

# CHAPTER 3

## Assigning the Switch IP Address and Default Gateway

This chapter describes how to create the initial switch configuration (for example, assigning the IP address and default gateway information) for the Catalyst 3560 switch by using a variety of automatic and manual methods. It also describes how to modify the switch startup configuration.

### Note

For complete syntax and usage information for the commands used in this chapter, see the command reference for this release and the *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services*

**Documentation > Cisco IOS Software 12.2 Mainline**

### Command References

This chapter consists of these sections:

- [Understanding the Boot Process, page 3-1](#)  
[Assigning Switch Information, page 3-2](#)  
[Checking and Saving the Running Configuration, page 3-15](#)  
[Modifying the Startup Configuration, page 3-16](#)  
[Scheduling a Reload of the Software Image, page 3-20](#)

Information in this chapter about configuring IP addresses and DHCP is specific to IP Version 4 (IPv4). If you plan to enable IP Version 6 (IPv6) forwarding on your switch, see [Chapter 37, “Configuring IPv6 Unicast Routing”](#) for information specific to IPv6 address format and configuration. To enable IPv6, the switch must be running the IP services image.

## Understanding the Boot Process

*Getting Started Guide*

- Performs low-level CPU initialization. It initializes the CPU registers, which control where physical memory is mapped, its quantity, its speed, and so forth.

Performs power-on self-test (POST) for the CPU subsystem. It tests the CPU DRAM and the portion of the flash device that makes up the flash file system.

Loads a default operating system software image into memory and boots up the switch.

The boot loader provides access to the flash file system before the operating system is loaded. Normally, the boot loader is used only to load, uncompress, and launch the operating system. After the boot loader gives the operating system control of the CPU, the boot loader is not active until the next system reset or power-on.

The boot loader also provides trap-door access into the system if the operating system has problems serious enough that it cannot be used. The trap-door mechanism provides enough access to the system so that if it is necessary, you can format the flash file system, reinstall the operating system software image by using the Xmodem Protocol, recover from a lost or forgotten password, and finally restart the operating system. For more information, see the [“Recovering from a Software Failure” section on page 47-2](#) and the [“Recovering from a Lost or Forgotten Password” section on page 47-3](#).

---

You can disable password recovery. For more information, see the [“Disabling Password Recovery” section on page 9-5](#).

---

Before you can assign switch information, make sure you have connected a PC or terminal to the console port, and configured the PC or terminal-emulation software baud rate and character format to match these of the switch console port:

Baud rate default is 9600.

Data bits default is 8.

---

If the data bits option is set to 8, set the parity option to none.

---

Stop bits default is 1.

Parity settings default is none.

## Assigning Switch Information

Use the switch setup program if you want to be prompted for specific IP information. With this program, you can also configure a hostname and an enable secret password. It gives you the option of assigning a Telnet password (to provide security during remote management) and configuring your switch as a command or member switch of a cluster or as a standalone switch. For more information about the setup program, see the hardware installation guide.

Use a DHCP server for centralized control and automatic assignment of IP information after the server is configured.

Note

## Default Switch Information

Table 3-1 Default Switch Information

Feature	Default Setting
Enable secret password	No password is defined.
Hostname	The factory-assigned default hostname is <i>Switch</i>

## Understanding DHCP-Based Autoconfiguration

## DHCP Client Request Process

ip address dhcp

**Figure 3-1** *DHCP Client and Server Message Exchange*

In a DHCPREQUEST broadcast message, the client returns a formal request for the offered configuration information to the DHCP server. The formal request is broadcast so that all other DHCP servers that received the DHCPDISCOVER broadcast message from the client can reclaim the IP addresses that they offered to the client.

The DHCP server confirms that the IP address has been allocated to the client by returning a DHCPACK unicast message to the client. With this message, the client and server are bound, and the client uses configuration information received from the server. The amount of information the switch receives depends on how you configure the DHCP server. For more information, see the [“Configuring the TFTP Server” section on page 3-7](#).

If the configuration parameters sent to the client in the DHCPOFFER unicast message are invalid (a configuration error exists), the client returns a DHCPDECLINE broadcast message to the DHCP server.

The DHCP server sends the client a DHCPNAK denial broadcast message, which means that the offered configuration parameters have not been assigned, that an error has occurred during the negotiation of the parameters, or that the client has been slow in responding to the DHCPOFFER message. (The DHCP server assigned the parameters to another client.)

A DHCP client might receive offers from multiple DHCP or BOOTP servers and can accept any of the offers; however, the client usually accepts the first offer it receives. The offer from the DHCP server is not a guarantee that the IP address is allocated to the. However, the server usually reserves the address until the client has had a chance to formally request the address. If the switch accepts replies from a BOOTP server and configures itself, the switch broadcasts, instead of unicasts, TFTP requests to obtain the switch configuration file.

## Configuring the TFTP Server

switch's current hostname. The TFTP server addresses used include the specified TFTP server address (if any) and the broadcast address (255.255.255.255).

For the switch to successfully download a configuration file, the TFTP server must contain one or more configuration files in its base directory. The files can include these files:

- The configuration file named in the DHCP reply (the actual switch configuration file).
- The network-config or the cisco.net.cfg file (known as the default configuration files).
- The router-config or the cisco.rtr.cfg file (These files contain commands common to all switches. Normally, if the DHCP and TFTP servers are properly configured, these files are not accessed.)

If you specify the TFTP server name in the DHCP server-lease database, you must also configure the TFTP server name-to-IP-address mapping in the DNS-server database.

If the TFTP server to be used is on a different LAN from the switch, or if it is to be accessed by the switch through the broadcast address (which occurs if the DHCP server response does not contain all the required information described previously), a relay must be configured to forward the TFTP packets to the TFTP server. For more information, see the [“Configuring the Relay Device” section on page 3-8](#). The preferred solution is to configure the DHCP server with all the required information.

