CHAPTER 1
  Using the Command-Line Interface 1
    Information About Using the Command-Line Interface 1
      Command Modes 1
      Understanding Abbreviated Commands 3
      No and Default Forms of Commands 3
      CLI Error Messages 3
      Configuration Logging 4
      Using the Help System 4
    How to Use the CLI to Configure Features 5
      Configuring the Command History 5
        Changing the Command History Buffer Size 5
        Recalling Commands 6
        Disabling the Command History Feature 6
      Enabling and Disabling Editing Features 7
        Editing Commands Through Keystrokes 7
        Editing Command Lines That Wrap 8
      Searching and Filtering Output of show and more Commands 9
      Accessing the CLI 10
        Accessing the CLI Through a Console Connection or Through Telnet 10

PART I
  Audio Video Bridging 13
# Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)

## Contents

**CHAPTER 2**  
**Audio Video Bridging**  
15

- Introduction to Audio Video Bridging Networks  
15
- Information about Audio Video Bridging (AVB)  
15
  - Licenses Supporting AVB  
15
  - Benefits of AVB  
16
  - Components of AVB Network  
16
  - Supported SKUs for AVB  
17
- Information about Generalized Precision Time Protocol (gPTP)  
18
- Information about Multiple Stream Reservation Protocol (MSRP)  
19
  - Functions of MSRP  
19
- Information about QoS (HQoS)  
19
- Information about Multiple VLAN Registration Protocol (MVRP)  
20

**Configuring the AVB Network**  
21

- Configuring AVB  
21
  - Enabling AVB on the switch  
21
  - Configuring AVB on the devices  
22
- Configuring gPTP  
24
  - Enabling gPTP on a port  
24
  - Configuring the values of PTP clocks  
25
- Configuring HQoS  
26
  - Enabling HQoS  
26
  - Migrating from Flat Policy Formats to Hierarchical Policy Formats - Guidelines and Restrictions  
26
  - Hierarchical QoS Policy Formats  
27
- Configuring MVRP  
28
  - Enabling MVRP  
28
  - Configuring MVRP on the switch interface  
29

**Monitoring the AVB Network**  
31

- Monitoring AVB  
31
- Monitoring gPTP  
31
- Monitoring MSRP  
31
- Monitoring HQoS  
32
- Monitoring MVRP  
32
Examples of AVB Configurations and Monitoring 32
Examples for AVB 32
Examples for gPTP 35
Examples for MSRP 38
Examples for HQoS 41
Examples for MVRP 52
Feature Information for AVB 53

PART II

Campus Fabric 55

CHAPTER 3

Campus Fabric 57
Information About Campus Fabric 57
Campus Fabric Overview 57
Understanding Fabric Domain Elements 57
Campus Fabric Configuration Guidelines 58
How to Configure Fabric Overlay 59
Configuring Fabric Edge Devices 59
Configuring Fabric Control-Plane Devices 62
Configuring Fabric Border Devices 63
Security Group Tags and Policy Enforcement in Campus Fabric 65
Multicast Using Campus Fabric Overlay 65
Configuring Multicast PIM Sparse Mode in Campus Fabric 65
Configuring Multicast PIM SSM in Campus Fabric 67
Data Plane Security in Campus Fabric 69
Configuring Data Plane Security on Edge Devices 69
Configuring Data Plane Security on Control Plane Devices 70
Configuring Data Plane Security on Border Devices 71
Campus Fabric Configuration Examples 72

PART III

CleanAir 75

CHAPTER 4

CleanAir 77
Prerequisites for CleanAir 77
Restrictions for CleanAir 78
CHAPTER 6

Configuring Interface Characteristics 105

Information About Configuring Interface Characteristics 105

Interface Types 105
  Port-Based VLANs 105
  Switch Ports 106
  Routed Ports 107
  Switch Virtual Interfaces 107
  EtherChannel Port Groups 108
  Multigigabit Ethernet 109
  Power over Ethernet Ports 109

Using the Switch USB Ports 110
  USB Mini-Type B Console Port 110

Interface Connections 111

Default Ethernet Interface Configuration 111

Interface Speed and Duplex Mode 113

Speed and Duplex Configuration Guidelines 113

IEEE 802.3x Flow Control 113

Layer 3 Interfaces 114

Digital Optical Monitoring 115

How to Configure Interface Characteristics 115

Configuring Interfaces 115

Adding a Description for an Interface 116

Configuring a Range of Interfaces 118

Configuring and Using Interface Range Macros 119

Configuring Ethernet Interfaces 121
  Setting the Interface Speed and Duplex Parameters 121

Configuring Multigigabit Ethernet Parameters 122

Configuring IEEE 802.3x Flow Control 124

Configuring Layer 3 Interfaces 125

Configuring Logical Layer 3 GRE Tunnel Interfaces 126

Configuring SVI Autostate Exclude 127

Shutting Down and Restarting the Interface 128

Configuring the Console Media Type 130
### Supported Protocols and Standards 185

- Powered-Device Detection and Initial Power Allocation 186
- Power Management Modes 187
- Cisco Universal Power Over Ethernet 189

### How to Configure PoE 190

- Configuring a Power Management Mode on a PoE Port 190
- Enabling Power on Signal/Spare Pairs 192
- Configuring Power Policing 192

### Monitoring Power Status 195

- Additional References 195
- Feature Information for PoE 196

## CHAPTER 13

### Configuring EEE 197

- Information About EEE 197
  - EEE Overview 197
- Default EEE Configuration 197
  - Restrictions for EEE 197
- How to Configure EEE 198
  - Enabling or Disabling EEE 198
- Monitoring EEE 199
  - Configuration Examples for Configuring EEE 200
- Additional References for EEE 200
  - Feature Information for Configuring EEE 201

## PART V

### IPv6 203

## CHAPTER 14

### Configuring MLD Snooping 205

- Information About Configuring IPv6 MLD Snooping 205
- Understanding MLD Snooping 206
  - MLD Messages 206
  - MLD Queries 207
  - Multicast Client Aging Robustness 207
  - Multicast Router Discovery 207
  - MLD Reports 208
Enabling IPv6 PBR on an Interface 240
Enabling Local PBR for IPv6 242
Configuring RIP for IPv6 243
Configuring OSPF for IPv6 245
Configuring EIGRP for IPv6 247
Configuring IPv6 Unicast Reverse Path Forwarding 248
Displaying IPv6 248
Configuring DHCP for IPv6 Address Assignment 249
Default DHCPv6 Address Assignment Configuration 249
DHCPv6 Address Assignment Configuration Guidelines 249
Enabling DHCPv6 Server Function (CLI) 250
Enabling DHCPv6 Client Function 252
Configuration Examples for IPv6 Unicast Routing 253
Configuring IPv6 Addressing and Enabling IPv6 Routing: Example 253
Configuring Default Router Preference: Example 254
Configuring IPv4 and IPv6 Protocol Stacks: Example 254
Enabling DHCPv6 Server Function: Example 254
Enabling DHCPv6 Client Function: Example 255
Configuring IPv6 ICMP Rate Limiting: Example 255
Configuring Static Routing for IPv6: Example 255
Example: Enabling PBR on an Interface 255
Example: Enabling Local PBR for IPv6 256
Configuring RIP for IPv6: Example 256
Displaying IPv6: Example 256

CHAPTER 16

Implementing IPv6 Multicast 259
Information About Implementing IPv6 Multicast Routing 259
IPv6 Multicast Overview 259
IPv6 Multicast Routing Implementation 260
IPv6 Multicast Listener Discovery Protocol 260
Multicast Queriers and Hosts 260
MLD Access Group 260
Explicit Tracking of Receivers 260
Protocol Independent Multicast 261
PIM-Sparse Mode  261
IPv6 BSR: Configure RP Mapping  261
PIM-Source Specific Multicast  262
Routable Address Hello Option  262
PIM IPv6 Stub Routing  263
Static Mroutes  263
MRIB  264
MFIB  264
IPv6 Multicast Process Switching and Fast Switching  265
Multiprotocol BGP for the IPv6 Multicast Address Family  265
Implementing IPv6 Multicast  266
Enabling IPv6 Multicast Routing  266
Customizing and Verifying the MLD Protocol  266
  Customizing and Verifying MLD on an Interface  266
Implementing MLD Group Limits  268
Configuring Explicit Tracking of Receivers to Track Host Behavior  270
Resetting the MLD Traffic Counters  270
Clearing the MLD Interface Counters  271
Configuring PIM  271
  Configuring PIM-SM and Displaying PIM-SM Information for a Group Range  271
  Configuring PIM Options  273
  Resetting the PIM Traffic Counters  274
  Clearing the PIM Topology Table to Reset the MRIB Connection  275
Configuring PIM IPv6 Stub Routing  277
  PIM IPv6 Stub Routing Configuration Guidelines  277
Default IPv6 PIM Routing Configuration  277
  Enabling IPv6 PIM Stub Routing  277
  Monitoring IPv6 PIM Stub Routing  279
Configuring a BSR  280
  Configuring a BSR and Verifying BSR Information  280
Sending PIM RP Advertisements to the BSR  281
Configuring BSR for Use Within Scoped Zones  281
Configuring BSR Switches to Announce Scope-to-RP Mappings  282
CHAPTER 17 IPv6 Client IP Address Learning 289

Prerequisites for IPv6 Client Address Learning 289
Information About IPv6 Client Address Learning 289

SLAAC Address Assignment 290
Stateful DHCPv6 Address Assignment 291
Static IP Address Assignment 292
Router Solicitation 292
Router Advertisement 292
Neighbor Discovery 292
Neighbor Discovery Suppression 292
RA Guard 293
RA Throttling 293
Configuring IPv6 Unicast 294
Configuring RA Guard Policy 294
Applying RA Guard Policy 295
Configuring RA Throttle Policy (CLI) 296
Applying RA Throttle Policy on VLAN (CLI) 297
How to Configure IPv6 Neighbor Probing 298
Configuring IPv6 Snooping 301
Configuring IPv6 ND Suppress Policy 302
Configuring IPv6 Snooping on VLAN/PortChannel 303
Configuring IPv6 on Interface 304
Configuring DHCP Pool 305
Configuring Stateless Auto Address Configuration Without DHCP (CLI) 306
Configuring Stateless Auto Address Configuration With DHCP 308
Configuring Stateful DHCP Locally 309
Configuring Stateful DHCP Externally 311
Verifying IPv6 Address Learning Configuration 313
### Chapter 18: Configuring IPv6 WLAN Security

PART VI
IP 379

CHAPTER 23
Configuring HSRP 381
Configuring HSRP 381
Finding Feature Information 381
Information About Configuring HSRP 381
HSRP Overview 381
HSRP Versions 383
Multiple HSRP 384
SSO HSRP 384
HSRP and Switch Stacks 385
Configuring HSRP for IPv6 385

How to Configure HSRP 385
Default HSRP Configuration 385
HSRP Configuration Guidelines 385
Enabling HSRP 386
Configuring HSRP Priority 388
Configuring MHSRP 390
Configuring HSRP Authentication and Timers 396
Enabling HSRP Support for ICMP Redirect Messages 398
Configuring HSRP Groups and Clustering 398

Verifying HSRP 398
Verifying HSRP Configurations 398
Configuration Examples for Configuring HSRP 399
Enabling HSRP: Example 399
Configuring HSRP Priority: Example 399
Configuring MHSRP: Example 399
Configuring HSRP Authentication and Timer: Example 400
Configuring HSRP Groups and Clustering: Example 400

Additional References for Configuring HSRP 400
Feature Information for Configuring HSRP 401

CHAPTER 24

Configuring NHRP 403
Information About Configuring NHRP 403
NHRP and NBMA Network Interaction 403
Dynamically Built Hub-and-Spoke Networks 404

How to Configure NHRP 404
Enabling NHRP on an Interface 404
Configuring a GRE Tunnel for Multipoint Operation 405
Configuration Examples for NHRP 408
Physical Network Designs for Logical NBMA Examples 408
Information About GLBP 428

GLBP Overview 428
GLBP Active Virtual Gateway 428
GLBP Virtual MAC Address Assignment 429
GLBP Virtual Gateway Redundancy 429
GLBP Virtual Forwarder Redundancy 429
GLBP Gateway Priority 430
GLBP Gateway Weighting and Tracking 430
GLBP MD5 Authentication 430
ISSU-GLBP 431
GLBP SSO 431
GLBP Benefits 432
How to Configure GLBP 432

Customizing GLBP 432
Configuring GLBP MD5 Authentication Using a Key String 435
Configuring GLBP MD5 Authentication Using a Key Chain 437
Configuring GLBP Text Authentication 439
Configuring GLBP Weighting Values and Object Tracking 440
Troubleshooting GLBP 442
Configuration Examples for GLBP 444
Example: Customizing GLBP Configuration 444
Example: Configuring GLBP MD5 Authentication Using Key Strings 444
Example: Configuring GLBP MD5 Authentication Using Key Chains 444
Example: Configuring GLBP Text Authentication 444
Example: Configuring GLBP Weighting 445
Example: Enabling GLBP Configuration 445
Additional References for GLBP 445
Feature Information for GLBP 446
Glossary 447

PART VII

IP Multicast Routing 449

CHAPTER 27

IP Multicast Routing Technology Overview 451
Information About IP Multicast Technology 451
## Contents

- Role of IP Multicast in Information Delivery 451
- IP Multicast Routing Protocols 451
- Multicast Group Transmission Scheme 452
- IP Multicast Boundary 454
- IP Multicast Group Addressing 455
  - IP Class D Addresses 455
- IP Multicast Address Scoping 455
- Layer 2 Multicast Addresses 457
- IP Multicast Delivery Modes 457
  - Source Specific Multicast 457

### CHAPTER 28 Configuring IGMP 459

- Finding Feature Information 459
- Prerequisites for IGMP and IGMP Snooping 459
  - Prerequisites for IGMP 459
  - Prerequisites for IGMP Snooping 460
- Restrictions for IGMP and IGMP Snooping 460
  - Restrictions for Configuring IGMP 460
  - Restrictions for IGMP Snooping 461

CHAPTER 54

Configuring Adaptive Wireless Intrusion Prevention System

Finding Feature Information

Prerequisites for Configuring wIPS

How to Configure wIPS on Access Points

Configuring wIPS on an Access Point (CLI)

Monitoring wIPS Information

Configuration Examples for Configuring wIPS on Access Points
CHAPTER 55

Configuring Authentication for Access Points 933
Finding Feature Information 933
Prerequisites for Configuring Authentication for Access Points 933
Restrictions for Configuring Authentication for Access Points 934
Information about Configuring Authentication for Access Points 934
How to Configure Authentication for Access Points 934
Configuring Global Credentials for Access Points (CLI) 934
Configuring Authentication for Access Points (CLI) 936
Configuring the Switch for Authentication (CLI) 938
Configuration Examples for Configuring Authentication for Access Points 940
Displaying the Authentication Settings for Access Points: Examples 940

CHAPTER 56

Converting Autonomous Access Points to Lightweight Mode 941
Finding Feature Information 941
Guidelines for Converting Autonomous Access Points to Lightweight Mode 941
Information About Autonomous Access Points Converted to Lightweight Mode 942
Reverting from Lightweight Mode to Autonomous Mode 942
Using DHCP Option 43 and DHCP Option 60 942
How Converted Access Points Send Crash Information to the Device 943
Uploading Memory Core Dumps from Converted Access Points 943
Displaying MAC Addresses for Converted Access Points 943
Configuring a Static IP Address for a Lightweight Access Point 943
How to Convert a Lightweight Access Point Back to an Autonomous Access Point 944
Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI) 944
Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server) 944
Disabling the Reset Button on Converted Access Points (CLI) 945
Monitoring the AP Crash Log Information 946
How to Configure a Static IP Address on an Access Point 946
Configuring a Static IP Address on an Access Point (CLI) 946
Configuring a Static IP Address on an Access Point (GUI) 948
Recovering the Access Point Using the TFTP Recovery Procedure 948
Configuration Examples for Converting Autonomous Access Points to Lightweight Mode 949
  Example: Displaying the IP Address Configuration for Access Points 949
  Example: Displaying Access Point Crash File Information 949
Ethernet VLAN Tagging on Access Points 949
  Information About Ethernet VLAN Tagging on Access Points 949
  Configuring Ethernet VLAN Tagging on Access Points (GUI) 949
  Configuring Ethernet VLAN Tagging on Access Points (CLI) 950

CHAPTER 57  Using Cisco Workgroup Bridges 951
  Finding Feature Information 951
  Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges 951
  Monitoring the Status of Workgroup Bridges 952
  Debugging WGB Issues (CLI) 952
  Configuration Examples for Configuring Workgroup Bridges 954
    WGB Configuration: Example 954

CHAPTER 58  Configuring Probe Request Forwarding 955
  Finding Feature Information 955
  Information About Configuring Probe Request Forwarding 955
  How to Configure Probe Request Forwarding (CLI) 955

CHAPTER 59  Optimizing RFID Tracking 957
  Finding Feature Information 957
  Optimizing RFID Tracking on Access Points 957
  How to Optimize RFID Tracking on Access Points 957
    Optimizing RFID Tracking on Access Points (CLI) 957
  Configuration Examples for Optimizing RFID Tracking 959
    Displaying all the Access Points in Monitor Mode: Example 959

CHAPTER 60  Country Codes 961
  Finding Feature Information 961
  Information About Country Codes 961
  Prerequisites for Configuring Country Codes 962
Example: Limiting the Number of Multicast Routes 1001
Additional References for Configuring Multicast VPN 1001

PART XI

CHAPTER 65

Configuring Autoconf 1005
   Prerequisites for Autoconf 1005
   Restrictions for Autoconf 1005
   Information About Autoconf 1006
      Benefits of Autoconf 1006
      Identity Session Management and Templates 1006
   Autoconf Operation 1007
   Advantages of Using Templates 1009
   Autoconf Functionality 1010
   How to Configure Autoconf 1011
      Applying a Built-in Template to an End Device 1011
      Applying a Modified Built-in Template to an End Device 1015
      Migrating from ASP to Autoconf 1017
   Configuration Examples for Autoconf 1018
      Example: Applying a Built-in Template to an End Device 1018
      Example: Applying a Modified Built-in Template to an End Device 1018
      Example: Migrating from ASP Macros to Autoconf 1019
   Additional References for Autoconf 1019
   Feature Information for Autoconf 1020

CHAPTER 66

Configuring Cisco IOS Configuration Engine 1021
   Prerequisites for Configuring the Configuration Engine 1021
   Restrictions for Configuring the Configuration Engine 1021
   Information About Configuring the Configuration Engine 1022
      Cisco Configuration Engine Software 1022
      Configuration Service 1023
      Event Service 1023
      NameSpace Mapper 1024

CHAPTER 76

Radio Resource Management

Finding Feature Information
Prerequisites for Configuring Radio Resource Management
Restrictions for Radio Resource Management
Information About Radio Resource Management
  Radio Resource Monitoring
  Information About RF Groups
  RF Group Leader
  RF Group Name
  Mobility Controller
  Mobility Agent
  Rogue Access Point Detection in RF Groups
Transmit Power Control
  Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings
  Dynamic Channel Assignment
  Coverage Hole Detection and Correction
How to Configure RRM
  Configuring Advanced RRM CCX Parameters (CLI)
  Configuring Neighbor Discovery Type (CLI)
  Configuring RRM Profile Thresholds, Monitoring Channels, and Monitoring Intervals (GUI)
Configuring RF Groups
  Configuring the RF Group Mode (GUI)
  Configuring RF Group Selection Mode (CLI)
  Configuring an RF Group Name (CLI)
  Configuring an RF Group Name (GUI)
  Configuring Members in an 802.11 Static RF Group (CLI)
Configuring Transmit Power Control
  Configuring the Tx-Power Control Threshold (CLI)
  Configuring the Tx-Power Level (CLI)
  Configuring Transmit Power Control (GUI)
CHAPTER 82

Configuring MSDP  1487
Finding Feature Information  1487
Information About Configuring MSDP  1487
  MSDP Overview  1488
  MSDP Operation  1488
  MSDP Benefits  1489
How to Configure MSDP  1490
  Default MSDP Configuration  1490
  Configuring a Default MSDP Peer  1490
  Caching Source-Active State  1492
  Requesting Source Information from an MSDP Peer  1493
  Controlling Source Information that Your Switch Originates  1494
    Redistributing Sources  1494
    Filtering Source-Active Request Messages  1496
  Controlling Source Information that Your Switch Forwards  1498
    Using a Filter  1498
      Using TTL to Limit the Multicast Data Sent in SA Messages  1500
  Controlling Source Information that Your Switch Receives  1501
  Configuring an MSDP Mesh Group  1503
  Shutting Down an MSDP Peer  1504
  Including a Bordering PIM Dense-Mode Region in MSDP  1505
  Configuring an Originating Address other than the RP Address  1507
Monitoring and Maintaining MSDP  1508
Configuration Examples for Configuring MSDP  1509
  Configuring a Default MSDP Peer: Example  1509
  Caching Source-Active State: Example  1509
  Requesting Source Information from an MSDP Peer: Example  1510
  Controlling Source Information that Your Switch Originates: Example  1510
  Controlling Source Information that Your Switch Forwards: Example  1510
  Controlling Source Information that Your Switch Receives: Example  1510
CHAPTER 83

Configuring IP Unicast Routing 1511

Finding Feature Information 1512

Information About Configuring IP Unicast Routing 1512

Information About IP Routing 1512

Types of Routing 1513

IP Routing and Switch Stacks 1514

Classless Routing 1515

Address Resolution 1516

Proxy ARP 1517

ICMP Router Discovery Protocol 1517

UDP Broadcast Packets and Protocols 1518

Broadcast Packet Handling 1518

IP Broadcast Flooding 1518

How to Configure IP Routing 1519

How to Configure IP Addressing 1520

Default IP Addressing Configuration 1520

Assigning IP Addresses to Network Interfaces 1522

Using Subnet Zero 1523

Disabling Classless Routing 1524

Configuring Address Resolution Methods 1525

Defining a Static ARP Cache 1525

Setting ARP Encapsulation 1527

Enabling Proxy ARP 1528

Routing Assistance When IP Routing is Disabled 1529

Proxy ARP 1529

Default Gateway 1529

ICMP Router Discovery Protocol (IRDP) 1530

Configuring Broadcast Packet Handling 1532

Enabling Directed Broadcast-to-Physical Broadcast Translation 1532

Forwarding UDP Broadcast Packets and Protocols 1534

Establishing an IP Broadcast Address 1535

Flooding IP Broadcasts 1536

Monitoring and Maintaining IP Addressing 1538
Configuring VRF-Aware Services 1624

Configuring VRF-Aware Services for ARP 1624
Configuring VRF-Aware Services for Ping 1625
Configuring VRF-Aware Services for SNMP 1625
Configuring VRF-Aware Services for uRPF 1626
Configuring VRF-Aware RADIUS 1627
Configuring VRF-Aware Services for Syslog 1627
Configuring VRF-Aware Services for Traceroute 1628
Configuring VRF-Aware Services for FTP and TFTP 1628

Configuring Multicast VRFs 1629

Configuring a VPN Routing Session 1631
Configuring BGP PE to CE Routing Sessions 1632
Monitoring Multi-VRF CE 1634

Configuration Examples for Multi-VRF CE 1634
Multi-VRF CE Configuration Example 1634

Configuring Unicast Reverse Path Forwarding 1637

Protocol-Independent Features 1638

Distributed Cisco Express Forwarding 1638

Information About Cisco Express Forwarding 1638
How to Configure Cisco Express Forwarding 1638

Load-Balancing Scheme for CEF Traffic 1640

Restrictions for Configuring a Load-Balancing Scheme for CEF Traffic 1640
Prerequisites for Configuring a Load-Balancing Scheme for CEF Traffic 1640
CEF Load-Balancing Overview 1640

Per-Destination Load Balancing for CEF Traffic 1641
Per-Packet Load Balancing for CEF Traffic 1641
Load-Balancing Algorithms for CEF Traffic 1641

