Considerations

Auto-QoS is enhanced to support video. Automatic configurations are generated that classify and trust traffic from Cisco TelePresence systems and Cisco IP cameras.

Before configuring auto-QoS enhanced, you should be aware of this information:

- The auto qos srnd4 global configuration command is generated as a result of enhanced auto-QoS configuration.

Restrictions for Auto-QoS

The following are restrictions for automatic QoS (auto-QoS):

- After auto-QoS is enabled, do not modify a policy map or aggregate policer that includes AutoQoS in its name. If you need to modify the policy map or aggregate policer, make a copy of it, and change the copied policy map or policer. To use this new policy map instead of the generated one, remove the generated policy map from the interface, and apply the new policy map to the interface.
- To take advantage of the auto-QoS defaults, you should enable auto-QoS before you configure other QoS commands. If necessary, you can fine-tune the QoS configuration, but we recommend that you do so only after the auto-QoS configuration is completed.
- By default, the CDP is enabled on all ports. For auto-QoS to function properly, do not disable CDP.

  Note You can enable auto-QoS on static, dynamic-access, voice VLAN access, and trunk ports.
Information About Configuring Auto-QoS

Auto-QoS Overview

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows. It uses the egress queues instead of using the default (disabled) QoS behavior. The switch offers best-effort service to each packet, regardless of the packet contents or size, and sends it from a single queue.

When you enable auto-QoS, it automatically classifies traffic based on the traffic type and ingress packet label. The switch uses the classification results to choose the appropriate egress queue.

You can use auto-QoS commands to identify ports connected to the following Cisco devices:

- Cisco IP Phones
- Devices running the Cisco SoftPhone application
- Cisco TelePresence
- Cisco IP Camera
- Cisco digital media player

You also use the auto-QoS commands to identify ports that receive trusted traffic through an uplink. Auto-QoS then performs these functions:

- Detects the presence or absence of auto-QoS devices through conditional trusted interfaces.
- Configures QoS classification
- Configures egress queues

Auto-QoS Compact Overview

When you enter an auto-QoS command, the switch displays all the generated commands as if the commands were entered from the CLI. You can use the auto-QoS compact feature to hide the auto-QoS generated commands from the running configuration. This would make it easier to comprehend the running-configuration and also help to increase efficient usage of memory.

Generated Auto-QoS Configuration

By default, auto-QoS is disabled on all ports. Packets are not modified—the CoS, DSCP and IP precedence values in the packet are not changed.

When you enable the auto-QoS feature on the first port of the interface:

- Ingress packet label is used to categorize traffic, to assign packet labels, and to configure the ingress and egress queues.
- QoS is globally enabled (mls qos global configuration command), and other global configuration commands are automatically generated. (See Examples: Global Auto-QoS Configuration, on page 851).
VoIP Device Specifics

The following actions occur when you issue these auto-QoS commands on a port:

- **auto qos voip cisco-phone**—When you enter this command on a port at the network edge connected to a Cisco IP Phone, the switch enables the trusted boundary feature. If the packet does not have a DSCP value of 24, 26, or 46 or is out of profile, the switch changes the DSCP value to 0. When there is no Cisco IP Phone, the ingress classification is set to not trust the QoS label in the packet. The policing is applied to the traffic matching the policy-map classification before the switch enables the trust boundary feature.

- **auto qos voip cisco-softphone** —When you enter this interface configuration command on a port at the network edge that is connected to a device running the Cisco SoftPhone, the switch uses policing to determine whether a packet is in or out of profile and to specify the action on the packet. If the packet does not have a DSCP value of 24, 26, or 46 or is out of profile, the switch changes the DSCP value to 0.

- **auto qos voip trust**—When you enter this interface configuration command on a port connected to the network interior, the switch trusts the CoS value for nonrouted ports or the DSCP value for routed ports in ingress packets (the assumption is that traffic has already been classified by other edge devices).

The switch configures egress queues on the port according to the settings in the following tables.

### Table 88: Traffic Types, Packet Labels, and Queues

<table>
<thead>
<tr>

<td>10 percent</td>
<td>25 percent</td>
<td>25 percent</td>
</tr>
</tbody>
</table>
### Effects of Auto-QoS on Running Configuration

When auto-QoS is enabled, the `auto qos` interface configuration commands and the generated global configuration are added to the running configuration.

The switch applies the auto-QoS-generated commands as if the commands were entered from the CLI. An existing user configuration can cause the application of the generated commands to fail or to be overridden by the generated commands. These actions may occur without warning. If all the generated commands are successfully applied, any user-entered configuration that was not overridden remains in the running configuration. Any user-entered configuration that was overridden can be retrieved by reloading the switch without saving the current configuration to memory. If the generated commands are not applied, the previous running configuration is restored.

### Effects of Auto-Qos Compact on Running Configuration

If auto-QoS compact is enabled:

- Only the auto-QoS commands entered from the CLI are displayed in running-config.
- The generated global and interface configurations are hidden.
- When you save the configuration, only the auto-qos commands you have entered are saved (and not the hidden configuration).
- When you reload the switch, the system detects and re-executes the saved auto-QoS commands and the AutoQoS SRND4.0 compliant config-set is generated.

---

**Note**

Do not make changes to the auto-QoS-generated commands when auto-QoS compact is enabled, because user-modifications are overridden when the switch reloads.

When auto-qos global compact is enabled:

- `show derived-config` command can be used to view hidden AQC derived commands.
- AQC commands will not be stored to memory. They will be regenerated every time the switch is reloaded.
- When compaction is enabled, auto-qos generated commands should not be modified.

---

</tbody>
</table>

*When you enable auto-QoS by using the `auto qos voip cisco-phone`, the `auto qos voip cisco-softphone`, or the `auto qos voip trust` interface configuration command, the switch automatically generates a QoS configuration based on the traffic type and ingress packet label and applies the commands listed in Examples: Global Auto-QoS Configuration, on page 851 to the port.*
• If the interface is configured with auto-QoS and if AQC needs to be disabled, auto-qos should be disabled at interface level first.

How to Configure Auto-QoS

Configuring Auto-QoS

Enabling Auto-QoS

For optimum QoS performance, enable auto-QoS on all the devices in your network.

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. Use one of the following:
   • auto qos voip {cisco-phone | cisco-softphone | trust}
   • auto qos video {cts | ip-camera | media-player}
   • auto qos classify [police]
   • auto qos trust {cos | dscp}
4. exit
5. interface interface-id
6. auto qos trust
7. end
8. show auto qos interface interface-id

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Specifies the port that is connected to a video device or the uplink port that is connected to another trusted switch or router in the network interior, and enters interface configuration mode.</td>
</tr>
<tr>
<td>interface interface-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 3/0/1</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Enables auto-QoS for VoIP.</td>
</tr>
<tr>
<td>Use one of the following:</td>
<td></td>

</tbody>
</table>
## Enabling Auto-QoS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`auto qos voip {cisco-phone</td>
<td>cisco-softphone</td>
</tr>
<tr>
<td>`auto qos video {cts</td>
<td>ip-camera</td>
</tr>
<tr>
<td><code>auto qos classify [police]</code></td>
<td>- <code>trust</code>—The uplink port is connected to a trusted switch or router, and the VoIP traffic classification in the ingress packet is trusted.</td>
</tr>
<tr>
<td>`auto qos trust {cos</td>
<td>dscp}`</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>cts</code>—A port connected to a Cisco Telepresence system.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>ip-camera</code>—A port connected to a Cisco video surveillance camera.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>media-player</code>—A port connected to a CDP-capable Cisco digital media player.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>QoS labels of incoming packets are trusted only when the system is detected. Enables auto-QoS for classification.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>police</code>—Policing is set up by defining the QoS policy maps and applying them to ports (port-based QoS). Enables auto-QoS for trusted interfaces.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>cos</code>—Class of service.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>dscp</code>—Differentiated Services Code Point.</td>
</tr>
<tr>
<td><code>auto qos trust dscp</code></td>
<td>- <code>&lt;cr&gt;</code>—Trust interface.</td>
</tr>
</tbody>
</table>

### Example:

```
Device(config-if)# auto qos trust dscp
```

### Step 4:

**Example:**

```
Device(config-if)# exit
```

**Step 5:**

**interface interface-id**

**Example:**

```
Specifies the switch port identified as connected to a trusted switch or router, and enters interface configuration mode.
```

---

**Note**

To view a list of commands that are automatically generated by issuing one of the auto-QoS commands listed here, you need to be in debug mode. Refer to the *Catalyst 2960-XR Switch QoS Command Reference Guide* for examples of how to run the appropriate debug command to view a list of these commands.

**Step 4**

**Example:**

```
Device(config-if)# exit
```

**Returns to global configuration mode.**
Enabling Auto-Qos Compact

To enable auto-Qos compact, enter this command:

**SUMMARY STEPS**

1. configure terminal
2. auto qos global compact

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> auto qos global compact</td>
<td>Enables auto-Qos compact and generates (hidden) the global configurations for auto-QoS. You can then enter the auto-QoS command you want to configure in the interface configuration mode and the interface commands that the system generates are also hidden.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# auto qos global compact</td>
<td></td>
</tr>
</tbody>
</table>

---

Enabling Auto-QoS

Device(config)# interface gigabitethernet 2/0/1

Enables auto-QoS on the port, and specifies that the port is connected to a trusted router or switch.

**Example:**

**Step 6**

Device(config-if)# auto qos trust

Returns to privileged EXEC mode.

**Example:**

**Step 7**

Device(config-if)# end

Verifies your entries.

**Example:**

**Step 8**

Device# show auto qos interface gigabitethernet 2/0/1

This command displays the auto-QoS command on the interface on which auto-QoS was enabled. You can use the `show running-config` privileged EXEC command to display the auto-QoS configuration and the user modifications.

---

Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)
To display the auto-QoS configuration that has been applied, use these privileged EXEC commands:

- `show derived-config`
- `show policy-map`
- `show access-list`
- `show class-map`
- `show table-map`
- `show auto-qos`
- `show policy-map interface`
- `show ip access-lists`

These commands will have keyword "AutoQos-".

### What to do next

To disable auto-QoS compact, remove auto-QoS instances from all interfaces by entering the `no` form of the corresponding auto-QoS commands and then enter the `no auto qos global compact` global configuration command.

### Troubleshooting Auto-QoS

To display the QoS commands that are automatically generated when auto-QoS is enabled or disabled, enter the `debug auto qos` privileged EXEC command before you enable auto-QoS. For more information, see the `debug auto qos` command in the command reference for this release.

To disable auto-QoS on a port, use the `no` form of the `auto qos` command interface configuration command, such as `no auto qos voip`.

**Note**

Auto-QoS generated global commands can also be removed manually if desired.

Only the auto-QoS-generated interface configuration commands for this port are removed. If this is the last port on which auto-QoS is enabled and you enter the `no auto qos voip` command, auto-QoS is considered disabled even though the auto-QoS-generated global configuration commands remain (to avoid disrupting traffic on other ports affected by the global configuration).

You can use the `no mls qos` global configuration command to disable the auto-QoS-generated global configuration commands. With QoS disabled, there is no concept of trusted or untrusted ports because the packets are not modified (the CoS, DSCP, and IP precedence values in the packet are not changed). Traffic is switched in pass-through mode (packets are switched without any rewrites and classified as best effort without any policing).
# Monitoring Auto-QoS

## Table 90: Commands for Monitoring Auto-QoS

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>show auto qos [interface [interface-type]]</strong></td>
<td>Displays the initial auto-QoS configuration. You can compare the <strong>show auto qos</strong> and the <strong>show running-config</strong> command output to identify the user-defined QoS settings.</td>
</tr>
<tr>
<td>**show mls qos [ aggregate policer</td>
<td>interface</td>
</tr>
<tr>
<td><strong>show mls qos aggregate policer policer_name</strong></td>
<td>Displays information about the QoS aggregate policer configuration that might be affected by auto-QoS.</td>
</tr>
<tr>
<td>**show mls qos interface [interface-type</td>
<td>buffers</td>
</tr>
<tr>
<td>**show mls qos maps [cos-dscp</td>
<td>cos-output-q</td>
</tr>
<tr>
<td><strong>show mls qos queue-set queue-set ID</strong></td>
<td>Displays information about the QoS queue-set configuration that might be affected by auto-QoS.</td>
</tr>
<tr>
<td><strong>show mls qos stack-port buffers</strong></td>
<td>Displays information about the QoS stack port buffer configuration that might be affected by auto-QoS.</td>
</tr>
<tr>
<td><strong>show mls qos stack-qset</strong></td>
<td>Displays information about the QoS stack queue set configuration that might be affected by auto-QoS.</td>
</tr>
<tr>
<td><strong>show running-config</strong></td>
<td>Displays information about the QoS configuration that might be affected by auto-QoS. You can compare the <strong>show auto qos</strong> and the <strong>show running-config</strong> command output to identify the user-defined QoS settings.</td>
</tr>
</tbody>
</table>
Configuration Examples for Auto-Qos

Examples: Global Auto-QoS Configuration

The following table describes the automatically generated commands for auto-QoS and enhanced auto-QoS by the switch.

| Description | Automatically Generated Command {voip} | Enhanced Automatically Generated Command {Video|Trust|Classify} |
|-------------|----------------------------------------|---------------------------------------------|
| The switch automatically enables standard QoS and configures the CoS-to-DSCP map (maps CoS values in incoming packets to a DSCP value). | Device(config)# mls qos cos-dscp 0 8 16 26 32 46 48 56 | Device(config)# mls qos cos-dscp 0 8 16 24 32 46 48 56 |
| The switch automatically maps CoS values to an egress queue and to a threshold ID. | Device(config)# no mls qos srr-queue output cos-map Device(config)# mls qos srr-queue output cos-map queue 1 threshold 3 5 Device(config)# mls qos srr-queue output cos-map queue 2 threshold 3 3 6 7 Device(config)# mls qos srr-queue output cos-map queue 3 threshold 3 2 4 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 2 1 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 3 0 | Device(config)# no mls qos srr-queue output cos-map Device(config)# mls qos srr-queue output cos-map queue 1 threshold 3 4 5 Device(config)# mls qos srr-queue output cos-map queue 2 threshold 3 6 7 Device(config)# mls qos srr-queue output cos-map queue 2 threshold 1 2 Device(config)# mls qos srr-queue output cos-map queue 3 threshold 2 3 Device(config)# mls qos srr-queue output cos-map queue 3 threshold 3 0 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 3 1 |
The switch automatically maps DSCP values to an egress queue and to a threshold ID.

| Description | Automatically Generated Command (voip) | Enhanced Automatically Generated Command (Video|Trust|Classify) |
|-------------|----------------------------------------|----------------|
|             | Device(config)# no mls qos srr-queue  | Device(config)# no mls qos srr-queue |
|             | output dscp-map                         | output dscp-map |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 1 threshold 3     | output dscp-map queue 1 threshold 3 |
|             | 40 41 42 43 44 45 46 47                | 32 40 41 42 43 44 45 46 47 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 2 threshold 3     | output dscp-map queue 2 threshold 3 |
|             | 24 25 26 27 28 29 30 31                 | 16 17 18 19 20 21 22 23 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 2 threshold 3     | output dscp-map queue 2 threshold 3 |
|             | 48 49 50 51 52 53 54 55                 | 32 33 34 35 36 37 38 39 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 2 threshold 3     | output dscp-map queue 2 threshold 3 |
|             | 56 57 58 59 60 61 62 63                 | 1 2 3 4 5 6 7 8 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 3 threshold 3     | output dscp-map queue 3 threshold 3 |
|             | 16 17 18 19 20 21 22 23                 | 9 11 13 15 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 3 threshold 3     | output dscp-map queue 4 threshold 2 |
|             | 32 33 34 35 36 37 38 39                 | 10 11 12 13 14 15 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 4 threshold 1 8   | output dscp-map queue 4 threshold 2 |
|             | Device(config)# mls qos srr-queue       | Device(config)# mls qos srr-queue |
|             | output dscp-map queue 4 threshold 1 8   | output dscp-map queue 4 threshold 2 |
|             | 9 11 13 15                              | 10 12 14 |
The switch automatically configures the egress queue buffer sizes. It configures the bandwidth and the SRR mode (shaped or shared) on the egress queues mapped to the port.

**Examples: Auto-QoS Generated Configuration for VoIP Devices**

If you entered the `auto qos voip cisco-phone` command, the switch automatically enables the trusted boundary feature, which uses the CDP to detect the presence or absence of a Cisco IP Phone.

```
Device(config-if)# mls qos trust device cisco-phone
```
If you entered the `auto qos voip cisco-softphone` command, the switch automatically creates class maps and policy maps.

```plaintext
Device(config)# mls qos map policed-dscp 24 26 46 to 0
Device(config)# class-map match-all AutoQoS-VoIP-RTP-Trust
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AutoQoS-VoIP-Control-Trust
Device(config-cmap)# match ip dscp cs3 af31
Device(config)# policy-map AutoQoS-Police-SoftPhone
Device(config-pmap)# class AutoQoS-VoIP-RTP-Trust
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# policy 320000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AutoQoS-VoIP-Control-Trust
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# policy 320000 8000 exceed-action policed-dscp-transmit
```

After creating the class maps and policy maps, the switch automatically applies the policy map called `AutoQoS-Police-SoftPhone` to an ingress interface on which auto-QoS with the Cisco SoftPhone feature is enabled.

```plaintext
Device(config-if)# service-policy input AutoQoS-Police-SoftPhone
```

If you entered the `auto qos voip cisco-phone` command, the switch automatically creates class maps and policy maps.

```plaintext
Device(config-if)# mls qos trust device cisco-phone
```

If you entered the `auto qos voip cisco-softphone` command, the switch automatically creates class maps and policy maps.

```plaintext
Device(config)# mls qos map policed-dscp 24 26 46 to 0
Device(config)# class-map match-all AutoQoS-VoIP-RTP-Trust
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AutoQoS-VoIP-Control-Trust
Device(config-cmap)# match ip dscp cs3 af31
Device(config)# policy-map AutoQoS-Police-CiscoPhone
Device(config-pmap)# class AutoQoS-VoIP-RTP-Trust
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# policy 320000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AutoQoS-VoIP-Control-Trust
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# policy 320000 8000 exceed-action policed-dscp-transmit
```

After creating the class maps and policy maps, the switch automatically applies the policy map called `AutoQoS-Police-SoftPhone` to an ingress interface on which auto-QoS with the Cisco SoftPhone feature is enabled.

```plaintext
Device(config-if)# service-policy input AutoQoS-Police-SoftPhone
```
Examples: Auto-QoS Generated Configuration For Enhanced Video, Trust, and Classify Devices

If you entered the following enhanced auto-QoS commands, the switch configures a CoS-to-DSCP map (maps CoS values in incoming packets to a DSCP value):

- auto qos video cts
- auto qos video ip-camera
- auto qos video media-player
- auto qos trust
- auto qos trust cos
- auto qos trust dscp

The following command is initiated after entering one of the above auto-QoS commands:

```
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
```

Note
No class maps and policy maps are configured.

If you entered the `auto qos classify` command, the switch automatically creates class maps and policy maps (as shown below).

```
Device(config)# mls qos map policed-dscp 0 10 18 24 32 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 56
Device(config)# class-map match-all AUTOQOS_MULTIENHANCED_CONF_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-MULTIENHANCED-CONF
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_TRANSACTION_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-TRANSACTIONAL-DATA
Device(config)# class-map match-all AUTOQOS_SIGNALING_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SIGNALING
Device(config)# class-map match-all AUTOQOS_BULK_DATA_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-BULK-DATA
Device(config)# class-map match-all AUTOQOS_SCAVANGER_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SCAVANGER
Device(config)# policy-map AUTOQOS-SRND4-CLASSIFY-POLICY
Device(config-pmap)# class AUTOQOS_MULTIENHANCED_CONF_CLASS
Device(config-pmap-c)# set dscp af41
Device(config-pmap-c)# set dscp af11
Device(config-pmap-c)# set dscp af21
Device(config-pmap-c)# set dscp cs1
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# set dscp default
```

If you entered the `auto qos classify policy` command, the switch automatically creates class maps and policy maps (as shown below).

```
Device(config)# service-policy input AUTOQOS-SRND4-CLASSIFY-POLICY

Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 48 56
Device(config)# class-map match-all AUTOQOS_MULTIENHANCED_CONF_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-MULTIENHANCED-CONF
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_TRANSACTION_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-TRANSACTIONAL-DATA
Device(config)# class-map match-all AUTOQOS_SIGNALING_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SIGNALING
Device(config)# class-map match-all AUTOQOS_BULK_DATA_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-BULK-DATA
Device(config)# class-map match-all AUTOQOS_SCAVANGER_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SCAVANGER
Device(config)# policy-map AUTOQOS-SRND4-CLASSIFY-POLICY
Device(config-pmap)# class AUTOQOS_MULTIENHANCED_CONF_CLASS
Device(config-pmap-c)# set dscp af41
Device(config-pmap-c)# police 5000000 8000 exceed-action drop
Device(config-pmap-c)# set dscp af11
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AUTOQOS_TRANSACTION_CLASS
Device(config-pmap-c)# set dscp af21
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# set dscp cs1
Device(config-pmap-c)# police 10000000 8000 exceed-action drop
Device(config-pmap-c)# class AUTOQOS_DEFAULT_CLASS
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action drop
Device(config-pmap-c)# class AUTOQOS_DEFAULT_CLASS
Device(config-pmap-c)# set dscp default
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
;
Device(config-if)# service-policy input AUTOQOS-SRND4-CLASSIFY-POLICY-POLICY
```

This is the enhanced configuration for the `auto qos voip cisco-phone` command:

```
Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 48 56
Device(config)# class-map match-all AUTOQOS_VOIP_DATA_CLASS
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-cmap)# match ip dscp cs3
Device(config)# policy-map AUTOQOS-SRND4-CISCOPHONE-POLICY
Device(config-pmap)# class AUTOQOS_VOIP_DATA_CLASS
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# police 128000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AUTOQOS_DEFAULT_CLASS
```
Device(config-pmap-c)# set dscp default
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
;
Device(config-if)# service-policy input AUTOQOS-SRND4-CISCOPHONE-POLICY

This is the enhanced configuration for the auto qos voip cisco-softphone command:

Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
Device(config-cmap)# class-map match-all AUTOQOS_MULTIENHANCED_CONF_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-MULTIENHANCED-CONF
Device(config)# class-map match-all AUTOQOS_VOIP_DATA_CLASS
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_TRANSACTION_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-TRANSACTIONAL-DATA
Device(config)# class-map match-all AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-cmap)# match ip dscp cs3

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IP Unicast Routing

This module describes how to configure IP Version 4 (IPv4) unicast routing on the switch.
A switch stack operates and appears as a single router to the rest of the routers in the network. Basic routing functions like static routing are available with IP Lite both the IP Base feature set and the IP Services feature set.