## Configuring the DNS

## Configuring the Relay Device

*relay agent*

```
router(config-if)# ip helper-address 20.0.0.2
                  ip helper-address 20.0.0.3
                  ip helper-address 20.0.0.4

                  ip helper-address 10.0.0.1
```

**Figure 3-2**      *Relay Device Used in Autoconfiguration*

## Obtaining Configuration Files

.

## Example Configuration

shows a sample network for retrieving IP information by using DHCP-based autoconfiguration.

### *DHCP-Based Autoconfiguration Network Example*

	Switch A	Switch B	Switch C	Switch D
	10.0.0.3	<i>tftpserver</i> 10.0.0.3	<i>tftpserver</i> 10.0.0.3	<i>tftpserver</i> 10.0.0.3

## DNS Server Configuration

*tftpserver*

## TFTP Server Configuration (on UNIX)

The TFTP server base directory is set to /tftpserver/work/. This directory contains the network-config file used in the two-file read method. This file contains the hostname to be assigned to the switch based on its IP address. The base directory also contains a configuration file for each switch (*switcha-config* *switchb-config*

```
prompt> cd /tftpserver/work/
ls
network-config
switcha-config
switchb-config
switchc-config
switchd-config
prompt> cat network-config
ip host switcha 10.0.0.21
ip host switchb 10.0.0.22
ip host switchc 10.0.0.23
ip host switchd 10.0.0.24
```

## DHCP Client Configuration

## Configuration Explanation

# Configuring the DHCP Auto Configuration and Image Update Features

## Configuring DHCP Autoconfiguration (Only Configuration File)

	Command	Purpose
Step 1		
Step 2		
Step 3	bootfile	
Step 4	network network-number mask prefix-length	
Step 5	address	
Step 6	option 150	
Step 7	exit	
Step 8		
Step 9		
Step 10		
Step 11		
Step 12		
Step 13		

```
Switch# configure terminal
      ip dhcp pool pool1
          network 10.10.10.0 255.255.255.0
          bootfile config-boot.text
          default-router 10.10.10.1
          option 150 10.10.10.1
          exit
      tftp-server flash:config-boot.text
      interface gigabitethernet0/4
          no switchport
          ip address 10.10.10.1 255.255.255.0
          end
```

## 1

Before following the steps in this table, you must create a text file (for example, `autoinstall_dhcp`) that will be uploaded to the switch. In the text file, put the name of the image that you want to download (for example, `c3560-ipservices-mz.122-44.3.SE.tar`). This image must be a tar and not a bin file.

tftp-server flash:	
tftp-server flash:	
tftp-server flash:	
interface	
no switchport	
ip address	
end	
copy running-config startup-config	

This example shows how to configure a switch as a DHCP server so it downloads a configuration file:

0000.0009.0a05.08661.7574.6f69.6e73.7461.6c6c.5f64.686370

```

exit
tftp-server flash:config-boot.text
tftp-server flash:c3560-ipservices-mz.122-44.3.SE.tar
tftp-server flash:boot-config.text
tftp-server flash: autoinstall_dhcp
interface gigabitethernet0/4
  no switchport
  ip address 10.10.10.1 255.255.255.0
end

```

banner config-save ^C	^C
end	
show boot	

```

configure terminal
  boot host dhcp
  boot host retry timeout 300
  banner config-save ^C Caution - Saving Configuration File to NVRAM May Cause
You to No longer Automatically Download Configuration Files at Reboot^C
  vlan 99
Switch(config-vlan)#

BOOT	set BOOT            :/	boot system <i>ilesystem:/file-url ...</i>
MANUAL_BOOT	set MANUAL_BOOT yes	boot manual  boot flash:            :/
CONFIG_FILE	set CONFIG_FILE flash:/	boot config-file flash:/

# Scheduling a Reload of the Software Image

Note

## Configuring a Scheduled Reload

- **reload in [ ] [ ]**

This command schedules a reload of the software to take effect in the specified minutes or hours and minutes. The reload must take place within approximately 24 days. You can specify the reason for the reload in a string up to 255 characters in length.

[ ] [ ] [ ]

This command schedules a reload of the software to take place at the specified time (using a 24-hour clock). If you specify the month and day, the reload is scheduled to take place at the specified time and date. If you do not specify the month and day, the reload takes place at the specified time on the current day (if the specified time is later than the current time) or on the next day (if the specified time is earlier than the current time). Specifying 00:00 schedules the reload for midnight.

Use the **keyword** only if the switch system clock has been set (through Network Time Protocol (NTP), the hardware calendar, or manually). The time is relative to the configured time zone on the switch. To schedule reloads across several switches to occur simultaneously, the time on each switch must be synchronized with NTP.

The **command** halts the system. If the system is not set to manually boot up, it reboots itself. Use the **command** after you save the switch configuration information to the startup configuration ( ).

If your switch is configured for manual booting, do not reload it from a virtual terminal. This restriction prevents the switch from entering the boot loader mode and thereby taking it from the remote user's control.

If you modify your configuration file, the switch prompts you to save the configuration before reloading. During the save operation, the system requests whether you want to proceed with the save if the CONFIG\_FILE environment variable points to a startup configuration file that no longer exists. If you proceed in this situation, the system enters setup mode upon reload.

This example shows how to reload the software on the switch on the current day at 7:30 p.m:

```
Reload scheduled for 19:30:00 UTC Wed Jun 5 1996 (in 2 hours and 25 minutes)
Proceed with reload? [confirm]
```

This example shows how to reload the software on the switch at a future time:

```
Switch# reload at 02:00 jun 20
```