How to Configure a Load-Balancing for CEF Traffic 1641
Configuration Examples for CEF Traffic Load-Balancing 1644

Number of Equal-Cost Routing Paths 1645

Information About Equal-Cost Routing Paths 1645
How to Configure Equal-Cost Routing Paths 1645

Static Unicast Routes 1646

Information About Static Unicast Routes 1646
Username and Password Pairs 1671
Privilege Levels 1671
How to Control Switch Access with Passwords and Privilege Levels 1672
  Setting or Changing a Static Enable Password 1672
  Protecting Enable and Enable Secret Passwords with Encryption 1674
  Disabling Password Recovery 1675
  Setting a Telnet Password for a Terminal Line 1677
  Configuring Username and Password Pairs 1678
  Setting the Privilege Level for a Command 1680
  Changing the Default Privilege Level for Lines 1682
  Logging into and Exiting a Privilege Level 1683
Monitoring Switch Access 1684
Configuration Examples for Setting Passwords and Privilege Levels 1684
  Example: Setting or Changing a Static Enable Password 1684
  Example: Protecting Enable and Enable Secret Passwords with Encryption 1684
  Example: Setting a Telnet Password for a Terminal Line 1684
  Example: Setting the Privilege Level for a Command 1685
Additional References 1685

CHAPTER 86

Configuring TACACS+ 1687
  Finding Feature Information 1687
  Prerequisites for TACACS+ 1687
  Information About TACACS+ 1689
    TACACS+ and Switch Access 1689
    TACACS+ Overview 1689
    TACACS+ Operation 1690
    Method List 1691
    TACACS+ Configuration Options 1692
    TACACS+ Login Authentication 1692
    TACACS+ Authorization for Privileged EXEC Access and Network Services 1692
    TACACS+ Accounting 1692
    Default TACACS+ Configuration 1692
  How to Configure Switch Access with TACACS+ 1693
    Identifying the TACACS+ Server Host and Setting the Authentication Key 1693
MACsec Encryption 1703

Finding Feature Information 1703

Information About MACsec Encryption 1703

- Media Access Control Security and MACsec Key Agreement 1704
  - MKA Policies 1705
  - Virtual Ports 1705
- MACsec and Stacking 1705
  - MACsec, MKA and 802.1x Host Modes 1706

Configuring MKA and MACsec 1712

- Default MACsec MKA Configuration 1712
- Configuring an MKA Policy 1712
- Configuring MACsec on an Interface 1714

Configuring MACsec MKA using PSK 1716

- Configuring MACsec MKA on an Interface using PSK 1717

Information About MACsec MKA using EAP-TLS 1718

- Prerequisites for MACsec MKA using EAP-TLS 1718
- Limitations for MACsec MKA using EAP-TLS 1719

Configuring MACsec MKA using EAP-TLS 1719

Remote Authentication 1719

- Generating Key Pairs 1719
- Configuring Enrollment using SCEP 1720
- Configuring Enrollment Manually 1721
- Enabling 802.1x Authentication and Configuring AAA 1723
- Configuring EAP-TLS Profile and 802.1x Credentials 1724
- Applying the 802.1x MACsec MKA Configuration on Interfaces 1724

Local Authentication 1725

- Configuring the EAP Credentials using Local Authentication 1725
- Configuring the Local EAP-TLS Authentication and Authorization Profile 1726
Configuring Enrollment using SCEP 1726
Configuring Enrollment Manually 1728
Configuring EAP-TLS Profile and 802.1x Credentials 1729
Applying the 802.1x MKA MACsec Configuration on Interfaces 1730
Verifying MACsec MKA using EAP-TLS 1731
Cisco TrustSec Overview 1732
Configuring Cisco TrustSec MACsec 1734
Configuring Cisco TrustSec Switch-to-Switch Link Security in Manual Mode 1734
Configuration Examples 1736
Configuring MACsec on an Interface 1736
Configuration Examples for MACsec MKA using EAP-TLS 1738
Example: Enrolling the Certificate 1738
Example: Enabling 802.1x Authentication and AAA Configuration 1739
Example: Configuring EAP-TLS Profile and 802.1X Credentials 1739
Example: Applying 802.1X, PKI, and MACsec Configuration on the Interface 1739
Example: Cisco TrustSec Switch-to-Switch Link Security Configuration 1740

CHAPTER 88  1743

Configuring RADIUS 1743
Finding Feature Information 1743
Prerequisites for Configuring RADIUS 1743
Restrictions for Configuring RADIUS 1744
Information about RADIUS 1745
RADIUS and Switch Access 1745
RADIUS Overview 1745
RADIUS Operation 1746
RADIUS Change of Authorization 1747
Change-of-Authorization Requests 1748
CoA Request Response Code 1750
CoA Request Commands 1751
Stacking Guidelines for Session Termination 1753
Default RADIUS Configuration 1754
RADIUS Server Host 1754
RADIUS Login Authentication 1755
AAA Server Groups 1756
AAA Authorization 1756
RADIUS Accounting 1756
Vendor-Specific RADIUS Attributes 1756
Vendor-Proprietary RADIUS Server Communication 1768

How to Configure RADIUS 1768
Identifying the RADIUS Server Host 1768
Configuring RADIUS Login Authentication 1771
Defining AAA Server Groups 1773
Configuring RADIUS Authorization for User Privileged Access and Network Services 1775
Starting RADIUS Accounting 1777
Configuring Settings for All RADIUS Servers 1778
Configuring the Device to Use Vendor-Specific RADIUS Attributes 1780
Configuring the Device for Vendor-Proprietary RADIUS Server Communication 1781
Configuring CoA on the Device 1783
Monitoring CoA Functionality 1785

Additional References for Configuring Secure Shell 1786

CHAPTER 89
Configuring Kerberos 1787
Finding Feature Information 1787
Prerequisites for Controlling Switch Access with Kerberos 1787
Information about Kerberos 1788
Kerberos and Switch Access 1788
Kerberos Overview 1788
Kerberos Operation 1790
Authenticating to a Boundary Switch 1790
Obtaining a TGT from a KDC 1791
Authenticating to Network Services 1791
How to Configure Kerberos 1791
Monitoring the Kerberos Configuration 1791
Additional References 1791

CHAPTER 90
Configuring Local Authentication and Authorization 1793
Finding Feature Information 1793
How to Configure Local Authentication and Authorization 1793
Example: Configuring IOS SSH Server to Verify User's Digital Certificate for User Authentication
1812
Additional References for X.509v3 Certificates for SSH Authentication 1813
Feature Information for X.509v3 Certificates for SSH Authentication 1814

CHAPTER 93

Configuring Secure Socket Layer HTTP 1815
Finding Feature Information 1815
Information about Secure Sockets Layer (SSL) HTTP 1815
  Secure HTTP Servers and Clients Overview 1815
  Certificate Authority Trustpoints 1816
CipherSuites 1817
Default SSL Configuration 1818
SSL Configuration Guidelines 1818
How to Configure Secure HTTP Servers and Clients 1819
  Configuring a CA Trustpoint 1819
  Configuring the Secure HTTP Server 1821
  Configuring the Secure HTTP Client 1825
Monitoring Secure HTTP Server and Client Status 1826
Additional References for Configuring Secure Shell 1826

CHAPTER 94

IPv4 ACLs 1829
Finding Feature Information 1829
Information about Network Security with ACLs 1829
  ACL Overview 1829
    Access Control Entries 1830
    ACL Supported Types 1830
Supported ACLs 1830
  ACL Precedence 1830
Port ACLs 1831
Router ACLs 1832
VLAN Maps 1833
ACEs and Fragmented and Unfragmented Traffic 1833
  ACEs and Fragmented and Unfragmented Traffic Examples 1833
ACLs and Switch Stacks 1834
Active Switch and ACL Functions 1834
Stack Member and ACL Functions 1835
Active Switch Failure and ACLs 1835
Standard and Extended IPv4 ACLs 1835
IPv4 ACL Switch Unsupported Features 1835
Access List Numbers 1835
Numbered Standard IPv4 ACLs 1836
Numbered Extended IPv4 ACLs 1837
Named IPv4 ACLs 1837
ACL Logging 1838
Hardware and Software Treatment of IP ACLs 1838
VLAN Map Configuration Guidelines 1839
VLAN Maps with Router ACLs 1839
VLAN Maps and Router ACL Configuration Guidelines 1840
Time Ranges for ACLs 1840
IPv4 ACL Interface Considerations 1841
Prerequisites for Configuring IPv4 Access Control Lists 1841
Restrictions for Configuring IPv4 Access Control Lists 1842
How to Configure ACLs 1843
Configuring IPv4 ACLs 1843
Creating a Numbered Standard ACL (CLI) 1843
Creating a Numbered Extended ACL (CLI) 1845
Creating Named Standard ACLs 1848
Creating Extended Named ACLs 1850
Configuring Time Ranges for ACLs 1852
Applying an IPv4 ACL to a Terminal Line 1853
Applying an IPv4 ACL to an Interface (CLI) 1855
Creating Named MAC Extended ACLs 1856
Applying a MAC ACL to a Layer 2 Interface 1858
Configuring VLAN Maps 1859
Creating a VLAN Map 1861
Applying a VLAN Map to a VLAN 1863
Monitoring IPv4 ACLs 1864
Configuration Examples for ACLs 1865
Examples: Using Time Ranges with ACLs 1865
Examples: Including Comments in ACLs 1865
IPv4 ACL Configuration Examples 1866
   ACLs in a Small Networked Office 1866
   Examples: ACLs in a Small Networked Office 1867
   Example: Numbered ACLs 1868
   Examples: Extended ACLs 1868
   Examples: Named ACLs 1869
   Examples: Time Range Applied to an IP ACL 1869
   Examples: Configuring Commented IP ACL Entries 1870
   Examples: ACL Logging 1870
Configuration Examples for ACLs and VLAN Maps 1872
   Example: Creating an ACL and a VLAN Map to Deny a Packet 1872
   Example: Creating an ACL and a VLAN Map to Permit a Packet 1872
   Example: Default Action of Dropping IP Packets and Forwarding MAC Packets 1872
   Example: Default Action of Dropping MAC Packets and Forwarding IP Packets 1873
   Example: Default Action of Dropping All Packets 1873
Configuration Examples for Using VLAN Maps in Your Network 1874
   Example: Wiring Closet Configuration 1874
   Example: Restricting Access to a Server on Another VLAN 1875
   Example: Denying Access to a Server on Another VLAN 1875
Configuration Examples of Router ACLs and VLAN Maps Applied to VLANs 1876
   Example: ACLs and Switched Packets 1876
   Example: ACLs and Bridged Packets 1876
   Example: ACLs and Routed Packets 1877
   Example: ACLs and Multicast Packets 1878
Additional References 1878

CHAPTER 95 IPv6 ACLs 1881
   Finding Feature Information 1881
   IPv6 ACLs Overview 1881
   Switch Stacks and IPv6 ACLs 1882
   ACL Precedence 1882
   VLAN Maps 1883
Interactions with Other Features and Switches  1883
Restrictions for IPv6 ACLs  1884
Default Configuration for IPv6 ACLs  1884
Configuring IPv6 ACLs  1885
Attaching an IPv6 ACL to an Interface  1888
Configuring VLAN Maps  1890
Applying a VLAN Map to a VLAN  1892
Monitoring IPv6 ACLs  1893
Additional References  1894

CHAPTER 96

Configuring DHCP  1895
Finding Feature Information  1895
Information About DHCP  1895
  DHCP Server  1895
  DHCP Relay Agent  1895
  DHCP Snooping  1896
  Option-82 Data Insertion  1897
Cisco IOS DHCP Server Database  1900
DHCP Snooping Binding Database  1900
DHCP Snooping and Switch Stacks  1901
How to Configure DHCP Features  1902
  Default DHCP Snooping Configuration  1902
  DHCP Snooping Configuration Guidelines  1903
  Configuring the DHCP Server  1903
  DHCP Server and Switch Stacks  1903
  Configuring the DHCP Relay Agent  1903
  Specifying the Packet Forwarding Address  1904
  Prerequisites for Configuring DHCP Snooping and Option 82  1907
  Enabling the Cisco IOS DHCP Server Database  1908
  Monitoring DHCP Snooping Information  1908
Configuring DHCP Server Port-Based Address Allocation  1908
  Information About Configuring DHCP Server Port-Based Address Allocation  1908
  Default Port-Based Address Allocation Configuration  1909
  Port-Based Address Allocation Configuration Guidelines  1909
VLAN Assignment, Guest VLAN, Restricted VLAN, and Inaccessible Authentication Bypass
1990
MAC Authentication Bypass 1991
Maximum Number of Allowed Devices Per Port 1991
Configuring 802.1x Readiness Check 1992
Configuring Voice Aware 802.1x Security 1994
Configuring 802.1x Violation Modes 1995
Configuring 802.1x Authentication 1997
Configuring 802.1x Port-Based Authentication 1998
Configuring the Switch-to-RADIUS-Server Communication 2000
Configuring the Host Mode 2002
Configuring Periodic Re-Authentication 2003
Changing the Quiet Period 2005
Changing the Switch-to-Client Retransmission Time 2006
Setting the Switch-to-Client Frame-Retransmission Number 2007
Setting the Re-Authentication Number 2008
Enabling MAC Move 2009
Enabling MAC Replace 2010
Configuring 802.1x Accounting 2012
Configuring a Guest VLAN 2013
Configuring a Restricted VLAN 2015
Configuring Number of Authentication Attempts on a Restricted VLAN 2016
Configuring 802.1x Inaccessible Authentication Bypass with Critical Voice VLAN 2017
Example of Configuring Inaccessible Authentication Bypass 2020
Configuring 802.1x Authentication with WoL 2021
Configuring MAC Authentication Bypass 2022
Configuring 802.1x User Distribution 2023
Example of Configuring VLAN Groups 2024
Configuring NAC Layer 2 802.1x Validation 2025
Configuring an Authenticator Switch with NEAT 2027
Configuring a Supplicant Switch with NEAT 2029
Configuring 802.1x Authentication with Downloadable ACLs and Redirect URLs 2031
Configuring Downloadable ACLs 2031
Configuring a Downloadable Policy 2033

   Additional References 2099
   Feature Information 2099
   Finding Feature Information 2099
   Information About Port Blocking 2099
      Port Blocking 2099
   How to Configure Port Blocking 2100
      Blocking Flooded Traffic on an Interface 2100
   Monitoring Port Blocking 2102
   Where to Go Next 2102
Additional References 2102
Feature Information 2103
Monitoring Port Security 2103
Configuration Examples for Port Security 2103

CHAPTER 102

Configuring IPv6 First Hop Security 2105

Finding Feature Information 2105
Prerequisites for First Hop Security in IPv6 2105
Restrictions for First Hop Security in IPv6 2106
Information about First Hop Security in IPv6 2106
How to Configure an IPv6 Snooping Policy 2108
How to Attach an IPv6 Snooping Policy to an Interface 2109
How to Attach an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface 2111
How to Attach an IPv6 Snooping Policy to VLANs Globally 2112
How to Configure the IPv6 Binding Table Content 2113
How to Configure an IPv6 Neighbor Discovery Inspection Policy 2114
How to Attach an IPv6 Neighbor Discovery Inspection Policy to an Interface 2115
How to Attach an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface 2116
How to Attach an IPv6 Neighbor Discovery Inspection Policy to VLANs Globally 2117
How to Configure an IPv6 Router Advertisement Guard Policy 2118
How to Attach an IPv6 Router Advertisement Guard Policy to an Interface 2121
How to Attach an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface 2122
How to Attach an IPv6 Router Advertisement Guard Policy to VLANs Globally 2123
How to Configure an IPv6 DHCP Guard Policy 2123
How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface 2126
How to Attach an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface 2127
How to Attach an IPv6 DHCP Guard Policy to VLANs Globally 2128
How to Configure IPv6 Source Guard 2129
How to Attach an IPv6 Source Guard Policy to an Interface 2130
How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface 2131
How to Configure IPv6 Prefix Guard 2132
How to Attach an IPv6 Prefix Guard Policy to an Interface 2133
CHAPTER 105
Configuring Control Plane Policing 2159
Restrictions for CoPP 2159
Information About Control Plane Policing 2160
   CoPP Overview 2160
   System-Defined Aspects of CoPP 2160
   User-Configurable Aspects of CoPP 2163
How to Configure CoPP 2164
   Enabling a CPU Queue or Changing the Policer Rate 2164
   Disabling a CPU Queue 2166
   Setting the Default Policer Rates for All CPU Queues 2167
Examples for Configuring CoPP 2168
   Example: Enabling a CPU Queue or Changing the Policer Rate of a CPU Queue 2168
   Example: Setting the Default Policer Rates for All CPU Queues 2169
Monitoring CoPP 2172
Feature History and Information For CoPP 2172

CHAPTER 106
Configuring Wireless Guest Access 2175
Finding Feature Information 2175
Prerequisites for Guest Access 2175
Restrictions for Guest Access 2176
Information about Wireless Guest Access 2176
Fast Secure Roaming 2176
How to Configure Guest Access 2177
   Creating a Lobby Administrator Account 2177
   Configuring Guest User Accounts 2178
   Configuring Mobility Agent (MA) 2179
   Configuring Mobility Controller 2180
   Obtaining a Web Authentication Certificate 2182
   Displaying a Web Authentication Certificate 2182
   Choosing the Default Web Authentication Login Page 2183
   Choosing a Customized Web Authentication Login Page from an External Web Server 2184
   Assigning Login, Login Failure, and Logout Pages per WLAN 2186
Configuring AAA-Override  2187
Configuring Client Load Balancing  2188
Configuring Preauthentication ACL  2189
Configuring IOS ACL Definition  2190
Configuring Webpassthrough  2191

Configuration Examples for Guest Access  2192
  Example: Creating a Lobby Ambassador Account  2192
  Example: Obtaining Web Authentication Certificate  2192
  Example: Displaying a Web Authentication Certificate  2194
  Example: Configuring Guest User Accounts  2194
  Example: Configuring Mobility Controller  2195
  Example: Choosing the Default Web Authentication Login Page  2195
  Example: Choosing a Customized Web Authentication Login Page from an IPv4 External Web Server  2196
  Example: Assigning Login, Login Failure, and Logout Pages per WLAN  2196
  Example: Configuring AAA-Override  2197
  Example: Configuring Client Load Balancing  2197
  Example: Configuring Preauthentication ACL  2197
  Example: Configuring IOS ACL Definition  2198
  Example: Configuring Webpassthrough  2198

Additional References for Guest Access  2198
  Feature History and Information for Guest Access  2199

-------------------------

CHAPTER 107  Managing Rogue Devices  2201

  Finding Feature Information  2201
  Information About Rogue Devices  2201
  How to Configure Rogue Detection  2206
    Configuring Rogue Detection (CLI)  2206
    Verifying Rogue Detection  2208
  Examples: Rogue Detection Configuration  2208
  Additional References for Rogue Detection  2209
  Feature History and Information For Performing Rogue Detection Configuration  2210
  Finding Feature Information  2210
  Information About Rogue Devices  2210
How to Configure Rogue Detection 2215
   Configuring Rogue Detection (CLI) 2215
Verifying Rogue Detection 2216
Examples: Rogue Detection Configuration 2217
Additional References for Rogue Detection 2218
Feature History and Information For Performing Rogue Detection Configuration 2218

CHAPTER 108
Classifying Rogue Access Points 2219
   Finding Feature Information 2219
   Information About Classifying Rogue Access Points 2219
   Restrictions on Classifying Rogue Access Points 2222
   How to Classify Rogue Access Points 2223
      Configuring Rogue Classification Rules (CLI) 2223
   Examples: Classifying Rogue Access Points 2226
   Additional References for Classifying Rogue Access Points 2226
   Feature History and Information For Classifying Rogue Access Points 2227

CHAPTER 109
Configuring wIPS 2229
   Finding Feature Information 2229
   Information About wIPS 2229
   How to Configure wIPS on an Access Point 2236
      Configuring wIPS on an Access Point (CLI) 2236
   Monitoring wIPS Information 2236
   Examples: wIPS Configuration 2237
   Additional References for Configuring wIPS 2237
   Feature History for Performing wIPS Configuration 2238

CHAPTER 110
Configuring Intrusion Detection System 2239
   Finding Feature Information 2239
   Information About Intrusion Detection System 2239
   How to Configure Intrusion Detection System 2240
      Configuring IDS Sensors 2240
   Monitoring Intrusion Detection System 2241
Chapter 112: Configuring Cisco NSF with SSO

Finding Feature Information 2275
Prerequisites for NSF with SSO 2275
Restrictions for NSF with SSO 2276
Information About NSF with SSO 2276
   Overview of NSF with SSO 2276
SSO Operation 2277
NSF Operation 2278
Cisco Express Forwarding 2279
BGP Operation 2279
OSPF Operation 2280
EIGRP Operation 2281
How to Configure Cisco NSF with SSO 2282
   Configuring SSO 2282
   Configuring SSO Example 2282
   Verifying CEF NSF 2283
CHAPTER 113

Configuring Wireless High Availability 2289
Finding Feature Information 2289
Information about High Availability 2289
Information About Redundancy 2290
  Configuring Redundancy in Access Points 2290
  Configuring Heartbeat Messages 2291
Information about Access Point Stateful Switch Over 2292
Initiating Graceful Switchover 2292
Configuring EtherChannels for High Availability 2293
Configuring LACP 2293
Troubleshooting High Availability 2294
  Access the Standby Console 2294
  Before a Switchover 2295
  After a Switchover 2296
  Monitoring the Device Stack 2297
  LACP Configuration: Example 2298

PART XVII

System Management 2301

CHAPTER 114

Administering the Switch 2303
Finding Feature Information 2303
Information About Administering the Device 2303
  System Time and Date Management 2303
  System Clock 2304
  Network Time Protocol 2304
    NTP Stratum 2305

DHCP-Based Autoconfiguration Overview 2347
DHCP Client Request Process 2348
DHCP-based Autoconfiguration and Image Update 2349
Restrictions for DHCP-based Autoconfiguration 2349
DHCP Autoconfiguration 2349
DHCP Auto-Image Update 2349
DHCP Server Configuration Guidelines 2350
  Purpose of the TFTP Server 2350
  Purpose of the DNS Server 2351
How to Obtain Configuration Files 2351
How to Control Environment Variables 2352
  Common Environment Variables 2353
  Environment Variables for TFTP 2354
Scheduled Reload of the Software Image 2355
How to Perform Device Setup Configuration 2355
  Configuring DHCP Autoconfiguration (Only Configuration File) 2355
  Configuring DHCP Auto-Image Update (Configuration File and Image) 2358
  Configuring the Client to Download Files from DHCP Server 2361
  Manually Assigning IP Information to Multiple SVIs 2362
  Modifying the Device Startup Configuration 2364
    Specifying the Filenname to Read and Write the System Configuration 2364
    Manually Booting the Switch 2365
    Booting the Device in Installed Mode 2366
    Booting the Device in Bundle Mode 2368
    Booting a Specific Software Image On a Switch Stack 2368
    Configuring a Scheduled Software Image Reload 2369
Monitoring Device Setup Configuration 2371
  Example: Verifying the Device Running Configuration 2371
  Examples: Displaying Software Bootup in Install Mode 2371
  Example: Emergency Installation 2373
Configuration Examples for Performing Device Setup 2375
  Example: Configuring a Device as a DHCP Server 2375
  Example: Configuring DHCP Auto-Image Update 2375
  Example: Configuring a Device to Download Configurations from a DHCP Server 2375
  Examples: Scheduling Software Image Reload 2376
Additional References For Performing Device Setup 2376
Installing WCM Sub-Package 2377
  Benefits 2378
  Prerequisites 2378
Restrictions 2378
Installing WCM Sub-Package 2378
Feature History and Information For Performing Device Setup Configuration 2379