**Note**
In addition to IPv4 traffic, you can also enable IP Version 6 (IPv6) unicast routing and configure interfaces to forward IPv6 traffic if the switch or switch stack is running the IP Base or IP Services feature set.

---

**Information About IP Routing**

In some network environments, VLANs are associated with individual networks or subnetworks. In an IP network, each subnetwork is mapped to an individual VLAN. Configuring VLANs helps control the size of the broadcast domain and keeps local traffic local. However, network devices in different VLANs cannot communicate with one another without a Layer 3 device (router) to route traffic between the VLAN, referred to as inter-VLAN routing. You configure one or more routers to route traffic to the appropriate destination VLAN.

![Routing Topology Example](image)

**Figure 82: Routing Topology Example**

This figure shows a basic routing topology. Switch A is in VLAN 10, and Switch B is in VLAN 20. The router has an interface in each VLAN.

When Host A in VLAN 10 needs to communicate with Host B in VLAN 10, it sends a packet addressed to that host. Switch A forwards the packet directly to Host B, without sending it to the router.

When Host A sends a packet to Host C in VLAN 20, Switch A forwards the packet to the router, which receives the traffic on the VLAN 10 interface. The router checks the routing table, finds the correct outgoing interface, and forwards the packet on the VLAN 20 interface to Switch B. Switch B receives the packet and forwards it to Host C.

**Types of Routing**

Routers and Layer 3 switches can route packets in these ways:

- By using default routing
- By using preprogrammed static routes for the traffic
- By dynamically calculating routes by using a routing protocol

Default routing refers to sending traffic with a destination unknown to the router to a default outlet or destination.

Static unicast routing forwards packets from predetermined ports through a single path into and out of a network. Static routing is secure and uses little bandwidth, but does not automatically respond to changes in
the network, such as link failures, and therefore, might result in unreachable destinations. As networks grow, static routing becomes a labor-intensive liability.

Switches running the LAN base feature set support 16 user-configured static routes, in addition to any default routes used for the management interface. The LAN base image supports static routing only on SVIs.

Dynamic routing protocols are used by routers to dynamically calculate the best route for forwarding traffic. There are two types of dynamic routing protocols:

- Routers using distance-vector protocols maintain routing tables with distance values of networked resources, and periodically pass these tables to their neighbors. Distance-vector protocols use one or a series of metrics for calculating the best routes. These protocols are easy to configure and use.

- Routers using link-state protocols maintain a complex database of network topology, based on the exchange of link-state advertisements (LSAs) between routers. LSAs are triggered by an event in the network, which speeds up the convergence time or time required to respond to these changes. Link-state protocols respond quickly to topology changes, but require greater bandwidth and more resources than distance-vector protocols.

Distance-vector protocols supported by the switch are Routing Information Protocol (RIP), which uses a single distance metric (cost) to determine the best path. The switch also supports the Open Shortest Path First (OSPF) link-state protocol, which adds some link-state routing features to traditional Interior Gateway Routing Protocol (IGRP) to improve efficiency.

**IP Routing and Switch Stacks**

A switch stack appears to the network as a single switch, regardless of which switch in the stack is connected to a routing peer.

The active switch performs these functions:

- It initializes and configures the routing protocols.
- It sends routing protocol messages and updates to other routers.
- It processes routing protocol messages and updates received from peer routers.
- It generates, maintains, and distributes the distributed Cisco Express Forwarding (dCEF) database to all stack members. The routes are programmed on all switches in the stack bases on this database.
- The MAC address of the active switch is used as the router MAC address for the whole stack, and all outside devices use this address to send IP packets to the stack.
- All IP packets that require software forwarding or processing go through the CPU of the active switch.

Stack members perform these functions:

- They act as routing standby switches, ready to take over in case they are elected as the new active switch if the active switch fails.
- They program the routes into hardware.

If a active switch fails, the stack detects that the active switch is down and elects one of the stack members to be the new active switch. During this period, except for a momentary interruption, the hardware continues to forward packets with no active protocols.
However, even though the switch stack maintains the hardware identification after a failure, the routing protocols on the router neighbors might flap during the brief interruption before the active switch restarts. Routing protocols such as OSPF and EIGRP need to recognize neighbor transitions.

Upon election, the new active switch performs these functions:

- It starts generating, receiving, and processing routing updates.
- It builds routing tables, generates the CEF database, and distributes it to stack members.
- It uses its MAC address as the router MAC address. To notify its network peers of the new MAC address, it periodically (every few seconds for 5 minutes) sends a gratuitous ARP reply with the new router MAC address.

**Note**

If you configure the persistent MAC address feature on the stack and the active switch changes, the stack MAC address does not change for the configured time period. If the previous active switch rejoins the stack as a member switch during that time period, the stack MAC address remains the MAC address of the previous active switch.

- It attempts to determine the reachability of every proxy ARP entry by sending an ARP request to the proxy ARP IP address and receiving an ARP reply. For each reachable proxy ARP IP address, it generates a gratuitous ARP reply with the new router MAC address. This process is repeated for 5 minutes after a new active switch election.

**Caution**

Partitioning of the switch stack into two or more stacks might lead to undesirable behavior in the network.

If the switch is reloaded, then all the ports on that switch go down and there is a loss of traffic for the interfaces involved in routing.

### Classless Routing

By default, classless routing behavior is enabled on the Device when it is configured to route. With classless routing, if a router receives packets for a subnet of a network with no default route, the router forwards the packet to the best supernet route. A supernet consists of contiguous blocks of Class C address spaces used to simulate a single, larger address space and is designed to relieve the pressure on the rapidly depleting Class B address space.

In the figure, classless routing is enabled. When the host sends a packet to 120.20.4.1, instead of discarding the packet, the router forwards it to the best supernet route. If you disable classless routing and a router receives packets destined for a subnet of a network with no network default route, the router discards the packet.
In the figure, the router in network 128.20.0.0 is connected to subnets 128.20.1.0, 128.20.2.0, and 128.20.3.0. If the host sends a packet to 120.20.4.1, because there is no network default route, the router discards the packet.

To prevent the Device from forwarding packets destined for unrecognized subnets to the best supernet route possible, you can disable classless routing behavior.

**Address Resolution**

You can control interface-specific handling of IP by using address resolution. A device using IP can have both a local address or MAC address, which uniquely defines the device on its local segment or LAN, and a network address, which identifies the network to which the device belongs.
In a switch stack, network communication uses a single MAC address and the IP address of the stack.

The local address or MAC address is known as a data link address because it is contained in the data link layer (Layer 2) section of the packet header and is read by data link (Layer 2) devices. To communicate with a device on Ethernet, the software must learn the MAC address of the device. The process of learning the MAC address from an IP address is called address resolution. The process of learning the IP address from the MAC address is called reverse address resolution.

The Device can use these forms of address resolution:

- Address Resolution Protocol (ARP) is used to associate IP address with MAC addresses. Taking an IP address as input, ARP learns the associated MAC address and then stores the IP address/MAC address association in an ARP cache for rapid retrieval. Then the IP datagram is encapsulated in a link-layer frame and sent over the network. Encapsulation of IP datagrams and ARP requests or replies on IEEE 802 networks other than Ethernet is specified by the Subnetwork Access Protocol (SNAP).

- Proxy ARP helps hosts with no routing tables learn the MAC addresses of hosts on other networks or subnets. If the Device (router) receives an ARP request for a host that is not on the same interface as the ARP request sender, and if the router has all of its routes to the host through other interfaces, it generates a proxy ARP packet giving its own local data link address. The host that sent the ARP request then sends its packets to the router, which forwards them to the intended host.

The Device also uses the Reverse Address Resolution Protocol (RARP), which functions the same as ARP does, except that the RARP packets request an IP address instead of a local MAC address. Using RARP requires a RARP server on the same network segment as the router interface. Use the `ip rarp-server address` interface configuration command to identify the server.

For more information on RARP, see the Cisco IOS Configuration Fundamentals Configuration Guide

Proxy ARP

Proxy ARP, the most common method for learning about other routes, enables an Ethernet host with no routing information to communicate with hosts on other networks or subnets. The host assumes that all hosts are on the same local Ethernet and that they can use ARP to learn their MAC addresses. If a Device receives an ARP request for a host that is not on the same network as the sender, the Device evaluates whether it has the best route to that host. If it does, it sends an ARP reply packet with its own Ethernet MAC address, and the host that sent the request sends the packet to the Device, which forwards it to the intended host. Proxy ARP treats all networks as if they are local, and performs ARP requests for every IP address.

ICMP Router Discovery Protocol

Router discovery allows the Device to dynamically learn about routes to other networks using ICMP router discovery protocol (IRDP). IRDP allows hosts to locate routers. When operating as a client, the Device generates router discovery packets. When operating as a host, the Device receives router discovery packets. The Device can also listen to Routing Information Protocol (RIP) routing updates and use this information to infer locations of routers. The Device does not actually store the routing tables sent by routing devices; it merely keeps track of which systems are sending the data. The advantage of using IRDP is that it allows each router to specify both a priority and the time after which a device is assumed to be down if no further packets are received.
Each device discovered becomes a candidate for the default router, and a new highest-priority router is selected when a higher priority router is discovered, when the current default router is declared down, or when a TCP connection is about to time out because of excessive retransmissions.

**UDP Broadcast Packets and Protocols**

User Datagram Protocol (UDP) is an IP host-to-host layer protocol, as is TCP. UDP provides a low-overhead, connectionless session between two end systems and does not provide for acknowledgment of received datagrams. Network hosts occasionally use UDP broadcasts to find address, configuration, and name information. If such a host is on a network segment that does not include a server, UDP broadcasts are normally not forwarded. You can remedy this situation by configuring an interface on a router to forward certain classes of broadcasts to a helper address. You can use more than one helper address per interface.

You can specify a UDP destination port to control which UDP services are forwarded. You can specify multiple UDP protocols. You can also specify the Network Disk (ND) protocol, which is used by older diskless Sun workstations and the network security protocol SDNS.

By default, both UDP and ND forwarding are enabled if a helper address has been defined for an interface. The description for the `ip forward-protocol` interface configuration command in the *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services* lists the ports that are forwarded by default if you do not specify any UDP ports.

**Broadcast Packet Handling**

After configuring an IP interface address, you can enable routing and configure one or more routing protocols, or you can configure the way the Device responds to network broadcasts. A broadcast is a data packet destined for all hosts on a physical network. The Device supports two kinds of broadcasting:

- A directed broadcast packet is sent to a specific network or series of networks. A directed broadcast address includes the network or subnet fields.

- A flooded broadcast packet is sent to every network.

**Note**

You can also limit broadcast, unicast, and multicast traffic on Layer 2 interfaces by using the `storm-control` interface configuration command to set traffic suppression levels.

Routers provide some protection from broadcast storms by limiting their extent to the local cable. Bridges (including intelligent bridges), because they are Layer 2 devices, forward broadcasts to all network segments, thus propagating broadcast storms. The best solution to the broadcast storm problem is to use a single broadcast address scheme on a network. In most modern IP implementations, you can set the address to be used as the broadcast address. Many implementations, including the one in the Device, support several addressing schemes for forwarding broadcast messages.

**IP Broadcast Flooding**

You can allow IP broadcasts to be flooded throughout your internetwork in a controlled fashion by using the database created by the bridging STP. Using this feature also prevents loops. To support this capability, bridging must be configured on each interface that is to participate in the flooding. If bridging is not configured
on an interface, it still can receive broadcasts. However, the interface never forwards broadcasts it receives, and the router never uses that interface to send broadcasts received on a different interface.

Packets that are forwarded to a single network address using the IP helper-address mechanism can be flooded. Only one copy of the packet is sent on each network segment.

To be considered for flooding, packets must meet these criteria. (Note that these are the same conditions used to consider packet forwarding using IP helper addresses.)

- The packet must be a MAC-level broadcast.
- The packet must be an IP-level broadcast.
- The packet must be a TFTP, DNS, Time, NetBIOS, ND, or BOOTP packet, or a UDP specified by the `ip forward-protocol udp` global configuration command.
- The time-to-live (TTL) value of the packet must be at least two.

A flooded UDP datagram is given the destination address specified with the `ip broadcast-address` interface configuration command on the output interface. The destination address can be set to any address. Thus, the destination address might change as the datagram propagates through the network. The source address is never changed. The TTL value is decremented.

When a flooded UDP datagram is sent out an interface (and the destination address possibly changed), the datagram is handed to the normal IP output routines and is, therefore, subject to access lists, if they are present on the output interface.

In the Device, the majority of packets are forwarded in hardware; most packets do not go through the Device CPU. For those packets that do go to the CPU, you can speed up spanning tree-based UDP flooding by a factor of about four to five times by using turbo-flooding. This feature is supported over Ethernet interfaces configured for ARP encapsulation.

### How to Configure IP Routing

By default, IP routing is disabled on the Device, and you must enable it before routing can take place. For detailed IP routing configuration information, see the *Cisco IOS IP Configuration Guide*.

In the following procedures, the specified interface must be one of these Layer 3 interfaces:

- A routed port: a physical port configured as a Layer 3 port by using the `no switchport` interface configuration command.

- A switch virtual interface (SVI): a VLAN interface created by using the `interface vlan vlan_id` global configuration command and by default a Layer 3 interface.

- An EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the `interface port-channel port-channel-number` global configuration command and binding the Ethernet interface into the channel group. For more information, see the “Configuring Layer 3 EtherChannels” chapter in the Layer 2 Configuration Guide.

> **Note**  
> The switch does not support tunnel interfaces for unicast routed traffic.

All Layer 3 interfaces on which routing will occur must have IP addresses assigned to them.
A Layer 3 switch can have an IP address assigned to each routed port and SVI.

Configuring routing consists of several main procedures:

- To support VLAN interfaces, create and configure VLANs on the Device or switch stack, and assign VLAN membership to Layer 2 interfaces. For more information, see the "Configuring VLANs" chapter in the VLAN Configuration Guide.

- Configure Layer 3 interfaces.

- Enable IP routing on the switch.

- Assign IP addresses to the Layer 3 interfaces.

- Enable selected routing protocols on the switch.

- Configure routing protocol parameters (optional).

## How to Configure IP Addressing

A required task for configuring IP routing is to assign IP addresses to Layer 3 network interfaces to enable the interfaces and allow communication with the hosts on those interfaces that use IP. The following sections describe how to configure various IP addressing features. Assigning IP addresses to the interface is required; the other procedures are optional.

- Default Addressing Configuration

- Assigning IP Addresses to Network Interfaces

- Configuring Address Resolution Methods

- Routing Assistance When IP Routing is Disabled

- Configuring Broadcast Packet Handling

- Monitoring and Maintaining IP Addressing

### Default IP Addressing Configuration

<table>
<thead>

**Assigning IP Addresses to Network Interfaces**

An IP address identifies a location to which IP packets can be sent. Some IP addresses are reserved for special uses and cannot be used for host, subnet, or network addresses. RFC 1166, “Internet Numbers,” contains the official description of IP addresses.
An interface can have one primary IP address. A mask identifies the bits that denote the network number in an IP address. When you use the mask to subnet a network, the mask is referred to as a subnet mask. To receive an assigned network number, contact your Internet service provider.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
<tr>
<td><strong>Purpose</strong></td>
<td></td>
</tr>
<tr>
<td>show ip route</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Using Subnet Zero

Subnetting with a subnet address of zero is strongly discouraged because of the problems that can arise if a network and a subnet have the same addresses. For example, if network 131.108.0.0 is subnetworked as 255.255.255.0, subnet zero would be written as 131.108.0.0, which is the same as the network address.

You can use the all ones subnet (131.108.255.0) and even though it is discouraged, you can enable the use of subnet zero if you need the entire subnet space for your IP address.

Use the `no ip subnet-zero` global configuration command to restore the default and disable the use of subnet zero.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  - `enable`  
  **Example:**
  `Device> enable` | Enables privileged EXEC mode.
  * Enter your password if prompted. |
| **Step 2**
  - `configure terminal`  
  **Example:**
  `Device# configure terminal` | Enters global configuration mode. |
| **Step 3**
  - `ip subnet-zero`  
  **Example:** | Enables the use of subnet zero for interface addresses and routing updates. |
### Disabling Classless Routing

To prevent the Device from forwarding packets destined for unrecognized subnets to the best supernet route possible, you can disable classless routing behavior.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2: configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3: no ip classless</td>
<td>Disables classless routing behavior.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# no ip classless</td>
<td></td>
</tr>
<tr>
<td>Step 4: end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Address Resolution Methods

You can perform the following tasks to configure address resolution.

#### Defining a Static ARP Cache

ARP and other address resolution protocols provide dynamic mapping between IP addresses and MAC addresses. Because most hosts support dynamic address resolution, you usually do not need to specify static ARP cache entries. If you must define a static ARP cache entry, you can do so globally, which installs a permanent entry in the ARP cache that the Device uses to translate IP addresses into MAC addresses. Optionally, you can also specify that the Device respond to ARP requests as if it were the owner of the specified IP address. If you do not want the ARP entry to be permanent, you can specify a timeout period for the ARP entry.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable                 | Enables privileged EXEC mode.  
  Example:  
  Device> enable                     |
| **Step 2** configure terminal     | Enters global configuration mode.  
  Example:  
  Device# configure terminal        |
| **Step 3** arp ip-address hardware-address type | Associates an IP address with a MAC (hardware) address in the ARP cache, and specifies encapsulation type as one of these:  
  • **arpa**—ARP encapsulation for Ethernet interfaces  
  Example:  
  Device(config)# ip 10.1.5.1 c2f3.220a.12f4 arpa |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **snap**—Subnetwork Address Protocol encapsulation for Token Ring and FDDI interfaces  
**sap**—HP’s ARP type |

**Step 4**  
arp ip-address hardware-address type [alias]  
**Example:**  
Device(config)# ip 10.1.5.3 d7f3.220d.12f5 arpa alias  
(Optional) Specifies that the switch respond to ARP requests as if it were the owner of the specified IP address.

**Step 5**  
interface interface-id  
**Example:**  
Device(config)# interface gigabitethernet 1/0/1  
Enters interface configuration mode, and specifies the interface to configure.

**Step 6**  
arp timeout seconds  
**Example:**  
Device(config-if)# arp 20000  
(Optional) Sets the length of time an ARP cache entry will stay in the cache. The default is 14400 seconds (4 hours). The range is 0 to 2147483 seconds.

**Step 7**  
end  
**Example:**  
Device(config)# end  
Returns to privileged EXEC mode.

**Step 8**  
show interfaces [interface-id]  
**Example:**  
Device# show interfaces gigabitethernet 1/0/1  
Verifies the type of ARP and the timeout value used on all interfaces or a specific interface.

**Step 9**  
show arp  
**Example:**  
Device# show arp  
Views the contents of the ARP cache.

**Step 10**  
show ip arp  
**Example:**  
Device# show ip arp  
Views the contents of the ARP cache.

**Step 11**  
copy running-config startup-config  
**Example:**  
Device# copy running-config startup-config  
(Optional) Saves your entries in the configuration file.
Setting ARP Encapsulation

By default, Ethernet ARP encapsulation (represented by the `arpa` keyword) is enabled on an IP interface. You can change the encapsulation methods to SNAP if required by your network.

To disable an encapsulation type, use the `no arp arpa` or `no arp snap` interface configuration command.

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface interface-id</td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>arp {arpa</td>
<td>snap}</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# arp arpa</td>
<td>• arpa—Address Resolution Protocol</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• snap—Subnetwork Address Protocol</td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>show interfaces [interface-id]</td>
<td>Verifies ARP encapsulation configuration on all interfaces or the specified interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show interfaces</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
Enabling Proxy ARP

By default, the Device uses proxy ARP to help hosts learn MAC addresses of hosts on other networks or subnets.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td>interface interface-id</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Enables proxy ARP on the interface.</td>
</tr>
<tr>
<td>ip proxy-arp</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ip proxy-arp</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Verifies the configuration on the interface or all interfaces.</td>
</tr>
<tr>
<td>show ip interface [interface-id]</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show ip interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
Routing Assistance When IP Routing is Disabled

These mechanisms allow the Device to learn about routes to other networks when it does not have IP routing enabled:

- Proxy ARP
- Default Gateway
- ICMP Router Discovery Protocol (IRDP)

Proxy ARP

Proxy ARP is enabled by default. To enable it after it has been disabled, see the “Enabling Proxy ARP” section. Proxy ARP works as long as other routers support it.

Default Gateway

Another method for locating routes is to define a default router or default gateway. All non-local packets are sent to this router, which either routes them appropriately or sends an IP Control Message Protocol (ICMP) redirect message back, defining which local router the host should use. The Device caches the redirect messages and forwards each packet as efficiently as possible. A limitation of this method is that there is no means of detecting when the default router has gone down or is unavailable.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip default-gateway ip-address</td>
<td>Sets up a default gateway (router).</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ip default gateway 10.1.5.1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Displays the address of the default gateway router to verify the setting.</td>
</tr>
<tr>
<td><code>show ip redirects</code> Example: <code>Device# show ip redirects</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><code>copy running-config startup-config</code> Example: <code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

**ICMP Router Discovery Protocol (IRDP)**

The only required task for IRDP routing on an interface is to enable IRDP processing on that interface. When enabled, the default parameters apply.

You can optionally change any of these parameters. If you change the `maxadvertinterval` value, the `holdtime` and `minadvertinterval` values also change, so it is important to first change the `maxadvertinterval` value, before manually changing either the `holdtime` or `minadvertinterval` values.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code> Example: <code>Device&gt; enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code> Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td><code>interface interface-id</code> Example: <code>Device(config)# interface gigabitethernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Enables IRDP processing on the interface.</td>
</tr>
<tr>
<td><code>ip irdp</code> Example: <code>Device(config-if)# ip irdp</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>(Optional) Sends IRDP advertisements to the multicast address (224.0.0.1) instead of IP broadcasts.</td>
</tr>
<tr>
<td><code>ip irdp multicast</code> Example:</td>
<td></td>
</tr>
</tbody>
</table>
### ICMP Router Discovery Protocol (IRDP)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Device(config-if)# ip irdp multicast</strong></td>
<td>Note: This command allows for compatibility with Sun Microsystems Solaris, which requires IRDP packets to be sent out as multicasts. Many implementations cannot receive these multicasts; ensure end-host ability before using this command.</td>
</tr>
</tbody>
</table>

### Step 6
**ip irdp holdtime seconds**

**Example:**
```
Device(config-if)# ip irdp holdtime 1000
```

(Optional) Sets the IRDP period for which advertisements are valid. The default is three times the `maxadvertinterval` value. It must be greater than `maxadvertinterval` and cannot be greater than 9000 seconds. If you change the `maxadvertinterval` value, this value also changes.

### Step 7
**ip irdp maxadvertinterval seconds**

**Example:**
```
Device(config-if)# ip irdp maxadvertinterval 650
```

(Optional) Sets the IRDP maximum interval between advertisements. The default is 600 seconds.

### Step 8
**ip irdp minadvertinterval seconds**

**Example:**
```
Device(config-if)# ip irdp minadvertinterval 500
```

(Optional) Sets the IRDP minimum interval between advertisements. The default is 0.75 times the `maxadvertinterval`. If you change the `maxadvertinterval`, this value changes to the new default (0.75 of `maxadvertinterval`).

### Step 9
**ip irdp preference number**

**Example:**
```
Device(config-if)# ip irdp preference 2
```

(Optional) Sets a device IRDP preference level. The allowed range is –231 to 231. The default is 0. A higher value increases the router preference level.

### Step 10
**ip irdp address address [number]**

**Example:**
```
Device(config-if)# ip irdp address 10.1.10.10
```

(Optional) Specifies an IRDP address and preference to proxy-advertise.

### Step 11
**end**

**Example:**
```
Device(config)# end
```

Returns to privileged EXEC mode.

### Step 12
**show ip irdp**

**Example:**
```
Device# show ip irdp
```

Verifies settings by displaying IRDP values.

### Step 13
**copy running-config startup-config**

**Example:**
```

```

(Optional) Saves your entries in the configuration file.
### Configuring Broadcast Packet Handling

Perform the tasks in these sections to enable these schemes:

- Enabling Directed Broadcast-to-Physical Broadcast Translation
- Forwarding UDP Broadcast Packets and Protocols
- Establishing an IP Broadcast Address
- Flooding IP Broadcasts

#### Enabling Directed Broadcast-to-Physical Broadcast Translation

By default, IP directed broadcasts are dropped; they are not forwarded. Dropping IP-directed broadcasts makes routers less susceptible to denial-of-service attacks.

You can enable forwarding of IP-directed broadcasts on an interface where the broadcast becomes a physical (MAC-layer) broadcast. Only those protocols configured by using the `ip forward-protocol` global configuration command are forwarded.

You can specify an access list to control which broadcasts are forwarded. When an access list is specified, only those IP packets permitted by the access list are eligible to be translated from directed broadcasts to physical broadcasts. For more information on access lists, see the “Information about Network Security with ACLs” section in the Security Configuration Guide.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>

| **Example:** | |
Establishing an IP Broadcast Address

The most popular IP broadcast address (and the default) is an address consisting of all ones (255.255.255.255). However, the Device can be configured to generate any form of IP broadcast address.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>

</thead>
</table>
| **Step 6** show ip interface [interface-id]  
**Example:**  
Device# show ip interface | Verifies the broadcast address on the interface or all interfaces. |
| **Step 7** copy running-config startup-config  
**Example:**  
Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable  
**Example:**  
Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Step 2** configure terminal  
**Example:**  
Device# configure terminal | Enters global configuration mode. |
| **Step 3** ip forward-protocol spanning-tree  
**Example:**  
Device(config)# ip forward-protocol spanning-tree | Uses the bridging spanning-tree database to flood UDP datagrams. |
| **Step 4** end  
**Example:**  
Device(config)# end | Returns to privileged EXEC mode. |
| **Step 5** show running-config  
**Example:**  
Device# show running-config | Verifies your entries. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 6</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example: Device# copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> ip forward-protocol turbo-flood</td>
<td>Uses the spanning-tree database to speed up flooding of UDP datagrams.</td>
</tr>
<tr>
<td>Example: Device(config)# ip forward-protocol turbo-flood</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>

<tr>
<td>Example: Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example: Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

**Monitoring and Maintaining IP Addressing**

When the contents of a particular cache, table, or database have become or are suspected to be invalid, you can remove all its contents by using the `clear` privileged EXEC commands. The Table lists the commands for clearing contents.

*Table 93: Commands to Clear Caches, Tables, and Databases*

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear arp-cache</td>
<td>Clears the IP ARP cache and the fast-switching cache.</td>
</tr>
<tr>
<td>clear host `{name</td>
<td>*}`</td>
</tr>
</tbody>
</table>
Removes one or more routes from the IP routing table.

\[ \text{clear ip route} \ \{\text{network} \ [\text{mask}] \ | \ *\} \]

You can display specific statistics, such as the contents of IP routing tables, caches, and databases; the reachability of nodes; and the routing path that packets are taking through the network. The Table lists the privileged EXEC commands for displaying IP statistics.

**Table 94: Commands to Display Caches, Tables, and Databases**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show arp</code></td>
<td>Displays the entries in the ARP table.</td>

<tr>
<td><code>show hosts</code></td>
<td>Displays the default domain name, style of lookup service, name server hosts, and the cached list of hostnames and addresses.</td>
</tr>
<tr>
<td><code>show ip aliases</code></td>
<td>Displays IP addresses mapped to TCP ports (aliases).</td>
</tr>
<tr>
<td><code>show ip arp</code></td>
<td>Displays the IP ARP cache.</td>
</tr>
<tr>
<td><code>show ip interface [interface-id]</code></td>
<td>Displays the IP status of interfaces.</td>
</tr>
<tr>
<td><code>show ip irdp</code></td>
<td>Displays IRDP values.</td>
</tr>
<tr>
<td><code>show ip masks address</code></td>
<td>Displays the masks used for network addresses and the number of subnets using each mask.</td>
</tr>
<tr>
<td><code>show ip redirects</code></td>
<td>Displays the address of a default gateway.</td>
</tr>
<tr>
<td>`show ip route [address [mask]]</td>
<td>[protocol]`</td>
</tr>
<tr>
<td><code>show ip route summary</code></td>
<td>Displays the current state of the routing table in summary form.</td>
</tr>
</tbody>
</table>

### How to Configure IP Unicast Routing

#### Enabling IP Unicast Routing

By default, the Device is in Layer 2 switching mode and IP routing is disabled. To use the Layer 3 capabilities of the Device, you must enable IP routing.

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip routing</td>
<td>Enables IP routing.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip routing</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show running-config</td>
<td>Verifies your entries.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Example of Enabling IP Routing**

This example shows how to enable IP routing:

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# ip routing
Device(config-router)# end

**What to Do Next**

You can now set up parameters for the selected routing protocols as described in these sections:

- RIP
- OSPF,
- EIGRP
• Unicast Reverse Path Forwarding
• Protocol-Independent Features (optional)

Information About RIP

The Routing Information Protocol (RIP) is an interior gateway protocol (IGP) created for use in small, homogeneous networks. It is a distance-vector routing protocol that uses broadcast User Datagram Protocol (UDP) data packets to exchange routing information. The protocol is documented in RFC 1058. You can find detailed information about RIP in *IP Routing Fundamentals*, published by Cisco Press.

Note

RIP is supported in the IP Lite Network Essentials feature set.

Using RIP, the Device sends routing information updates (advertisements) every 30 seconds. If a router does not receive an update from another router for 180 seconds or more, it marks the routes served by that router as unusable. If there is still no update after 240 seconds, the router removes all routing table entries for the non-updating router.

RIP uses hop counts to rate the value of different routes. The hop count is the number of routers that can be traversed in a route. A directly connected network has a hop count of zero; a network with a hop count of 16 is unreachable. This small range (0 to 15) makes RIP unsuitable for large networks.

If the router has a default network path, RIP advertises a route that links the router to the pseudonetwork 0.0.0.0. The 0.0.0.0 network does not exist; it is treated by RIP as a network to implement the default routing feature. The Device advertises the default network if a default was learned by RIP or if the router has a gateway of last resort and RIP is configured with a default metric. RIP sends updates to the interfaces in specified networks. If an interface’s network is not specified, it is not advertised in any RIP update.

Summary Addresses and Split Horizon

Routers connected to broadcast-type IP networks and using distance-vector routing protocols normally use the split-horizon mechanism to reduce the possibility of routing loops. Split horizon blocks information about routes from being advertised by a router on any interface from which that information originated. This feature usually optimizes communication among multiple routers, especially when links are broken.

How to Configure RIP

Default RIP Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto summary</td>
<td>Enabled.</td>
</tr>
<tr>
<td>Default-information originate</td>
<td>Disabled.</td>
</tr>
</tbody>
</table>
### Configuring Basic RIP Parameters

To configure RIP, you enable RIP routing for a network and optionally configure other parameters. On the Device, RIP configuration commands are ignored until you configure the network number.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

<td><strong>Example:</strong> Device(config-router)# network 12.0.0.0</td>
<td><strong>Note</strong> You must configure a network number for the RIP commands to take effect.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>(Optional) Defines a neighboring router with which to exchange routing information. This step allows routing updates from RIP (normally a broadcast protocol) to reach nonbroadcast networks.</td>
<td></td>
</tr>
<tr>
<td>neighbor ip-address</td>
<td>(Optional) Defines a neighboring router with which to exchange routing information. This step allows routing updates from RIP (normally a broadcast protocol) to reach nonbroadcast networks.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-router)# neighbor 10.2.5.1</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>(Optional) Applies an offset list to routing metrics to increase incoming and outgoing metrics to routes learned through RIP. You can limit the offset list with an access list or an interface.</td>
<td></td>
</tr>
<tr>
<td>offset-list [access-list number</td>
<td>(Optional) Applies an offset list to routing metrics to increase incoming and outgoing metrics to routes learned through RIP. You can limit the offset list with an access list or an interface.</td>
<td></td>
</tr>
<tr>
<td>name] [in</td>
<td>out] offset [type number]</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-router)# offset-list 103 in 10</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>(Optional) Adjusts routing protocol timers. Valid ranges for all timers are 0 to 4294967295 seconds.</td>
<td></td>
</tr>
<tr>
<td>timers basic update invalid holddown flush</td>
<td>(Optional) Adjusts routing protocol timers. Valid ranges for all timers are 0 to 4294967295 seconds.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-router)# timers basic 45 360 400 300</td>
<td>• update—The time between sending routing updates. The default is 30 seconds.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>(Optional) Configures the switch to receive and send only RIP Version 1 or RIP Version 2 packets. By default, the switch receives Version 1 and 2 but sends only Version 1. You can also use the interface commands **ip rip {send</td>
<td>receive} version 1</td>
</tr>
<tr>
<td>version {1</td>
<td>2}</td>
<td>(Optional) Configures the switch to receive and send only RIP Version 1 or RIP Version 2 packets. By default, the switch receives Version 1 and 2 but sends only Version 1. You can also use the interface commands **ip rip {send</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-router)# version 2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring RIP Authentication

RIP Version 1 does not support authentication. If you are sending and receiving RIP Version 2 packets, you can enable RIP authentication on an interface. The key chain specifies the set of keys that can be used on the interface. If a key chain is not configured, no authentication is performed, not even the default.

The Device supports two modes of authentication on interfaces for which RIP authentication is enabled: plain text and MD5. The default is plain text.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td></td>
</tr>
<tr>
<td><strong>enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring RIP Authentication**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 10</td>
<td></td>
</tr>
<tr>
<td><strong>no auto summary</strong></td>
<td>(Optional) Disables automatic summarization. By default, the switch summarizes subprefixes when crossing classful network boundaries. Disable summarization (RIP Version 2 only) to advertise subnet and host routing information to classful network boundaries.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# no auto summary</td>
<td></td>
</tr>
</tbody>
</table>

| Step 11                                     |         |
| **output-delay delay**                      | (Optional) Adds interpacket delay for RIP updates sent. By default, packets in a multiple-packet RIP update have no delay added between packets. If you are sending packets to a lower-speed device, you can add an interpacket delay in the range of 8 to 50 milliseconds. |
| **Example:**                                |         |
| Device(config-router)# output-delay 8       |         |

| Step 12                                     |         |
| **end**                                      | Returns to privileged EXEC mode. |
| **Example:**                                |         |
| Device(config-router)# end                   |         |

| Step 13                                     |         |
| **show ip protocols**                       | Verifies your entries. |
| **Example:**                                |         |
| Device# show ip protocols                   |         |

<p>| Step 14                                     |         |
| <strong>copy running-config startup-config</strong>      | (Optional) Saves your entries in the configuration file. |
| <strong>Example:</strong>                                |         |
| Device# copy running-config startup-config  |         |</p>
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 2    | configure terminal  
  Example: Device# configure terminal | Enters global configuration mode. |
| 3    | interface interface-id  
  Example: Device(config)# interface gigabitethernet 1/0/1 | Enters interface configuration mode, and specifies the interface to configure. |
| 4    | ip rip authentication key-chain name-of-chain  
  Example: Device(config-if)# ip rip authentication key-chain trees | Enables RIP authentication. |
| 5    | ip rip authentication mode {text | md5}  
  Example: Device(config-if)# ip rip authentication mode md5 | Configures the interface to use plain text authentication (the default) or MD5 digest authentication. |
| 6    | end  
  Example: Device(config)# end | Returns to privileged EXEC mode. |
| 7    | show running-config  
  Example: Device# show running-config | Verifies your entries. |
| 8    | copy running-config startup-config  
  Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

**Configuring Summary Addresses and Split Horizon**

*Note*  
In general, disabling split horizon is not recommended unless you are certain that your application requires it to properly advertise routes.
If you want to configure an interface running RIP to advertise a summarized local IP address pool on a network access server for dial-up clients, use the `ip summary-address rip` interface configuration command.

---

**Note**

If split horizon is enabled, neither autosummary nor interface IP summary addresses are advertised.

---

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
| `Example:` | `enable` |  
| | | • Enter your password if prompted.  
| | Device> enable | |
| **Step 2** | `configure terminal` | Enters global configuration mode.  
| `Example:` | `configure terminal` | |
| | Device# configure terminal | |
| **Step 3** | `interface interface-id` | Enters interface configuration mode, and specifies the Layer 3 interface to configure.  
| `Example:` | `interface gigabitethernet 1/0/1` | |
| | Device(config)# interface gigabitethernet 1/0/1 | |
| **Step 4** | `ip address ip-address subnet-mask` | Configures the IP address and IP subnet.  
| `Example:` | `ip address 10.1.1.10 255.255.255.0` | |
| | Device(config-if)# ip address 10.1.1.10 255.255.255.0 | |
| **Step 5** | `ip summary-address rip ip address ip-network mask` | Configures the IP address to be summarized and the IP network mask.  
| `Example:` | `ip summary-address rip ip address 10.1.1.30 255.255.255.0` | |
| | Device(config-if)# ip summary-address rip ip address 10.1.1.30 255.255.255.0 | |
| **Step 6** | `no ip split horizon` | Disables split horizon on the interface.  
| `Example:` | `no ip split horizon` | |
| | Device(config-if)# no ip split horizon | |
| **Step 7** | `end` | Returns to privileged EXEC mode.  
| `Example:` | `end` | |
| | Device(config)# end | |
Configuring Split Horizon

Routers connected to broadcast-type IP networks and using distance-vector routing protocols normally use the split-horizon mechanism to reduce the possibility of routing loops. Split horizon blocks information about routes from being advertised by a router on any interface from which that information originated. This feature can optimize communication among multiple routers, especially when links are broken.

In general, we do not recommend disabling split horizon unless you are certain that your application requires it to properly advertise routes.

### Procedure

<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

**Purpose**

Verifies your entries.

(Optional) Saves your entries in the configuration file.
### Configuration Example for Summary Addresses and Split Horizon

In this example, the major net is 10.0.0.0. The summary address 10.2.0.0 overrides the autosummary address of 10.0.0.0 so that 10.2.0.0 is advertised out interface Gigabit Ethernet port 2, and 10.0.0.0 is not advertised. In the example, if the interface is still in Layer 2 mode (the default), you must enter a `no switchport` interface configuration command before entering the `ip address` interface configuration command.

#### Note
If split horizon is enabled, neither autosummary nor interface summary addresses (those configured with the `ip summary-address rip` router configuration command) are advertised.

```bash
Device(config)# router rip
Device(config-router)# interface gigabitethernet1/0/2
Device(config-if)# ip address 10.1.5.1 255.255.255.0
Device(config-if)# ip summary-address rip 10.2.0.0 255.255.0.0
Device(config-if)# no ip split-horizon
Device(config-if)# exit
Device(config)# router rip
Device(config-router)# network 10.0.0.0
Device(config-router)# neighbor 2.2.2.2 peer-group mygroup
Device(config-router)# end
```
Information About OSPF

OSPF is an Interior Gateway Protocol (IGP) designed expressly for IP networks, supporting IP subnetting and tagging of externally derived routing information. OSPF also allows packet authentication and uses IP multicast when sending and receiving packets. The Cisco implementation supports RFC 1253, OSPF management information base (MIB).

The Cisco implementation conforms to the OSPF Version 2 specifications with these key features:

- Definition of stub areas is supported.
- Routes learned through any IP routing protocol can be redistributed into another IP routing protocol. At the intradomain level, this means that OSPF can import routes learned through EIGRP and RIP. OSPF routes can also be exported into RIP.
- Plain text and MD5 authentication among neighboring routers within an area is supported.
- Configurable routing interface parameters include interface output cost, retransmission interval, interface transmit delay, router priority, router dead and hello intervals, and authentication key.
- Virtual links are supported.
- Not-so-stubby-areas (NSSAs) per RFC 1587 are supported.

OSPF typically requires coordination among many internal routers, area border routers (ABRs) connected to multiple areas, and autonomous system boundary routers (ASBRs). The minimum configuration would use all default parameter values, no authentication, and interfaces assigned to areas. If you customize your environment, you must ensure coordinated configuration of all routers.

OSPF for Routed Access

Note

OSPF is supported in IP Lite. OSPF for Routed Access supports only one OSPFv2 and one OSPFv3 instance with a combined total of 1000 dynamically learned routes. The IP Lite image provides OSPF for routed access. However, these restrictions are not enforced in this release.

With the typical topology (hub and spoke) in a campus environment, where the wiring closets (spokes) are connected to the distribution switch (hub) that forwards all nonlocal traffic to the distribution layer, the wiring closet switch need not hold a complete routing table. A best practice design, where the distribution switch sends a default route to the wiring closet switch to reach interarea and external routes (OSPF stub or totally stub area configuration) should be used when OSPF for Routed Access is used in the wiring closet.

For more details, see the “High Availability Campus Network Design—Routed Access Layer using EIGRP or OSPF” document.

OSPF Area Parameters

You can optionally configure several OSPF area parameters. These parameters include authentication for password-based protection against unauthorized access to an area, stub areas, and not-so-stubby-areas (NSSAs). Stub areas are areas into which information on external routes is not sent. Instead, the area border router (ABR)
generates a default external route into the stub area for destinations outside the autonomous system (AS). An NSSA does not flood all LSAs from the core into the area, but can import AS external routes within the area by redistribution.

Route summarization is the consolidation of advertised addresses into a single summary route to be advertised by other areas. If network numbers are contiguous, you can use the area range router configuration command to configure the ABR to advertise a summary route that covers all networks in the range.