CHAPTER 117 Configuring Autonomic Networking 2381
Autonomic Networking 2381
Prerequisites for Autonomic Networking 2381
Restrictions for Autonomic Networking 2382
Information About Autonomic Networking 2382
Overview of Autonomic Networking 2382
Autonomic Networking Infrastructure 2383
Channel Discovery in Autonomic Networking 2384
Adjacency Discovery in Autonomic Networking 2385
Service Discovery in Autonomic Networking 2385
Autonomic Control Plane 2385
How to Configure Autonomic Networking 2385
Configuring the Registrar 2385
Verifying and Monitoring Autonomic Networking Configuration 2387

CHAPTER 118 Configuring Right-To-Use Licenses 2389
Finding Feature Information 2389
Restrictions for Configuring RTU Licenses 2389
Information About Configuring RTU Licenses 2390
Right-To-Use Licensing 2390
Right-To-Use Image-Based Licenses 2390
Right-To-Use License States 2391
License Activation for Switch Stacks 2391
Mobility Controller Mode 2392
Right-To-Use AP-Count Licensing 2392
Right-to-Use AP-Count Evaluation Licenses 2392
Right-To-Use Adder AP-Count Rehosting Licenses 2393
How to Configure RTU Licenses 2393
Activating an Image Based License 2393
Activating an AP-Count License 2395
Contents

Obtaining an Upgrade or Capacity Adder License 2396
Rehosting a License 2396
Changing Mobility Mode 2397
Monitoring and Maintaining RTU Licenses 2398
Configuration Examples for RTU Licensing 2399
Examples: Activating RTU Image Based Licenses 2399
Examples: Displaying RTU Licensing Information 2399
Example: Displaying RTU License Details 2401
Example: Displaying RTU License Mismatch 2402
Example: Displaying RTU Licensing Usage 2403
Additional References for RTU Licensing 2403
Feature History and Information for RTU Licensing 2404

CHAPTER 119
Configuring Administrator Usernames and Passwords 2405
Finding Feature Information 2405
Information About Configuring Administrator Usernames and Passwords 2405
Configuring Administrator Usernames and Passwords 2406
Examples: Administrator Usernames and Passwords Configuration 2408
Additional References for Administrator Usernames and Passwords Configuration 2409
Feature History and Information For Performing Administrator Usernames and Passwords Configuration 2409

CHAPTER 120
802.11 parameters and Band Selection 2411
Finding Feature Information 2411
Restrictions on Band Selection, 802.11 Bands, and Parameters 2411
Information About Configuring Band Selection, 802.11 Bands, and Parameters 2412
Band Selection 2412
802.11 Bands 2413
802.11n Parameters 2413
802.11h Parameters 2413
How to Configure 802.11 Bands and Parameters 2414
Configuring Band Selection (CLI) 2414
Configuring the 802.11 Bands (CLI) 2415
Configuring 802.11n Parameters (CLI) 2417
Configuring 802.11h Parameters (CLI) 2420
Monitoring Configuration Settings for Band Selection, 802.11 Bands, and Parameters 2420
  Verifying Configuration Settings Using Band Selection and 802.11 Bands Commands 2420
  Example: Viewing the Configuration Settings for the 5-GHz Band 2421
  Example: Viewing the Configuration Settings for the 24-GHz Band 2422
  Example: Viewing the status of 802.11h Parameters 2424
  Example: Verifying the Band-Selection Settings 2424
Configuration Examples for Band Selection, 802.11 Bands, and Parameters 2425
  Examples: Band Selection Configuration 2425
  Examples: 802.11 Bands Configuration 2425
  Examples: 802.11n Configuration 2426
  Examples: 802.11h Configuration 2426
Additional References for 802.11 Parameters and Band Selection 2427
  Feature History and Information For Performing 802.11 parameters and Band Selection Configuration 2428

CHAPTER 121  Configuring Aggressive Load Balancing 2429
  Finding Feature Information 2429
  Restrictions for Aggressive Load Balancing 2429
  Information for Configuring Aggressive Load Balancing Parameters 2430
    Aggressive Load Balancing 2430
    How to Configure Aggressive Load Balancing 2431
    Configuring Aggressive Load Balancing (CLI) 2431
  Monitoring Aggressive Load Balancing 2432
  Additional References for Aggressive Load Balancing 2433
  Feature History and Information For Performing Aggressive Load Balancing Configuration 2434

CHAPTER 122  Configuring Client Roaming 2435
  Finding Feature Information 2435
  Restrictions for Configuring Client Roaming 2435
  Information About Client Roaming 2435
    Inter-Subnet Roaming 2437
    Voice-over-IP Telephone Roaming 2437
    CCX Layer 2 Client Roaming 2437
Configuring Application Visibility and Control in a Wireless Network 2481
Finding Feature Information 2481
Information About Application Visibility and Control 2482
Supported AVC Class Map and Policy Map Formats 2483
Prerequisites for Application Visibility and Control 2485
Guidelines for Inter-Device Roaming with Application Visibility and Control 2485
Restrictions for Application Visibility and Control 2485
How to Configure Application Visibility and Control 2487
Configuring Application Visibility and Control (CLI) 2487
    Creating a Flow Record 2487
    Creating a Flow Exporter (Optional) 2489
    Creating a Flow Monitor 2491
    Creating AVC QoS Policy 2492
    Configuring WLAN to Apply Flow Monitor in IPV4 Input/Output Direction 2500
AP Downstream QoS 2500
    Information About AP downstream QoS 2500
    Configuring Class-map for Downstream QoS 2501
    Configuring Policy with Policing for Downstream QoS 2501
    Configuring Policy-map for Downstream QoS (set-dscp) 2502
    Configuring Policy-map for Downstream QoS (drop) 2503
    Configuring Policy-map for Downstream QoS on the WLAN 2504
Monitoring Application Visibility and Control 2505
    Monitoring Application Visibility and Control (CLI) 2505
Examples: Application Visibility and Control 2507
    Examples: Application Visibility Configuration 2507
    Examples: Application Visibility and Control QoS Configuration 2507
    Example: Configuring QoS Attribute for Local Profiling Policy 2507
Additional References for Application Visibility and Control 2509
Feature History and Information For Application Visibility and Control 2510
### CHAPTER 125: Campus Fabric

- Information About Campus Fabric 2511
  - Campus Fabric Overview 2511
    - Understanding Fabric Domain Elements 2511
    - Campus Fabric Configuration Guidelines 2512
  - How to Configure Fabric Overlay 2513
    - Configuring Fabric Edge Devices 2513
    - Configuring Fabric Control-Plane Devices 2516
    - Configuring Fabric Border Devices 2517
  - Security Group Tags and Policy Enforcement in Campus Fabric 2519
  - Multicast Using Campus Fabric Overlay 2519
    - Configuring Multicast PIM Sparse Mode in Campus Fabric 2519
    - Configuring Multicast PIM SSM in Campus Fabric 2521
  - Data Plane Security in Campus Fabric 2523
    - Configuring Data Plane Security on Edge Devices 2523
    - Configuring Data Plane Security on Control Plane Devices 2524
    - Configuring Data Plane Security on Border Devices 2525
  - Campus Fabric Configuration Examples 2526

### CHAPTER 126: Configuring Voice and Video Parameters

- Finding Feature Information 2529
- Prerequisites for Voice and Video Parameters 2529
- Restrictions for Voice and Video Parameters 2529
- Information About Configuring Voice and Video Parameters 2530
  - Call Admission Control 2530
    - Static-Based CAC 2531
    - Load-Based CAC 2531
  - IOSd Call Admission Control 2531
  - Expedited Bandwidth Requests 2532
  - U-APSD 2533
  - Traffic Stream Metrics 2533
- Information About Configuring Voice Prioritization Using Preferred Call Numbers 2534
- Information About Enhanced Distributed Channel Access Parameters 2534

</tr>
</thead>
<tbody>
<tr>
<td>^ or Ctrl</td>
<td>Both the ^ symbol and Ctrl represent the Control (Ctrl) key on a keyboard.</td>
</tr>
<tr>
<td></td>
<td>For example, the key combination ^D or Ctrl-D means that you hold down the</td>
</tr>
<tr>
<td></td>
<td>Control key while you press the D key. (Keys are indicated in capital letters</td>
</tr>
<tr>
<td></td>
<td>but are not case sensitive.)</td>
</tr>
<tr>
<td><strong>bold</strong> font</td>
<td>Commands and keywords and user-entered text appear in <strong>bold</strong> font.</td>
</tr>
<tr>
<td><strong>Italic</strong> font</td>
<td>Document titles, new or emphasized terms, and arguments for which you supply</td>
</tr>
<tr>
<td></td>
<td>values are in <strong>italic</strong> font.</td>
</tr>
<tr>
<td><strong>Courier</strong> font</td>
<td>Terminal sessions and information the system displays appear in <strong>courier</strong></td>
</tr>
<tr>
<td><strong>Bold Courier</strong>font</td>
<td><strong>Bold Courier</strong> font indicates text that the user must enter.</td>
</tr>
<tr>
<td>[x]</td>
<td>Elements in square brackets are optional.</td>
</tr>
<tr>
<td>...</td>
<td>An ellipsis (three consecutive nonbolded periods without spaces) after a</td>
</tr>
<tr>
<td></td>
<td>syntax element indicates that the element can be repeated.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>or arguments.</td>
</tr>
<tr>
<td>[x</td>
<td>y]</td>
</tr>
<tr>
<td></td>
<td>vertical bars.</td>
</tr>
<tr>
<td>{x</td>
<td>y}</td>
</tr>
</tbody>
</table>
**Convention** | **Description**
--- | ---
\[x \{y | z\}\] | Nested set of square brackets or braces indicate optional or required choices within optional or required elements. Braces and a vertical bar within square brackets indicate a required choice within an optional element.

string | A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks.

< : > | Nonprinting characters such as passwords are in angle brackets.

[ ] | Default responses to system prompts are in square brackets.
!
# | An exclamation point (!) or a pound sign (#) at the beginning of a line of code indicates a comment line.

**Reader Alert Conventions**

This document may use the following conventions for reader alerts:

- **Note**
  Means reader take note. Notes contain helpful suggestions or references to material not covered in the manual.

- **Tip**
  Means the following information will help you solve a problem.

- **Caution**
  Means reader be careful. In this situation, you might do something that could result in equipment damage or loss of data.

- **Timesaver**
  Means the described action saves time. You can save time by performing the action described in the paragraph.

- **Warning**
  IMPORTANT SAFETY INSTRUCTIONS

  This warning symbol means danger. You are in a situation that could cause bodily injury. Before you work on any equipment, be aware of the hazards involved with electrical circuitry and be familiar with standard practices for preventing accidents. Use the statement number provided at the end of each warning to locate its translation in the translated safety warnings that accompanied this device. Statement 1071

  SAVE THESE INSTRUCTIONS
Related Documentation

Before installing or upgrading the device, refer to the device release notes.

- Error Message Decoder, located at: https://www.cisco.com/cgi-bin/Support/Errordecoder/index.cgi

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly What's New in Cisco Product Documentation, which also lists all new and revised Cisco technical documentation, at:

Subscribe to the What's New in Cisco Product Documentation as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS version 2.0.
CHAPTER 1

Using the Command-Line Interface

- Information About Using the Command-Line Interface, on page 1
- How to Use the CLI to Configure Features, on page 5

Information About Using the Command-Line Interface

Command Modes

The Cisco IOS user interface is divided into many different modes. The commands available to you depend on which mode you are currently in. Enter a question mark (?) at the system prompt to obtain a list of commands available for each command mode.

You can start a CLI session through a console connection, through Telnet, an SSH, or by using the browser. When you start a session, you begin in user mode, often called user EXEC mode. Only a limited subset of the commands are available in user EXEC mode. For example, most of the user EXEC commands are one-time commands, such as show commands, which show the current configuration status, and clear commands, which clear counters or interfaces. The user EXEC commands are not saved when the device reboots.

To have access to all commands, you must enter privileged EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. From this mode, you can enter any privileged EXEC command or enter global configuration mode.

Using the configuration modes (global, interface, and line), you can make changes to the running configuration. If you save the configuration, these commands are stored and used when the device reboots. To access the various configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and line configuration mode.

This table describes the main command modes, how to access each one, the prompt you see in that mode, and how to exit the mode.
## Table 1: Command Mode Summary

<table>
<thead>
<tr>
<th>Mode</th>
<th>Access Method</th>
<th>Prompt</th>
<th>Exit Method</th>
<th>About This Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>User EXEC</td>
<td>Begin a session using Telnet, SSH, or console.</td>
<td>Device&gt;</td>
<td>Enter <code>logout</code> or <code>quit</code>.</td>
<td>Use this mode to</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Change terminal settings.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Perform basic tests.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Display system information.</td>
</tr>
<tr>
<td>Privileged EXEC</td>
<td>While in user EXEC mode, enter the <code>enable</code> command.</td>
<td>Device#</td>
<td>Enter <code>disable</code> to exit.</td>
<td>Use this mode to verify commands that you have entered. Use a password to protect access to this mode.</td>
</tr>
<tr>
<td>Global configuration</td>
<td>While in privileged EXEC mode, enter the <code>configure</code> command.</td>
<td>Device(config)#</td>
<td>To exit to privileged EXEC mode, enter <code>exit</code> or <code>end</code>, or press Ctrl-Z.</td>
<td>Use this mode to configure parameters that apply to the entire device.</td>
</tr>
<tr>
<td>VLAN configuration</td>
<td>While in global configuration mode, enter the <code>vlan vlan-id</code> command.</td>
<td>Device(config-vlan)#</td>
<td>To exit to global configuration mode, enter the <code>exit</code> command.</td>
<td>Use this mode to configure VLAN parameters. When VTP mode is transparent, you can create extended-range VLANs (VLAN IDs greater than 1005) and save configurations in the device startup configuration file.</td>
</tr>
</tbody>
</table>
### Understanding Abbreviated Commands

You need to enter only enough characters for the device to recognize the command as unique.

This example shows how to enter the `show configuration` privileged EXEC command in an abbreviated form:

```
Device# show conf
```

### No and Default Forms of Commands

Almost every configuration command also has a **no** form. In general, use the **no** form to disable a feature or function or reverse the action of a command. For example, the `no shutdown` interface configuration command reverses the shutdown of an interface. Use the command without the keyword **no** to reenable a disabled feature or to enable a feature that is disabled by default.

Configuration commands can also have a **default** form. The **default** form of a command returns the command setting to its default. Most commands are disabled by default, so the **default** form is the same as the **no** form. However, some commands are enabled by default and have variables set to certain default values. In these cases, the **default** command enables the command and sets variables to their default values.

### CLI Error Messages

This table lists some error messages that you might encounter while using the CLI to configure your device.
Table 2: Common CLI Error Messages

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Meaning</th>
<th>How to Get Help</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Ambiguous command: &quot;show con&quot;</td>
<td>You did not enter enough characters for your device to recognize the command.</td>
<td>Reenter the command followed by a question mark (?) without any space between the command and the question mark. The possible keywords that you can enter with the command appear.</td>
</tr>
<tr>
<td>% Incomplete command.</td>
<td>You did not enter all of the keywords or values required by this command.</td>
<td>Reenter the command followed by a question mark (?) with a space between the command and the question mark. The possible keywords that you can enter with the command appear.</td>
</tr>
<tr>
<td>% Invalid input detected at <code>^</code> marker.</td>
<td>You entered the command incorrectly. The caret (^) marks the point of the error.</td>
<td>Enter a question mark (?) to display all of the commands that are available in this command mode. The possible keywords that you can enter with the command appear.</td>
</tr>
</tbody>
</table>

Configuration Logging

You can log and view changes to the device configuration. You can use the Configuration Change Logging and Notification feature to track changes on a per-session and per-user basis. The logger tracks each configuration command that is applied, the user who entered the command, the time that the command was entered, and the parser return code for the command. This feature includes a mechanism for asynchronous notification to registered applications whenever the configuration changes. You can choose to have the notifications sent to the syslog.

Note

Only CLI or HTTP changes are logged.

Using the Help System

You can enter a question mark (?) at the system prompt to display a list of commands available for each command mode. You can also obtain a list of associated keywords and arguments for any command.

SUMMARY STEPS

1. help
2. abbreviated-command-entry ?
3. abbreviated-command-entry <Tab>
4. ?
5. command ?
6. command keyword ?
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 help</td>
<td>Obtains a brief description of the help system in any command mode.</td>
</tr>
<tr>
<td>Example: Device# help</td>
<td></td>
</tr>
<tr>
<td>Step 2 abbreviated-command-entry ?</td>
<td>Obtains a list of commands that begin with a particular character string.</td>
</tr>
<tr>
<td>Example: Device# di? dir disable disconnect</td>
<td></td>
</tr>
<tr>
<td>Step 3 abbreviated-command-entry &lt;Tab&gt;</td>
<td>Completes a partial command name.</td>
</tr>
<tr>
<td>Example: Device# sh conf&lt;tab&gt; Device# show configuration</td>
<td></td>
</tr>
<tr>
<td>Step 4 ?</td>
<td>Lists all commands available for a particular command mode.</td>
</tr>
<tr>
<td>Example: Device&gt; ?</td>
<td></td>
</tr>
<tr>
<td>Step 5 command ?</td>
<td>Lists the associated keywords for a command.</td>
</tr>
<tr>
<td>Example: Device&gt; show ?</td>
<td></td>
</tr>
<tr>
<td>Step 6 command keyword ?</td>
<td>Lists the associated arguments for a keyword.</td>
</tr>
<tr>
<td>Example: Device(config)# cdp holdtime ? &lt;10-255&gt; Length of time (in sec) that receiver must keep this packet</td>
<td></td>
</tr>
</tbody>
</table>

How to Use the CLI to Configure Features

Configuring the Command History

The software provides a history or record of commands that you have entered. The command history feature is particularly useful for recalling long or complex commands or entries, including access lists. You can customize this feature to suit your needs.

Changing the Command History Buffer Size

By default, the device records ten command lines in its history buffer. You can alter this number for a current terminal session or for all sessions on a particular line. This procedure is optional.
SUMMARY STEPS

1. `terminal history [size number-of-lines]`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>terminal history [size number-of-lines]</code></td>
<td>Changes the number of command lines that the device records during the current terminal session in privileged EXEC mode. You can configure the size from 0 to 256.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device# terminal history size 200
```

Recalling Commands

To recall commands from the history buffer, perform one of the actions listed in this table. These actions are optional.

### Note
The arrow keys function only on ANSI-compatible terminals such as VT100s.

SUMMARY STEPS

1. **Ctrl-P** or use the **up arrow** key
2. **Ctrl-N** or use the **down arrow** key
3. **show history**

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <strong>Ctrl-P</strong> or use the <strong>up arrow</strong> key</td>
<td>Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall successively older commands.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <strong>Ctrl-N</strong> or use the <strong>down arrow</strong> key</td>
<td>Returns to more recent commands in the history buffer after recalling commands with <strong>Ctrl-P</strong> or the up arrow key. Repeat the key sequence to recall successively more recent commands.</td>
</tr>
<tr>
<td><strong>Step 3</strong> <strong>show history</strong></td>
<td>Lists the last several commands that you just entered in privileged EXEC mode. The number of commands that appear is controlled by the setting of the <code>terminal history</code> global configuration command and the <code>history line</code> configuration command.</td>
</tr>
</tbody>
</table>

Disabling the Command History Feature

The command history feature is automatically enabled. You can disable it for the current terminal session or for the command line. This procedure is optional.
Enabling and Disabling Editing Features

Although enhanced editing mode is automatically enabled, you can disable it and reenable it.

**SUMMARY STEPS**

1. terminal no history

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  terminal no history  
  *Example: Device# terminal no history* | Enables the feature during the current terminal session in privileged EXEC mode. |

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 2**
  terminal no editing  
  *Example: Device# terminal no editing* | Enables the enhanced editing mode for the current terminal session in privileged EXEC mode. |

**Editing Commands Through Keystrokes**

The keystrokes help you to edit the command lines. These keystrokes are optional.

**Note**

The arrow keys function only on ANSI-compatible terminals such as VT100s.

**Table 3: Editing Commands**

<table>
<thead>
<tr>
<th>Editing Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl-B or use the left arrow key</td>
<td>Moves the cursor back one character.</td>
</tr>
<tr>
<td>Ctrl-F or use the right arrow key</td>
<td>Moves the cursor forward one character.</td>
</tr>
<tr>
<td><strong>Ctrl-A</strong></td>
<td>Moves the cursor to the beginning of the command line.</td>
</tr>
<tr>
<td><strong>Ctrl-E</strong></td>
<td>Moves the cursor to the end of the command line.</td>
</tr>
<tr>
<td><strong>Esc B</strong></td>
<td>Moves the cursor back one word.</td>
</tr>
<tr>
<td><strong>Esc F</strong></td>
<td>Moves the cursor forward one word.</td>
</tr>
<tr>
<td><strong>Ctrl-T</strong></td>
<td>Transposes the character to the left of the cursor with the character located at the cursor.</td>
</tr>
<tr>
<td><strong>Delete or Backspace key</strong></td>
<td>Erases the character to the left of the cursor.</td>
</tr>
<tr>
<td><strong>Ctrl-D</strong></td>
<td>Deletes the character at the cursor.</td>
</tr>
<tr>
<td><strong>Ctrl-K</strong></td>
<td>Deletes all characters from the cursor to the end of the command line.</td>
</tr>
<tr>
<td><strong>Ctrl-U or Ctrl-X</strong></td>
<td>Deletes all characters from the cursor to the beginning of the command line.</td>
</tr>
<tr>
<td><strong>Ctrl-W</strong></td>
<td>Deletes the word to the left of the cursor.</td>

<td>Designates a particular keystroke as an executable command, perhaps as a shortcut.</td>
</tr>
<tr>
<td><strong>Return key</strong></td>
<td>Scrolls down a line or screen on displays that are longer than the terminal screen can display. <strong>Note</strong> The More prompt is used for any output that has more lines than can be displayed on the terminal screen, including show command output. You can use the Return and Space bar keystrokes whenever you see the More prompt.</td>
</tr>
<tr>
<td><strong>Space bar</strong></td>
<td>Scrolls down one screen.</td>
</tr>
<tr>
<td><strong>Ctrl-L or Ctrl-R</strong></td>
<td>Redisplays the current command line if the device suddenly sends a message to your screen.</td>
</tr>
</tbody>
</table>

**Editing Command Lines That Wrap**

You can use a wraparound feature for commands that extend beyond a single line on the screen. When the cursor reaches the right margin, the command line shifts ten spaces to the left. You cannot see the first ten characters of the line, but you can scroll back and check the syntax at the beginning of the command. The keystroke actions are optional.

To scroll back to the beginning of the command entry, press **Ctrl-B** or the left arrow key repeatedly. You can also press **Ctrl-A** to immediately move to the beginning of the line.
The arrow keys function only on ANSI-compatible terminals such as VT100s.

The following example shows how to wrap a command line that extends beyond a single line on the screen.

**SUMMARY STEPS**

1. access-list
2. Ctrl-A
3. Return key

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Displays the global configuration command entry that extends beyond one line.</td>
</tr>
<tr>
<td>access-list</td>
<td>When the cursor first reaches the end of the line, the line is shifted ten spaces to the left and redisplayed. The dollar sign ($) shows that the line has been scrolled to the left. Each time the cursor reaches the end of the line, the line is again shifted ten spaces to the left.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 Device(config)# $ 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.25 Device(config)# $t tcp 10.15.22.25 255.255.255.0 131.108.1.20 255.255.255.0 eq 255.255.255.0 eq 45</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Checks the complete syntax.</td>
</tr>
<tr>
<td>Ctrl-A</td>
<td>The dollar sign ($) appears at the end of the line to show that the line has been scrolled to the right.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.25</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Execute the commands.</td>
</tr>
<tr>
<td>Return key</td>
<td>The software assumes that you have a terminal screen that is 80 columns wide. If you have a different width, use the terminal width privileged EXEC command to set the width of your terminal. Use line wrapping with the command history feature to recall and modify previous complex command entries.</td>
</tr>
</tbody>
</table>

**Searching and Filtering Output of show and more Commands**

You can search and filter the output for `show` and `more` commands. This is useful when you need to sort through large amounts of output or if you want to exclude output that you do not need to see. Using these commands is optional.
Summary Steps

1. `{show | more} command | {begin | include | exclude} regular-expression`

Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{show</td>
<td>more} command</td>
</tr>
</tbody>
</table>

Step 1

Example:
```
Device# show interfaces | include protocol
Vlan1 is up, line protocol is up
Vlan10 is up, line protocol is down
GigabitEthernet1/0/1 is up, line protocol is down
GigabitEthernet1/0/2 is up, line protocol is up
```

Accessing the CLI

You can access the CLI through a console connection, through Telnet, a SSH, or by using the browser.

You manage the switch stack and the stack member interfaces through the active switch. You cannot manage stack members on an individual switch basis. You can connect to the active switch through the console port or the Ethernet management port of one or more stack members. Be careful with using multiple CLI sessions on the active switch. Commands that you enter in one session are not displayed in the other sessions. Therefore, it is possible to lose track of the session from which you entered commands.

Note

We recommend using one CLI session when managing the switch stack.

If you want to configure a specific stack member port, you must include the stack member number in the CLI command interface notation.

To debug the standby switch, use the `session standby ios` privileged EXEC command from the active switch to access the IOS console of the standby switch. To debug a specific stack member, use the `session switch stack-member-number` privileged EXEC command from the active switch to access the diagnostic shell of the stack member. For more information about these commands, see the switch command reference.

Accessing the CLI Through a Console Connection or Through Telnet

Before you can access the CLI, you must connect a terminal or a PC to the device console or connect a PC to the Ethernet management port and then power on the device, as described in the hardware installation guide that shipped with your device.

If your device is already configured, you can access the CLI through a local console connection or through a remote Telnet session, but your device must first be configured for this type of access.

You can use one of these methods to establish a connection with the device:
Procedure

- Connect the device console port to a management station or dial-up modem, or connect the Ethernet management port to a PC. For information about connecting to the console or Ethernet management port, see the device hardware installation guide.

- Use any Telnet TCP/IP or encrypted Secure Shell (SSH) package from a remote management station. The device must have network connectivity with the Telnet or SSH client, and the device must have an enable secret password configured.
  - The device supports up to 16 simultaneous Telnet sessions. Changes made by one Telnet user are reflected in all other Telnet sessions.
  - The device supports up to five simultaneous secure SSH sessions.

After you connect through the console port, through the Ethernet management port, through a Telnet session or through an SSH session, the user EXEC prompt appears on the management station.
Accessing the CLI Through a Console Connection or Through Telnet

Audio Video Bridging

Introduction to Audio Video Bridging Networks

Information about Audio Video Bridging (AVB)

Audio and video equipment deployments have traditionally been analog single-purpose point-to-point one-way links. Migration to digital transmission also continued to retain the point-to-point one-way links architecture. The dedicated connection model resulted in a mass of cabling in professional and consumer applications, which was hard to manage and operate.

In order to accelerate the adoption to Ethernet based audio/video deployments in an interoperable way IEEE came up with the IEEE Audio Video Bridging standards - IEEE 802.1BA. This defines a mechanism where endpoints and the network will function as a whole to enable high quality A/V streaming across consumer applications to professional audio-video over an Ethernet infrastructure.

Note

• AVB is not supported on stacked systems.
• AVB is not supported on Etherchannel interfaces.
• AVB is supported only on STP-enabled network.

Licenses Supporting AVB

AVB is supported on the following two license levels only:

• ipbase
• ipservices
Benefits of AVB

AVB is a standard based mechanism to enable Ethernet based audio-video transmission which has the following benefits:

- Guaranteed max Latency
- Synchronized Time
- Guaranteed Bandwidth
- Professional Grade

Components of AVB Network

AVB protocols operate only in domains where every device is AVB capable. The AVB network comprises of the AVB talkers, AVB listeners, AVB switches and the grandmaster clock source.

- AVB Talker - An AVB end station that is the source or producer of a stream, i.e. microphones, video camera, and so on.
- AVB Listener - An AVB end station that is the destination or consumer of a stream, i.e. speaker, video screen, and so on.
- AVB Switch - An Ethernet switch that complies with IEEE802.1 AVB standards.
- AVB stream: A data stream associated with a stream reservation compliant with the Stream Reservation Protocol (SRP).

Note

In some instances, the word “bridge” is used. In this context, it references to a switch.

The IEEE 802.1BA specification requires that an AVB talker must be grandmaster capable. In a typical deployment a network node can also be the grandmaster, provided it can either source or derive timing from a grandmaster capable device and provide the timing to the AVB network using IEEE 802.1AS.

Figure 1 shows a simple illustration of AVB network with different components.
In many instances, the Audio/Video end points (Microphone, Speaker, etc.) are analog devices. AVB end-point vendors introduce Digital Signal Processors (DSP) and I/O devices that provide extensive audio/video processing and aggregate the end-points into an AVB Ethernet interface, as shown in Figure 2.

**Supported SKUs for AVB**

AVB is supported on the following Catalyst 3850 and Catalyst 3650 SKUs.
- WS-C3650-24PDM
- WS-C3650-48FQM
• WS-C3650-8X24UQ
• WS-C3650-12X48UQ
• WS-C3850-12X48U
• WS-C3850-12XS
• WS-C3850-16XS
• WS-C3850-24XS
• WS-C3850-24XU
• WS-C3850-32XS
• WS-C3850-48XS

Note
In Cisco IOS XE Denali 16.3.1, AVB is supported only on the non-mGig interfaces on WS-3850-12X48U. Starting from Cisco IOS XE Denali 16.3.2, AVB is supported on the mGig interfaces on WS-3850-12X48U and WS-C3850-24XU.

Information about Generalized Precision Time Protocol (gPTP)

Generalized Precision Time Protocol (gPTP) is an IEEE 802.1AS standard, which provides a mechanism to synchronize clocks of the bridges and end point devices in an AVB network. It defines the mechanism to elect the grandmaster clock (BMCA) among the time-aware bridges and talker and listener. The grandmaster is the root of the timing hierarchy that gets established in the time-aware network and distributes time to nodes below to enable synchronization.

Time synchronization also requires determining the link delay and switch delays in the network nodes. The gptp switch is a IEEE 1588 boundary clock, which also determines the link delay using the peer-to-peer delay mechanism. The delays computed are included in the correction field of the PTP messages and relayed to the end-points. The talker and listener use this gPTP time as a shared clock reference, which is used to relay and recover the media clock. gPTP currently defines only domain 0, which is what the switch supports.

The peer to peer delay mechanism runs on STP blocked ports as well. No other PTP messages are sent over blocked ports.

In a PTP domain, Best Master Clock (BMC) algorithm organizes Clocks and Ports into a hierarchical fashion, which includes clocks and port states:

Clocks
• Grandmaster (GM/GMC)
• Boundary Clock (BC)

Port States
• Master (M)
• Slave (S)
• Passive (P)
Information about Multiple Stream Reservation Protocol (MSRP)

Multiple Stream Reservation Protocol (MSRP) provides a mechanism for end stations to reserve network resources that will guarantee the transmission and reception of data streams across a network with the requested QoS. It is one of the core protocols required on an AVB device (talker, listener and switches). It allows talkers to advertise streams across a network of AVB switches and listeners to register for receiving the streams.

MSRP is the key software protocol module for supporting AVB. It enables stream establishment and teardown. It interfaces with gPTP to update the latency information for the streams. It interfaces with the QoS module to setup the hardware resources that would guarantee requested bandwidth for the streams. It also provides the QoS shaping parameters required for the credit based shaper.

When AVB is enabled globally the default queuing values will be programmed to 1% bandwidth on the 10G interface. When stream reservation happens via MSRP, the ports will be moved accordingly from the boundary to the core port and the calculated bandwidth will be reserved for the outgoing interfaces for given streams. If a port is enabled with a capture feature like SPAN, RSPAN or Wireshark, there is no MSRP stream reservation. Queuing is programmed with default values of 1% for Class A & Class B of AVB traffic. Hence, all AVB traffic is rate limited to 1% of the bandwidth.

Functions of MSRP

MSRP performs the following functions:

- Allows Talkers to advertise Streams and Listeners to discover and register for Streams.
- Establishes a path through an Ethernet between a Talker and one or more Listeners.
- Provides guaranteed bandwidth for AVB Streams.
- Guarantees an upper bound on latency.
- Discovers and reports the worst case end-to-end latency between the Talker and each of its Listeners.
- Reports failure reason and location when a path between the Talker and a Listener cannot satisfy bandwidth requirements.
- Supports multiple classes of traffic with different latency targets.
- Protects best effort traffic from starvation by limiting AVB traffic.
- MSRP Talker declarations are not forwarded along the STP blocked ports.
- MSRP listens to the STP TCN notification to generate MSRP declarations tear/modify/establish streams.

Information about QoS HQoS

AVB networks guarantee bandwidth and minimum bounded latency for the time-sensitive audio and video streams. AVB defines Class A and Class B as the time-sensitive streams, based on the worst-case latency targets of the traffic from talker to listener.

The latency targets for the two streams are listed as below:

- SR-Class A: 2ms
SR-Class B: 50ms

The sum of the worst-case latency contributions per hop should result in an overall end-to-end latency of 2 ms or less for SR-Class A and 50ms or less for SR-Class B. A typical AVB deployment of 7 hops from talker to listener meets these latency requirements.

The priority code points map the traffic to the specific stream. Frame forwarding behavior is based on this priority. A credit-based shaper is used to shape the transmission of these streams in accordance with the bandwidth that has been reserved on a given outbound queue so that the latency targets are met.

Starting with Cisco XE Denali 16.3.2, support for hierarchical QoS for AVB is enabled. AVB Hierarchical QoS policy is two level Parent-Child Policy. AVB Parent policy segregates audio, video traffic streams(SR-Class A, SR-Class B) and Network Control packets from standard best-effort ethernet traffic (Non-SR) and manage streams accordingly. Hierarchical QoS allows you to specify QoS behavior at multiple policy levels, which provides a high degree of granularity in traffic management. You can use hierarchical policies to:

- Allow a parent class to shape multiple queues in a child policy
- Apply specific policy map actions on the aggregate traffic
- Apply class-specific policy map actions

You can modify only ingress and egress HQoS child policy's class-map and its actions using policy-map AVB-Output-Child-Policy and policy-map AVB-Input-Child-Policy command.

Note: You should not modify the PCP in child policy to map with PCP configured in Parent Policy, e.g. SR Class A cos 3 and SR Class B Cos 2.

Hierarchical Policing

Hierarchical policing is supported on ingress and egress interfaces. Hierarchical QoS separates the SR and Non-SR class related rules into parent and child policies respectively. AVB SR classes are completely controlled by MSRP client and hence, parent policies containing SR class attributes are governed by MSRP. The end user has complete control over child policies which contain Non-SR class attributes and can modify only the child policies.

AVB HQoS child policies are user modifiable and NVGENed to preserve the configuration if user saves the configuration to the startup-config. So, AVB HQoS child policy configurations are retained even after reload.

Information about Multiple VLAN Registration Protocol (MVRP)

Multiple VLAN Registration Protocol (MVRP) is an application based on MRP. MVRP provides a mechanism for dynamic maintenance of the contents of Dynamic VLAN Registration Entries for each vlan ids, and for propagating the information they contain to other Bridges. This information allows MVRP-aware devices to dynamically establish and update their knowledge of the set of vlan ids associated with VLANs that currently have active members, and through which Ports those members can be reached.

MVRP, from an AVB perspective, is mandatory on the talkers and the listeners. Independent of AVB, MVRP is an IEEE 802.1Q requirement on the VLAN-aware switches. However, manual configuration of VLANS on the switches is sufficient for AVB.
VTP should be in the disabled mode or transparent mode for MVRP to work.

Configuring the AVB Network

Configuring AVB

This section describes the various configurations available for AVB.

Enabling AVB on the switch

Perform the following task to enable AVB on the switch.

Note

Both, the `avb` and `avb strict` commands must be configured to enable AVB.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `avb`
4. `avb strict`
5. `end`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: <code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td><code>avb</code></td>
<td>Enables AVB on the switch.</td>
</tr>
<tr>
<td>Example: <code>Device(config)# avb</code></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring AVB on the devices

You can configure the interfaces along the connectivity path for AVB devices as dot1q trunk ports by using the below commands.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport mode trunk`
5. `exit`
6. `vlan 2`
7. `avb vlan vlan-id`
8. `avb`
9. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

<p>| <strong>Step 2</strong> configure terminal | Enters global configuration mode. |
| Example:                      |                                  |
| <code>Device# configure terminal</code>  |                                  |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td>Defines the interface to be configured as a trunk, and enters interface configuration mode.</td>
</tr>
<tr>
<td><code>interface interface-id</code> <strong>Example:</strong> Device(config)# interface te1/1/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Configures the port as a trunk port.</td>
</tr>
<tr>
<td><code>switchport mode trunk</code> <strong>Example:</strong> Device(config-if)# switchport mode trunk</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td><code>exit</code> <strong>Example:</strong> Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Configures VLAN 2 on the switch.</td>
</tr>
<tr>
<td><code>vlan 2</code> <strong>Example:</strong> Device(config)# vlan 2</td>
<td><strong>Note</strong> VLAN 2 is the default AVB VLAN. If you need to configure another VLAN as the default AVB VLAN, use the command in Step 7.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>(Optional) Sets the specified VLAN as the default AVB VLAN on the switch. Use this command when you need to set the default AVB VLAN other than VLAN 2. The range for <code>vlan-id</code> varies from 2 to 4094.</td>
</tr>
<tr>
<td><code>avb vlan vlan-id</code> <strong>Example:</strong> Device(config)# avb vlan 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Configures AVB on the specified interface.</td>
</tr>
<tr>
<td><code>avb</code> <strong>Example:</strong> Device(config-vlan)# avb</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code> <strong>Example:</strong> Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**
To disable AVB on the switch, use the "no" form of the command.
## Configuring gPTP

This section describes the various configurations available for gPTP.

### Enabling gPTP on a port

When AVB is enabled on the switch, gPTP for AVB also gets enabled.

- **Note**
  
  When gPTP is enabled, Flowcontrol is disabled on all ports.

  You can also enable gPTP globally using the command given below:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ptp profile dot1as`
4. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td>ptp profile dot1as</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# ptp profile dot1as</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>
Enabling gPTP on an interface

You can also enable gPTP on an interface using the command given below:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ptp enable
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Defines the interface to be configured as a trunk, and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# interface te1/1/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ptp enable</td>
<td>Enables gPTP on the specified interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ptp enable</td>
<td></td>
</tr>
<tr>
<td>To disable gPTP on the interface, use the no form of this command as shown below:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# no ptp enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

Configuring the values of PTP clocks

You can configure the values of ptp clock priority1 and priority2 using the commands below:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ptp priority1
4. ptp priority2
5. exit
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Enable privileged EXEC mode.</strong></td>
</tr>
<tr>
<td><strong>Device&gt; enable</strong></td>
<td><strong>• Enter your password if prompted.</strong></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Enters global configuration mode.</strong></td>
</tr>
<tr>
<td><strong>Device# configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>ptp priority1</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Configure the values of ptp clock priority1.</strong></td>
</tr>
<tr>
<td><strong>Device(config)# ptp priority1</strong></td>
<td><strong>0-255 - This is the range for the value of the ptp clock priority. Select a value withing this range.</strong></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td><strong>If the value of priority1 is configured to 255, the clock cannot become as Grandmaster.</strong></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>ptp priority2</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Configure the values of ptp clock priority2.</strong></td>
</tr>
<tr>
<td><strong>Device(config)# ptp priority2</strong></td>
<td><strong>0-255 - This is the range for the value of the ptp clock priority. Select a value withing this range.</strong></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>exit</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Returns to global configuration mode.</strong></td>

<tr>
<td><strong>Device(config)# exit</strong></td>
<td></td>
</tr>
</tbody>
</table>

### Configuring HQoS

This section describes the various configurations available for HQoS.

#### Enabling HQoS

When AVB is enabled on the switch, HQoS for AVB also gets enabled.

#### Migrating from Flat Policy Formats to Hierarchical Policy Formats - Guidelines and Restrictions

Follow the below guidelines when migrating from flat policy formats to hierarchical policy formats for AVB:

- If you upgrade from Cisco IOS XE Denali 16.3.1 to Cisco IOS XE Denali 16.3.2, QoS policies that are in startup configuration of the device will fail with errors. Follow the steps below to properly install HQoS policies on your device:
1. Use the `no avb` command to disable AVB globally.

**Note** When you disable AVB, all the policy-maps and class-maps are automatically removed from the configuration. But, the access-lists are not removed automatically. You must remove the access-lists manually. Ensure that all the QoS policy constructs are removed before upgrading to Cisco IOS XE Denali 16.3.2.

2. Enable AVB using the `avb` command. When AVB is enabled, HQoS for AVB also gets enabled.

- We do not recommend migrating from a hierarchical policy format supported release to a flat policy format supported release.
- You can only modify child policies. Parent policies are completely governed by MSRP.
- `show running config` command displays only the child policies.
- Starting from Cisco IOS XE Denali 16.3.2, `show running config interface` command will not display any details of the policy attached. You should use `show policy-map interface` command for displaying all the details of the policy attached.

### Hierarchical QoS Policy Formats

This following example shows hierarchical remarking policy at the ingress interface:

```plaintext
policy-map AVB-Input-Child-Policy
  class VOIP-DATA-CLASS
    set dscp EF
  class MULTIMEDIA-CONF-CLASS

  service-policy AVB-Output-Child-Policy

Configuring MVRP

This section describes the various configurations available for MVRP.

Enabling MVRP

You can enable MVRP on the switches in the topology to enable Vlan propagation using the below command.

Note
You must change VTP mode to **transparent** or **off**, before enabling dynamic vlan creation via MVRP.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `mvrp global`
4. `vtp mode {transparent | off}`
5. `mvrp vlan create`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | `enable`          | Enables privileged EXEC mode.  
Example: `Device> enable`
- Enter your password if prompted. |
| 2    | `configure terminal` | Enters global configuration mode.  
Example: `Device# configure terminal` |
| 3    | `mvrp global`     | Enters the MVRP Global configuration mode.  
Example: `Device(config)# mvrp global` |
| 4    | `vtp mode {transparent | off}` | Sets the VTP to `transparent` or `off` mode.  
Example: `Device(config)# vtp mode transparent`
Example: `Device(config)# vtp mode off` |
| 5    | `mvrp vlan create` | Enables MVRP on the switches.  
Example: `Device(config)# mvrp vlan create` |

### Configuring MVRP on the switch interface

You can configure MVRP on the switch interfaces using the below commands
SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. mvrp registration {fixed | forbidden | normal}
5. mvrp timer {join | leave | leave-all | periodic}
6. exit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Defines the interface to be configured as a trunk, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface tel/1/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> mvrp registration {fixed</td>
<td>forbidden</td>
</tr>
<tr>
<td>Example:</td>
<td>• fixed - Fixed registration</td>
</tr>
<tr>
<td>Device(config-if)# mvrp registration fixed</td>
<td>• forbidden - Forbidden registration</td>
</tr>
<tr>
<td></td>
<td>• normal - Normal registration</td>
</tr>
<tr>
<td><strong>Step 5</strong> mvrp timer {join</td>
<td>leave</td>
</tr>
<tr>
<td>Example:</td>
<td>• join - Timer controls the interval between transmit opportunities that are applied to the ASM</td>
</tr>
<tr>
<td>Device(config-if)# mvrp timer join</td>
<td>• leave - The timer controls the RSM waits in the LV state before transiting to the MT state</td>
</tr>
<tr>
<td></td>
<td>• leave-all - The timer control the frequency with which the LeaveAll SM generates LeaveAll PDUs</td>
</tr>
<tr>
<td></td>
<td>• periodic - Periodic timer</td>
</tr>

</table>
Monitoring the AVB Network

Monitoring AVB

To display the AVB details, use the commands in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show avb domain</td>
<td>Displays the AVB domain.</td>
</tr>
<tr>
<td>show avb streams</td>
<td>Displays the AVB stream information.</td>
</tr>
</tbody>
</table>

Monitoring gPTP

To display the gPTP protocol details, use the commands in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ptp brief</td>
<td>Displays a brief status of ptp on the interfaces.</td>
</tr>
<tr>
<td>show ptp clock</td>
<td>Displays ptp clock information.</td>
</tr>
<tr>
<td>show ptp parent</td>
<td>Displays the parent clock information.</td>
</tr>
<tr>
<td>show ptp port</td>
<td>Displays the ptp port information.</td>
</tr>
<tr>
<td>show platform software fed switch active ptp if-id {interface-id}</td>
<td>Displays details info about ptp status on the port.</td>
</tr>
</tbody>
</table>

Monitoring MSRP

To display the MSRP details, use the commands in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show msrp streams</td>
<td>Displays MSRP stream information.</td>
</tr>
<tr>
<td>show msrp streams detailed</td>
<td>Displays detailed MSRP stream information.</td>
</tr>
<tr>
<td>show msrp streams brief</td>
<td>Displays MSRP stream information in brief.</td>
</tr>
</tbody>
</table>
## Monitoring HQoS

To display the HQoS details, use the commands in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show run</code></td>
<td>Displays all the child policy map details.</td>
</tr>
<tr>
<td><code>show policy-map</code></td>
<td>Displays the details of the policy map configuration.</td>
</tr>
<tr>
<td><code>show platform hardware fed switch active qos queue stats interface interface-id</code></td>
<td>Displays the QoS statistics for different queue mappings in AVB.</td>
</tr>
<tr>
<td><code>show platform hardware fed switch active qos queue config interface interface-id</code></td>
<td>Displays the QoS queue configurations.</td>
</tr>
<tr>
<td>`show policy-map interface interface-id [input</td>
<td>output]`</td>
</tr>
</tbody>
</table>

## Monitoring MVRP

To display the MVRP details, use the commands in the following table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show mvrp summary</code></td>
<td>Displays MVRP summary information.</td>
</tr>
<tr>
<td><code>show mvrp interface</code></td>
<td>Displays interface MVRP information.</td>
</tr>
</tbody>
</table>

## Examples of AVB Configurations and Monitoring

### Examples for AVB

This example shows how you can view the AVB domain.

```
Device#show avb domain

### Feature Information for AVB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

#### Table 4: Feature Information for AVB

Campus Fabric

- Campus Fabric, on page 57
Campus Fabric

Information About Campus Fabric

Campus Fabric provides the basic infrastructure for building virtual networks based on policy-based segmentation constructs. This module describes how to configure Campus Fabric on your device.

Campus Fabric Overview

Campus Fabric Overlay provisioning consists of three main components:

- Control-Plane
- Data-Plane
- Policy-Plane

Understanding Fabric Domain Elements

Figure 3: Elements of a Fabric Domain displays the elements that make up the fabric domain.
The following is a description of the fabric domain elements illustrated in the Figure 3: Elements of a Fabric Domain.

- Fabric Edge Devices—Provide connectivity to users and devices that connect to the fabric domain. Fabric edge devices identify and authenticate end points, and register end-point ID information in the fabric host-tracking database. These devices encapsulate at ingress and decapsulate at egress, to forward traffic to and from the end points connected to the fabric domain.

- Fabric Control-Plane Devices—Provide overlay reachability information and end points-to-routing locator mapping, in the host-tracking database. A control-plane device receives registrations from fabric edge devices having local end points, and resolves requests from edge devices to locate remote end points. You can configure up to three control-plane devices—internally (a fabric border device) and externally (a designated control-plane device, such as Cisco CSR1000v), to allow redundancy in your network.

- Fabric Border Devices — Connect traditional Layer 3 networks or different fabric domains to the local domain, and translate reachability and policy information, such as virtual routing and forwarding (VRF) and SGT information, from one domain to another.

- Virtual Contexts—Provide virtualization at the device level, using VRF to create multiple instances of Layer 3 routing tables. Contexts or VRFs provide segmentation across IP addresses, allowing for overlapped address space and traffic separation. You can configure up to 32 contexts in the fabric domain.

- Host-Pools—Group end points that are present in the fabric domain into IP pools, and identify them with a VLAN ID and an IP subnet.

**Campus Fabric Configuration Guidelines**

Consider the following guidelines and limitations when configuring campus fabric elements:

- Configure no more than 3 control-plane devices in each fabric domain.

- Each fabric edge device supports up to 2000 hosts.

- Each control-plane device supports up to 5000 fabric edge device registrations.
• Configure no more than 32 virtual contexts in each fabric domain.

## How to Configure Fabric Overlay

### Configuring Fabric Edge Devices

Follow these steps to configure fabric edge devices:

**Before you begin**

Configure a loopback0 IP address for each edge device to ensure that the device is reachable. Ensure that you run the `ip lisp source-locator loopback0` command on the uplink interface.

### SUMMARY STEPS

1. enable
2. configure terminal
3. fabric auto
4. domain {default | name fabric domain name}
5. control-plane ipv4 address auth_key key
6. border ipv4 address
7. context name name id ID
8. host-pool name name
9. host-vlan ID
10. context name name
11. gateway IP address/mask
12. use-dhcp IP address
13. exit
14. show fabric domain

### DETAILED STEPS

<table>

### Auto-Configured Commands on Fabric Edge Devices

As a part of Fabric Overlay provisioning, some LISP-based configuration, SGT (security group tag) configuration and EID to RLOC mapping configuration is auto-generated, and is displayed in your running configuration.

For example, consider this configuration scenario for an edge device (loopback address 2.1.1.1/32):