### Other OSPF Parameters

You can optionally configure other OSPF parameters in router configuration mode.

- **Route summarization**: When redistributing routes from other protocols. Each route is advertised individually in an external LSA. To help decrease the size of the OSPF link state database, you can use the `summary-address` router configuration command to advertise a single router for all the redistributed routes included in a specified network address and mask.

- **Virtual links**: In OSPF, all areas must be connected to a backbone area. You can establish a virtual link in case of a backbone-continuity break by configuring two Area Border Routers as endpoints of a virtual link. Configuration information includes the identity of the other virtual endpoint (the other ABR) and the nonbackbone link that the two routers have in common (the transit area). Virtual links cannot be configured through a stub area.

- **Default route**: When you specifically configure redistribution of routes into an OSPF routing domain, the route automatically becomes an autonomous system boundary router (ASBR). You can force the ASBR to generate a default route into the OSPF routing domain.

- **Domain Name Server (DNS) names for use in all OSPF show privileged EXEC command displays makes it easier to identify a router than displaying it by router ID or neighbor ID.**

- **Default Metrics**: OSPF calculates the OSPF metric for an interface according to the bandwidth of the interface. The metric is calculated as $\text{ref-bw} / \text{bandwidth}$, where $\text{ref}$ is 10 by default, and bandwidth ($\text{bw}$) is specified by the `bandwidth` interface configuration command. For multiple links with high bandwidth, you can specify a larger number to differentiate the cost on those links.

- **Administrative distance**: is a rating of the trustworthiness of a routing information source, an integer between 0 and 255, with a higher value meaning a lower trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored. OSPF uses three different administrative distances: routes within an area (interarea), routes to another area (interarea), and routes from another routing domain learned through redistribution (external). You can change any of the distance values.

- **Passive interfaces**: Because interfaces between two devices on an Ethernet represent only one network segment, to prevent OSPF from sending hello packets for the sending interface, you must configure the sending device to be a passive interface. Both devices can identify each other through the hello packet for the receiving interface.

- **Route calculation timers**: You can configure the delay time between when OSPF receives a topology change and when it starts the shortest path first (SPF) calculation and the hold time between two SPF calculations.

- **Log neighbor changes**: You can configure the router to send a syslog message when an OSPF neighbor state changes, providing a high-level view of changes in the router.
**LSA Group Pacing**

The OSPF LSA group pacing feature allows the router to group OSPF LSAs and pace the refreshing, check-summing, and aging functions for more efficient router use. This feature is enabled by default with a 4-minute default pacing interval, and you will not usually need to modify this parameter. The optimum group pacing interval is inversely proportional to the number of LSAs the router is refreshing, check-summing, and aging. For example, if you have approximately 10,000 LSAs in the database, decreasing the pacing interval would benefit you. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might benefit you slightly.

**Loopback Interfaces**

OSPF uses the highest IP address configured on the interfaces as its router ID. If this interface is down or removed, the OSPF process must recalculate a new router ID and resend all its routing information out its interfaces. If a loopback interface is configured with an IP address, OSPF uses this IP address as its router ID, even if other interfaces have higher IP addresses. Because loopback interfaces never fail, this provides greater stability. OSPF automatically prefers a loopback interface over other interfaces, and it chooses the highest IP address among all loopback interfaces.

**Configuring Basic OSPF Parameters**

To enable OSPF, create an OSPF routing process, specify the range of IP addresses to associate with the routing process, and assign area IDs to be associated with that range.
### Configuring OSPF Interfaces

You can use the `ip ospf` interface configuration commands to modify interface-specific OSPF parameters. You are not required to modify any of these parameters, but some interface parameters (hello interval, dead interval, and authentication key) must be consistent across all routers in an attached network. If you modify these parameters, be sure all routers in the network have compatible values.
The `ip ospf` interface configuration commands are all optional.

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `configure terminal`  
*Example:*  
Device# `configure terminal` | Enters global configuration mode. |
| Step 2 | `interface interface-id`  
*Example:*  
Device(config)# `interface gigabitethernet 1/0/1` | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| Step 3 | `ip ospf cost`  
*Example:*  
Device(config-if)# `ip ospf 8` | (Optional) Explicitly specifies the cost of sending a packet on the interface. |
| Step 4 | `ip ospf retransmit-interval` seconds  
*Example:*  
Device(config-if)# `ip ospf transmit-interval 10` | (Optional) Specifies the number of seconds between link state advertisement transmissions. The range is 1 to 65535 seconds. The default is 5 seconds. |
| Step 5 | `ip ospf transmit-delay` seconds  
*Example:*  
Device(config-if)# `ip ospf transmit-delay 2` | (Optional) Sets the estimated number of seconds to wait before sending a link state update packet. The range is 1 to 65535 seconds. The default is 1 second. |
| Step 6 | `ip ospf priority` number  
*Example:*  
Device(config-if)# `ip ospf priority 5` | (Optional) Sets priority to help find the OSPF designated router for a network. The range is from 0 to 255. The default is 1. |
| Step 7 | `ip ospf hello-interval` seconds  
*Example:*  
Device(config-if)# `ip ospf hello-interval 12` | (Optional) Sets the number of seconds between hello packets sent on an OSPF interface. The value must be the same for all nodes on a network. The range is 1 to 65535 seconds. The default is 10 seconds. |
| Step 8 | `ip ospf dead-interval` seconds  
*Example:*  
Device(config-if)# `ip ospf dead-interval 8` | (Optional) Sets the number of seconds after the last device hello packet was seen before its neighbors declare the OSPF router to be down. The value must be the same for all nodes on a network. The range is 1 to 65535 seconds. The default is 4 times the hello interval. |

# Configuring OSPF Area Parameters

## Before you begin

**Note**
The OSPF *area* router configuration commands are all optional.

## Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> router ospf process-id</td>
<td>Enables OSPF routing, and enter router configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# router ospf 109</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> area area-id authentication</td>
<td>(Optional) Allow password-based protection against unauthorized access to the identified area. The identifier can be either a decimal value or an IP address.</td>
</tr>
<tr>
<td>Example: Device(config-router)# area 1 authentication</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> area area-id authentication message-digest</td>
<td>(Optional) Enables MD5 authentication on the area.</td>
</tr>
<tr>
<td>Example: Device(config-router)# area 1 authentication message-digest</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> area area-id stub [no-summary]</td>
<td>(Optional) Define an area as a stub area. The <code>no-summary</code> keyword prevents an ABR from sending summary link advertisements into the stub area.</td>
</tr>
<tr>
<td>Example: Device(config-router)# area 1 stub</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> area area-id nssa [no-redistribution] [default-information-originate] [no-summary]</td>
<td>(Optional) Defines an area as a not-so-stubby-area. Every router within the same area must agree that the area is NSSA. Select one of these keywords:</td>
</tr>
<tr>
<td>Example: Device(config-router)# area 1 nssa default-information-originate</td>
<td>• <code>no-redistribution</code>—Select when the router is an NSSA ABR and you want the <code>redistribute</code> command to import routes into normal areas, but not into the NSSA.</td>
</tr>
<tr>
<td></td>
<td>• <code>default-information-originate</code>—Select on an ABR to allow importing type 7 LSAs into the NSSA.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>area area-id range address mask</td>
<td>(Optional) Specifies an address range for which a single route is advertised. Use this command only with area border routers.</td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>show ip ospf [process-id]</td>
<td>Displays information about the OSPF routing process in general or for a specific process ID to verify configuration.</td>
</tr>
<tr>
<td>show ip ospf [process-id [area-id]] database</td>
<td>Displays lists of information related to the OSPF database for a specific router.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Configuring Other OSPF Parameters

<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td><code>ip address address mask</code></td>
<td>Assign an IP address to this interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ip address 10.1.1.5 255.255.240.0</td>
<td></td>
</tr>
</tbody>
</table>
Purpose

**Step 4**

**Command or Action**

```
end
Example:
Device(config)# end
```

**Purpose**

Returns to privileged EXEC mode.

**Step 5**

**Command or Action**

```
show ip interface
Example:
Device# show ip interface
```

**Purpose**

Verifies your entries.

**Step 6**

**Command or Action**

```
copy running-config startup-config
Example:
Device# copy running-config startup-config
```

**Purpose**

(Optional) Saves your entries in the configuration file.

---

## Monitoring OSPF

You can display specific statistics such as the contents of IP routing tables, caches, and databases.

### Table 97: Show IP OSPF Statistics Commands

**Configuration Examples for OSPF**

**Example: Configuring Basic OSPF Parameters**

This example shows how to configure an OSPF routing process and assign it a process number of 109:

```
Device(config)# router ospf 109
Device(config-router)# network 131.108.0.0 255.255.255.0 area 24
```

**Information About EIGRP**

Enhanced IGRP (EIGRP) is a Cisco proprietary enhanced version of the IGRP. EIGRP uses the same distance vector algorithm and distance information as IGRP; however, the convergence properties and the operating efficiency of EIGRP are significantly improved.

The convergence technology employs an algorithm referred to as the Diffusing Update Algorithm (DUAL), which guarantees loop-free operation at every instant throughout a route computation and allows all devices involved in a topology change to synchronize at the same time. Routers that are not affected by topology changes are not involved in recomputations.

IP EIGRP provides increased network width. With RIP, the largest possible width of your network is 15 hops. Because the EIGRP metric is large enough to support thousands of hops, the only barrier to expanding the network is the transport-layer hop counter. EIGRP increments the transport control field only when an IP packet has traversed 15 routers and the next hop to the destination was learned through EIGRP. When a RIP route is used as the next hop to the destination, the transport control field is incremented as usual.

**EIGRP Stub Routing**

The EIGRP stub routing feature reduces resource utilization by moving routed traffic closer to the end user.

---

**Note**

The device uses EIGRP stub routing at the access layer to eliminate the need for other types of routing advertisements.
In a network using EIGRP stub routing, the only allowable route for IP traffic to the user is through a device that is configured with EIGRP stub routing. The device sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRP stub routing, you need to configure the distribution and remote routers to use EIGRP and to configure only the device as a stub. Only specified routes are propagated from the device. The device responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In the figure given below, device B is configured as an EIGRP stub router. Devicees A and C are connected to the rest of the WAN. Device B advertises connected, static, redistribution, and summary routes to Device A and C. Device B does not advertise any routes learned from Device A (and the reverse).

Figure 85: EIGRP Stub Router Configuration

### Configuring Unicast Reverse Path Forwarding

The unicast reverse path forwarding (unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

---

**Note**

- Unicast RPF is supported in IP Lite.
For detailed IP unicast RPF configuration information, see the Other Security Features chapter in the Cisco IOS Security Configuration Guide.

Protocol-Independent Features

This section describes IP routing protocol-independent features that are available on switches running the IP Lite feature set. For a complete description of the IP routing protocol-independent commands in this chapter, see the “IP Routing Protocol-Independent Commands” chapter of the Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols.

Distributed Cisco Express Forwarding

Information About Cisco Express Forwarding

Cisco Express Forwarding (CEF) is a Layer 3 IP switching technology used to optimize network performance. CEF implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. CEF is less CPU-intensive than fast switching route caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed CEF (dCEF) in the stack. In dynamic networks, fast switching cache entries are frequently invalidated because of routing changes, which can cause traffic to be process switched using the routing table, instead of fast switched using the route cache. CEF and dCEF use the Forwarding Information Base (FIB) lookup table to perform destination-based switching of IP packets.

The two main components in CEF and dCEF are the distributed FIB and the distributed adjacency tables.

- The FIB is similar to a routing table or information base and maintains a mirror image of the forwarding information in the IP routing table. When routing or topology changes occur in the network, the IP routing table is updated, and those changes are reflected in the FIB. The FIB maintains next-hop address information based on the information in the IP routing table. Because the FIB contains all known routes that exist in the routing table, CEF eliminates route cache maintenance, is more efficient for switching traffic, and is not affected by traffic patterns.

- Nodes in the network are said to be adjacent if they can reach each other with a single hop across a link layer. CEF uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all FIB entries.

Because the switch or switch stack uses Application Specific Integrated Circuits (ASICs) to achieve Gigabit-speed line rate IP traffic, CEF or dCEF forwarding applies only to the software-forwarding path, that is, traffic that is forwarded by the CPU.

How to Configure Cisco Express Forwarding

CEF or distributed CEF is enabled globally by default. If for some reason it is disabled, you can re-enable it by using the ip cef or ip cef distributed global configuration command.

The default configuration is CEF or dCEF enabled on all Layer 3 interfaces. Entering the no ip route-cache cef interface configuration command disables CEF for traffic that is being forwarded by software. This command does not affect the hardware forwarding path. Disabling CEF and using the debug ip packet detail privileged EXEC command can be useful to debug software-forwarded traffic. To enable CEF on an interface for the software-forwarding path, use the ip route-cache cef interface configuration command.
Although the `no ip route-cache cef` interface configuration command to disable CEF on an interface is visible in the CLI, we strongly recommend that you do not disable CEF or dCEF on interfaces except for debugging purposes.

To enable CEF or dCEF globally and on an interface for software-forwarded traffic if it has been disabled:

### Procedure

### Number of Equal-Cost Routing Paths

#### Information About Equal-Cost Routing Paths

When a router has two or more routes to the same network with the same metrics, these routes can be thought of as having an equal cost. The term parallel path is another way to see occurrences of equal-cost routes in a routing table. If a router has two or more equal-cost paths to a network, it can use them concurrently. Parallel paths provide redundancy in case of a circuit failure and also enable a router to load balance packets over the available paths for more efficient use of available bandwidth. Equal-cost routes are supported across switches in a stack.

Even though the router automatically learns about and configures equal-cost routes, you can control the maximum number of parallel paths supported by an IP routing protocol in its routing table. Although the switch software allows a maximum of 32 equal-cost routes, the switch hardware will never use more than 16 paths per route.

#### How to Configure Equal-Cost Routing Paths

### Table: Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# show cef linecard detail</td>
<td>(Optional) Displays CEF-related interface information on a switch by stack member for all switches in the stack or for the specified switch. (Optional) For slot-number, enter the stack member switch number.</td>
</tr>
<tr>
<td>Step 9 show cef linecard [slot-number] [detail]</td>
<td>Displays detailed CEF information for all interfaces or the specified interface.</td>
</tr>
<tr>
<td>Step 11 show adjacency</td>
<td></td>
</tr>
<tr>
<td>Step 12 copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

### Static Unicast Routes

#### Information About Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

The switch retains static routes until you remove them. However, you can override static routes with dynamic routing information by assigning administrative distance values. Each dynamic routing protocol has a default administrative distance, as listed in Table 41-16. If you want a static route to be overridden by information from a dynamic routing protocol, set the administrative distance of the static route higher than that of the dynamic protocol.

#### Table 98: Dynamic Routing Protocol Default Administrative Distances

<table>
<thead>
<tr>
<th>Route Source</th>
<th>Default Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected interface</td>
<td>0</td>
</tr>
<tr>
<td>Static route</td>
<td>1</td>
</tr>
</tbody>
</table>
Configuring Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

Follow these steps to configure a static route:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters global configuration mode. |
| `configure terminal` | |
| **Example:**      |         |
| `Device# configure terminal` | |

<p>| <strong>Step 3</strong>        | Establish a static route. |
| <code>ip route prefix mask {address | interface} [distance]</code> | |
| <strong>Example:</strong>      |         |
| <code>Device(config)# ip route prefix mask gigabitethernet 1/0/4</code> | |</p>
<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# <code>end</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 5</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>show ip route</code></td>
<td>Displays the current state of the routing table to verify the configuration.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# <code>show ip route</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 6</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# <code>copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

Use the **no ip route prefix mask {address|interface}** global configuration command to remove a static route. The device retains static routes until you remove them.

### Default Routes and Networks

**Information About Default Routes and Networks**

A router might not be able to learn the routes to all other networks. To provide complete routing capability, you can use some routers as smart routers and give the remaining routers default routes to the smart router. (Smart routers have routing table information for the entire internetwork.) These default routes can be dynamically learned or can be configured in the individual routers. Most dynamic interior routing protocols include a mechanism for causing a smart router to generate dynamic default information that is then forwarded to other routers.

If a router has a directly connected interface to the specified default network, the dynamic routing protocols running on that device generate a default route. In RIP, it advertises the pseudonetwork 0.0.0.0.

A router that is generating the default for a network also might need a default of its own. One way a router can generate its own default is to specify a static route to the network 0.0.0.0 through the appropriate device.

When default information is passed through a dynamic routing protocol, no further configuration is required. The system periodically scans its routing table to choose the optimal default network as its default route. In IGRP networks, there might be several candidate networks for the system default. Cisco routers use administrative distance and metric information to set the default route or the gateway of last resort.

If dynamic default information is not being passed to the system, candidates for the default route are specified with the **ip default-network** global configuration command. If this network appears in the routing table from any source, it is flagged as a possible choice for the default route. If the router has no interface on the default network, but does have a path to it, the network is considered as a possible candidate, and the gateway to the best default path becomes the gateway of last resort.
How to Configure Default Routes and Networks

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>

Route Maps to Redistribute Routing Information

Information About Route Maps

The switch can run multiple routing protocols simultaneously, and it can redistribute information from one routing protocol to another. Redistributing information from one routing protocol to another applies to all supported IP-based routing protocols.

You can also conditionally control the redistribution of routes between routing domains by defining enhanced packet filters or route maps between the two domains. The **match** and **set** route-map configuration commands define the condition portion of a route map. The **match** command specifies that a criterion must be matched. The **set** command specifies an action to be taken if the routing update meets the conditions defined by the match command. Although redistribution is a protocol-independent feature, some of the **match** and **set** route-map configuration commands are specific to a particular protocol.

One or more **match** commands and one or more **set** commands follow a **route-map** command. If there are no **match** commands, everything matches. If there are no **set** commands, nothing is done, other than the match. Therefore, you need at least one **match** or **set** command.
A route map with no `set` route-map configuration commands is sent to the CPU, which causes high CPU utilization.

You can also identify route-map statements as `permit` or `deny`. If the statement is marked as a deny, the packets meeting the match criteria are sent back through the normal forwarding channels (destination-based routing). If the statement is marked as permit, set clauses are applied to packets meeting the match criteria. Packets that do not meet the match criteria are forwarded through the normal routing channel.

### How to Configure a Route Map

Although each of Steps 3 through 14 in the following section is optional, you must enter at least one `match` route-map configuration command and one `set` route-map configuration command.

**Note**
The keywords are the same as defined in the procedure to control the route distribution.

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>route-map</code> map-tag `[permit</td>
<td>deny]<code> </code>[sequence number]`</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# route-map rip-to-ospf permit 4</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>match metric</code> metric-value</td>
<td>Matches the specified route metric. The <code>metric-value</code> can be an EIGRP metric with a specified value from 0 to 4294967295.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-route-map)# match metric 2000</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
<td></td>

</table>
| **Step 4**                                | **match ip next-hop** {access-list-number | access-list-name} \[
|                                           | ...access-list-number | ...access-list-name]}  
| Example:                                  | Matches a next-hop router address passed by one of the access lists specified (numbered from 1 to 199). |
| Device(config-route-map)# match ip next-hop 8 45 |                           |
| **Step 5**                                | **match tag** tag value [...tag-value]  
| Example:                                  | Matches the specified tag value in a list of one or more route tag values. Each can be an integer from 0 to 4294967295. |
| Device(config-route-map)# match tag 3500 |                           |
| **Step 6**                                | **match interface** type number [...type number]  
| Example:                                  | Matches the specified next hop route out one of the specified interfaces. |
| Device(config-route-map)# match interface gigabitethernet 1/0/1 |                           |
| **Step 7**                                | **match ip route-source** {access-list-number | access-list-name} \[
|                                           | ...access-list-number | ...access-list-name]}  
| Example:                                  | Matches the address specified by the specified advertised access lists. |
| Device(config-route-map)# match ip route-source 10 30 |                           |
| **Step 8**                                | **match route-type** {local | internal | external [type-1 | type-2]}  
| Example:                                  | Matches the specified route-type:  
|                                           | • internal—OSPF intra-area and interarea routes or EIGRP internal routes.  
|                                           | • external—OSPF external routes (Type 1 or Type 2) or EIGRP external routes. |
| Device(config-route-map)# match route-type local |                           |
| **Step 9**                                | **set metric** metric value  
| Example:                                  | Sets the metric value to give the redistributed routes (for EIGRP only). The metric value is an integer from -294967295 to 294967295. |
| Device(config-route-map)# set metric 100 |                           |
| **Step 10**                               | **set metric** bandwidth delay reliability loading mtu  
| Example:                                  | Sets the metric value to give the redistributed routes (for EIGRP only):  
|                                           | • bandwidth—Metric value or IGRP bandwidth of the route in kilobits per second in the range 0 to 4294967295  
|                                           | • delay—Route delay in tens of microseconds in the range 0 to 4294967295.  
|                                           | • reliability—Likelihood of successful packet transmission expressed as a number between 0 and |
### How to Control Route Distribution

Although each of Steps 3 through 14 in the following section is optional, you must enter at least one **match** route-map configuration command and one **set** route-map configuration command.

#### Purpose

255, where 255 means 100 percent reliability and 0 means no reliability.

- **loading**—Effective bandwidth of the route expressed as a number from 0 to 255 (255 is 100 percent loading).
- **mtu**—Minimum maximum transmission unit (MTU) size of the route in bytes in the range 0 to 4294967295.

### Command or Action

| Step 11 | set metric-type {type-1 | type-2} |
|---------|----------------------------------|
| Example:| Device(config-route-map)# set metric-type type-2 |

Sets the OSPF external metric type for redistributed routes.