```plaintext
device(config)#fabric auto
device(config-fabric-auto)#domain default
device(config-fabric-auto-domain)#control-plane 192.168.1.4 auth-key example-key1
device(config-fabric-auto-domain)#control-plane 192.168.1.5 auth-key example-key2
device(config-fabric-auto-domain)#border 192.168.1.6
device(config-fabric-auto-domain)#context name example-context ID 10
device(config-fabric-auto-domain)#host-pool name VOICE_DOMAIN
device(config-fabric-auto-domain-host-pool)#vlan 10
device(config-fabric-auto-domain-host-pool)#context example-context
device(config-fabric-auto-domain-host-pool)#gateway 192.168.1.254/24
device(config-fabric-auto-domain-host-pool)#use-dhcp 209.165.201.6
```

This is sample output for your fabric edge configuration:

```plaintext
device#show running-config
router lisp
encapsulation vxlan
locator-set default.RLOC
IPv4-interface Loopback0 priority 10 weight 10
exit
!
edid-table default instance-id 0
exit
!
edid-table vrf example-context instance-id 10
dynamic-edid example-context.EID.VOICE_DOMAIN
database-mapping 192.168.1.0/24 locator-set default.RLOC
exit
```
Configuring Fabric Control-Plane Devices

Follow these steps to configure your control-plane device.

Before you begin

Configure a loopback0 IP address for each edge device to ensure that the device is reachable. Ensure that you run the `ip lisp source-locator loopback0` command on the uplink interface.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. fabric auto
4. domain { default | name fabric domain name }
5. control-plane self auth_key key
6. host-prefix prefix context name name id ID
7. exit
8. show fabric domain

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 3</th>
<th>fabric auto</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)#fabric auto</td>
</tr>
</tbody>
</table>

Enables automatic fabric provisioning and enters automatic fabric configuration mode.

| Step 4 | domain { default | name fabric domain name } |
|--------|----------------------------------|
| **Example:** | Device(config-fabric-auto)#domain default |

Configures the default fabric domain and enters domain configuration mode. The `name` keyword allows you to add a new fabric domain.

<table>
<thead>
<tr>
<th>Step 5</th>
<th>control-plane self auth_key key</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-fabric-auto-domain)#control-plane self auth_key example-key1</td>
</tr>
</tbody>
</table>

Enables the control-plane service with the authentication key, for the configured host-prefix.

<table>
<thead>
<tr>
<th>Step 6</th>
<th>host-prefix prefix context name name id ID</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-fabric-auto-domain)#host-prefix 192.168.1.0/24 context name example-context id 10</td>
</tr>
</tbody>
</table>

Creates a new context or a VRF and assigns an ID to it. If you don't specify a context, the default context is used.

<table>
<thead>
<tr>
<th>Step 7</th>
<th>exit</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-fabric-auto-domain)# exit</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 8</th>
<th>show fabric domain</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device# show fabric domain</td>
</tr>
</tbody>
</table>

Displays your control-plane device configuration. As part of this configuration, additional CLI commands are automatically generated.

### Configuring Fabric Border Devices

Follow these steps to configure your device as a fabric border device.

**Before you begin**

Configure a loopback0 IP address for each edge device to ensure that the device is reachable. Ensure that you run the `ip lisp source-locator loopback0` command on the uplink interface.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. fabric auto
4. domain { default | name fabric domain name }
5. control-plane ipv4 address auth_key key
6. border self
### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
Example:  
Device> enable |
| **Step 2** | `configure terminal` | Enters global configuration mode.  
Example:  
Device# configure terminal |
| **Step 3** | `fabric auto` | Enables automatic fabric provisioning and enters automatic fabric configuration mode.  
Example:  
Device(config)# fabric auto |
| **Step 4** | `domain { default | name fabric domain name}` | Configures the default fabric domain and enters domain configuration mode. The `name` keyword allows you to add a new fabric domain.  
Example:  
Device(config-fabric-auto)# domain default  
Device(config-fabric-auto)# domain name example-domain |
| **Step 5** | `control-plane ipv4 address auth_key key` | Configures the IP address and the authentication key of the control-plane device, to allow the fabric border device to communicate with the control-plane device.  
Example:  
Device(config-fabric-auto-domain)# control-plane 198.51.100.2  
auth_key example-key1 |
| **Step 6** | `border self` | Enables the device as a fabric border device.  
Example:  
Device(config-fabric-auto-domain)# border self |
| **Step 7** | `context name name id/D` | Creates a new context or VRF and assigns a new ID to it. If you don't configure a context, the default context is used.  
Example:  
Device(config-fabric-auto-domain)# context name example-nh id 10 |
| **Step 8** | `host-prefix prefix context name name` | Creates a host-prefix or a subnet mask with the context.  
Example: |
### Security Group Tags and Policy Enforcement in Campus Fabric

Campus Fabric overlay propagates source group tags (SGTs) across devices in the fabric domain. Packets are encapsulated using virtual extensible LAN (VXLAN) and carry the SGT information in the header. When you configure an edge device, the `ipv4 sgt` command is auto-generated. The SGT mapped to the IP address of the edge device is carried within the encapsulated packet and propagated to the destination device, where the packet is decapsulated and the Source Group Access Control List (SGACL) policy is enforced.

For more information on Cisco TrustSec and Source Group Tags, see the [Cisco TrustSec Switch Configuration Guide](#).

### Multicast Using Campus Fabric Overlay

You can use Campus Fabric overlay to carry multicast traffic over core networks that do not have native multicast capabilities. Campus Fabric overlay allows unicast transport of multicast traffic with head-end replication in the edge device.

**Note**

Only Protocol Independent Multicast (PIM) Sparse Mode and PIM Source Specific Multicast (SSM) are supported in Campus Fabric; dense mode is not supported.

### Configuring Multicast PIM Sparse Mode in Campus Fabric

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast-routing`
4. `ip pim rp-address rp address`
5. `interface LISP interface number`
6. `ip pim sparse-mode`
7. `exit`
8. `interface interface type interface number`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip multicast-routing</td>
<td>Enables IP multicast routing.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device(config-if)#ip pim sparse-mode</td>
<td>Configuring Multicast PIM SSM in Campus Fabric</td>
</tr>
</tbody>
</table>

### Step 10
Ends the current configuration session and returns to privileged EXEC mode.

### Step 11
Verifies the multicast routes on the device.

### Step 12
Verifies basic multicast connectivity by pinging the multicast address.

### Step 13
Displays the forwarding entries and interfaces in the IPv4 Multicast Forwarding Information Base (MFIB)

## Configuring Multicast PIM SSM in Campus Fabric

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast-routing`
4. `ip pim ssm {default | range} {access-list-number | access-list-name}`
5. `interface LISP interface number`
6. `ip pim sparse-mode`
7. `exit`
8. `interface interface type interface number`
9. `ip pim sparse-mode`
10. `ip igmp version 3`
11. `end`
12. `show ip mroutemulticast ip-address`
13. `ping multicast ip-address`
14. `show ip mfib`

Data Plane Security in Campus Fabric

Campus Fabric Data Plane Security ensures that only traffic from within a fabric domain can be decapsulated, by an edge device at the destination. Edge and border devices in the fabric domain validate that the source Routing Locator (RLOC), or the uplink interface address, carried by the data packet is a member of the fabric domain.

Data Plane Security ensures that the edge device source addresses in the encapsulated data packets cannot be spoofed. Packets from outside the fabric domain carry invalid source RLOCs that are blocked during decapsulation by edge and border devices.

Configuring Data Plane Security on Edge Devices

Before you begin

- Configure a loopback0 IP address for each edge device to ensure that the device is reachable.

  Ensure that you apply the `ip lisp source-locator loopback0` command to the uplink interface.

- Ensure that your underlay configuration is set up.

- Ensure that you have configured edge, control-plane, and border devices.

SUMMARY STEPS

1. `configure terminal`
2. `router lisp`
3. `decapsulation filter rloc source member`
4. `exit`
5. `show lisp [session [established] | vrf [vrf-name [session [peer-address]]]][`]
6. `show lisp decapsulation filter [IPv4-rloc-address | IPv6-rloc-address] [eid-table eid-table-vrf | instance-id iid]`

DETAILED STEPS

<table>

### Configuring Data Plane Security on Control Plane Devices

#### Before you begin
- Configure a loopback0 IP address for each control plane device to ensure that the device is reachable. Ensure that you apply the `ip lisp source-locator loopback0` command to the uplink interface.
- Ensure that your underlay configuration is set up.
- Ensure that you have configured edge, control-plane, and border devices.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

### Configuring Data Plane Security on Border Devices

#### Before you begin
- Configure a loopback0 IP address for each border device to ensure that the device is reachable. Ensure that you apply the `ip lisp source-locator loopback0` command to the uplink interface.
- Ensure that your underlay configuration is set up.
- Ensure that you have configured edge, control-plane, and border devices.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. router lisp
4. decapsulation filter rloc source member
5. exit
6. `show lisp [session [established] | vrf [vrf-name [session [peer-address]]]]`
7. `show lisp decapsulation filter [IPv4-rloc-address | IPv6-rloc-address] [eid-table eid-table-vrf | instance-id iid]`

PART III

CleanAir

- Cisco CleanAir, on page 77
- Bluetooth Low Energy, on page 99
Cisco CleanAir

Prerequisites for CleanAir

You can configure Cisco CleanAir only on CleanAir-enabled access points. Only Cisco CleanAir-enabled access points using the following access point modes can perform Cisco CleanAir spectrum monitoring:

- Local—In this mode, each Cisco CleanAir-enabled access point radio provides air quality and interference detection reports for the current operating channel only.

- Monitor—When Cisco CleanAir is enabled in monitor mode, the access point provides air quality and interference detection reports for all monitored channels.

The following options are available:

- All—All channels
- DCA—Channel selection governed by the DCA list
- Country—All channels are legal within a regulatory domain

Note

The access point does not participate in AQ HeatMap in Prime Infrastructure.

- SE-Connect—This mode enables a user to connect a Spectrum Expert application running on an external Microsoft Windows XP or Vista PC to a Cisco CleanAir-enabled access point in order to display and
analyze detailed spectrum data. The Spectrum Expert application connects directly to the access point, bypassing the device. An access point in SE-Connect mode does not provide any Wi-Fi, RF, or spectrum data to the device. All CleanAir system functionality is suspended while the AP is in this mode, and no clients are served. This mode is intended for remote troubleshooting only. Up to three active Spectrum Expert connections are possible.

Restrictions for CleanAir

• Access points in monitor mode do not transmit Wi-Fi traffic or 802.11 packets. They are excluded from radio resource management (RRM) planning and are not included in the neighbor access point list. IDR clustering depends on the device’s ability to detect neighboring in-network access points. Correlating interference device detections from multiple access points is limited between monitor-mode access points.

• Monitor Mode access point in slot 2 operates at 2.4 GHz only.

• We recommend a ratio of 1 monitor-mode access point for every 5 local-mode access points; this can vary based on the network design and expert guidance for best coverage.

• Spectrum Expert (Windows XP laptop client) and AP should be pingable, otherwise; it will not work.

• CleanAir is not supported wherein the channel width is 160 MHz.

Information About Cisco CleanAir

Cisco CleanAir is a solution designed to proactively manage the challenges of a shared wireless spectrum. It allows you to see all the users of a shared spectrum (both native devices and foreign interferers). It also enables the network to act upon this information. For example, you can manually remove the interfering device, or the system can automatically change the channel away from the interference. CleanAir provides spectrum management and Radio Frequency (RF) visibility.

A Cisco CleanAir system consists of CleanAir-enabled access points, Cisco Wireless LAN Controllers, and Cisco Prime Infrastructure. These access points collect information about all the devices that operate in the industrial, scientific, and medical (ISM) bands, identify and evaluate the information as a potential interference source, and forward it to the controller. The controller controls the access points, collects spectrum data, and forwards information to Cisco Prime Infrastructure or a Cisco mobility services engine (MSE) upon request.

Any networking configurations can be performed only on the mobility controller, configurations cannot be performed in the MA mode. However, any radio level CleanAir configurations can be done using mobility anchor.

For every device operating in the unlicensed band, Cisco CleanAir provides information about what it is, where it is, how it is impacting your wireless network, and what actions you or your network should take. It simplifies RF.

Wireless LAN systems operate in unlicensed 2.4-GHz and 5-GHz ISM bands. Many devices, such as microwave ovens, cordless phones, and Bluetooth devices also operate in these bands and can negatively affect the Wi-Fi operations.

Some of the most advanced WLAN services, such as voice-over-wireless and IEEE 802.11n radio communications, might be significantly impaired by the interference caused by other legal users of the ISM bands. The integration of Cisco CleanAir functionality addresses this problem of RF interference.
Cisco CleanAir Components

The basic Cisco CleanAir architecture consists of Cisco CleanAir-enabled APs and device. Cisco Prime Infrastructure (PI), Mobility Services Engine (MSE) and Cisco Spectrum Expert are optional system components. Cisco PI and MSE provide user interfaces for advanced spectrum capabilities such as historic charts, tracking interference devices, location services and impact analysis.

**Figure 4: Cisco CleanAir Solution**

An access point equipped with Cisco CleanAir technology collects information about non-Wi-Fi interference sources, processes it, and forwards it to the MA. The access point sends the Air Quality Report (AQR) and Interference Device Report (IDR) to the controller.

The mobility controller (MC) controls and configures CleanAir-capable access points, and collects and processes spectrum data, and provides it to the PI and/or the MSE. The MC provides local user interfaces (GUI and CLI) to configure basic CleanAir features and services and display current spectrum information. The MC also detects, merges, and mitigates interference devices using RRM TPC and DCM. For details, see Interference Device Merging.

Cisco PI provides advanced user interfaces for CleanAir that include feature enabling and configuration, consolidated display information, historic AQ records and reporting engines. PI also shows charts of interference devices, AQ trends, and alerts.

Cisco MSE is required for location and historic tracking of interference devices, and provides coordination and consolidation of interference reports across multiple controllers. MSE also provides adaptive Wireless Intrusion Prevention System (WIPS) service that provides comprehensive over-the-air threat detection, location and mitigation. MSE also merges all the interference data.

To obtain detailed spectrum data that can be used to generate RF analysis plots similar to those provided by a spectrum analyzer, you can configure a Cisco CleanAir-enabled access point to connect directly to a Microsoft Windows XP or Vista PC running the Cisco Spectrum Expert application.
The device performs the following tasks in a Cisco CleanAir system:

- Configures Cisco CleanAir capabilities on the access point.
- Provides interfaces (CLI, and SNMP) for configuring Cisco CleanAir features and retrieving data.
- Displays spectrum data.
- Collects and processes AQRs from the access point and stores them in the air quality database. AQRs contain information about the total interference from all the identified sources represented by the Air Quality Index (AQI) and the summary for the most severe interference categories. The CleanAir system can also include unclassified interference information under per-interference type reports that enable you to take action in scenarios where interference because of unclassified interfering devices is more.
- Collects and processes IDR from the access point and stores them in the interference device database.
- Forwards spectrum data to Prime Infrastructure and the MSE.

**Note**

In Cisco Catalyst 9800 Series Wireless Controller, when Cisco CleanAir is disabled, both CleanAir and Air Quality reporting are disabled. In spite of this, Air Quality is still populated.

---

### Cisco CleanAir-Related Terms

#### Table 5: CleanAir-Related Terms

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AQI</td>
<td>Air Quality Index. The AQI is an indicator of air quality, based on the air pollutants. An AQI of 0 is bad and an AQI &gt; 85 is good.</td>
</tr>
<tr>
<td>AQR</td>
<td>Air Quality Report. AQRs contain information about total interference from all the identified sources represented by AQI and the summary of the most severe interference categories. AQRs are sent every 15 minutes to the Mobility Controller and every 30 seconds in the Rapid mode.</td>
</tr>
<tr>
<td>DC</td>
<td>Duty Cycle. Percentage of time that the channel is utilized by a device.</td>
</tr>
<tr>
<td>EDRRM</td>
<td>Event-Driven RRM. EDRRM allows an access point in distress to bypass normal RRM intervals and immediately change channels.</td>
</tr>
<tr>
<td>IDR</td>
<td>Interference Device Reports that an access point sends to the controller.</td>
</tr>
<tr>
<td>ISI</td>
<td>Interference Severity Index. The ISI is an indicator of the severity of the interference.</td>
</tr>
<tr>
<td>MA</td>
<td>Mobility Agent. An MA is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. An MA is the wireless component that maintains client mobility state machine for a mobile client that is connected to an access point to the device that the MA is running on.</td>
</tr>
<tr>
<td>MC</td>
<td>Mobility Controller. An MC provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members.</td>
</tr>
</tbody>
</table>
Received Signal Strength Indicator (RSSI) is a measurement of the power present in a received radio signal. It is the power at which an access point sees the interferer device.

### Interference Types that Cisco CleanAir can Detect

Cisco CleanAir can detect interference, report on the location and severity of the interference, and recommend different mitigation strategies. Two such mitigation strategies are persistent device avoidance and spectrum event-driven RRM.

Wi-Fi chip-based RF management systems share these characteristics:

- Any RF energy that cannot be identified as a Wi-Fi signal is reported as noise.
- Noise measurements that are used to assign a channel plan tend to be averaged over a period of time to avoid instability or rapid changes that can be disruptive to certain client devices.
- Averaging measurements reduces the resolution of the measurement. As such, a signal that disrupts clients might not look like it needs to be mitigated after averaging.
- All RF management systems available today are reactive in nature.

Cisco CleanAir is different and can positively identify not only the source of the noise but also its location and potential impact to a WLAN. Having this information allows you to consider the noise within the context of the network and make intelligent and, where possible, proactive decisions. For CleanAir, two types of interference events are common:

- Persistent interference
- Spontaneous interference

Persistent interference events are created by devices that are stationary in nature and have intermittent but largely repeatable patterns of interference. For example, consider the case of a microwave oven located in a break room. Such a device might be active for only 1 or 2 minutes at a time. When operating, however, it can be disruptive to the performance of the wireless network and associated clients. Using Cisco CleanAir, you can positively identify the device as a microwave oven rather than indiscriminate noise. You can also determine exactly which part of the band is affected by the device, and because you can locate it, you can understand which access points are most severely affected. You can then use this information to direct RRM in selecting a channel plan that avoids this source of interference for the access points within its range. Because this interference is not active for a large portion of the day, existing RF management applications might attempt to again change the channels of the affected access points. Persistent device avoidance is unique, however, in that it remains in effect as long as the source of interference is periodically detected to refresh the persistent status. The Cisco CleanAir system knows that the microwave oven exists and includes it in all future planning. If you move either the microwave oven or the surrounding access points, the algorithm updates RRM automatically.

---

**Note**

Spectrum event-driven RRM can be triggered only by Cisco CleanAir-enabled access points in local mode.
All the APs using Qualcomm Atheros chipset sends air-quality as 100 percent even if the radios detect interference.

Note

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a threshold for air quality (AQ) which, if exceeded, triggers an immediate channel change for the affected access point. Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an access point detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active. Cisco CleanAir also identifies and locates the source of interference so that more permanent mitigation of the device can be performed at a later time.

In the case of Bluetooth devices, Cisco CleanAir-enabled access points can detect and report interference only if the devices are actively transmitting. Bluetooth devices have extensive power-save modes. For example, interference can be detected when data or voice is being streamed between the connected devices.

Interference Device Merging

The Interference Devices (ID) messages are processed on a Mobility Controller (MC). The Mobility Anchor (MA) forwards the ID messages from APs and hence they are processed on the MC. The MC has visibility of the neighbor information across APs connected to different MAs.

ID merging logic requires AP neighbor information. Neighbor information is obtained from the RRM module. This API only gives neighbor information to the APs directly connected to MC.

Currently the AP neighbor list on MA is synced to MC once every 3 minutes; hence the AP neighbor list obtained by this API could be at most 3 mins old. This delay results in delay in merging of Devices as they are discovered. The subsequent periodic merge will pick up the updated neighbor information and merge is performed.

Persistent Devices

Some interference devices such as outdoor bridges and Microwave Ovens only transmit when needed. These devices can cause significant interference to the local WLAN due to short duration and periodic operation remain largely undetected by normal RF management metrics. With CleanAir the RRM DCA algorithm can detect, measure, register and remember the impact and adjust the DCA algorithm. This minimizes the use of channels affected by the persistent devices in the channel plan local to the interference source. Cisco CleanAir detects and stores the persistent device information in the device and this information is used to mitigate interfering channels.

Persistent Devices Detection

CleanAir-capable Monitor Mode access point collects information about persistent devices on all configured channels and store the information in controller. Local/Bridge mode AP detects interference devices on the serving channels only.
Persistent Device Avoidance

When a Persistent Device (PD) is detected in the CleanAir module, it is reported to the RRM module on the MA. This information is used in the channel selection by the subsequent EDRRM Event Driven RRM (ED-RRM) signal sent to the RRM module.

EDRRM and AQR Update Mode

EDRRM is a feature that allows an access point that is in distress to bypass normal RRM intervals and immediately change channels. A CleanAir access point always monitors AQ and reports the AQ every 15 minutes. AQ only reports classified interference devices. The key benefit of EDRRM is very fast action time. If an interfering device is operating on an active channel and causes enough AQ degradation to trigger an EDRRM, then no clients will be able to use that channel or the access point. You must remove the access point from the channel. EDRRM is not enabled by default, you must first enable CleanAir and then enable EDRRM.

AQRs are only available on the MC. The mode configuration and timers are held in Radio Control Block (RCB) on MA (for APs connected to MA). There is no change to the current API available for EMS/NMS. No change is required for directly connected APs as RCB (spectrum config and timers) is available locally. For remote APs (APs connected to MA), three new control messages are added. These three messages are for enable, restart timer and disable rapid update mode for a given AP MAC address and slot.

CleanAir High Availability

CleanAir configuration (network and radio) is stateful during the switchover. On the MC, Embedded Instrumentation Core (EICORE) provides the sync on network configurations across active and standby nodes. The radio configurations are synced using the HA Infrastructure. The CleanAir configurations on MA are pulled from the MC upon joining. The network configuration is not stored in the EICORE on MA, hence it is synced using HA Infrastructure.

CleanAir Data (AQ and IDR) reports are not stateful, that is, the standby and active nodes are not synced. On switchover, the APs send the reports to the current active slot. The RRM Client (HA Infra Client) is used for CleanAir HA sync.

How to Configure CleanAir

Enabling CleanAir for the 2.4-GHz Band (CLI)

SUMMARY STEPS

1. configure terminal
2. ap dot11 24ghz cleanair
3. end
DETAILED STEPS

Configuring Cisco CleanAir using the Controller GUI

Configuring Cisco Spectrum Expert

Configuring Spectrum Expert (CLI)

Before you begin

• Spectrum Expert (Windows XP laptop client) and access point should be pingable, otherwise; it will not work.

• Prior to establishing a connection between the Spectrum Expert console and the access point, make sure that IP address routing is properly configured and the network spectrum interface (NSI) ports are open in any intervening firewalls.

• The access point must be a TCP server listening on ports 37540 for 2.4-GHz and 37550 for 5-GHz frequencies. These ports must be opened for the spectrum expert application to connect to the access point using the NSI protocol.

• You can view the NSI key from the device CLI by using the show ap name ap_name config dot11 (24ghz | 5ghz) command.
### Step 1
To configure the access point for SE-Connect mode, enter this command:

```
ap name ap_name mode se-connect
```

**Example:**

```
Device#ap name Cisco_AP3500 mode se-connect
```

### Step 2
When prompted to reboot the access point, enter **Y**.

### Step 3
To view the NSI key for the access point, enter this command:

```
show ap name ap_name config dot11 (24ghz | 5ghz)
```

**Example:**

```
Device#show ap name Cisco_AP3500 config dot11 24ghz
```

---

**What to do next**

On the Windows PC, download Cisco Spectrum Expert:

- Access the Cisco Software Center from this URL: [http://www.cisco.com/cisco/software/navigator.html](http://www.cisco.com/cisco/software/navigator.html)

- Click **Product > Wireless > Cisco Spectrum Intelligence > Cisco Spectrum Expert > Cisco Spectrum Expert Wi-Fi**, and then download the Spectrum Expert 4.1.11 executable (*.exe) file.

- Run the Spectrum Expert application on the PC.

- When the Connect to Sensor dialog box appears, enter the IP address of the access point, choose the access point radio, and enter the 16-byte network spectrum interface (NSI) key to authenticate. The Spectrum Expert application opens a TCP/IP connection directly to the access point using the NSI protocol.

When an access point in SE-Connect mode joins a device, it sends a Spectrum Capabilities notification message, and the device responds with a Spectrum Configuration Request. The request contains the 16-byte random NSI key generated by the device for use in NSI authentication. The device generates one key per access point, which the access point stores until it is rebooted.

---

**Note**

You can establish up to three Spectrum Expert console connections per access point radio.

- Verify that the Spectrum Expert console is connected to the access point by selecting the Slave Remote Sensor text box in the bottom right corner of the Spectrum Expert application. If the two devices are connected, the IP address of the access point appears in this text box.
Verifying CleanAir Parameters

You can verify CleanAir parameters using the following commands:

Table 6: Commands for verifying CleanAir

<table>
<thead>
<tr>
<th>Command Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ap dot11 24ghz cleanair air-quality summary</td>
<td>Displays CleanAir AQ data for the 2.4-GHz band.</td>

</tr>
<tr>
<td>show ap dot11 24ghz clean device tdd-tx</td>
<td>Displays CleanAir interferers of type TDD Transmit for the 2.4-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 24ghz clean device video</td>
<td>Displays CleanAir interferers of type Video Camera for the 2.4-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 24ghz clean device wimax-fixed</td>
<td>Displays CleanAir interferers of type WiMax Fixed for the 2.4-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 24ghz clean device wimax-mobile</td>
<td>Displays CleanAir interferers of type WiMax Mobile for the 2.4-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 24ghz clean device xbox</td>
<td>Displays CleanAir interferers of type Xbox for the 2.4-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 24ghz clean device zigbee</td>
<td>Displays CleanAir interferers of type Zigbee for the 2.4-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean air-quality summary</td>
<td>Displays CleanAir AQ data for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean air-quality worst</td>
<td>Displays CleanAir AQ worst data for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz cleanair config</td>
<td>Displays CleanAir configuration for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device all</td>
<td>Displays all the CleanAir interferers for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device canopy</td>
<td>Displays CleanAir interferers of type Canopy for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device cont-tx</td>
<td>Displays CleanAir interferers of type Continuous TX for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device dect-like</td>
<td>Displays CleanAir interferers of type DECT Like for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device inv</td>
<td>Displays CleanAir interferers of type Wi-Fi Inverted for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device jammer</td>
<td>Displays CleanAir interferers of type Jammer for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device nonstd</td>
<td>Displays CleanAir interferers of type Wi-Fi inverted channel for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device persistent</td>
<td>Displays CleanAir interferers of type Persistent for the 5-GHz band.</td>
</tr>
<tr>
<td>show ap dot11 5ghz clean device superag</td>
<td>Displays CleanAir interferers of type SuperAG for the 5-GHz band.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

### Monitoring Interference Devices

When a CleanAir-enabled access point detects interference devices, detections of the same device from multiple sensors are merged together to create clusters. Each cluster is given a unique ID. Some devices conserve power by limiting the transmit time until actually needed, which results in the spectrum sensor to stop detecting the device temporarily. This device is then correctly marked as down. Such a device is correctly removed from the spectrum database. In cases when all the interferer detections for a specific device are reported, the cluster ID is kept alive for an extended period of time to prevent possible device-detection bouncing. If the same device is detected again, it is merged with the original cluster ID and the device-detection history is preserved.

For example, some bluetooth headsets operate on battery power. These devices employ methods to reduce power consumption, such as turning off the transmitter when not actually needed. Such devices can appear to come and go from the classification. To manage these devices, CleanAir keeps the cluster IDs for longer and they are remerged into a single record upon detection. This process smoothens the user records and accurately represents the device history.

### Configuration Examples for CleanAir

This example shows how to enable CleanAir on the 2.4-GHz band and an access point operating in the channel:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair
Device(config)#exit
Device#ap name TAP1 dot11 24ghz cleanair
Device#end
```

**Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices: Example**

This example shows how to configure a CleanAir Alarm for 2.4-GHz Air-Quality threshold of 50 dBm and an Xbox device:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair alarm air-quality threshold 50
Device(config)#ap dot11 24ghz cleanair alarm device xbox
Device(config)#end
```
**Configuring Interference Reporting for 5-GHz Devices: Example**

This example shows how to configure interference reporting for 5-GHz devices:

```
Device# configure terminal
Device(config)# ap dot11 5ghz cleanair alarm device xbox
Device(config)# end
```

This example shows how to enable an EDRRM CleanAir event in the 2.4-GHz band and configure high sensitivity to non-Wi-Fi interference:

```
Device# configure terminal
Device(config)# ap dot11 24ghz rrm channel cleanair-event
Device(config)# ap dot11 24ghz rrm channel cleanair-event sensitivity high
Device(config)# end
```

**Configuring Persistent Device Avoidance: Example**

This example shows how to enable persistent non Wi-Fi device avoidance in the 2.4-GHz band:

```
Device# configure terminal
Device(config)# ap dot11 24ghz rrm channel device
Device(config)# end
```

**Configuring an Access Point for SE-Connect Mode: Example**

This example shows how to configure an access point in the SE-Connect mode:

```
Device# ap name Cisco_AP3500 mode se-connect
```

**CleanAir FAQs**

**Q.** How do I check if my MC is up?  
**A.** To check if the MC is up, use the command: `show wireless mobility summary`.

This example shows how to display the mobility summary:

```
Device# show wireless mobility summary

Mobility Controller Summary:
Mobility Role : Mobility Controller
Mobility Protocol Port : 16666
Mobility Group Name : MG-AK
Mobility Oracle : Disabled
Mobility Oracle IP Address : 0.0.0.0
DTLS Mode : Enabled
Mobility Domain ID for 802.11r : 0x39b2
Mobility Keepalive Interval : 10
Mobility Keepalive Count : 3
Mobility Control Message DSCP Value : 48
Mobility Domain Member Count : 2
Link Status is Control Link Status : Data Link Status
Controllers configured in the Mobility Domain:
IP Public IP Group Name Multicast IP Link Status
```

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
Q. Multiple access points detect the same interference device. However, the device shows them as separate clusters or different suspected devices clustered together. Why does this happen?
A. Access points must be RF neighbors for the device to consider merging the devices that are detected by these access points. An access point takes time to establish neighbor relationships. A few minutes after the device reboots or after there is a change in the RF group, and similar events, clustering will not be very accurate.

Q. Can I merge two monitor-mode access points using a device?
A. No, you cannot merge two monitor-mode access points using a device. You can merge the monitor mode access points only using MSE.

Q. How do I view neighbor access points?
A. To view neighbor access points, use the `show ap ap_name auto-rf dot11 {24ghz | 5ghz}` command.

This example shows how to display the neighbor access points:

```
Device# show ap name AS-5508-5-AP3 auto-rf dot11 24ghz
Nearby APs
 AP 0C85.259E.C350 slot 0 : -12 dBm on 1 (10.10.0.5)
 AP 0C85.25AB.CCA0 slot 0 : -24 dBm on 6 (10.10.0.5)
 AP 0C85.25C7.B7A0 slot 0 : -26 dBm on 11 (10.10.0.5)
 AP 0C85.25DE.2C10 slot 0 : -24 dBm on 6 (10.10.0.5)
 AP 0C85.25DE.C8E0 slot 0 : -14 dBm on 11 (10.10.0.5)
 AP 0C85.25DF.3280 slot 0 : -31 dBm on 6 (10.10.0.5)
 AP 0CD9.96BA.5600 slot 0 : -44 dBm on 6 (10.0.0.2)
 AP 24B6.5734.C570 slot 0 : -48 dBm on 11 (10.0.0.2)
```

Q. What are the debug commands available for CleanAir?
A. The debug commands for CleanAir are:

```
• debug cleanair { all | error | event | internal-event | nmsp | packet}
• debug rrm { all | channel | detail | error | group | ha | manager | message | packet | power | prealarm | profile | radar | rf-change | scale | spectrum}
```

Q. Why are CleanAir Alarms not generated for interferer devices?
A. Verify that the access points are CleanAir-capable and CleanAir is enabled both on the access point and the device.

Q. Can the Cisco Catalyst 3850 and 3650 Series Switches function as a Mobility Agent (MA)?
A. Yes, the Cisco Catalyst 3850 and 3650 Series Switches can function as an MA.

Q. Are CleanAir configurations available on the MA?
A. From Release 3.3 SE, CleanAir configurations are available on the MA. You can use the following two CleanAir commands on the MA:

```
• show ap dot11 5ghz cleanair config
```

Bluetooth Low Energy

Information About Bluetooth Low Energy

Bluetooth low energy (BLE) is a wireless personal area network technology aimed at enhancing location services for mobile devices. The small bluetooth tag devices placed at strategic locations transmit universally unique identifiers (UUIDs) and, Major and Minor fields as their identity. These details are picked up by bluetooth-enabled smartphones and devices. The location information of these devices are sent to the corresponding back-end server. Relevant advertisements and other important information are then pushed to the devices using this location-specific information.

The BLE feature also provides BLE beacon management support and specifies its behavior when used within the Cisco WLAN system. Using the Cisco CleanAir, an access point can identify an iBeacon signal and decode the payload content. The extracted tag device details are used for better management of the device.

By treating a tag device as an interferer and using the existing system capabilities, such as interference location, the tag device can be located on a map display in a wireless LAN deployment and its movement monitored. Besides this, information on missing tags can also be obtained. This feature can determine rogue and malicious tags using the unique identifier associated with each tag (or family of tags) against a predetermined whitelist from a customer. Using the management function, alerts can be displayed or emailed based on rogue tags, missing tags, or moved tags.

Limitations of BLE Feature

- The wireless infrastructure must support Cisco CleanAir.
- Supports a maximum of only 250 unique BLE beacons (cluster entries) and 1000 device entries.
- The BLE feature on the Cisco Aironet 3700 Series Access Points with Halo module gets deactivated when NTP is configured (This behavior is also observed when Cisco CMX is not present.) So, the legacy BLE does not work when Cisco CMX is present or not configured for Hyperlocation.

Areas of Use

Since the BLE feature provides granular location details of devices (smart phones or bluetooth-enabled devices) that helps push context-sensitive advertising and other information to users. Possible areas of application include retail stores, museums, zoo, healthcare, fitness, security, advertising, and so on.
# Enabling Bluetooth Low Energy Beacon

Bluetooth low energy (BLE) detection is enabled by default. Use the procedure given below to enable BLE when it is disabled.

### Before you begin
- The wireless infrastructure must support Cisco CleanAir.
- Cisco CleanAir configuration and show commands are available only in Mobility Controller (MC) mode.

### SUMMARY STEPS

1. `configure terminal`
2. `[no] ap dot11 24ghz cleanair device [ble-beacon]`
3. `exit`
4. `show ap dot11 24ghz cleanair config`
5. `show ap dot11 24ghz cleanair device type ble-beacon`

Information About Configuring Interface Characteristics

Interface Types

This section describes the different types of interfaces supported by the device. The rest of the chapter describes configuration procedures for physical interface characteristics.

Note
The stack ports on the rear of the stacking-capable devices are not Ethernet ports and cannot be configured.

Port-Based VLANs

A VLAN is a switched network that is logically segmented by function, team, or application, without regard to the physical location of the users. Packets received on a port are forwarded only to ports that belong to the same VLAN as the receiving port. Network devices in different VLANs cannot communicate with one another without a Layer 3 device to route traffic between the VLANs.

VLAN partitions provide hard firewalls for traffic in the VLAN, and each VLAN has its own MAC address table. A VLAN comes into existence when a local port is configured to be associated with the VLAN, when the VLAN Trunking Protocol (VTP) learns of its existence from a neighbor on a trunk, or when a user creates a VLAN. VLANs can be formed with ports across the stack.

To configure VLANs, use the `vlan vlan-id` global configuration command to enter VLAN configuration mode. The VLAN configurations for normal-range VLANs (VLAN IDs 1 to 1005) are saved in the VLAN database. If VTP is version 1 or 2, to configure extended-range VLANs (VLAN IDs 1006 to 4094), you must first set VTP mode to transparent. Extended-range VLANs created in transparent mode are not added to the VLAN.
database but are saved in the device running configuration. With VTP version 3, you can create extended-range VLANs in client or server mode. These VLANs are saved in the VLAN database.

In a switch stack, the VLAN database is downloaded to all switches in a stack, and all switches in the stack build the same VLAN database. The running configuration and the saved configuration are the same for all switches in a stack.

Add ports to a VLAN by using the switchport interface configuration commands:

- Identify the interface.
- For a trunk port, set trunk characteristics, and, if desired, define the VLANs to which it can belong.
- For an access port, set and define the VLAN to which it belongs.

**Switch Ports**

Switch ports are Layer 2-only interfaces associated with a physical port. Switch ports belong to one or more VLANs. A switch port can be an access port or a trunk port. You can configure a port as an access port or trunk port or let the Dynamic Trunking Protocol (DTP) operate on a per-port basis to set the switchport mode by negotiating with the port on the other end of the link. switch ports are used for managing the physical interface and associated Layer 2 protocols and do not handle routing or bridging.

Configure switch ports by using the switchport interface configuration commands.

**Access Ports**

An access port belongs to and carries the traffic of only one VLAN (unless it is configured as a voice VLAN port). Traffic is received and sent in native formats with no VLAN tagging. Traffic arriving on an access port is assumed to belong to the VLAN assigned to the port. If an access port receives a tagged packet (Inter-Switch Link [ISL] or IEEE 802.1Q tagged), the packet is dropped, and the source address is not learned.

The types of access ports supported are:

- Static access ports are manually assigned to a VLAN (or through a RADIUS server for use with IEEE 802.1x).

You can also configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.

**Trunk Ports**

A trunk port carries the traffic of multiple VLANs and by default is a member of all VLANs in the VLAN database.

Although by default, a trunk port is a member of every VLAN known to the VTP, you can limit VLAN membership by configuring an allowed list of VLANs for each trunk port. The list of allowed VLANs does not affect any other port but the associated trunk port. By default, all possible VLANs (VLAN ID 1 to 4094) are in the allowed list. A trunk port can become a member of a VLAN only if VTP knows of the VLAN and if the VLAN is in the enabled state. If VTP learns of a new, enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of that VLAN and traffic is forwarded to and from the trunk port for that VLAN. If VTP learns of a new, enabled VLAN that is not in the allowed list for a trunk port, the port does not become a member of the VLAN, and no traffic for the VLAN is forwarded to or from the port.
Tunnel Ports

Tunnel ports are used in IEEE 802.1Q tunneling to segregate the traffic of customers in a service-provider network from other customers who are using the same VLAN number. You configure an asymmetric link from a tunnel port on a service-provider edge switch to an IEEE 802.1Q trunk port on the customer switch. Packets entering the tunnel port on the edge switch, already IEEE 802.1Q-tagged with the customer VLANs, are encapsulated with another layer of an IEEE 802.1Q tag (called the metro tag), containing a VLAN ID unique in the service-provider network, for each customer. The double-tagged packets go through the service-provider network keeping the original customer VLANs separate from those of other customers. At the outbound interface, also a tunnel port, the metro tag is removed, and the original VLAN numbers from the customer network are retrieved.

Tunnel ports cannot be trunk ports or access ports and must belong to a VLAN unique to each customer.

Routed Ports

A routed port is a physical port that acts like a port on a router; it does not have to be connected to a router. A routed port is not associated with a particular VLAN, as is an access port. A routed port behaves like a regular router interface, except that it does not support VLAN subinterfaces. Routed ports can be configured with a Layer 3 routing protocol. A routed port is a Layer 3 interface only and does not support Layer 2 protocols, such as DTP and STP.

Configure routed ports by putting the interface into Layer 3 mode with the no switchport interface configuration command. Then assign an IP address to the port, enable routing, and assign routing protocol characteristics by using the ip routing and router protocol global configuration commands.

Note
Entering a no switchport interface configuration command shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost.

The number of routed ports that you can configure is not limited by software. However, the interrelationship between this number and the number of other features being configured might impact CPU performance because of hardware limitations.

Note
The IP Base images supports static routing and the Routing Information Protocol (RIP). For full Layer 3 routing or for fallback bridging, you must enable the IP Services image on the standalone device, or the active device

Switch Virtual Interfaces

A switch virtual interface (SVI) represents a VLAN of switch ports as one interface to the routing or bridging function in the system. You can associate only one SVI with a VLAN. You configure an SVI for a VLAN only to route between VLANs or to provide IP host connectivity to the device. By default, an SVI is created for the default VLAN (VLAN 1) to permit remote device administration. Additional SVIs must be explicitly configured.

Note
You cannot delete interface VLAN 1.
SVIs provide IP host connectivity only to the system. SVIs are created the first time that you enter the `vlan` interface configuration command for a VLAN interface. The VLAN corresponds to the VLAN tag associated with data frames on an ISL or IEEE 802.1Q encapsulated trunk or the VLAN ID configured for an access port. Configure a VLAN interface for each VLAN for which you want to route traffic, and assign it an IP address.

You can also use the interface range command to configure existing VLAN SVIs within the range. The commands entered under the interface range command are applied to all existing VLAN SVIs within the range. You can enter the command `interface range create vlan x - y` to create all VLANs in the specified range that do not already exist. When the VLAN interface is created, `interface range vlan id` can be used to configure the VLAN interface.

Although the switch stack or device supports a total of 1005 VLANs and SVIs, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might impact CPU performance because of hardware limitations.

When you create an SVI, it does not become active until it is associated with a physical port.

### SVI Autostate Exclude

The line state of an SVI with multiple ports on a VLAN is in the *up* state when it meets these conditions:

- The VLAN exists and is active in the VLAN database on the device
- The VLAN interface exists and is not administratively down.
- At least one Layer 2 (access or trunk) port exists, has a link in the *up* state on this VLAN, and is in the spanning-tree forwarding state on the VLAN.

**Note**

The protocol link state for VLAN interfaces come up when the first switchport belonging to the corresponding VLAN link comes up and is in STP forwarding state.

The default action, when a VLAN has multiple ports, is that the SVI goes down when all ports in the VLAN go down. You can use the SVI autostate exclude feature to configure a port so that it is not included in the SVI line-state up-or-down calculation. For example, if the only active port on the VLAN is a monitoring port, you might configure autostate exclude on that port so that the VLAN goes down when all other ports go down. When enabled on a port, `autostate exclude` applies to all VLANs that are enabled on that port.

The VLAN interface is brought up when one Layer 2 port in the VLAN has had time to converge (transition from STP listening-learning state to forwarding state). This prevents features such as routing protocols from using the VLAN interface as if it were fully operational and minimizes other problems, such as routing black holes.

### EtherChannel Port Groups

EtherChannel port groups treat multiple switch ports as one switch port. These port groups act as a single logical port for high-bandwidth connections between devices or between devices and servers. An EtherChannel balances the traffic load across the links in the channel. If a link within the EtherChannel fails, traffic previously carried over the failed link changes to the remaining links. You can group multiple trunk ports into one logical trunk port, group multiple access ports into one logical access port, group multiple tunnel ports into one logical tunnel port, or group multiple routed ports into one logical routed port. Most protocols operate over either single ports or aggregated switch ports and do not recognize the physical ports within the port group. Exceptions...
are the DTP, the Cisco Discovery Protocol (CDP), and the Port Aggregation Protocol (PAgP), which operate only on physical ports.

When you configure an EtherChannel, you create a port-channel logical interface and assign an interface to the EtherChannel. For Layer 3 interfaces, you manually create the logical interface by using the interface port-channel global configuration command. Then you manually assign an interface to the EtherChannel by using the channel-group interface configuration command. For Layer 2 interfaces, use the channel-group interface configuration command to dynamically create the port-channel logical interface. This command binds the physical and logical ports together.

**Multigigabit Ethernet**

The MultiGigabit Ethernet (mGig) feature allows you to configure speeds beyond 1Gbps on Cisco 802.11ac Wave2 Access Points (APs) Ethernet port. This technology supports speeds of 100 Mbps, 1 Gbps, 2.5 Gbps, and 5 Gbps with automatic bandwidth negotiation over traditional CAT5e cables and higher cable variants. mGig is supported with Cisco 3800 Series access points and on the Cisco Catalyst switches mentioned below.

The following Cisco switches support the mGig feature:

- WS-C3650-8X24PD
- WS-C3650-8X24UQ
- WS-C3650-12X48FD
- WS-C3650-12X48UQ
- WS-C3650-12X48UR
- WS-C3650-12X48UZ

Multigigabit Ethernet supports multi-rate speeds where the ports exchange auto-negotiation pages to establish a link at the highest speed that is supported by both ends of the channel. In a high-noise environment, when port speed downshifting is enabled on an interface, the line rate automatically downgrades to a lower speed when a higher speed link cannot be established or when an established link quality has degraded to a level where the PHY needs to reestablish the link. The following downshift speed values are recommended:

- 10Gbs (downshift to 5Gbs)
- 5Gbs (downshift to 2.5Gbs)
- 2.5Gbs (downshift to 1Gbs)
- 1Gbs (downshift to 100Mbs)

**Power over Ethernet Ports**

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.
Using the Switch USB Ports

USB Mini-Type B Console Port

The device has the following console ports:

- USB mini-Type B console connection
- RJ-45 console port

Console output appears on devices connected to both ports, but console input is active on only one port at a time. By default, the USB connector takes precedence over the RJ-45 connector.

Note

Windows PCs require a driver for the USB port. See the hardware installation guide for driver installation instructions.

Use the supplied USB Type A-to-USB mini-Type B cable to connect a PC or other device to the device. The connected device must include a terminal emulation application. When the device detects a valid USB connection to a powered-on device that supports host functionality (such as a PC), input from the RJ-45 console is immediately disabled, and input from the USB console is enabled. Removing the USB connection immediately reenables input from the RJ-45 console connection. An LED on the device shows which console connection is in use.

Console Port Change Logs

At software startup, a log shows whether the USB or the RJ-45 console is active. Each device in a stack issues this log. Every device always first displays the RJ-45 media type.

In the sample output, Device 1 has a connected USB console cable. Because the bootloader did not change to the USB console, the first log from Device 1 shows the RJ-45 console. A short time later, the console changes and the USB console log appears. Device 2 and Device 3 have connected RJ-45 console cables.