<table>
<thead>
<tr>
<th>Step 12</th>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-route-map)# end</td>
</tr>
</tbody>
</table>

Returns to privileged EXEC mode.

<table>
<thead>
<tr>
<th>Step 13</th>
<th>show route-map</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# show route-map</td>
</tr>
</tbody>
</table>

Displays all route maps configured or only the one specified to verify configuration.

<table>
<thead>
<tr>
<th>Step 14</th>
<th>copy running-config startup-config</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# copy running-config startup-config</td>
</tr>
</tbody>
</table>

(Optional) Saves your entries in the configuration file.

### How to Control Route Distribution

The metrics of one routing protocol do not necessarily translate into the metrics of another. For example, the RIP metric is a hop count, and the IGRP metric is a combination of five qualities. In these situations, an artificial metric is assigned to the redistributed route. Uncontrolled exchanging of routing information between different routing protocols can create routing loops and seriously degrade network operation.

If you have not defined a default redistribution metric that replaces metric conversion, some automatic metric translations occur between routing protocols:

- RIP can automatically redistribute static routes. It assigns static routes a metric of 1 (directly connected).

---

**Note**

The keywords are the same as defined in the procedure to configure the route map for redistribution.
• Any protocol can redistribute other routing protocols if a default mode is in effect.

Policy-Based Routing

Information About Policy-Based Routing

You can use policy-based routing (PBR) to configure a defined policy for traffic flows. By using PBR, you can have more control over routing by reducing the reliance on routes derived from routing protocols. PBR can specify and implement routing policies that allow or deny paths based on:

- Identity of a particular end system
- Application
- Protocol

You can use PBR to provide equal-access and source-sensitive routing, routing based on interactive versus batch traffic, or routing based on dedicated links. For example, you could transfer stock records to a corporate office on a high-bandwidth, high-cost link for a short time while transmitting routine application data such as e-mail over a low-bandwidth, low-cost link.

With PBR, you classify traffic using access control lists (ACLs) and then make traffic go through a different path. PBR is applied to incoming packets. All packets received on an interface with PBR enabled are passed through route maps. Based on the criteria defined in the route maps, packets are forwarded (routed) to the appropriate next hop.

- Route map statement marked as permit is processed as follows:
  - A match command can match on length or multiple ACLs. A route map statement can contain multiple match commands. Logical or algorithm function is performed across all the match commands to reach a permit or deny decision.

  For example:

  match length A B
  match ip address acl1 acl2
  match ip address acl3

  A packet is permitted if it is permitted by match length A B or acl1 or acl2 or acl3

  - If the decision reached is permit, then the action specified by the set command is applied on the packet.
  - If the decision reached is deny, then the PBR action (specified in the set command) is not applied. Instead the processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.

  - For PBR, route-map statements marked as deny are not supported.

You can use standard IP ACLs to specify match criteria for a source address or extended IP ACLs to specify match criteria based on an application, a protocol type, or an end station. The process proceeds through the route map until a match is found. If no match is found, normal destination-based routing occurs. There is an implicit deny at the end of the list of match statements.

If match clauses are satisfied, you can use a set clause to specify the IP addresses identifying the next hop router in the path.
How to Configure PBR

- To use PBR, you must have the IP Lite feature set enabled on the switch or stack master.
- Multicast traffic is not policy-routed. PBR applies to only to unicast traffic.
- You can enable PBR on a routed port or an SVI.
- The switch supports PBR based on match length.
- You can apply a policy route map to an EtherChannel port channel in Layer 3 mode, but you cannot apply a policy route map to a physical interface that is a member of the EtherChannel. If you try to do so, the command is rejected. When a policy route map is applied to a physical interface, that interface cannot become a member of an EtherChannel.
- You can define a maximum of 128 IP policy route maps on the switch or switch stack.
- You can define a maximum of 512 access control entries (ACEs) for PBR on the switch or switch stack.
- When configuring match criteria in a route map, follow these guidelines:
  - Do not match ACLs that permit packets destined for a local address. PBR would forward these packets, which could cause ping or Telnet failure or route protocol flapping.
- VRF and PBR are mutually exclusive on a switch interface. You cannot enable VRF when PBR is enabled on an interface. The reverse is also true, you cannot enable PBR when VRF is enabled on an interface.
- The number of hardware entries used by PBR depends on the route map itself, the ACLs used, and the order of the ACLs and route-map entries.
- PBR based on TOS, DSCP and IP Precedence are not supported.
- Set interface, set default next-hop and set default interface are not supported.
- **ip next-hop recursive** and **ip next-hop verify availability** features are not available and the next-hop should be directly connected.
- Policy-maps with no set actions are supported. Matching packets are routed normally.
- Policy-maps with no match clauses are supported. Set actions are applied to all packets.

By default, PBR is disabled on the switch. To enable PBR, you must create a route map that specifies the match criteria and the resulting action. Then, you must enable PBR for that route map on an interface. All packets arriving on the specified interface matching the match clauses are subject to PBR.

Packets that are generated by the switch, or local packets, are not normally policy-routed. When you globally enable local PBR on the switch, all packets that originate on the switch are subject to local PBR. Local PBR is disabled by default.

</tbody>
</table>
| 2    | route-map map-tag [permit] [sequence number] | Defines route maps that are used to control where packets are output, and enters route-map configuration mode.  
  - `map-tag` — A meaningful name for the route map.  
    The `ip policy route-map` interface configuration command uses this name to reference the route map. Multiple route-map statements with the same map tag define a single route map.  
  - (Optional) `permit` — If `permit` is specified and the match criteria are met for this route map, the route is policy routed as defined by the set actions.  
  - (Optional) `sequence number` — The sequence number shows the position of the route-map statement in the given route map.  
  Example:  
  ```
  Device(config)# route-map pbr-map permit
  ```
| 3    | match ip address {access-list-number | access-list-name} [access-list-number] [..access-list-name] | Matches the source and destination IP addresses that are permitted by one or more standard or extended access lists. ACLs can match on more than one source and destination IP address.  
  Example:  
  ```
  Device(config-route-map)# match ip address 110 140
  ```
| 4    | match length min max | Matches the length of the packet.  
  Example:  
  ```
  Device(config-route-map)# match length 64 1500
  ```
| 5    | set ip next-hop ip-address [..ip-address] | Specifies the action to be taken on the packets that match the criteria. Sets next hop to which to route the packet (the next hop must be adjacent).  
  Example:  
  ```
  Device(config-route-map)# set ip next-hop 10.1.6.2
  ```
| 6    | exit | Returns to global configuration mode.  
  Example:  
  ```
  Device(config-route-map)# exit
  ```
| 7    | interface interface-id | Enters interface configuration mode, and specifies the interface to be configured.  
  Example:  
  ```
  Device(config)# interface gigabitethernet 1/0/1
  ```
| 8    | ip policy route-map map-tag | Enables PBR on a Layer 3 interface, and identify the route map to use. You can configure only one route map on an interface. However, you can have multiple route map entries with different sequence numbers. These entries are evaluated in the order of sequence number until the first match. If there is no match, packets are routed as usual.  
  Example:  
  ```
  Device(config-if)# ip policy route-map pbr-map
  ```

### Filtering Routing Information

You can filter routing protocol information by performing the tasks described in this section.

**Note**

When routes are redistributed between OSPF processes, no OSPF metrics are preserved.

### Setting Passive Interfaces

To prevent other routers on a local network from dynamically learning about routes, you can use the **passive-interface** router configuration command to keep routing update messages from being sent through a router interface. When you use this command in the OSPF protocol, the interface address you specify as passive appears as a stub network in the OSPF domain. OSPF routing information is neither sent nor received through the specified router interface.
In networks with many interfaces, to avoid having to manually set them as passive, you can set all interfaces to be passive by default by using the `passive-interface default` router configuration command and manually setting interfaces where adjacencies are desired.

Use a network monitoring privileged EXEC command such as `show ip ospf interface` to verify the interfaces that you enabled as passive, or use the `show ip interface` privileged EXEC command to verify the interfaces that you enabled as active.

### Procedure

### Controlling Advertising and Processing in Routing Updates

You can use the `distribute-list` router configuration command with access control lists to suppress routes from being advertised in routing updates and to prevent other routers from learning one or more routes. When used in OSPF, this feature applies to only external routes, and you cannot specify an interface name.

You can also use a `distribute-list` router configuration command to avoid processing certain routes listed in incoming updates. (This feature does not apply to OSPF.)

### Filtering Sources of Routing Information

Because some routing information might be more accurate than others, you can use filtering to prioritize information coming from different sources. An administrative distance is a rating of the trustworthiness of a routing information source, such as a router or group of routers. In a large network, some routing protocols can be more reliable than others. By specifying administrative distance values, you enable the router to intelligently discriminate between sources of routing information. The router always picks the route whose routing protocol has the lowest administrative distance.

Because each network has its own requirements, there are no general guidelines for assigning administrative distances.

</table>
Managing Authentication Keys

Key management is a method of controlling authentication keys used by routing protocols. Not all protocols can use key management. Authentication keys are available for EIGRP and RIP Version 2.

Prerequisites

Before you manage authentication keys, you must enable authentication. See the appropriate protocol section to see how to enable authentication for that protocol. To manage authentication keys, define a key chain, identify the keys that belong to the key chain, and specify how long each key is valid. Each key has its own key identifier (specified with the `key number` key chain configuration command), which is stored locally. The combination of the key identifier and the interface associated with the message uniquely identifies the authentication algorithm and Message Digest 5 (MD5) authentication key in use.

How to Configure Authentication Keys

You can configure multiple keys with life times. Only one authentication packet is sent, regardless of how many valid keys exist. The software examines the key numbers in order from lowest to highest, and uses the first valid key it encounters. The lifetimes allow for overlap during key changes. Note that the router must know these lifetimes.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Bidirectional Forwarding Detection

Prerequisites for BFD include:

- The switch’s feature set is IP Base or higher. The IP Base feature set supports only Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing, without BFD. The IP service feature set supports EIGRP with BFD.
- IP routing must be enabled on all participating switches
- Before BFD is deployed, configure one of the IP routing protocols supported by BFD on the switches. Also, implement fast convergence for the routing protocol that you plan to use.
Restrictions for Bidirectional Forwarding Detection

Restrictions for BFD include:

- BFD works only for directly connected neighbors. BFD neighbors must be no more than one IP hop away. Multihop configurations are not supported.
- The switch supports up to 100 BFD sessions with a minimum hello interval of 100 ms and a multiplier of 3. The multiplier specifies the minimum number of consecutive packets that can be missed before a session is declared down.
- To enable echo mode the peer system must be configured with the no ip redirects command.

Information About Bidirectional Forwarding Detection

BFD Operation

BFD provides a low-overhead, short-duration method of detecting failures in the forwarding path between two adjacent routers, including the interfaces, data links, and forwarding planes.

BFD is a detection protocol that you enable at the interface and routing protocol levels. Cisco supports the BFD asynchronous mode, which depends on the sending of BFD control packets between two systems to activate and maintain BFD neighbor sessions between routers. Therefore, in order for a BFD session to be created, you must configure BFD on both systems (or BFD peers). Once BFD has been enabled on the interfaces and at the router level for the appropriate routing protocols, a BFD session is created, BFD timers are negotiated, and the BFD peers will begin to send BFD control packets to each other at the negotiated interval.

Cisco supports BFD echo mode. Echo packets are sent by the forwarding engine and are forwarded back along the same path to perform detection. The BFD session at the other end does not participate in the actual forwarding of the echo packets.

This section includes the following subsections:

BFD Version Interoperability

The switch supports BFD Version 1 as well as BFD Version 0. All BFD sessions come up as Version 1 by default and will be interoperable with Version 0. The system automatically performs BFD version detection, and BFD sessions between neighbors will run in the highest common BFD version between neighbors. For example, if one BFD neighbor is running BFD Version 0 and the other BFD neighbor is running Version 1, the session will run BFD Version 0. The output from the `show bfd neighbors [details]` command will verify which BFD version a BFD neighbor is running.

BFD Session Limits

The minimum number of BFD sessions that can be created varies with the “hello” interval. With “hello” intervals of 100ms, 100 sessions are permitted. More sessions are permitted at larger hello intervals. For a VLAN interface, the minimum “hello” interval is 600ms.
BFD Support for Nonbroadcast Media Interfaces

The BFD feature is supported on VLAN interfaces on the switch.

The bfd interval command must be configured on the interface to initiate BFD monitoring.

BFD Support for Nonstop Forwarding with Stateful Switchover

Typically, when a networking device restarts, all routing peers of that device detect that the device went down and then came back up. This transition results in a routing flap, which could spread across multiple routing domains. Routing flaps caused by routing restarts create routing instabilities, which are detrimental to the overall network performance. Nonstop forwarding (NSF) helps to suppress routing flaps in devices that are enabled with stateful switchover (SSO), thereby reducing network instability.

NSF allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored after a switchover. With NSF, peer networking devices do not experience routing flaps. Data traffic is forwarded through intelligent line cards or dual forwarding processors while the standby RP assumes control from the failed active RP during a switchover. The ability of line cards and forwarding processors to remain up through a switchover and to be kept current with the Forwarding Information Base (FIB) on the active RP is key to NSF operation.

In devices that support dual RPs, SSO establishes one of the RPs as the active processor; the other RP is designated as the standby processor, and then synchronizes information between them. A switchover from the active to the standby processor occurs when the active RP fails, when it is removed from the networking device, or when it is manually taken down for maintenance.

BFD Support for Stateful Switchover

The BFD protocol provides short-duration detection of failures in the path between adjacent forwarding engines. In network deployments that use dual RP switches (to provide redundancy), the switches have a graceful restart mechanism that protects the forwarding state during a switchover between the active RP and the standby RP.

Stateful BFD on the Standby RP

To ensure a successful switchover to the standby RP, the BFD protocol uses checkpoint messages to send session information from the active RP Cisco IOS instance to the standby RP Cisco IOS instance. The session information includes local and remote discriminators, adjacent router timer information, BFD setup information, and session-specific information such as the type of session and the session version. In addition, the BFD protocol sends session creation and deletion checkpoint messages to create or delete a session on the standby RP.

The BFD sessions on the standby RP do not receive or send packets and do not process expired timers. These sessions wait for a switchover to occur and then send packets for any active sessions so that sessions do not time out on adjacent switches.

When the BFD protocol on the standby RP is notified of a switchover it changes its state to active, registers itself with Cisco Express Forwarding so that it can receive packets, and then sends packets for any elements that have expired.

BFD also uses checkpoint messages to ensure that sessions created by clients on the active RP are maintained during a switchover. When a switchover occurs, BFD starts an SSO reclaim timer. Clients must reclaim their sessions within the duration specified by the reclaim timer or else the session is deleted.
Timer values are different based on the number of BFD sessions and the platform.

### BFD Support for Static Routing

Unlike dynamic routing protocols, such as OSPF and BGP, static routing has no method of peer discovery. Therefore, when BFD is configured, the reachability of the gateway is completely dependent on the state of the BFD session to the specified neighbor. Unless the BFD session is up, the gateway for the static route is considered unreachable, and therefore the affected routes will not be installed in the appropriate Routing Information Base (RIB).

For a BFD session to be successfully established, BFD must be configured on the interface on the peer and there must be a BFD client registered on the peer for the address of the BFD neighbor. When an interface is used by dynamic routing protocols, the latter requirement is usually met by configuring the routing protocol instances on each neighbor for BFD. When an interface is used exclusively for static routing, this requirement must be met by configuring static routes on the peers.

If a BFD configuration is removed from the remote peer while the BFD session is in the up state, the updated state of the BFD session is not signaled to the static static. This will cause the static route to remain in the RIB. The only workaround is to remove the IPv4 static BFD neighbor configuration so that the static route no longer tracks BFD session state.

### Configuring BFD Echo Mode

BFD echo mode is enabled by default, but you can disable it such that it can run independently in each direction.

BFD echo mode works with asynchronous BFD. Echo packets are sent by the forwarding engine and forwarded back along the same path in order to perform detection—the BFD session at the other end does not participate in the actual forwarding of the echo packets. The echo function and the forwarding engine are responsible for the detection process; therefore, the number of BFD control packets that are sent out between two BFD neighbors is reduced. In addition, because the forwarding engine is testing the forwarding path on the remote (neighbor) system without involving the remote system, there is an opportunity to improve the interpacket delay variance, thereby achieving quicker failure detection times than when using BFD Version 0 with BFD control packets for the BFD session.

Echo mode is described as without asymmetry when it is running on both sides (both BFD neighbors are running echo mode).

### Prerequisites

BFD must be running on all participating switches.

Before using BFD echo mode, you must disable the sending of Internet Control Message Protocol (ICMP) redirect messages by entering the `no ip redirects` command, in order to avoid high CPU utilization.
The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the Configuring BFD Session Parameters on the Interface section for more information.

Restrictions

BFD echo mode, which is supported in BFD Version 1.

Note

BFD echo mode does not work in conjunction with Unicast Reverse Path Forwarding (uRPF) configuration. If BFD echo mode and uRPF configurations are enabled, then the sessions will flap.

How to Configure Bidirectional Forwarding Detection

You start a BFD process by configuring BFD on the interface. When the BFD process is started, no entries are created in the adjacency database; in other words, no BFD control packets are sent or received. BFD echo mode, which is supported in BFD Version 1.

BFD echo packets are sent and received, in addition to BFD control packets. The adjacency creation takes places once you have configured BFD support for the applicable routing protocols. This section contains the following procedures:

Configuring BFD Session Parameters on the Interface

Perform this task to configure BFD on an interface by setting the baseline BFD session parameters on the interface. Repeat this task on each interface over which you want to run BFD sessions to BFD neighbors.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. bfd interval milliseconds min_rx milliseconds multiplier interval-multiplier
5. no bfd echo
6. end

DETAILED STEPS

Disabling BFD Echo Mode Without Asymmetry

This task shows how to disable BFD echo mode without asymmetry—no echo packets will be sent by the switch, and the switch will not forward BFD echo packets that are received from any neighbor switches. Repeat the steps in this task for each BFD switch.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no bfd echo`
4. `end`

Configuration Examples for Bidirectional Forwarding Detection

**Example: Configuring BFD Session Parameters on the Interface**

```
Switch# configure terminal
Switch(config)# interface GigabitEthernet 6/1
Switch(config-if)# bfd interval 50 min_rx 50 multiplier 5
Switch(config-if)# no bfd echo
```

**Example: Configuring BFD Support for Static Routing**

In the following example, the network consists of Device A and Device B. Serial interface 2/0 on Device A is connected to the same network as serial interface 2/0 on Device B. In order for the BFD session to come up, Device B must be configured.
Device A

```bash
configure terminal
interface Serial 2/0
ip address 10.201.201.1 255.255.255.0
bfd interval 500 min_rx 500 multiplier 5
ip route static bfd Serial 2/0 10.201.201.2
ip route 10.0.0.0 255.0.0.0 Serial 2/0 10.201.201.2
```

Device B

```bash
configure terminal
interface Serial 2/0
ip address 10.201.201.2 255.255.255.0
bfd interval 500 min_rx 500 multiplier 5
ip route static bfd Serial 2/0 10.201.201.1
ip route 10.1.1.1 255.255.255.255 Serial 2/0 10.201.201.1
```

Note that the static route on Device B exists solely to enable the BFD session between 10.201.201.1 and 10.201.201.2. If there is no useful static route that needs to be configured, select a prefix that will not affect packet forwarding, for example, the address of a locally configured loopback interface.

In the following example, there is an active static BFD configuration to reach 209.165.200.225 through Ethernet interface 0/0 in the BFD group testgroup. As soon as the static route is configured that is tracked by the configured static BFD, a single hop BFD session is initiated to 209.165.200.225 through Ethernet interface 0/0. The prefix 10.0.0.0/8 is added to the RIB if a BFD session is successfully established.

```bash
configure terminal
ip route static bfd Ethernet 0/0 209.165.200.225 group testgroup
ip route 10.0.0.0 255.255.255.224 Ethernet 0/0 209.165.200.225
```

In the following example, a BFD session to 209.165.200.226 through Ethernet interface 0/0.1001 is marked to use the group testgroup. That is, this configuration is a passive static BFD. Though there are static routes to be tracked by the second static BFD configuration, a BFD session is not triggered for 209.165.200.226 through Ethernet interface 0/0.1001. The existence of the prefixes 10.1.1.1/8 and 10.2.2.2/8 is controlled by the active static BFD session (Ethernet interface 0/0 209.165.200.225).

```bash
configure terminal
ip route static bfd Ethernet 0/0 209.165.200.225 group testgroup
ip route 10.0.0.0 255.255.255.224 Ethernet 0/0 209.165.200.225
ip route static bfd Ethernet 0/0.1001 209.165.200.226 group testgroup passive
ip route 10.1.1.1 255.255.255.224 Ethernet 0/0.1001 209.165.200.226
ip route 10.2.2.2 255.255.255.224 Ethernet 0/0.1001 209.165.200.226
```

**Example: Configuring BFD Slow Timer**

```
Switch# configure terminal
Switch(config)# bfd slow-timer 12000
```

Feature Information for Bidirectional Forwarding Detection

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
The Bidirectional Forwarding Detection (BFD) protocol is a detection protocol that is designed to provide fast forwarding path failure detection for all media types, encapsulations, topologies, and routing protocols.