```console
switch-stack-1
*Mar 1 00:01:00.171: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
*Mar 1 00:01:00.431: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.
```

```console
switch-stack-2
*Mar 1 00:01:09.835: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

```console
switch-stack-3
*Mar 1 00:01:10.523: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

When the USB cable is removed or the PC de-activates the USB connection, the hardware automatically changes to the RJ-45 console interface:

```console
switch-stack-1
Mar 1 00:20:48.635: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

You can configure the console type to always be RJ-45, and you can configure an inactivity timeout for the USB connector.
Interface Connections

Devices within a single VLAN can communicate directly through any switch. Ports in different VLANs cannot exchange data without going through a routing device. With a standard Layer 2 device, ports in different VLANs have to exchange information through a router. By using the device with routing enabled, when you configure both VLAN 20 and VLAN 30 with an SVI to which an IP address is assigned, packets can be sent from Host A to Host B directly through the device with no need for an external router.

**Figure 5: Connecting VLANs with the Switch**

Devices running the LAN Base images support configuring only 16 static routes on SVIs.

- The routing function can be enabled on all SVIs and routed ports. The device routes only IP traffic. When IP routing protocol parameters and address configuration are added to an SVI or routed port, any IP traffic received from these ports is routed.

- Fallback bridging forwards traffic that the device does not route or traffic belonging to a nonroutable protocol, such as DECnet. Fallback bridging connects multiple VLANs into one bridge domain by bridging between two or more SVIs or routed ports. When configuring fallback bridging, you assign SVIs or routed ports to bridge groups with each SVI or routed port assigned to only one bridge group. All interfaces in the same group belong to the same bridge domain.

Default Ethernet Interface Configuration

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.
This table shows the Ethernet interface default configuration, including some features that apply only to Layer 2 interfaces.

**Table 7: Default Layer 2 Ethernet Interface Configuration**

</tbody>
</table>
Interface Speed and Duplex Mode

Ethernet interfaces on the switch operate at 10, 100, 1000, or 10,000 Mb/s and in either full- or half-duplex mode. In full-duplex mode, two stations can send and receive traffic at the same time. Normally, 10-Mb/s ports operate in half-duplex mode, which means that stations can either receive or send traffic.

Switch modules include Gigabit Ethernet (10/100/1000-Mb/s) ports, 10-Gigabit Ethernet ports, and small form-factor pluggable (SFP) module slots supporting SFP modules.

Speed and Duplex Configuration Guidelines

When configuring an interface speed and duplex mode, note these guidelines:

- The 10-Gigabit Ethernet ports do not support the speed and duplex features. These ports operate only at 10,000 Mb/s and in full-duplex mode.

- Do not disable Auto-Negotiation on PoE switches.

- Gigabit Ethernet (10/100/1000-Mb/s) ports support all speed options and all duplex options (auto, half, and full). However, Gigabit Ethernet ports operating at 1000 Mb/s do not support half-duplex mode.

- For SFP module ports, the speed and duplex CLI options change depending on the SFP module type:
  - The 1000BASE-x (where x is -BX, -CWDM, -LX, -SX, and -ZX) SFP module ports support the nonegotiate keyword in the speed interface configuration command. Duplex options are not supported.
  - The 1000BASE-T SFP module ports support the same speed and duplex options as the 10/100/1000-Mb/s ports.

- If both ends of the line support autonegotiation, we highly recommend the default setting of auto negotiation.

- If one interface supports autonegotiation and the other end does not, configure duplex and speed on both interfaces; do not use the auto setting on the supported side.

- When STP is enabled and a port is reconfigured, the device can take up to 30 seconds to check for loops. The port LED is amber while STP reconfigures.

- As best practice, we suggest configuring the speed and duplex options on a link to auto or to fixed on both the ends. If one side of the link is configured to auto and the other side is configured to fixed, the link will not be up and this is expected.

Caution

Changing the interface speed and duplex mode configuration might shut down and re-enable the interface during the reconfiguration.

IEEE 802.3x Flow Control

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If one port experiences congestion and cannot receive any more
traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

The switch ports can receive, but not send, pause frames.

Use the `flowcontrol` interface configuration command to set the interface’s ability to receive pause frames to on, off, or desired. Prior to Cisco IOS XE Denali 16.3.8 release, the default state is off. Starting Cisco IOS XE Denali 16.3.8 release, the default state is on.

When set to desired, an interface can operate with an attached device that is required to send flow-control packets or with an attached device that is not required to but can send flow-control packets.

These rules apply to flow control settings on the device:

- **receive on** (or desired): The port cannot send pause frames but can operate with an attached device that is required to or can send pause frames; the port can receive pause frames.

- **receive off**: Flow control does not operate in either direction. In case of congestion, no indication is given to the link partner, and no pause frames are sent or received by either device.

### Layer 3 Interfaces

The device supports these types of Layer 3 interfaces:

- **SVIs**: You should configure SVIs for any VLANs for which you want to route traffic. SVIs are created when you enter a VLAN ID following the `interface vlan` global configuration command. To delete an SVI, use the `no interface vlan` global configuration command. You cannot delete interface VLAN 1.

  **Note** When you create an SVI, it does not become active until it is associated with a physical port.

  When configuring SVIs, you can also configure SVI autostate exclude on a port in the SVI to exclude that port from being included in determining SVI line-state status.

- **Routed ports**: Routed ports are physical ports configured to be in Layer 3 mode by using the `no switchport` interface configuration command.

- **Layer 3 EtherChannel ports**: EtherChannel interfaces made up of routed ports.

A Layer 3 device can have an IP address assigned to each routed port and SVI.

There is no defined limit to the number of SVIs and routed ports that can be configured in a device or in a device stack. However, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might have an impact on CPU usage because of hardware limitations. If the device is using its maximum hardware resources, attempts to create a routed port or SVI have these results:

- If you try to create a new routed port, the device generates a message that there are not enough resources to convert the interface to a routed port, and the interface remains as a switchport.
• If you try to create an extended-range VLAN, an error message is generated, and the extended-range VLAN is rejected.

• If the device is notified by VLAN Trunking Protocol (VTP) of a new VLAN, it sends a message that there are not enough hardware resources available and shuts down the VLAN. The output of the `show vlan` user EXEC command shows the VLAN in a suspended state.

• If the device attempts to boot up with a configuration that has more VLANs and routed ports than hardware can support, the VLANs are created, but the routed ports are shut down, and the device sends a message that this was due to insufficient hardware resources.

---

**Note**

All Layer 3 interfaces require an IP address to route traffic. This procedure shows how to configure an interface as a Layer 3 interface and how to assign an IP address to an interface:

If the physical port is in Layer 2 mode (the default), you must enter the `no switchport` interface configuration command to put the interface into Layer 3 mode. Entering a `no switchport` command disables and then re-enables the interface, which might generate messages on the device to which the interface is connected. Furthermore, when you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

---

**Digital Optical Monitoring**

The switch supports Digital Optical Monitoring (DOM) as per the standard SFF-8724 Multi-Source Agreement (MSA). It enables you to monitor optical input and output power, temperature, and voltage. These parameters are monitored against threshold values and you can display threshold violations for a transceiver installed on a specific interface.

The feature is supported on all transceivers that support DOM and is disabled by default.

**Identifying DOM-Supported Transceivers**

OR

Display the list of DOM-supported transceivers on your device. Enter the `show interfaces transceiver supported-list` command in privileged EXEC mode.

---

**How to Configure Interface Characteristics**

**Configuring Interfaces**

These general instructions apply to all interface configuration processes.
### Adding a Description for an Interface

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
  Example: `Device> enable`  
  - Enter your password if prompted. |
| **Step 2** | `configure terminal` | Enters global configuration mode.  
  Example: `Device# configure terminal` |
| **Step 3** | `interface interface-id` | Identifies the interface type, the device number (only on stacking-capable switches), and the number of the connector.  
  Example:  
  Device(config)# interface gigabitethernet 1/0/1  
  Device(config-if)# |
| **Step 4** | Follow each `interface` command with the interface configuration commands that the interface requires. | Defines the protocols and applications that will run on the interface. The commands are collected and applied to the interface when you enter another interface command or enter `end` to return to privileged EXEC mode. |
| **Step 5** | `interface range` or `interface range macro` | (Optional) Configures a range of interfaces.  
  **Note** Interfaces configured in a range must be the same type and must be configured with the same feature options. |
| **Step 6** | `show interfaces` | Displays a list of all interfaces on or configured for the switch. A report is provided for each interface that the device supports or for the specified interface. |

#### Adding a Description for an Interface

**SUMMARY STEPS**

1. `enable`  
2. `configure terminal`  
3. `interface interface-id`  
4. `description string`  
5. `end`
6. `show interfaces interface-id description`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable&lt;br&gt;Enables privileged EXEC mode.&lt;br&gt;- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal&lt;br&gt;Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>interface interface-id</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# interface gigabitethernet 1/0/2&lt;br&gt;Specifies the interface for which you are adding a description, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>description string</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# description Connects to Marketing&lt;br&gt;Adds a description (up to 240 characters) for an interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>end</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# end&lt;br&gt;Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>show interfaces interface-id description</strong>&lt;br&gt;Verifies your entry.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>copy running-config startup-config</strong>&lt;br&gt;(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Configuring a Range of Interfaces

To configure multiple interfaces with the same configuration parameters, use the interface range global configuration command. When you enter the interface-range configuration mode, all command parameters that you enter are attributed to all interfaces within that range until you exit this mode.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface range \{port-range | macro macro_name\}
4. end
5. show interfaces [interface-id]
6. copy running-config startup-config

<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface range {port-range</td>
<td>macro macro_name}</td>
</tr>
<tr>
<td>Example:</td>
<td>• You can use the interface range command to configure up to five port ranges or a previously defined macro.</td>
</tr>
<tr>
<td>Device(config)# interface range macro</td>
<td>• The macro variable is explained in the section on Configuring and Using Interface Range Macros.</td>
</tr>
<tr>
<td></td>
<td>• In a comma-separated port-range, you must enter the interface type for each entry and enter spaces before and after the comma.</td>
</tr>
<tr>
<td></td>
<td>• In a hyphen-separated port-range, you do not need to re-enter the interface type, but you must enter a space before the hyphen.</td>
</tr>
</tbody>
</table>
### Configuring and Using Interface Range Macros

You can create an interface range macro to automatically select a range of interfaces for configuration. Before you can use the `macro` keyword in the `interface range macro` global configuration command string, you must use the `define interface-range` global configuration command to define the macro.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `define interface-range macro_name interface-range`
4. `interface range macro macro_name`
5. `end`
6. `show running-config | include define`
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**  
**Example:**  
Device# configure terminal  

Enters global configuration mode.

**Step 3**  
**Define interface-range**  
**Example:**  
Device(config)# define interface-range enet_list  
gigabitethernet 1/0/1 - 2  

Defines the interface-range macro, and save it in NVRAM.  
- The `macro_name` is a 32-character maximum character string.  
- A macro can contain up to five comma-separated interface ranges.  
- Each `interface-range` must consist of the same port type.  

**Note** Before you can use the `macro` keyword in the **interface range macro** global configuration command string, you must use the `define interface-range` global configuration command to define the macro.

**Step 4**  
**Example:**  
Device(config)# interface range macro enet_list  

Selects the interface range to be configured using the values saved in the interface-range macro called `macro_name`.  
You can now use the normal configuration commands to apply the configuration to all interfaces in the defined macro.

**Step 5**  
**Example:**  
Device(config)# end  

Returns to privileged EXEC mode.

**Step 6**  
**Example:**  
Device# show running-config | include define  

Shows the defined interface range macro configuration.

**Step 7**  
**Example:**  
Device# copy running-config startup-config  

(Optional) Saves your entries in the configuration file.
Configuring Ethernet Interfaces

Setting the Interface Speed and Duplex Parameters

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `speed {10 | 100 | 1000 | 2500 | 5000 | 10000 | auto [10 | 100 | 1000 | 2500 | 5000 | 10000] | nonegotiate}`
5. `duplex {auto | full | half}`
6. `end`
7. `show interfaces interface-id`
8. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specifies the physical interface to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/3</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Enter the appropriate speed parameter for the interface:</td>
</tr>
<tr>
<td>`speed {10</td>
<td>100</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• Enter 10, 100, 1000 2500, 5000, or 10000 to set a specific speed for the interface.</td>
</tr>
<tr>
<td>Device(config-if)# speed 10</td>
<td>• Enter auto to enable the interface to autonegotiate speed with the connected device. If you specify a speed and also set the auto keyword, the port autonegotiates only at the specified speeds.</td>
</tr>
<tr>
<td></td>
<td>• The nonegotiate keyword is available only for SFP module ports. SFP module ports operate only at 1000 Mb/s but can be configured to not negotiate if</td>
</tr>
</tbody>
</table>
## Configuring Multigigabit Ethernet Parameters

### SUMMARY STEPS

1. `interface tengigabitethernet interface number`
2. `speed auto`
3. `downshift`
4. `no downshift`
5. `end`
6. `show interfaces downshift`
7. `show interfaces interface-number downshift`
8. `show interfaces downshift module module-number`
9. `show ap name ap-name ethernet statistics`

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`duplex {auto</td>
<td>full</td>
</tr>
</tbody>
</table>

**Step 5**

Example:

```
Device(config-if)# duplex half
```

This command is not available on a 10-Gigabit Ethernet interface.

Enter the duplex parameter for the interface.

Enable half-duplex mode (for interfaces operating only at 10 or 100 Mb/s). You cannot configure half-duplex mode for interfaces operating at 1000 Mb/s.

You can configure the duplex setting when the speed is set to `auto`.

**Step 6**

Example:

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

**Step 7**

Example:

```
Device# show interfaces gigabitethernet 1/0/3
```

Displays the interface speed and duplex mode configuration.

**Step 8**

Example:

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
## DETAILED STEPS

</table>
### Configuring Logical Layer 3 GRE Tunnel Interfaces

**Before you begin**

Generic Routing Encapsulation (GRE) is a tunneling protocol used to encapsulate network layer protocols inside virtual point-to-point links. A GRE tunnel only provides encapsulation and not encryption.

**Attention**

Beginning in Cisco IOS XE Release 3.7.2E, GRE tunnels are supported on the hardware on Cisco Catalyst switches. When GRE is configured without tunnel options, packets are hardware-switched. When GRE is configured with tunnel options (such as key, checksum, etc.), packets are switched in the software. A maximum of 10 GRE tunnels are supported.

**Note**

Other features like Access Control Lists (ACL) and Quality of Service (QoS) are not supported for the GRE tunnels.

To configure a GRE tunnel, perform this task:

**SUMMARY STEPS**

1. `interface tunnel number`
2. `ip address ip_address subnet_mask`
3. `tunnel source ip_address | type_number`
4. `tunnel destination host_name | ip_address`
5. tunnel mode gre ip
6. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>interface tunnel number</td>
<td>Enables tunneling on the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)#interface tunnel 2</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>ip address ip_address subnet_mask</td>
<td>Configures the IP address and IP subnet.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)#ip address 100.1.1.1 255.255.255.0</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>tunnel source {ip_address</td>
<td>type_number}</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)#tunnel source 10.10.1.1</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>tunnel destination {host_name</td>
<td>ip_address}</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)#tunnel destination 10.10.10.2</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>tunnel mode gre ip</td>
<td>Configures the tunnel mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)#tunnel mode gre ip</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>end</td>
<td>Exit configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)#end</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring SVI Autostate Exclude**

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. switchport autostate exclude
5. end
6. show running config interface interface-id
7. copy running-config startup-config
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>interface &lt;interface-id&gt;</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# interface gigabitethernet1/0/2</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>switchport autostate exclude</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# switchport autostate exclude</td>
</tr>
<tr>

<td><strong>end</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>show running config interface &lt;interface-id&gt;</strong>&lt;br&gt;<strong>(Optional) Shows the running configuration.</strong>&lt;br&gt;<strong>Verifies the configuration.</strong></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>copy running-config startup-config</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# copy running-config startup-config</td>
</tr>
</tbody>
</table>

## Shutting Down and Restarting the Interface

Shutting down an interface disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface is not mentioned in any routing updates.
### SUMMARY STEPS

1. enable  
2. configure terminal  
3. interface {vlan vlan-id} | {gigabitethernet interface-id} | {port-channel port-channel-number}  
4. shutdown  
5. no shutdown  
6. end  
7. show running-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 enable     | Enables privileged EXEC mode.  
| Example: Device> enable |   
| Step 2 configure terminal | Enters global configuration mode.  
| Example: Device# configure terminal |   |
| Step 3 interface {vlan vlan-id} | Selects the interface to be configured.  
| Example: Device(config)# interface gigabitethernet 1/0/2 |   |
| Step 4 shutdown | Shuts down an interface.  
| Example: Device(config-if)# shutdown |   |
| Step 5 no shutdown | Restarts an interface.  
| Example: Device(config-if)# no shutdown |   |
| Step 6 end | Returns to privileged EXEC mode.  
| Example: Device(config-if)# end |   |
Configuring the Console Media Type

Follow these steps to set the console media type to RJ-45. If you configure the console as RJ-45, USB console operation is disabled, and input comes only through the RJ-45 connector.

This configuration applies to all switches in a stack.

SUMMARY STEPS

1. enable
2. configure terminal
3. line console 0
4. media-type rj45
5. end
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>line console 0</td>
<td>Configures the console and enters line configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# line console 0</td>
<td></td>
</tr>
</tbody>
</table>
Configuring the USB Inactivity Timeout

The configurable inactivity timeout reactivates the RJ-45 console port if the USB console port is activated but no input activity occurs on it for a specified time period. When the USB console port is deactivated due to a timeout, you can restore its operation by disconnecting and reconnecting the USB cable.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. line console 0
4. usb-inactivity-timeout timeout-minutes
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>

**Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches) 131**
### Enabling Digital Optical Monitoring

Complete the following steps to enable transceiver monitoring:

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables privileged EXEC mode.</td>
<td><code>enable</code></td>
</tr>
<tr>
<td>Enter your password if prompted.</td>
<td><code>enable</code></td>
</tr>
</tbody>
</table>

**Note**
- In case of combo ports with an SFP and RJ45 provision, when an SFP transceiver is inserted in the slot or port and media type is not configured as SFP, DOM is functional only if global transceiver monitoring is enabled.
- CISCO-ENTITY-SENSOR-MIB traps are sent only once after a threshold violation. However, SYSLOG messages are sent according to the monitoring interval.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `transceiver type all`
4. `monitoring interval seconds`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables privileged EXEC mode.</td>
<td><code>enable</code></td>
</tr>
<tr>
<td>Enter your password if prompted.</td>
<td><code>enable</code></td>
</tr>
</tbody>
</table>
### What to do next

After you have enabled monitoring, you can use these `show` commands to display real-time parameters of the device:

- `show interfaces transceiver`
- `show interfaces transceiver detail`
- `show interfaces interface-id transceiver`

### Monitoring Interface Characteristics

#### Monitoring Interface Status

Commands entered at the privileged EXEC prompt display information about the interface, including the versions of the software and the hardware, the configuration, and statistics about the interfaces.

*Table 8: Show Commands for Interfaces*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show interfaces interface-number downshift module module-number</code></td>
<td>Displays the downshift status details of the specified interfaces and modules.</td>
</tr>
<tr>
<td><code>show interfaces interface-id status [err-disabled]</code></td>
<td>Displays interface status or a list of interfaces in the error-disabled state.</td>
</tr>
</tbody>
</table>
### Clearing and Resetting Interfaces and Counters

**Table 9: Clear Commands for Interfaces**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear counters [interface-id]</td>
<td>Clears interface counters.</td>
</tr>
<tr>
<td>clear interface interface-id</td>
<td>Resets the hardware logic on an interface.</td>
</tr>
<tr>
<td>clear line [number</td>
<td>console 0</td>
</tr>
</tbody>
</table>

**Note** The **clear counters** privileged EXEC command does not clear counters retrieved by using Simple Network Management Protocol (SNMP), but only those seen with the **show interface** privileged EXEC command.
Configuration Examples for Interface Characteristics

Adding a Description to an Interface: Example

Displaying Downshift Status of Interfaces: Examples

This example shows how to display the downshift status of all the multi-gigabit ports.

```
Device# show interfaces downshift
Port  Enabled  Active  AdminSpeed  OperSpeed
Te2/0/37 yes  no     auto      auto
Te2/0/38 yes  no     auto      10G
Te2/0/39 yes  no     auto      auto
Te2/0/40 yes  no     auto      10G
Te2/0/41 yes  no     auto      auto
Te2/0/42 yes  no     auto      auto
Te2/0/43 yes  yes    auto      5000
Te2/0/44 yes  no     auto      auto
Te2/0/45 yes  yes    auto      2500
Te2/0/46 yes  no     auto      auto
Te2/0/47 yes  no     auto      10G
Te2/0/48 yes  no     auto      auto
```

This example shows how to display the downshift status of the specified multi-gigabit port.

```
Device# show interfaces te2/0/43 downshift
Port  Enabled  Active  AdminSpeed  OperSpeed
Te2/0/43 yes  yes    10G  5000
```

The fields in command output are explained below:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Displays the interface number</td>
</tr>
<tr>
<td>Enabled</td>
<td>Indicates that Downshift is enabled (yes) / disabled (no) on the specified port</td>
</tr>
<tr>
<td>Active</td>
<td>Displays whether Downshift has occurred on the interface or not</td>
</tr>
<tr>
<td>AdminSpeed</td>
<td>Displays the speed set by the user (or) default interface speed</td>
</tr>
<tr>
<td>OperSpeed</td>
<td>Displays current operational speed on the interface</td>
</tr>
</tbody>
</table>

Configuring a Range of Interfaces: Examples

This example shows how to use the `interface range` global configuration command to set the speed to 100 Mb/s on ports 1 to 4 on switch 1:

```
Device# configure terminal
```
Configuring and Using Interface Range Macros: Examples

This example shows how to use a comma to add different interface type strings to the range to enable Gigabit Ethernet ports 1 to 3 and 10-Gigabit Ethernet ports 1 and 2 to receive flow-control pause frames:

Device# configure terminal
Device(config)# interface range gigabitethernet 1/0/1 - 4
Device(config-if-range)# speed 100
Device(config-if-range)# flowcontrol receive on

If you enter multiple configuration commands while you are in interface-range mode, each command is executed as it is entered. The commands are not batched and executed after you exit interface-range mode. If you exit interface-range configuration mode while the commands are being executed, some commands might not be executed on all interfaces in the range. Wait until the command prompt reappears before exiting interface-range configuration mode.

Configuring and Using Interface Range Macros: Examples

This example shows how to define an interface-range named `enet_list` to include ports 1 and 2 on switch 1 and to verify the macro configuration:

Device# configure terminal
Device(config)# define interface-range enet_list gigabitethernet 1/1/1 - 2
Device(config)# end
Device# show running-config | include define
define interface-range enet_list gigabitethernet 1/1/1 - 2

This example shows how to create a multiple-interface macro named `macro1`:

Device# configure terminal
Device(config)# define interface-range macro1 gigabitethernet1/1/1 - 2, gigabitethernet1/1/5 - 7, tengigabitethernet1/1/1 -2
Device(config)# end

This example shows how to enter interface-range configuration mode for the interface-range macro `enet_list`:

Device# configure terminal
Device(config)# interface range macro enet_list
Device(config-if-range)#

This example shows how to delete the interface-range macro `enet_list` and to verify that it was deleted:

Device# configure terminal
Device(config)# no define interface-range enet_list
Device(config)# end
Device# show run | include define
Device#
Setting Interface Speed and Duplex Mode: Example

This example shows how to set the interface speed to 100 Mb/s and the duplex mode to half on a 10/100/1000 Mb/s port:

Device# configure terminal
Device(config)# interface gigabitethernet 1/0/3
Device(config-if)# speed 10
Device(config-if)# duplex half

This example shows how to set the interface speed to 100 Mb/s on a 10/100/1000 Mb/s port:

Device# configure terminal
Device(config)# interface gigabitethernet 1/0/2
Device(config-if)# speed 100

Configuring Layer 3 Interfaces: Example

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 192.20.135.21 255.255.255.0
Device(config-if)# no shutdown

Configuring the Console Media Type: Example

This example disables the USB console media type and enables the RJ-45 console media type.