BFD provides a consistent failure detection method for network administrators, in addition to fast forwarding path failure detection. Because the network administrator can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms, network profiling and planning will be easier, and reconvergence time will be consistent and predictable.

This feature was implemented on Cisco Catalyst 2960-XR Series Switches.
Feature Information for Bidirectional Forwarding Detection
Bidirectional Forwarding Detection

The Bidirectional Forwarding Detection (BFD) protocol is a detection protocol that provides fast forwarding path failure detection for all media types, encapsulations, topologies, and routing protocols.

BFD provides a consistent failure detection method for network administrators, in addition to fast forwarding path failure detection. Because the network administrator can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms, network profiling and planning will be easier, and reconvergence time will be consistent and predictable.

This module explains how to configure multihop BFD sessions.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Bidirectional Forwarding Detection

Prerequisites for BFD include:
• The switch’s feature set is IP Base or higher. The IP Base feature set supports only Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing, without BFD. The IP service feature set supports EIGRP with BFD.

• IP routing must be enabled on all participating switches.

• Before BFD is deployed, configure one of the IP routing protocols supported by BFD on the switches. Also, implement fast convergence for the routing protocol that you plan to use.

Restrictions for Bidirectional Forwarding Detection

Restrictions for BFD include:

• BFD works only for directly connected neighbors. BFD neighbors must be no more than one IP hop away. Multihop configurations are not supported.

• The switch supports up to 100 BFD sessions with a minimum hello interval of 100 ms and a multiplier of 3. The multiplier specifies the minimum number of consecutive packets that can be missed before a session is declared down.

• To enable echo mode the peer system must be configured with the no ip redirects command.

Information About Bidirectional Forwarding Detection

BFD Operation

BFD provides a low-overhead, short-duration method of detecting failures in the forwarding path between two adjacent routers, including the interfaces, data links, and forwarding planes.

BFD is a detection protocol that you enable at the interface and routing protocol levels. Cisco supports the BFD asynchronous mode, which depends on the sending of BFD control packets between two systems to activate and maintain BFD neighbor sessions between routers. Therefore, in order for a BFD session to be created, you must configure BFD on both systems (or BFD peers). Once BFD has been enabled on the interfaces and at the router level for the appropriate routing protocols, a BFD session is created, BFD timers are negotiated, and the BFD peers will begin to send BFD control packets to each other at the negotiated interval.

Cisco supports BFD echo mode. Echo packets are sent by the forwarding engine and are forwarded back along the same path to perform detection. The BFD session at the other end does not participate in the actual forwarding of the echo packets.

This section includes the following subsections:

BFD Version Interoperability

The switch supports BFD Version 1 as well as BFD Version 0. All BFD sessions come up as Version 1 by default and will be interoperable with Version 0. The system automatically performs BFD version detection, and BFD sessions between neighbors will run in the highest common BFD version between neighbors. For example, if one BFD neighbor is running BFD Version 0 and the other BFD neighbor is running Version 1,
the session will run BFD Version 0. The output from the `show bfd neighbors [details]` command will verify which BFD version a BFD neighbor is running.

**BFD Session Limits**

The minimum number of BFD sessions that can be created varies with the “hello” interval. With “hello” intervals of 100ms, 100 sessions are permitted. More sessions are permitted at larger hello intervals. For a VLAN interface, the minimum “hello” interval is 600ms.

**BFD Support for Nonbroadcast Media Interfaces**

The BFD feature is supported on VLAN interfaces on the switch.

The `bfd interval` command must be configured on the interface to initiate BFD monitoring.

**BFD Support for Nonstop Forwarding with Stateful Switchover**

Typically, when a networking device restarts, all routing peers of that device detect that the device went down and then came back up. This transition results in a routing flap, which could spread across multiple routing domains. Routing flaps caused by routing restarts create routing instabilities, which are detrimental to the overall network performance. Nonstop forwarding (NSF) helps to suppress routing flaps in devices that are enabled with stateful switchover (SSO), thereby reducing network instability.

NSF allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored after a switchover. With NSF, peer networking devices do not experience routing flaps. Data traffic is forwarded through intelligent line cards or dual forwarding processors while the standby RP assumes control from the failed active RP during a switchover. The ability of line cards and forwarding processors to remain up through a switchover and to be kept current with the Forwarding Information Base (FIB) on the active RP is key to NSF operation.

In devices that support dual RPs, SSO establishes one of the RPs as the active processor; the other RP is designated as the standby processor, and then synchronizes information between them. A switchover from the active to the standby processor occurs when the active RP fails, when it is removed from the networking device, or when it is manually taken down for maintenance.

**BFD Support for Stateful Switchover**

The BFD protocol provides short-duration detection of failures in the path between adjacent forwarding engines. In network deployments that use dual RP switches (to provide redundancy), the switches have a graceful restart mechanism that protects the forwarding state during a switchover between the active RP and the standby RP.

**Stateful BFD on the Standby RP**

To ensure a successful switchover to the standby RP, the BFD protocol uses checkpoint messages to send session information from the active RP Cisco IOS instance to the standby RP Cisco IOS instance. The session information includes local and remote discriminators, adjacent router timer information, BFD setup information, and session-specific information such as the type of session and the session version. In addition, the BFD protocol sends session creation and deletion checkpoint messages to create or delete a session on the standby RP.
The BFD sessions on the standby RP do not receive or send packets and do not process expired timers. These sessions wait for a switchover to occur and then send packets for any active sessions so that sessions do not time out on adjacent switches.

When the BFD protocol on the standby RP is notified of a switchover it changes its state to active, registers itself with Cisco Express Forwarding so that it can receive packets, and then sends packets for any elements that have expired.

BFD also uses checkpoint messages to ensure that sessions created by clients on the active RP are maintained during a switchover. When a switchover occurs, BFD starts an SSO reclaim timer. Clients must reclaim their sessions within the duration specified by the reclaim timer or else the session is deleted.

Timer values are different based on the number of BFD sessions and the platform.

### BFD Support for Static Routing

Unlike dynamic routing protocols, such as OSPF and BGP, static routing has no method of peer discovery. Therefore, when BFD is configured, the reachability of the gateway is completely dependent on the state of the BFD session to the specified neighbor. Unless the BFD session is up, the gateway for the static route is considered unreachable, and therefore the affected routes will not be installed in the appropriate Routing Information Base (RIB).

For a BFD session to be successfully established, BFD must be configured on the interface on the peer and there must be a BFD client registered on the peer for the address of the BFD neighbor. When an interface is used by dynamic routing protocols, the latter requirement is usually met by configuring the routing protocol instances on each neighbor for BFD. When an interface is used exclusively for static routing, this requirement must be met by configuring static routes on the peers.

If a BFD configuration is removed from the remote peer while the BFD session is in the up state, the updated state of the BFD session is not signaled to the static static. This will cause the static route to remain in the RIB. The only workaround is to remove the IPv4 static BFD neighbor configuration so that the static route no longer tracks BFD session state.

### Configuring BFD Echo Mode

BFD echo mode is enabled by default, but you can disable it such that it can run independently in each direction. BFD echo mode works with asynchronous BFD. Echo packets are sent by the forwarding engine and forwarded back along the same path in order to perform detection—the BFD session at the other end does not participate in the actual forwarding of the echo packets. The echo function and the forwarding engine are responsible for the detection process; therefore, the number of BFD control packets that are sent out between two BFD neighbors is reduced. In addition, because the forwarding engine is testing the forwarding path on the remote (neighbor) system without involving the remote system, there is an opportunity to improve the interpacket delay variance, thereby achieving quicker failure detection times than when using BFD Version 0 with BFD control packets for the BFD session.
Echo mode is described as without asymmetry when it is running on both sides (both BFD neighbors are running echo mode).

**Prerequisites**

BFD must be running on all participating switches.

Before using BFD echo mode, you must disable the sending of Internet Control Message Protocol (ICMP) redirect messages by entering the `no ip redirects` command, in order to avoid high CPU utilization.

The baseline parameters for BFD sessions on the interfaces over which you want to run BFD sessions to BFD neighbors must be configured. See the Configuring BFD Session Parameters on the Interface section for more information.

**Restrictions**

BFD echo mode, which is supported in BFD Version 1.

---

**Note**

BFD echo mode does not work in conjunction with Unicast Reverse Path Forwarding (uRPF) configuration. If BFD echo mode and uRPF configurations are enabled, then the sessions will flap.

---

**How to Configure Bidirectional Forwarding Detection**

You start a BFD process by configuring BFD on the interface. When the BFD process is started, no entries are created in the adjacency database; in other words, no BFD control packets are sent or received. BFD echo mode, which is supported in BFD Version 1.

BFD echo packets are sent and received, in addition to BFD control packets. The adjacency creation takes places once you have configured BFD support for the applicable routing protocols. This section contains the following procedures:

**Configuring BFD Session Parameters on the Interface**

Perform this task to configure BFD on an interface by setting the baseline BFD session parameters on the interface. Repeat this task on each interface over which you want to run BFD sessions to BFD neighbors.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface type number
4. bfd interval milliseconds min_rx milliseconds multiplier interval-multiplier
5. no bfd echo
6. end

### Configuring the BFD Slow Timer

This task shows how to change the value of the BFD slow timer. Repeat the steps in this task for each BFD switch.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. bfd slow-timer milliseconds
4. end

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 bfd slow-timer milliseconds</td>
<td></td>
</tr>
<tr>
<td>Step 4 end</td>
<td></td>
</tr>
</tbody>
</table>

### Example:

Switch(config)# enable

Switch(config)# configure terminal

Switch(config)# bfd slow-timer 5000

Switch(config)# end

---

### Purpose

- The `interface-type`, `interface-number`, and `ip-address` arguments are required because BFD support exists only for directly connected neighbors.

### Example:

```
Switch(config)# ip route static bfd serial 2/0 10.1.1.1 group group1 passive
```

Specifies a static route BFD neighbor.

### Step 9

```
ip route [vrf vrf-name] prefix mask {ip-address | interface-type interface-number [ip-address]} [dhc] [distance] [name next-hop-name] [permanent | track number] [tag tag]
```

Specify a static route BFD neighbor.

### Example:

```
Switch(config)# ip route 10.0.0.0 255.0.0.0 Gigabitethernet 6/1 10.201.201.2
```

Exits global configuration mode and returns to privileged EXEC mode.

### Step 10

```
exit
```

(Optional) Displays static route database information.

### Step 11

```
show ip static route
```

(Optional) Displays information about the static BFD configuration from the configured BFD groups and non-group entries.

### Step 12

```
show ip static route bfd
```

**Configuring the BFD Slow Timer**

This task shows how to change the value of the BFD slow timer. Repeat the steps in this task for each BFD switch.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. bfd slow-timer milliseconds
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 bfd slow-timer milliseconds</td>
<td></td>
</tr>
<tr>
<td>Step 4 end</td>
<td></td>
</tr>
</tbody>
</table>

---

**Example:**

```
Switch(config)# ip route static bfd serial 2/0 10.1.1.1 group group1 passive
```

Specifies a static route BFD neighbor.

**Step 9**

```
ip route [vrf vrf-name] prefix mask {ip-address | interface-type interface-number [ip-address]} [dhc] [distance] [name next-hop-name] [permanent | track number] [tag tag]
```

Specify a static route BFD neighbor.

**Example:**

```
Switch(config)# ip route 10.0.0.0 255.0.0.0 Gigabitethernet 6/1 10.201.201.2
```

Exits global configuration mode and returns to privileged EXEC mode.

**Step 10**

```
exit
```

(Optional) Displays static route database information.

**Step 11**

```
show ip static route
```

(Optional) Displays information about the static BFD configuration from the configured BFD groups and non-group entries.

**Step 12**

```
show ip static route bfd
```

```
### Disabling BFD Echo Mode Without Asymmetry

This task shows how to disable BFD echo mode without asymmetry—no echo packets will be sent by the switch, and the switch will not forward BFD echo packets that are received from any neighbor switches.

Repeat the steps in this task for each BFD switch.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no bfd echo`
4. `end`

#### DETAILED STEPS

<table>

Configuration Examples for Bidirectional Forwarding Detection

Example: Configuring BFD Session Parameters on the Interface

```plaintext
Switch# configure terminal
Switch(config)# interface GigabitEthernet 6/1
Switch(config-if)# bfd interval 50 min_rx 50 multiplier 5
Switch(config-if)# no bfd echo
```

Example: Configuring BFD Support for Static Routing

In the following example, the network consists of Device A and Device B. Serial interface 2/0 on Device A is connected to the same network as serial interface 2/0 on Device B. In order for the BFD session to come up, Device B must be configured.

**Device A**

```plaintext
configure terminal
interface Serial 2/0
ip address 10.201.201.1 255.255.255.0
bfd interval 500 min_rx 500 multiplier 5
ip route static bfd Serial 2/0 10.201.201.2
ip route 10.0.0.0 255.0.0.0 Serial 2/0 10.201.201.2
```

**Device B**

```plaintext
configure terminal
interface Serial 2/0
ip address 10.201.201.2 255.255.255.0
bfd interval 500 min_rx 500 multiplier 5
ip route static bfd Serial 2/0 10.201.201.1
ip route 10.1.1.1 255.255.255.255 Serial 2/0 10.201.201.1
```

Note that the static route on Device B exists solely to enable the BFD session between 10.201.201.1 and 10.201.201.2. If there is no useful static route that needs to be configured, select a prefix that will not affect packet forwarding, for example, the address of a locally configured loopback interface.

In the following example, there is an active static BFD configuration to reach 209.165.200.225 through Ethernet interface 0/0 in the BFD group testgroup. As soon as the static route is configured that is tracked by the configured static BFD, a single hop BFD session is initiated to 209.165.200.225 through Ethernet interface 0/0. The prefix 10.0.0.0/8 is added to the RIB if a BFD session is successfully established.

```plaintext
configure terminal
ip route static bfd Ethernet 0/0 209.165.200.225 group testgroup
ip route 10.0.0.0 255.255.255.224 Ethernet 0/0 209.165.200.225
```

In the following example, a BFD session to 209.165.200.226 through Ethernet interface 0/0.1001 is marked to use the group testgroup. That is, this configuration is a passive static BFD. Though there are static routes to be tracked by the second static BFD configuration, a BFD session is not triggered for 209.165.200.226 through Ethernet interface 0/0.1001. The existence of the prefixes 10.1.1.1/8 and 10.2.2.2/8 is controlled by the active static BFD session (Ethernet interface 0/0 209.165.200.225).
Example: Configuring BFD Slow Timer

Switch# configure terminal
Switch(config)# bfd slow-timer 12000

Feature Information for Bidirectional Forwarding Detection

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
The Bidirectional Forwarding Detection (BFD) protocol is a detection protocol that is designed to provide fast forwarding path failure detection for all media types, encapsulations, topologies, and routing protocols.

BFD provides a consistent failure detection method for network administrators, in addition to fast forwarding path failure detection. Because the network administrator can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms, network profiling and planning will be easier, and reconvergence time will be consistent and predictable.

This feature was implemented on Cisco Catalyst 2960-XR Series Switches.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for First Hop Security in IPv6

- You have configured the necessary IPv6 enabled SDM template.
- You should be familiar with the IPv6 neighbor discovery feature.
Restrictions for First Hop Security in IPv6

- The following restrictions apply when applying FHS policies to EtherChannel interfaces (Port Channels):
  - A physical port with an FHS policy attached cannot join an EtherChannel group.
  - An FHS policy cannot be attached to a physical port when it is a member of an EtherChannel group.

- By default, a snooping policy has a security-level of guard. When such a snooping policy is configured on an access switch, external IPv6 Router Advertisement (RA) or Dynamic Host Configuration Protocol for IPv6 (DHCPv6) server packets are blocked, even though the uplink port facing the router or DHCP server/relay is configured as a trusted port. To allow IPv6 RA or DHCPv6 server messages, do the following:
  - Apply an IPv6 RA-guard policy (for RA) or IPv6 DHCP-guard policy (for DHCP server messages) on the uplink port.
  - Configure a snooping policy with a lower security-level, for example glean or inspect. However; configuring a lower security level is not recommended with such a snooping policy, because benefits of First Hop security features are not effective.

Information about First Hop Security in IPv6

First Hop Security in IPv6 (FHS IPv6) is a set of IPv6 security features, the policies of which can be attached to a physical interface, or a VLAN. An IPv6 software policy database service stores and accesses these policies. When a policy is configured or modified, the attributes of the policy are stored or updated in the software policy database, then applied as was specified. The following IPv6 policies are currently supported:

- IPv6 FHS Binding Table Content—A database table of IPv6 neighbors connected to the switch is created from information sources such as Neighbor Discovery (ND) protocol snooping. This database, or binding, table is used by various IPv6 guard features (such as IPv6 ND Inspection) to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors to prevent spoofing and redirect attacks.

- IPv6 Neighbor Discovery Inspection—IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables. IPv6 ND inspection analyzes neighbor discovery messages in order to build a trusted binding table database and IPv6 neighbor discovery messages that do not conform are dropped. An ND message is considered trustworthy if its IPv6-to-Media Access Control (MAC) mapping is verifiable.

  This feature mitigates some of the inherent vulnerabilities of the ND mechanism, such as attacks on DAD, address resolution, router discovery, and the neighbor cache.

- IPv6 Router Advertisement Guard—The IPv6 Router Advertisement (RA) guard feature enables the network administrator to block or reject unwanted or rogue RA guard messages that arrive at the network switch platform. RAs are used by routers to announce themselves on the link. The RA Guard feature analyzes the RAs and filters out bogus RAs sent by unauthorized routers. In host mode, all router
advertisement and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 device with the information found in the received RA frame. Once the Layer 2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.

- IPv6 DHCP Guard—The IPv6 DHCP Guard feature blocks reply and advertisement messages that come from unauthorized DHCPv6 servers and relay agents. IPv6 DHCP guard can prevent forged messages from being entered in the binding table and block DHCPv6 server messages when they are received on ports that are not explicitly configured as facing a DHCPv6 server or DHCP relay. To use this feature, configure a policy and attach it to an interface or a VLAN. To debug DHCP guard packets, use the `debug ipv6 snooping dhcp-guard` privileged EXEC command.

- IPv6 Source Guard—Like IPv4 Source Guard, IPv6 Source Guard validates the source address or prefix to prevent source address spoofing.

  A source guard programs the hardware to allow or deny traffic based on source or destination addresses. It deals exclusively with data packet traffic.

  The IPv6 source guard feature provides the ability to use the IPv6 binding table to install PACLs to prevent a host from sending packets with an invalid IPv6 source address.

To debug source-guard packets, use the `debug ipv6 snooping source-guard` privileged EXEC command.

  **Note** The IPv6 PACL feature is supported only in the ingress direction; it is not supported in the egress direction.

The following restrictions apply:

- An FHS policy cannot be attached to a physical port when it is a member of an EtherChannel group.

- When IPv6 source guard is enabled on a switch port, NDP or DHCP snooping must be enabled on the interface to which the switch port belongs. Otherwise, all data traffic from this port will be blocked.

- An IPv6 source guard policy cannot be attached to a VLAN. It is supported only at the interface level.

- When you configure IPv4 and IPv6 source guard together on an interface, it is recommended to use `ip verify source mac-check` instead of `ip verify source`. IPv4 connectivity on a given port might break due to two different filtering rules set — one for IPv4 (IP-filter) and the other for IPv6 (IP-MAC filter).

- You cannot use IPv6 Source Guard and Prefix Guard together. When you attach the policy to an interface, it should be “validate address” or “validate prefix” but not both.

- PVLAN and Source/Prefix Guard cannot be applied together.

For more information on IPv6 Source Guard, see the IPv6 Source Guard chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Prefix Guard—The IPv6 prefix guard feature works within the IPv6 source guard feature, to enable the device to deny traffic originated from non-topologically correct addresses. IPv6 prefix guard is often
used when IPv6 prefixes are delegated to devices (for example, home gateways) using DHCP prefix delegation. The feature discovers ranges of addresses assigned to the link and blocks any traffic sourced with an address outside this range.

For more information on IPv6 Prefix Guard, see the IPv6 Prefix Guard chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Destination Guard—The IPv6 destination guard feature works with IPv6 neighbor discovery to ensure that the device performs address resolution only for those addresses that are known to be active on the link. It relies on the address glean functionality to populate all destinations active on the link into the binding table and then blocks resolutions before they happen when the destination is not found in the binding table.

  Note: IPv6 Destination Guard is recommended only on Layer 3. It is not recommended on Layer2.

For more information about IPv6 Destination Guard, see the IPv6 Destination Guard chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Neighbor Discovery Multicast Suppress—The IPv6 Neighbor Discovery multicast suppress feature is an IPv6 snooping feature that runs on a switch or a wireless controller and is used to reduce the amount of control traffic necessary for proper link operations.

- DHCPv6 Relay—Lightweight DHCPv6 Relay Agent—The DHCPv6 Relay—Lightweight DHCPv6 Relay Agent feature allows relay agent information to be inserted by an access node that performs a link-layer bridging (non-routing) function. Lightweight DHCPv6 Relay Agent (LDRA) functionality can be implemented in existing access nodes, such as DSL access multiplexers (DSLAMs) and Ethernet switches, that do not support IPv6 control or routing functions. LDRA is used to insert relay-agent options in DHCP version 6 (DHCPv6) message exchanges primarily to identify client-facing interfaces. LDRA functionality can be enabled on an interface and on a VLAN.

  Note: If an LDRA device is directly connected to a client, the interface must have the pool configuration to fetch the specific subnet or link information at the server side. In this case, if the LDRA device is present in different subnets or links, the server may not be able to fetch the correct subnet. You can now configure the pool name in the interface so as to choose the proper subnet or link for the client.

For more information about DHCPv6 Relay, See the DHCPv6 Relay—Lightweight DHCPv6 Relay Agent section of the IP Addressing: DHCP Configuration Guide, Cisco IOS Release 15.1SG.

### How to Configure an IPv6 Snooping Policy

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Snooping Policy:

**SUMMARY STEPS**

1. `configure terminal`
### How to Configure an IPv6 Snooping Policy

Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)
### How to Attach an IPv6 Snooping Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping policy on an interface or VLAN:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface Interface_type stack/module/port`
3. `switchport`
4. `ipv6 snooping [attach-policy policy_name [ [vlan vlan_id | add vlan_ids | except vlan_ids | none] [remove vlan_ids]] | vlan vlan_id | add vlan_ids | except vlan_ids | none | remove vlan_ids | all]`
5. `do show running-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>interface Interface_type stack/module/port</code></td>
<td>Specifies an interface type and identifier; enters the interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

#### What to do next

Attach an IPv6 Snooping policy to interfaces or VLANs.
### How to Attach an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping policy on an EtherChannel interface or VLAN:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)# interface gigabitethernet 1/1/4</td>
<td>Enters the Switchport mode.</td>
</tr>
</tbody>
</table>

**Step 3**

**switchport**

*Example:*

Device(config-if)# switchport

**Note**  
To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the switchport interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration. The command prompt displays as (config-if)# in Switchport configuration mode.

**Step 4**

ipv6 snooping [attach-policy policy_name [ vlan vlan_id | add vlan_ids | except vlan_ids | none | remove vlan_ids]_vlan vlan_id | add vlan_ids | except vlan_ids | none | remove vlan_ids | all |]

*Example:*

Device(config-if)# ipv6 snooping

or

Device(config-if)# ipv6 snooping attach-policy example_policy

or

Device(config-if)# ipv6 snooping vlan 111,112

or

Device(config-if)# ipv6 snooping attach-policy example_policy vlan 111,112

Attaches a custom ipv6 snooping policy to the interface or the specified VLANs on the interface. To attach the default policy to the interface, use the ipv6 snooping command without the attach-policy keyword. To attach the default policy to VLANs on the interface, use the ipv6 snooping vlan command. The default policy is, security-level guard, device-role node, protocol ndp and dhcp.

**Step 5**

*do show running-config*

*Example:*

Device(config-if)# do show running-config

Verifies that the policy is attached to the specified interface without exiting the interface configuration mode.
### How to Configure the IPv6 Binding Table Content

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content:

**SUMMARY STEPS**

1. `configure terminal`
2. `[no] ipv6 neighbor binding [vlan vlan-id] ipv6-address interface interface_type stack/module/port hw_address [reachable-lifetimevalue [seconds | default | infinite] | [tracking] [default | disable]`

### How to Attach an IPv6 Router Advertisement Guard Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement policy to an interface or to VLANs on the interface:

#### SUMMARY STEPS

1. `configure terminal`
2. `interface Interface_type stack/module/port`
3. `ipv6 nd raguard [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ] | vlan [ {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ]]

   Example:
   ```
   Device(config-if)# ipv6 nd raguard attach-policy example_policy
   or
   Device(config-if)# ipv6 nd raguard attach-policy example_policy vlan 222,223,224
   or
   ```
4. `do show running-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>interface Interface_type stack/module/port</code></td>
<td>Specifies an interface type and identifier; enters the interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>interface gigabitethernet 1/1/4</code></td>
<td></td>
</tr>
</tbody>
</table>
| Step 3 | `ipv6 nd raguard [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ] | vlan [ {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ]]

   Example:
   ```
   Device(config-if)# ipv6 nd raguard attach-policy example_policy
   or
   Device(config-if)# ipv6 nd raguard attach-policy example_policy vlan 222,223,224
   or
   ``` | Attaches the Neighbor Discovery Inspection policy to the interface or the specified VLANs on that interface. The default policy is attached if the `attach-policy` option is not used. |
How to Attach an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement Guard Policy on an EtherChannel interface or VLAN:

**SUMMARY STEPS**

1. configure terminal
2. interface range  *Interface_name*
3. ipv6 nd raguard [attach-policy  *policy_name* [vlan *vlan_ids* | add *vlan_ids* | except *vlan_ids* | none | remove *vlan_ids* | all]] | vlan [ {vlan_ids | add *vlan_ids* | except *vlan_ids* | none | remove *vlan_ids* | all} ]
4. do show running-config interface *portchannel_interface_name*

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| configure terminal | Enters the global configuration mode. |
| Example:
| Device# configure terminal | |
| **Step 2**
| interface range  *Interface_name*
| Example:
| Device(config)# interface Po11 | Specify the port-channel interface name assigned when the EtherChannel was created. Enters the interface range configuration mode. |
| **Tip** | Enter the do show interfaces summary command for quick reference to interface names and types. |
| **Step 3**
| ipv6 nd raguard [attach-policy  *policy_name* [vlan *vlan_ids* | add *vlan_ids* | except *vlan_ids* | none | remove *vlan_ids* | all]] | Attaches the RA Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |
| Example:
| Device(config-if-range)# ipv6 nd raguard attach-policy example_policy | |
How to Configure an IPv6 DHCP Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 DHCP (DHCPv6) Guard policy:

**SUMMARY STEPS**

1. configure terminal
2. [no]ipv6 dhcp guard policy policy-name
3. [no]device-role {client | server}
4. [no]match server access-list ipv6-access-list-name
5. [no]match reply prefix-list ipv6-prefix-list-name
6. [no]preference { max limit | min limit }
7. [no]trusted-port
8. default {device-role | trusted-port}
9. do show ipv6 dhcp guard policy policy_name

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>[no]ipv6 dhcp guard policy policy-name</td>
<td>Specifies the DHCPv6 Guard policy name and enters DHCPv6 Guard Policy configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 dhcp guard policy example_policy</td>
<td></td>
</tr>
</tbody>
</table>
### How to Configure an IPv6 DHCP Guard Policy

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>[no]device-role {client</td>
<td>server}</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-dhcp-guard)# device-role server</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>[no] match server access-list ipv6-access-list-name</td>
<td>(Optional). Enables verification that the advertised DHCPv6 server or relay address is from an authorized server access list (The destination address in the access list is 'any'). If not configured, this check will be bypassed. An empty access list is treated as a permit all.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>;;Assume a preconfigured IPv6 Access List as follows:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 access-list my_acls</td>
<td></td>
</tr>
<tr>
<td>Device(config-ipv6-acl)# permit host FE80::A8BB:CCFF:FE01:F700 any</td>
<td></td>
</tr>
<tr>
<td>;;configure DHCPv6 Guard to match approved access list.</td>
<td></td>

### Consolidated Platform Configuration Guide, Cisco IOS 15.2(6)E (Catalyst 2960-XR Switch)
### How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface Interface_type stack/module/port`
3. `ipv6 dhcp guard [attach-policy policy_name [vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all} ] | vlan [ {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all} ]]`
4. `do show running-config interface Interface_type stack/module/port`
How to Attach an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 DHCP Guard policy on an EtherChannel interface or VLAN:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface range Interface_name`
3. `ipv6 dhcp guard [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all} ] | vlan [ {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all} ]]`

---

4. `do show running-config interface portchannel_interface_name`

### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `configure terminal`  
**Example:**  
Device# configure terminal | Enters the global configuration mode. |
| Step 2 | `interface range Interface_name`  
**Example:**  
Device(config)# interface Po11 | Specify the port-channel interface name assigned when the EtherChannel was created. Enters the interface range configuration mode.  
**Tip**  
Enter the `do show interfaces summary` command for quick reference to interface names and types. |
| Step 3 | `ipv6 dhcp guard [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } | vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ]`  
**Example:**  
Device(config-if-range)# ipv6 dhcp guard attach-policy example_policy  
or  
Device(config-if-range)# ipv6 dhcp guard attach-policy example_policy vlan 222,223,224  
or  
Device(config-if-range)#ipv6 dhcp guard vlan 222,223,224 | Attaches the DHCP Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the `attach-policy` option is not used. |
| Step 4 | `do show running-config interface portchannel_interface_name`  
**Example:**  
Device#(config-if-range)# do show running-config int poll | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

### How to Configure IPv6 Source Guard

### Step 2

**configure terminal**

**Example:**

Device# configure terminal

**Purpose:** Enters the global configuration mode.

### Step 3

**interface port-channel port-channel-number**

**Example:**

Device (config)# interface Po4

**Purpose:** Specifies an interface type and port number and places the switch in the port channel configuration mode.

### Step 4

**ipv6 source-guard**

**Example:**

Device(config-if)# ipv6 source-guard attach-policy example_policy

**Purpose:** Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the `attach-policy` option is not used.

### Step 5

**show ipv6 source-guard policy policy_name**

**Example:**

Device(config-if)# show ipv6 source-guard policy example_policy

**Purpose:** Shows the policy configuration and all the interfaces where the policy is applied.

---

**Configuration Examples for IPv6 First Hop Security**

**Examples: How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface**

The following example shows how to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface:

Switch# configure terminal
Switch(config)# ipv6 source-guard policy POL
Switch(config-sisf-sourceguard)# validate address
Switch(config-sisf-sourceguard)# exit
Switch(config)# interface Po4
Switch(config)# ipv6 snooping
Switch(config-if)# ipv6 source-guard attach-policy POL
Switch(config-if)# exit
Switch(config)#

**Examples: How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface**

The following example shows how to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface:

Switch# configure terminal
Switch(config)# ipv6 source-guard policy POL
Switch(config-sisf-sourceguard)# no validate address
Switch((config-sisf-sourceguard)# validate prefix
Switch(config)# interface Po4
Switch(config-if)# ipv6 snooping
Switch(config-if)# ipv6 source-guard attach-policy POL

Routing Information Protocol

RIP is a commonly used routing protocol in small to medium TCP/IP networks. Routing Information Protocol (RIP) is a stable protocol that uses a distance-vector algorithm to calculate routes.

This module describes how to configure RIP.

• Prerequisites for RIP, on page 995
• Restrictions for RIP, on page 995
• Information About Routing Information Protocol, on page 995
• How to Configure Routing Information Protocol, on page 999
• Configuration Examples for Routing Information Protocol, on page 1002
• Additional References for RIP, on page 1003
• Feature Information for RIP, on page 1003

Prerequisites for RIP

You must configure `ip routing` command before you configure RIP.

Restrictions for RIP

Routing Information Protocol (RIP) uses hop count as the metric to rate the value of different routes. The hop count is the number of devices that can be traversed in a route. A directly connected network has a metric of zero; an unreachable network has a metric of 16. This limited metric range makes RIP unsuitable for large networks.

Information About Routing Information Protocol

RIP Overview

The Routing Information Protocol (RIP) Version 1 uses broadcast UDP data packets, and RIPv2 uses multicast packets to exchange the routing information. Cisco software sends routing information updates every 30 seconds, which is termed advertising. If a device does not receive an update from another device for 180
seconds or more, the receiving device marks the routes served by the nonupdating device as unusable. If there is still no update after 240 seconds, the device removes all routing table entries for the nonupdating device.

A device that is running RIP can receive a default network via an update from another device that is running RIP, or the device can source the default network using RIP. In both cases, the default network is advertised through RIP to other RIP neighbors.

The Cisco implementation of RIP Version 2 (RIPv2) supports plain text and message digest algorithm 5 (MD5) authentication, route summarization, classless interdomain routing (CIDR), and variable-length subnet masks (VLSMs).

### RIP Routing Updates

The Routing Information Protocol (RIP) sends routing-update messages at regular intervals and when the network topology changes. When a device receives a RIP routing update that includes changes to an entry, the device updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP devices maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the device immediately begins transmitting RIP routing updates to inform other network devices of the change. These updates are sent independently of the regularly scheduled updates that RIP devices send.

### Authentication in RIP

The Cisco implementation of the Routing Information Protocol (RIP) Version 2 (RIPv2) supports authentication, key management, route summarization, classless interdomain routing (CIDR), and variable-length subnet masks (VLSMs).

By default, the software receives RIPv1 and RIPv2 packets, but sends only RIPv1 packets. You can configure the software to receive and send only RIPv1 packets. Alternatively, you can configure the software to receive and send only RIPv2 packets. To override the default behavior, you can configure the RIP version that an interface sends. Similarly, you can also control how packets received from an interface are processed.

RIPv1 does not support authentication. If you are sending and receiving RIPv2 packets, you can enable RIP authentication on an interface.

The key chain determines the set of keys that can be used on the interface. Authentication, including default authentication, is performed on that interface only if a key chain is configured.

Cisco supports two modes of authentication on an interface on which RIP is enabled: plain-text authentication and message digest algorithm 5 (MD5) authentication. Plain-text authentication is the default authentication in every RIPv2 packet.

---

**Note**

Do not use plain text authentication in RIP packets for security purposes, because the unencrypted authentication key is sent in every RIPv2 packet. Use plain-text authentication when security is not an issue; for example, you can use plain-text authentication to ensure that misconfigured hosts do not participate in routing.
RIP Routing Metric

The Routing Information Protocol (RIP) uses a single routing metric to measure the distance between the source and the destination network. Each hop in a path from the source to the destination is assigned a hop-count value, which is typically 1. When a device receives a routing update that contains a new or changed destination network entry, the device adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop. If an interface network is not specified in the routing table, it will not be advertised in any RIP update.

RIP Versions

The original version of Routing Information Protocol (RIP), is known as RIP Version 1 (RIPv1). The specification of the RIP, defined in RFC 1058, uses classful routing. Periodic routing updates do not support variable length subnet masks (VLSM) because periodic routing updates do not contain subnet information. All subnets in a network class must be of the same size. Because RIP, as per RFC 1058, does not support VLSM, it is not possible to have subnets of varying sizes inside the same network class. This limitation makes RIP vulnerable to attacks.

To rectify the deficiencies of the original RIP specification, RIP Version 2 (RIPv2), as described in RFC 2453, was developed. RIPv2 has the ability to carry subnet information; thus, it supports Classless Inter-Domain Routing (CIDR).

Exchange of Routing Information

Routing Information Protocol (RIP) is normally a broadcast protocol, and for RIP routing updates to reach nonbroadcast networks, you must configure the Cisco software to permit this exchange of routing information.

To control the set of interfaces with which you want to exchange routing updates, you can disable the sending of routing updates on specified interfaces by configuring the `passive-interface` router configuration command.

You can use an offset list to increase increasing incoming and outgoing metrics to routes learned via RIP. Optionally, you can limit the offset list with either an access list or an interface.

Routing protocols use several timers that determine variables such as the frequency of routing updates, the length of time before a route becomes invalid, and other parameters. You can adjust these timers to tune routing protocol performance to better suit your internetwork needs. You can make the following timer adjustments:

- The rate (time, in seconds, between updates) at which routing updates are sent
- The interval of time, in seconds, after which a route is declared invalid
- The interval, in seconds, during which routing information about better paths is suppressed
- The amount of time, in seconds, that must pass before a route is removed from the routing table
- The amount of time for which routing updates will be postponed

You can adjust the IP routing support in the Cisco software to enable faster convergence of various IP routing algorithms, and hence, cause quicker fallback to redundant devices. The total effect is to minimize disruptions to end users of the network in situations where quick recovery is essential.

In addition, an address family can have timers that explicitly apply to that address family (or Virtual Routing and Forwarding [VRF]) instance). The `timers-basic` command must be specified for an address family or the
system defaults for the `timers-basic` command are used regardless of the timer that is configured for RIP routing. The VRF does not inherit the timer values from the base RIP configuration. The VRF will always use the system default timers unless the timers are explicitly changed using the `timers-basic` command.

**Neighbor Router Authentication**

You can prevent your router from receiving fraudulent route updates by configuring neighbor router authentication. When configured, neighbor authentication occurs whenever routing updates are exchanged between neighbor routers. This authentication ensures that a router receives reliable routing information from a trusted source.

Without neighbor authentication, unauthorized or deliberately malicious routing updates could compromise the security of your network traffic. A security compromise could occur if an unfriendly party diverts or analyzes your network traffic. For example, an unauthorized router could send a fictitious routing update to convince your router to send traffic to an incorrect destination. This diverted traffic could be analyzed to learn confidential information about your organization or merely used to disrupt your organization’s ability to effectively communicate using the network. Neighbor authentication prevents any such fraudulent route updates from being received by your router.

When neighbor authentication has been configured on a router, the router authenticates the source of each routing update packet that it receives. This is accomplished by the exchange of an authenticating key (sometimes referred to as a password) that is known to both the sending and the receiving router.

There are two types of neighbor authentication used: plaintext authentication and Message Digest Algorithm Version 5 (MD5) authentication. Both forms work in the same way, with the exception that MD5 sends a "message digest" instead of the authenticating key itself. The message digest is created using the key and a message, but the key itself is not sent, preventing it from being read while it is being transmitted. Plain text authentication sends the authenticating key itself over the wire.

---

**Note**

Note that plain text authentication is not recommended for use as part of your security strategy. Its primary use is to avoid accidental changes to the routing infrastructure. Using MD5 authentication, however, is a recommended security practice.

In plain text authentication, each participating neighbor router must share an authenticating key. This key is specified at each router during configuration. Multiple keys can be specified with some protocols; each key must then be identified by a key number.

In general, when a routing update is sent, the following authentication sequence occurs:

1. A router sends a routing update with a key and the corresponding key number to the neighbor router. In protocols that can have only one key, the key number is always zero. The receiving (neighbor) router checks the received key against the same key stored in its own memory.

2. If the two keys match, the receiving router accepts the routing update packet. If the two keys do not match, the routing update packet is rejected.

MD5 authentication works similarly to plain text authentication, except that the key is never sent over the wire. Instead, the router uses the MD5 algorithm to produce a "message digest" of the key (also called a "hash"). The message digest is then sent instead of the key itself. This ensures that nobody can eavesdrop on the line and learn keys during transmission.
Another form of neighbor router authentication is to configure key management using key chains. When you configure a key chain, you specify a series of keys with lifetimes, and the Cisco IOS software rotates through each of these keys. This decreases the likelihood that keys will be compromised.

How to Configure Routing Information Protocol

Enabling RIP and Configuring RIP Parameters

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `router rip`
4. `network ip-address`
5. `neighbor ip-address`
6. `auto-summary`
7. `offset-list [access-list-number | access-list-name] {in | out} offset [interface-type interface-number]`
8. `timers basic update invalid holddown flush [sleeptime]`
9. `maximum-paths maximum`
10. `distance admin-distance [prefix prefix-length | prefix-mask ]`
11. `end`

DETAILED STEPS

**Specifying a RIP Version and Enabling Authentication**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `router rip`
4. `version {1 | 2}`
### Specifying a RIP Version and Enabling Authentication

5. `exit`
6. `interface type number`
7. `ip rip send version [1] [2]`
8. `ip rip receive version [1] [2]`
9. `ip rip authentication key-chain name-of-chain`
10. `ip rip authentication mode {text | md5}`
11. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable                      | Enables privileged EXEC mode.  
  Example:  
  Device> enable |
| **Step 2** configure terminal          | Enters global configuration mode.  
  Example:  
  Device# configure terminal |
| **Step 3** router rip                   | Enters router configuration mode.  
  Example:  
  Device(config)# router rip |
| **Step 4** version {1 | 2}             | Enables the Cisco software to send only RIP Version 2 (RIPv2) packets.  
  Example:  
  Device(config-router)# version 2 |
| **Step 5** exit                        | Exits the router configuration mode and enters the global configuration mode.  
  Example:  
  Device(config-router)# exit |
| **Step 6** interface type number       | Specifies an interface and enters interface configuration mode.  
  Example:  
  Device(config)# interface GigabitEthernet 0/0 |
| **Step 7** ip rip send version [1] [2]  | Configures an interface to send only RIPv2 packets.  
  Example:  
  Device(config-if)# ip rip send version 2 |
| **Step 8** ip rip receive version [1] [2] | Configures an interface to accept only RIPv2 packets.  
  Example:  
  Device(config-if)# ip rip receive version 2 |

Configuration Examples for Routing Information Protocol

Example: Enabling RIP and Configuring RIP Parameters

Device> enable
Device# configure terminal
Device(config)# router rip
Device(config-router)# network 10.1.1.0
Device(config-router)# neighbor 10.1.1.2
Device(config-router)# auto-summary
Device(config-router)# offset-list 98 in 1 GigabitEthernet 1/0
Device(config-router)# timers basic 1 2 3 4
Device(config-router)# maximum-paths 16
Device(config-router)# distance 85 192.168.10.0/24
Device(config-router)# end

Example: Specifying a RIP Version and Enabling Authentication

Device> enable
Device# configure terminal
Device(config)# router rip
Device(config-router)# version 2
Device(config-router)# exit
Device(config)# interface GigabitEthernet 0/0
Device(config-if)# ip rip send version 2
Device(config-if)# ip rip receive version 2
Device(config-if)# ip rip authentication key-chain name-of-chain
Device(config-if)# ip rip authentication mode md5
Device(config-if)# end

Security Features Overview

The switch supports a LAN base image or a LAN lite image with a reduced feature set, depending on switch hardware. The security features are as follows:

- **IPv6 First Hop Security**—A suite of security features to be applied at the first hop switch to protect against vulnerabilities inherent in IPv6 networks. These include, Binding Integrity Guard (Binding Table), Router Advertisement Guard (RA Guard), DHCP Guard, IPv6 Neighbor Discovery Inspection (ND Guard).

- **Web Authentication**—Allows a supplicant (client) that does not support IEEE 802.1x functionality to be authenticated using a web browser.

- **Local Web Authentication Banner**—A custom banner or an image file displayed at a web authentication login screen.

- **IEEE 802.1x Authentication with ACLs and the RADIUS Filter-Id Attribute**

- **Password-protected access** (read-only and read-write access) to management interfaces (device manager, Network Assistant, and the CLI) for protection against unauthorized configuration changes

- **Multilevel security for a choice of security level, notification, and resulting actions**

- **Static MAC addressing for ensuring security**

- **Protected port option for restricting the forwarding of traffic to designated ports on the same switch**

- **Port security option for limiting and identifying MAC addresses of the stations allowed to access the port**

- **VLAN aware port security option to shut down the VLAN on the port when a violation occurs, instead of shutting down the entire port.**

- **Port security aging to set the aging time for secure addresses on a port.**

- **Protocol storm protection to control the rate of incoming protocol traffic to a switch by dropping packets that exceed a specified ingress rate.**

- **BPDUs guard for shutting down a Port Fast-configured port when an invalid configuration occurs.**
• Standard and extended IP access control lists (ACLs) for defining inbound security policies on Layer 2 interfaces (port ACLs).

• Extended MAC access control lists for defining security policies in the inbound direction on Layer 2 interfaces.

• Source and destination MAC-based ACLs for filtering non-IP traffic.

• DHCP snooping to filter untrusted DHCP messages between untrusted hosts and DHCP servers.

• IP source guard to restrict traffic on nonrouted interfaces by filtering traffic based on the DHCP snooping database and IP source bindings.

• Dynamic ARP inspection to prevent malicious attacks on the switch by not relaying invalid ARP requests and responses to other ports in the same VLAN.

• IEEE 802.1x port-based authentication to prevent unauthorized devices (clients) from gaining access to the network. These 802.1x features are supported:
  • Support for single-host, multi-host, multi-auth, and multi-domain-auth modes.
  • Multidomain authentication (MDA) to allow both a data device and a voice device, such as an IP phone (Cisco or non-Cisco), to independently authenticate on the same IEEE 802.1x-enabled switch port.
  • Dynamic voice virtual LAN (VLAN) for MDA to allow a dynamic voice VLAN on an MDA-enabled port.
  • VLAN assignment for restricting 802.1x-authenticated users to a specified VLAN.
  • Support for VLAN assignment on a port configured for multi-auth mode. The RADIUS server assigns a VLAN to the first host to authenticate on the port, and subsequent hosts use the same VLAN. Voice VLAN assignment is supported for one IP phone.
  • Port security for controlling access to 802.1x ports.
  • Voice VLAN to permit a Cisco IP Phone to access the voice VLAN regardless of the authorized or unauthorized state of the port.
  • IP phone detection enhancement to detect and recognize a Cisco IP phone.
  • Guest VLAN to provide limited services to non-802.1x-compliant users.
  • Restricted VLAN to provide limited services to users who are 802.1x compliant, but do not have the credentials to authenticate via the standard 802.1x processes.
  • 802.1x accounting to track network usage.
  • 802.1x with wake-on-LAN to allow dormant PCs to be powered on based on the receipt of a specific Ethernet frame.
  • 802.1x readiness check to determine the readiness of connected end hosts before configuring IEEE 802.1x on the switch.
  • Voice aware 802.1x security to apply traffic violation actions only on the VLAN on which a security violation occurs.
  • MAC authentication bypass (MAB) to authorize clients based on the client MAC address.
• Network Admission Control (NAC) Layer 2 802.1x validation of the antivirus condition or posture of endpoint systems or clients before granting the devices network access.

**Note** NAC is not supported on LanLite images.

• Network Edge Access Topology (NEAT) with 802.1X switch supplicant, host authorization with CISP, and auto enablement to authenticate a switch outside a wiring closet as a supplicant to another switch.

**Note** NEAT is not supported on LanLite images.

• IEEE 802.1x with open access to allow a host to access the network before being authenticated.

**Note** This feature is not supported on LanLite images.

• IEEE 802.1x authentication with downloadable ACLs and redirect URLs to allow per-user ACL downloads from a Cisco Secure ACS server to an authenticated switch.

• Support for dynamic creation or attachment of an auth-default ACL on a port that has no configured static ACLs.

**Note** This feature is not supported on LanLite images.

• Flexible-authentication sequencing to configure the order of the authentication methods that a port tries when authenticating a new host.

• Multiple-user authentication to allow more than one host to authenticate on an 802.1x-enabled port.

• TACACS+, a proprietary feature for managing network security through a TACACS server for both IPv4 and IPv6.

• RADIUS for verifying the identity of, granting access to, and tracking the actions of remote users through authentication, authorization, and accounting (AAA) services for both IPv4 and IPv6.

• Enhancements to RADIUS, TACACS+, and SSH to function over IPv6.

• Secure Socket Layer (SSL) Version 3.0 support for the HTTP 1.1 server authentication, encryption, and message integrity and HTTP client authentication to allow secure HTTP communications (requires the cryptographic version of the software).

• IEEE 802.1x Authentication with ACLs and the RADIUS Filter-Id Attribute.

• Support for IP source guard on static hosts.

• RADIUS Change of Authorization (CoA) to change the attributes of a certain session after it is authenticated. When there is a change in policy for a user or user group in AAA, administrators can send
the RADIUS CoA packets from the AAA server, such as Cisco Identity Services Engine, or Cisco Secure ACS to reinitialize authentication, and apply to the new policies.

- IEEE 802.1x User Distribution to allow deployments with multiple VLANs (for a group of users) to improve scalability of the network by load balancing users across different VLANs. Authorized users are assigned to the least populated VLAN in the group, assigned by RADIUS server.

  Note  
  This feature is not supported on LanLite images.

- Support for critical VLAN—multi-host/multi-auth enabled ports are placed in a critical VLAN in order to permit access to critical resources if AAA server becomes unreachable.

  Note  
  This feature is not supported on LanLite images.

- Support for Network Edge Access Topology (NEAT) to change the port host mode and to apply a standard port configuration on the authenticator switch port.

- VLAN-ID based MAC authentication to use the combined VLAN and MAC address information for user authentication to prevent network access from unauthorized VLANs.

- MAC move to allow hosts (including the hosts connected behind an IP phone) to move across ports within the same switch without any restrictions to enable mobility. With MAC move, the switch treats the reappearance of the same MAC address on another port in the same way as a completely new MAC address.

- Support for 3DES and AES with version 3 of the Simple Network Management Protocol (SNMPv3). This release adds support for the 168-bit Triple Data Encryption Standard (3DES) and the 128-bit, 192-bit, and 256-bit Advanced Encryption Standard (AES) encryption algorithms to SNMPv3.

- Support for Cisco TrustSec SXP protocol. This feature is not supported on LanLite images.
Preventing Unauthorized Access

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Preventing Unauthorized Access

You can prevent unauthorized users from reconfiguring your switch and viewing configuration information. Typically, you want network administrators to have access to your switch while you restrict access to users who dial from outside the network through an asynchronous port, connect from outside the network through a serial port, or connect through a terminal or workstation from within the local network.

To prevent unauthorized access into your switch, you should configure one or more of these security features:

- At a minimum, you should configure passwords and privileges at each switch port. These passwords are locally stored on the switch. When users attempt to access the switch through a port or line, they must enter the password specified for the port or line before they can access the switch.

- For an additional layer of security, you can also configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

- If you want to use username and password pairs, but you want to store them centrally on a server instead of locally, you can store them in a database on a security server. Multiple networking devices can then use the same database to obtain user authentication (and, if necessary, authorization) information.
• You can also enable the login enhancements feature, which logs both failed and unsuccessful login attempts. Login enhancements can also be configured to block future login attempts after a set number of unsuccessful attempts are made. For more information, see the Cisco IOS Login Enhancements documentation.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Controlling Switch Access with Passwords and Privileges

The following are the restrictions for controlling switch access with passwords and privileges:

- Disabling password recovery will not work if you have set the switch to boot up manually by using the boot manual global configuration command. This command produces the boot loader prompt (switch:) after the switch is power cycled.
Information About Passwords and Privilege Levels

Default Password and Privilege Level Configuration

A simple way of providing terminal access control in your network is to use passwords and assign privilege levels. Password protection restricts access to a network or network device. Privilege levels define what commands users can enter after they have logged into a network device.

This table shows the default password and privilege level configuration.

**Table 105: Default Password and Privilege Levels**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable password and privilege level</td>
<td>No password is defined. The default is level 15 (privileged EXEC level). The password is not encrypted in the configuration file.</td>
</tr>
<tr>
<td>Enable secret password and privilege level</td>
<td>No password is defined. The default is level 15 (privileged EXEC level). The password is encrypted before it is written to the configuration file.</td>
</tr>
<tr>
<td>Line password</td>
<td>No password is defined.</td>
</tr>
</tbody>
</table>

Additional Password Security

To provide an additional layer of security, particularly for passwords that cross the network or that are stored on a Trivial File Transfer Protocol (TFTP) server, you can use either the `enable password` or `enable secret` global configuration commands. Both commands accomplish the same thing; that is, you can establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify.

We recommend that you use the `enable secret` command because it uses an improved encryption algorithm.

If you configure the `enable secret` command, it takes precedence over the `enable password` command; the two commands cannot be in effect simultaneously.

If you enable password encryption, it applies to all passwords including username passwords, authentication key passwords, the privileged command password, and console and virtual terminal line passwords.

Password Recovery

By default, any end user with physical access to the switch can recover from a lost password by interrupting the boot process while the switch is powering on and then by entering a new password.

The password-recovery disable feature protects access to the switch password by disabling part of this functionality. When this feature is enabled, the end user can interrupt the boot process only by agreeing to set the system back to the default configuration. With password recovery disabled, you can still interrupt the boot process and change the password, but the configuration file (config.text) and the VLAN database file (vlan.dat) are deleted.
If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

To re-enable password recovery, use the `service password-recovery` global configuration command.

### Terminal Line Telnet Configuration

When you power-up your switch for the first time, an automatic setup program runs to assign IP information and to create a default configuration for continued use. The setup program also prompts you to configure your switch for Telnet access through a password. If you did not configure this password during the setup program, you can configure it when you set a Telnet password for a terminal line.

### Username and Password Pairs

You can configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

### Privilege Levels

Cisco devices use privilege levels to provide password security for different levels of switch operation. By default, the Cisco IOS software operates in two modes (privilege levels) of password security: user EXEC (Level 1) and privileged EXEC (Level 15). You can configure up to 16 hierarchical levels of commands for each mode. By configuring multiple passwords, you can allow different sets of users to have access to specified commands.

### Privilege Levels on Lines

Users can override the privilege level you set using the `privilege level` line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the `disable` command. If users know the password to a higher privilege level, they can use that password to enable the higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

For example, if you want many users to have access to the `clear line` command, you can assign it level 2 security and distribute the level 2 password fairly widely. But if you want more restricted access to the `configure` command, you can assign it level 3 security and distribute that password to a more restricted group of users.

### Command Privilege Levels

When you set a command to a privilege level, all commands whose syntax is a subset of that command are also set to that level. For example, if you set the `show ip traffic` command to level 15, the `show` commands and `show ip` commands are automatically set to privilege level 15 unless you set them individually to different levels.
How to Control Switch Access with Passwords and Privilege Levels

Setting or Changing a Static Enable Password

The enable password controls access to the privileged EXEC mode. Follow these steps to set or change a static enable password:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `enable password password`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>enable password password</code></td>
<td>Defines a new password or changes an existing password</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>for access to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>Device(config)# enable password secret321</code></td>
<td>By default, no password is defined.</td>
</tr>
<tr>
<td></td>
<td>For password, specify a string from 1 to 25 alphanumeric characters.</td>
</tr>
<tr>
<td></td>
<td>The string cannot start with a number, is case sensitive, and allows</td>
</tr>
<tr>
<td></td>
<td>spaces but ignores leading spaces. It can contain the question mark (?)</td>
</tr>
<tr>
<td></td>
<td>character if you precede the question mark with the key combination</td>
</tr>
<tr>
<td></td>
<td>Ctrl-v when you create the password; for example, to create the password</td>
</tr>
<tr>
<td></td>
<td>abc?123, do this:</td>
</tr>
<tr>
<td></td>
<td>1. Enter abc.</td>
</tr>
<tr>
<td></td>
<td>2. Enter Ctrl-v.</td>
</tr>
</tbody>
</table>
When the system prompts you to enter the enable password, you need not precede the question mark with the Ctrl-v; you can simply enter abc?123 at the password prompt.

**Step 4**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
</tbody>
</table>

**Step 6**

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
</thead>
<tbody>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

## Protecting Enable and Enable Secret Passwords with Encryption

Follow these steps to establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify:

### SUMMARY STEPS

1. enable
2. configure terminal
3. Use one of the following:
   
   • enable password [level level]
     
     {password encryption-type encrypted-password}
   
   • enable secret [level level]
     
     {password encryption-type encrypted-password}
4. service password-encryption
5. end
6. show running-config
7. copy running-config startup-config
## DETAILED STEPS

<table>
<thead>

| **Step 1** | enable | Enables privileged EXEC mode.  
Example:  
Device> enable | |
| **Step 2** | configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal | |
| **Step 3** | Use one of the following:  
• enable password [level level]  
{password encryption-type encrypted-password}  
• enable secret [level level]  
{password encryption-type encrypted-password}  
Example:  
Device(config)# enable password example102  
or  
Device(config)# enable secret level 1 password secret123sample | • Defines a new password or changes an existing password for access to privileged EXEC mode.  
• Defines a secret password, which is saved using a nonreversible encryption method.  
  • (Optional) For level, the range is from 0 to 15. Level 1 is normal user EXEC mode privileges. The default level is 15 (privileged EXEC mode privileges).  
  • For password, specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined.  
  • (Optional) For encryption-type, only type 5, a Cisco proprietary encryption algorithm, is available. If you specify an encryption type, you must provide an encrypted password—an encrypted password that you copy from another switch configuration.  
  **Note** If you specify an encryption type and then enter a clear text password, you cannot re-enter privileged EXEC mode. You cannot recover a lost encrypted password by any method. |
| **Step 4** | service password-encryption | (Optional) Encrypts the password when the password is defined or when the configuration is written. Encryption prevents the password from being readable in the configuration file.  
Example:  
Device(config)# service password-encryption | |
Disabling Password Recovery

Follow these steps to disable password recovery to protect the security of your switch:

**Before you begin**

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. system disable password recovery switch {all | <1-9>}
4. end

### Setting a Telnet Password for a Terminal Line

Beginning in user EXEC mode, follow these steps to set a Telnet password for the connected terminal line:

**Before you begin**

- Attach a PC or workstation with emulation software to the switch console port, or attach a PC to the Ethernet management port.
- The default data characteristics of the console port are 9600, 8, 1, no parity. You might need to press the Return key several times to see the command-line prompt.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. line vty 0 15
4. password password
5. end
6. show running-config
7. copy running-config startup-config

---

## Configuring Username and Password Pairs

Follow these steps to configure username and password pairs:
SUMMARY STEPS

1. enable
2. configure terminal
3. username name [privilege level] {password encryption-type password}
4. Use one of the following:
   - line console 0
   - line vty 0 15
5. login local
6. end
7. show running-config
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>

<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> username name [privilege level] {password encryption-type password}</td>
<td>Sets the username, privilege level, and password for each user.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# username adamsample privilege 1 password secret456</td>
<td></td>
</tr>
<tr>
<td>Device(config)# username 111111111111 mac attribute</td>
<td>• For name, specify the user ID as one word or the MAC address. Spaces and quotation marks are not allowed.</td>
</tr>
<tr>
<td></td>
<td>• You can configure a maximum of 12000 clients each, for both username and MAC filter.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For level, specify the privilege level the user has after gaining access. The range is 0 to 15. Level 15 gives privileged EXEC mode access. Level 1 gives user EXEC mode access.</td>
</tr>
<tr>
<td></td>
<td>• For encryption-type, enter 0 to specify that an unencrypted password will follow. Enter 7 to specify that a hidden password will follow.</td>
</tr>
<tr>
<td></td>
<td>• For password, specify the password the user must enter to gain access to the Device. The password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the username command.</td>
</tr>
</tbody>
</table>
### Setting the Privilege Level for a Command

Follow these steps to set the privilege level for a command:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. privilege mode level level command
4. enable password level level password
5. end
6. copy running-config startup-config

---

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
What to do next

Users can override the privilege level you set using the `privilege level` line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the `disable` command. If users know the password to a higher privilege level, they can use that password to enable the higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

Logging into and Exiting a Privilege Level

Beginning in user EXEC mode, follow these steps to log into a specified privilege level and exit a specified privilege level.

**SUMMARY STEPS**

1. `enable level`
2. `disable level`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Logs in to a specified privilege level. Following the example, Level 15 is privileged EXEC mode. For <code>level</code>, the range is 0 to 15.</td>
</tr>
<tr>
<td><code>enable level</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable 15</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>

<td>Displays the privilege level configuration.</td>
</tr>
</tbody>
</table>
Configuration Examples for Setting Passwords and Privilege Levels

Example: Setting or Changing a Static Enable Password

This example shows how to change the enable password to l1u2c3k4y5. The password is not encrypted and provides access to level 15 (traditional privileged EXEC mode access):

```
Device(config)# enable password l1u2c3k4y5
```

Example: Protecting Enable and Enable Secret Passwords with Encryption

This example shows how to configure the encrypted password $1$FaD0$Xyti5Rkls3LoyxzS8 for privilege level 2:

```
Device(config)# enable secret level 2 5 $1$FaD0$Xyti5Rkls3LoyxzS8
```

Example: Setting a Telnet Password for a Terminal Line

This example shows how to set the Telnet password to let45me67in89:

```
Device(config)# line vty 10
Device(config-line)# password let45me67in89
```

Example: Setting the Privilege Level for a Command

This example shows how to set the `configure` command to privilege level 14 and define `SecretPswd14` as the password users must enter to use level 14 commands:

```
Device(config)# privilege exec level 14 configure
Device(config)# enable password level 14 SecretPswd14
```

CHAPTER 50

Configuring TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through authentication, authorization and accounting (AAA) and can be enabled only through AAA commands.

- Finding Feature Information, on page 1029
- Prerequisites for TACACS+, on page 1029
- Restrictions for TACACS+, on page 1030
- Information About TACACS+, on page 1031
- How to Configure TACACS+, on page 1055
- Configuration Examples for TACACS+, on page 1066
- Additional References for TACACS+, on page 1070
- Feature Information for TACACS+, on page 1070

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for TACACS+

The following are the prerequisites for set up and configuration of switch access with TACACS+ (must be performed in the order presented):

1. Configure the switches with the TACACS+ server addresses.
2. Set an authentication key.
3. Configure the key from Step 2 on the TACACS+ servers.
4. Enable authentication, authorization, and accounting (AAA).
5. Create a login authentication method list.

6. Apply the list to the terminal lines.

7. Create an authorization and accounting method list.

The following are the prerequisites for controlling switch access with TACACS+:

- You must have access to a configured TACACS+ server to configure TACACS+ features on your switch. Also, you must have access to TACACS+ services maintained in a database on a TACACS+ daemon typically running on a LINUX or Windows workstation.

- We recommend a redundant connection between a switch stack and the TACACS+ server. This is to help ensure that the TACACS+ server remains accessible in case one of the connected stack members is removed from the switch stack.

- You need a system running the TACACS+ daemon software to use TACACS+ on your switch.

- To use TACACS+, it must be enabled.

- Authorization must be enabled on the switch to be used.

- Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

- To use any of the AAA commands listed in this section or elsewhere, you must first enable AAA with the `aaa new-model` command.

- At a minimum, you must identify the host or hosts maintaining the TACACS+ daemon and define the method lists for TACACS+ authentication. You can optionally define method lists for TACACS+ authorization and accounting.

- The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list (which, by coincidence, is named `default`). The default method list is automatically applied to all ports except those that have a named method list explicitly defined. A defined method list overrides the default method list.

- Use TACACS+ for privileged EXEC access authorization if authentication was performed by using TACACS+.

- Use the local database if authentication was not performed by using TACACS+.

## Restrictions for TACACS+

TACACS+ can be enabled only through AAA commands.
Information About TACACS+

TACACS+ and Switch Access

This section describes TACACS+. TACACS+ provides detailed accounting information and flexible administrative control over the authentication and authorization processes. It is facilitated through authentication, authorization, accounting (AAA) and can be enabled only through AAA commands.

TACACS+ Overview

TACACS+ is a security application that provides centralized validation of users attempting to gain access to your switch.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a method for managing multiple network access points from a single management service. Your switch can be a network access server along with other Cisco routers and access servers.

Figure 86: Typical TACACS+ Network Configuration

TACACS+, administered through the AAA security services, can provide these services:

- Authentication—Provides complete control of authentication through login and password dialog, challenge and response, and messaging support.

The authentication facility can conduct a dialog with the user (for example, after a username and password are provided, to challenge a user with several questions, such as home address, mother’s maiden name, etc.)
service type, and social security number). The TACACS+ authentication service can also send messages to user screens. For example, a message could notify users that their passwords must be changed because of the company’s password aging policy.

- Authorization—Provides fine-grained control over user capabilities for the duration of the user’s session, including but not limited to setting autocmds, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user can execute with the TACACS+ authorization feature.