Device# configure terminal
Device(config)# line console 0
Device(config-line)# media-type rj45

This example reverses the previous configuration and immediately activates any USB console that is connected.

Device# configure terminal
Device(config)# line console 0
Device(config-line)# no media-type rj45

Configuring the USB Inactivity Timeout: Example

This example configures the inactivity timeout to 30 minutes:

Device# configure terminal
Device(config)# line console 0
Device(config-line)# usb-inactivity-timeout 30

To disable the configuration, use these commands:
Device# configure terminal
Device(config)# line console 0
Device(config-line)# no usb-inactivity-timeout

If there is no (input) activity on a USB console port for the configured number of minutes, the inactivity timeout setting applies to the RJ-45 port, and a log shows this occurrence:

*Mar 1 00:47:25.625: %USB_CONSOLE-6-INACTIVITY_DISABLE: Console media-type USB disabled due to inactivity, media-type reverted to RJ45.

At this point, the only way to reactivate the USB console port is to disconnect and reconnect the cable.

When the USB cable on the switch has been disconnected and reconnected, a log similar to this appears:

*Mar 1 00:48:28.640: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.

</tr>
<tr>
<td>Cisco IOS XE Denali 16.3.6</td>
<td>Support for Digital Optical Monitoring was introduced. It enables you to monitor optical input and output power, temperature, and voltage.  The feature is supported on all transceivers that support DOM and is disabled by default.</td>
</tr>
</tbody>
</table>
Prerequisites for Auto-MDIX

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

Automatic medium-dependent interface crossover (auto-MDIX) is enabled by default.

Auto-MDIX is supported on all 10/100/1000-Mb/s and on 10/100/1000BASE-TX small form-factor pluggable (SFP)-module interfaces. It is not supported on 1000BASE-SX or -LX SFP module interfaces.

Restrictions for Auto-MDIX

The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MIDX is enabled on the switch port.
Information About Configuring Auto-MDIX

Auto-MDIX on an Interface

When automatic medium-dependent interface crossover (auto-MDIX) is enabled on an interface, the interface automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting devices without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other devices or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

This table shows the link states that result from auto-MDIX settings and correct and incorrect cabling.

</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

### Step 2

**Example:**

Device# configure terminal

**Purpose:** Enters global configuration mode

### Step 3

**interface interface-id**

**Example:**

Device(config)# interface gigabitethernet 1/0/1

**Purpose:** Specifies the physical interface to be configured, and enter interface configuration mode.

### Step 4

**speed auto**

**Example:**

Device(config-if)# speed auto

**Purpose:** Configures the interface to autonegotiate speed with the connected device.

### Step 5

**duplex auto**

**Example:**

Device(config-if)# duplex auto

**Purpose:** Configures the interface to autonegotiate duplex mode with the connected device.

### Step 6

**end**

**Example:**

Device(config-if)# end

**Purpose:** Returns to privileged EXEC mode.

### Step 7

**copy running-config startup-config**

**Example:**

Device# copy running-config startup-config

**(Optional) Saves your entries in the configuration file.**

---

**Example for Configuring Auto-MDIX**

This example shows how to enable auto-MDIX on a port:

```
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# speed auto
Device(config-if)# duplex auto
Device(config-if)# mdix auto
```

CHAPTER 8

Configuring Ethernet Management Port

- Prerequisites for Ethernet Management Ports, on page 145
- Information About the Ethernet Management Port, on page 145
- How to Configure the Ethernet Management Port, on page 148
- Additional References for Ethernet Management Ports, on page 149
- Feature History and Information for Ethernet Management Ports, on page 149

Prerequisites for Ethernet Management Ports

When connecting a PC to the Ethernet management port, you must first assign an IP address.

Information About the Ethernet Management Port

The Ethernet management port, also referred to as the Gi0/0 or GigabitEthernet0/0 port, is a VRF (VPN routing/forwarding) interface to which you can connect a PC. You can use the Ethernet management port instead of the device console port for network management. When managing a device stack, connect the PC to the Ethernet management port on a stack member.

Ethernet Management Port Direct Connection to a Device

Figure 6: Connecting a Switch to a PC

This figure displays how to connect the Ethernet management port to the PC for a device or a standalone device.
Ethernet Management Port Connection to Stack Devices using a Hub

In a stack with only stack devices, all the Ethernet management ports on the stack members are connected to a hub to which the PC is connected. The active link is from the Ethernet management port on the active switch through the hub, to the PC. If the active device fails and a new active device is elected, the active link is now from the Ethernet management port on the new active device to the PC.

*Figure 7: Connecting a Device Stack to a PC*

This figure displays how a PC uses a hub to connect to a device stack.

<table>
<thead>
<tr>
<th>1</th>
<th>Switch stack</th>
<th>3</th>
<th>Hub</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Management port</td>
<td>4</td>
<td>PC</td>
</tr>
</tbody>
</table>

Ethernet Management Port and Routing

By default, the Ethernet management port is enabled. The device cannot route packets from the Ethernet management port to a network port, and the reverse. Even though the Ethernet management port does not support routing, you may need to enable routing protocols on the port.

*Figure 8: Network Example with Routing Protocols Enabled*

Enable routing protocols on the Ethernet management port when the PC is multiple hops away from the device and the packets must pass through multiple Layer 3 devices to reach the PC.

In the above figure, if the Ethernet management port and the network ports are associated with the same routing process, the routes are propagated as follows:

- The routes from the Ethernet management port are propagated through the network ports to the network.
• The routes from the network ports are propagated through the Ethernet management port to the network.

Because routing is not supported between the Ethernet management port and the network ports, traffic between these ports cannot be sent or received. If this happens, data packet loops occur between the ports, which disrupt the device and network operation. To prevent the loops, configure route filters to avoid routes between the Ethernet management port and the network ports.

**Supported Features on the Ethernet Management Port**

The Ethernet management port supports these features:

- Express Setup (only in switch stacks)
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SMNP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features
  - Speed—10 Mb/s, 100 Mb/s, and autonegotiation
  - Duplex mode—Full, half, and autonegotiation
  - Loopback detection
- Cisco Discovery Protocol (CDP)
- DHCP relay agent
- IPv4 and IPv6 access control lists (ACLs)
- Routing protocols

---

**Caution**

Before enabling a feature on the Ethernet management port, make sure that the feature is supported. If you try to configure an unsupported feature on the Ethernet Management port, the feature might not work properly, and the device might fail.
How to Configure the Ethernet Management Port

Disabling and Enabling the Ethernet Management Port

SUMMARY STEPS

1. configure terminal
2. interface gigabitethernet0/0
3. shutdown
4. no shutdown
5. exit
6. show interfaces gigabitethernet0/0

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About LLDP, LLDP-MED, and Wired Location Service

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, switches, and controllers). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the device supports the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol
runs over the data-link layer, which allows two systems running different network layer protocols to learn
about each other.

LLDP Supported TLVs

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type,
length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive
and send information to their neighbors. This protocol can advertise details such as configuration information,
device capabilities, and device identity.

The switch supports these basic management TLVs. These are mandatory LLDP TLVs.

• Port description TLV
• System name TLV
• System description TLV
• System capabilities TLV
• Management address TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

• Port VLAN ID TLV (IEEE 802.1 organizationally specific TLVs)
• MAC/PHY configuration/status TLV (IEEE 802.3 organizationally specific TLVs)

LLDP and Cisco Device Stacks

A device stack appears as a single device in the network. Therefore, LLDP discovers the device stack, not the
individual stack members.

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint
devices such as IP phones and network devices. It specifically provides support for voice over IP (VoIP)
applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet,
inventory management and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED Supported TLVs

LLDP-MED supports these TLVs:

• LLDP-MED capabilities TLV
  Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and has
  enabled.

• Network policy TLV
  Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated
  Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify
  a phone of the VLAN number that it should use. The phone can connect to any device, obtain its VLAN
  number, and then start communicating with the call control.
By defining a network-policy profile TLV, you can create a profile for voice and voice-signaling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

• Power management TLV

Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows devices and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

LLDP-MED also supports an extended power TLV to advertise fine-grained power requirements, end-point power priority, and end-point and network connectivity-device power status. LLDP is enabled and power is applied to a port, the power TLV determines the actual power requirement of the endpoint device so that the system power budget can be adjusted accordingly. The device processes the requests and either grants or denies power based on the current power budget. If the request is granted, the switch updates the power budget. If the request is denied, the device turns off power to the port, generates a syslog message, and updates the power budget. If LLDP-MED is disabled or if the endpoint does not support the LLDP-MED power TLV, the initial allocation value is used throughout the duration of the connection.

You can change power settings by entering the `power inline {auto [max max-wattage] | never | static [max max-wattage]}` interface configuration command. By default the PoE interface is in `auto` mode; If no value is specified, the maximum is allowed (30 W).

• Inventory management TLV

Allows an endpoint to send detailed inventory information about itself to the device, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

• Location TLV

Provides location information from the device to the endpoint device. The location TLV can send this information:

• Civic location information

  Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

• ELIN location information

  Provides the location information of a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

• Geographic location information

  Provides the geographical details of a switch location such as latitude, longitude, and altitude of a switch.

• custom location

  Provides customized name and value of a switch location.
Wired Location Service

The device uses the location service feature to send location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired device or controller. The device notifies the MSE of device link up and link down events through the Network Mobility Services Protocol (NMSP) location and attachment notifications.

The MSE starts the NMSP connection to the device, which opens a server port. When the MSE connects to the device there are a set of message exchanges to establish version compatibility and service exchange information followed by location information synchronization. After connection, the device periodically sends location and attachment notifications to the MSE. Any link up or link down events detected during an interval are aggregated and sent at the end of the interval.

When the device determines the presence or absence of a device on a link-up or link-down event, it obtains the client-specific information such as the MAC address, IP address, and username. If the client is LLDP-MED- or CDP-capable, the device obtains the serial number and UDI through the LLDP-MED location TLV or CDP.

Depending on the device capabilities, the device obtains this client information at link up:

- Slot and port specified in port connection
- MAC address specified in the client MAC address
- IP address specified in port connection
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *new*
- Serial number, UDI
- Model number
- Time in seconds since the device detected the association

Depending on the device capabilities, the device obtains this client information at link down:

- Slot and port that was disconnected
- MAC address
- IP address
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *delete*
- Serial number, UDI
- Time in seconds since the device detected the disassociation

When the device shuts down, it sends an attachment notification with the state *delete* and the IP address before closing the NMSP connection to the MSE. The MSE interprets this notification as disassociation for all the wired clients associated with the device.
If you change a location address on the device, the device sends an NMSP location notification message that identifies the affected ports and the changed address information.

**Default LLDP Configuration**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLDP global state</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP holdtime (before discarding)</td>
<td>120 seconds</td>
</tr>
<tr>
<td>LLDP timer (packet update frequency)</td>
<td>30 seconds</td>
</tr>
<tr>
<td>LLDP reinitialization delay</td>
<td>2 seconds</td>

<tr>
<td>LLDP transmit</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP med-tlv-select</td>
<td>Disabled to send all LLDP-MED TLVs. When LLDP is globally enabled, LLDP-MED-TLV is also enabled.</td>
</tr>
</tbody>
</table>

**Restrictions for LLDP**

- If the interface is configured as a tunnel port, LLDP is automatically disabled.
- If you first configure a network-policy profile on an interface, you cannot apply the `switchport voice vlan` command on the interface. If the `switchport voice vlan vlan-id` is already configured on an interface, you can apply a network-policy profile on the interface. This way the interface has the voice or voice-signaling VLAN network-policy profile applied on the interface.
- You cannot configure static secure MAC addresses on an interface that has a network-policy profile.
- When Cisco Discovery Protocol and LLDP are both in use within the same switch, it is necessary to disable LLDP on interfaces where Cisco Discovery Protocol is in use for power negotiation. LLDP can be disabled at interface level with the commands `no lldp tlv-select power-management` or `no lldp transmit / no lldp receive`. 
How to Configure LLDP, LLDP-MED, and Wired Location Service

Enabling LLDP

SUMMARY STEPS

1. enable
2. configure terminal
3. lldp run
4. interface interface-id
5. lldp transmit
6. lldp receive
7. end
8. show lldp
9. copy running-config startup-config

</table>
| **Step 6** lldp receive  
**Example:**  
Device(config-if)# **lldp receive** | |
| **Step 7** end  
**Example:**  
Device(config-if)# **end** | Returns to privileged EXEC mode. |
| **Step 8** show lldp  
**Example:**  
Device# **show lldp** | Verifies the configuration. |
| **Step 9** copy running-config startup-config  
**Example:**  
Device# **copy running-config startup-config** | (Optional) Saves your entries in the configuration file. |

### Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, and the initialization delay time. You can also select the LLDP and LLDP-MED TLVs to send and receive.

#### Note
Steps 3 through 6 are optional and can be performed in any order.

### SUMMARY STEPS

1. enable  
2. configure terminal  
3. lldp holdtime seconds  
4. lldp reinit delay  
5. lldp timer rate  
6. lldp tlv-select  
7. interface interface-id  
8. lldp med-tlv-select  
9. end
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**        | Enables privileged EXEC mode.  
| `enable`           | • Enter your password if prompted.  
| **Example:**      | Device> `enable` |
| **Step 2**        | Enters global configuration mode.  
| `configure terminal` | Device# `configure terminal` |
| **Step 3**        | (Optional) Specifies the amount of time a receiving device should hold the information from your device before discarding it.  
| `lldp holdtime seconds` | The range is 0 to 65535 seconds; the default is 120 seconds.  
| **Example:**      | Device(config)# `lldp holdtime 120` |
| **Step 4**        | (Optional) Specifies the delay time in seconds for LLDP to initialize on an interface.  
| `lldp reinit delay` | The range is 2 to 5 seconds; the default is 2 seconds.  
| **Example:**      | Device(config)# `lldp reinit 2` |
| **Step 5**        | (Optional) Sets the sending frequency of LLDP updates in seconds.  
| `lldp timer rate` | The range is 5 to 65534 seconds; the default is 30 seconds.  
| **Example:**      | Device(config)# `lldp timer 30` |
| **Step 6**        | (Optional) Specifies the LLDP TLVs to send or receive.  
| `lldp tlv-select` |  
| **Example:**      | Device(config)# `tlv-select` |
| **Step 7**        | Specifies the interface on which you are enabling LLDP, and enter interface configuration mode.  
| `interface interface-id` |  
| **Example:**      | Device (config)# `interface gigabitethernet 2/0/1` |
Configuring LLDP-MED TLVs

By default, the device only sends LLDP packets until it receives LLDP-MED packets from the end device. It then sends LLDP packets with MED TLVs, as well. When the LLDP-MED entry has been aged out, it again only sends LLDP packets.

By using the `lldp` interface configuration command, you can configure the interface not to send the TLVs listed in the following table.

*Table 12: LLDP-MED TLVs*

<table>
<thead>
<tr>
<th>LLDP-MED TLV</th>
<th>Description</th>

Configuring Network-Policy TLV

SUMMARY STEPS

1. enable
2. configure terminal
3. network-policy profile profile number
4. {voice | voice-signaling} vlan [vlan-id {cos cvalue | dscp dvalue}] [dot1p {cos cvalue | dscp dvalue}] none | untagged
5. exit
6. interface interface-id
7. network-policy profile number
8. lldp med-tlv-select network-policy
9. end
10. show network-policy profile
11. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
  Example:  
  Device# configure terminal |
| **Step 3** network-policy profile profile number | Specifies the network-policy profile number, and enter network-policy configuration mode. The range is 1 to 4294967295.  
  Example:  
  Device(config)# network-policy profile 1 |
| **Step 4** {voice | voice-signaling} vlan [vlan-id {cos cvalue | dscp dvalue}] [dot1p {cos cvalue | dscp dvalue}] none | Configures the policy attributes:  
  • voice—Specifies the voice application type.  
  • voice-signaling—Specifies the voice-signaling application type.  
  • vlan—Specifies the native VLAN for voice traffic.  
  • vlan-id—(Optional) Specifies the VLAN for voice traffic. The range is 1 to 4094.  
  Example:  
  Device(config-network-policy)# voice vlan 100 cos 4 |
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>cos</strong> <em>cvalue</em>—(Optional) Specifies the Layer 2 priority class of service (CoS) for the configured VLAN. The range is 0 to 7; the default is 5.</td>
<td></td>
</tr>
<tr>
<td>• <strong>dscp</strong> <em>dvalue</em>—(Optional) Specifies the differentiated services code point (DSCP) value for the configured VLAN. The range is 0 to 63; the default is 46.</td>
<td></td>
</tr>
<tr>
<td>• <strong>dot1p</strong>—(Optional) Configures the telephone to use IEEE 802.1p priority tagging and use VLAN 0 (the native VLAN).</td>
<td></td>
</tr>
<tr>
<td>• <strong>none</strong>—(Optional) Do not instruct the IP telephone about the voice VLAN. The telephone uses the configuration from the telephone key pad.</td>
<td></td>
</tr>
<tr>
<td>• <strong>untagged</strong>—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone.</td>
<td></td>
</tr>
<tr>
<td>• <strong>untagged</strong>—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

**exit**

*Example:*

Device(config)# exit

Returns to global configuration mode.

**Step 6**

**interface** *interface-id*

*Example:*

Device(config)# interface gigabitethernet 2/0/1

Specifies the interface on which you are configuring a network-policy profile, and enter interface configuration mode.

**Step 7**

**network-policy** *profile number*

*Example:*

Device(config-if)# network-policy 1

Specifies the network-policy profile number.

**Step 8**

**lldp med-tlv-select network-policy**

*Example:*

Device(config-if)# lldp med-tlv-select network-policy

Specifies the network-policy TLV.

**Step 9**

**end**

*Example:*

Returns to privileged EXEC mode.
Configuring Location TLV and Wired Location Service

Beginning in privileged EXEC mode, follow these steps to configure location information for an endpoint and to apply it to an interface.

### SUMMARY STEPS

1. configure terminal
2. location {admin-tag string | civic-location identifier {id | host} |elin-location string identifier id | custom-location identifier {id | host} | geo-location identifier {id | host}}
3. exit
4. interface interface-id
5. location {additional-location-information word | civic-location-id {id | host} |elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host}}
6. end
7. Use one of the following:
   - show location admin-tag string
   - show location civic-location identifier id
   - show location elin-location identifier id
8. copy running-config startup-config

### DETAILED STEPS

<tr>
<td>Device(config-civic)# country US</td>
<td></td>
</tr>
</tbody>
</table>

**Step 3** exit                                                                  Returns to global configuration mode.

Example:

Device(config-civic)# exit

**Step 4** interface interface-id                                               Specifies the interface on which you are configuring the location information, and enter interface configuration mode.

Example:

Device (config)# interface gigabitethernet2/0/1

**Step 5** location {additional-location-information word | civic-location-id {id | host} | elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host} }                                                                 Enters location information for an interface:

Example:

Device(config-if)# location elin-location-id 1

- **admin-tag**—Specifies an administrative tag or site information.
- **civic-location**—Specifies civic location information.
- **elin-location**—Specifies emergency location information (ELIN).
- **custom-location**—Specifies custom location information.
- **geo-location**—Specifies geo-spatial location information.
- **identifier id**—Specifies the ID for the civic, ELIN, custom, or geo location.
- **host**—Specifies the host civic, custom, or geo location.
- **string**—Specifies the site or location information in alphanumeric format.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| • *word*—Specifies a word or phrase with additional location information.  
• *id*—Specifies the ID for the civic, ELIN, custom, or geo location. The ID range is 1 to 4095. |

**Step 6**  
**Example:**  
Device(config-if)# **end**  
Returns to privileged EXEC mode.

**Step 7**  
**Example:**  
Device# **show location admin-tag string**  
or  
Device# **show location civic-location identifier id**  
or  
Device# **show location elin-location identifier id**  
Verifies the configuration.

**Step 8**  
**Example:**  
Device# **copy running-config startup-config**  
(Optional) Saves your entries in the configuration file.

---

**Enabling Wired Location Service on the Device**

**Before you begin**  
For wired location to function, you must first enter the **ip device tracking** global configuration command.

**SUMMARY STEPS**

1. enable  
2. configure terminal
3. `nmsp notification interval {attachment | location} interval-seconds`
4. `end`
5. `show network-policy profile`
6. `copy running-config startup-config`

### DETAILED STEPS

Configuration Examples for LLDP, LLDP-MED, and Wired Location Service

Configuring Network-Policy TLV: Examples

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
# configure terminal
(config)# network-policy 1
(config-network-policy)# voice vlan 100 cos 4
(config-network-policy)# exit
(config)# interface gigabitethernet 1/0/1
(config-if)# network-policy profile 1
(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
(config-network-policy)# voice vlan dot1p cos 4
(config-network-policy)# voice vlan dot1p dscp 34
```

Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service

Configuring System MTU

- Information About the MTU, on page 171
- How to Configure MTU Sizes, on page 172
- Configuration Examples for System MTU, on page 174
- Additional References for System MTU, on page 175
- Feature Information for System MTU, on page 175
- Information About the MTU, on page 175
- How to Configure MTU Sizes, on page 176
- Configuration Examples for System MTU, on page 178
- Additional References for System MTU, on page 179
- Feature Information for System MTU, on page 179

Information About the MTU

The default maximum transmission unit (MTU) size for frames received and sent on all device interfaces is 1500 bytes.

Restrictions for System MTU

When configuring the system MTU values, follow these guidelines:

- The device does not support the MTU on a per-interface basis.
- If you enter the `system mtu bytes` global configuration command, the command affects all the switched and routed ports on the switch.

System MTU Value Application

In a switch stack, the MTU values applied to member switches depends upon the stack configuration. The following stack configurations are supported:
The upper limit of the IP or IPv6 MTU value is based on the switch configuration and refers to the currently applied system MTU or the system jumbo MTU value. For more information about setting the MTU sizes, see the `system mtu` global configuration command in the command reference for this release.

# How to Configure MTU Sizes

## Configuring the System MTU

Follow these steps to change the MTU size for switched packets:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `system mtu bytes`
4. `end`
5. `copy running-config startup-config`
6. `show system mtu`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Device>` enable |
| Step 2 `configure terminal` | Enters global configuration mode.  
  Example:  
  Device>` configure terminal |
| Step 3 `system mtu bytes` | (Optional) Changes the MTU size for all Gigabit Ethernet and 10-Gigabit Ethernet interfaces.  
  Example:  
  Device(config)` system mtu 1900 |
| Step 4 `end` | Returns to privileged EXEC mode.  
  Example:  
  Device(config)` end |
| Step 5 `copy running-config startup-config` | Saves your entries in the configuration file.  
  Example:  
  Device>` copy running-config startup-config |
### Configuring Protocol-Specific MTU

To override system MTU values on routed interfaces, configure protocol-specific MTU under each routed interface.

Beginning in privileged EXEC mode, follow these steps to change the MTU size for routed ports:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface`
3. `ip mtu bytes`
4. `ipv6 mtu bytes`
5. `end`
6. `copy running-config startup-config`
7. `show system mtu`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td><code>Device# configure terminal</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>interface interface</code> Enters interface configuration mode.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td><code>Device(config)# interface gigabitethernet0/0</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>ip mtu bytes</code> Changes the IPv4 MTU size</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td><code>Device(config-if)# ip mtu 68</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>ipv6 mtu bytes</code> (Optional) Changes the IPv6 MTU size.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td><code>Device(config-if)# ipv6 mtu 1280</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>end</code> Returns to privileged EXEC mode.</td>

</tbody>
</table>

### Configuration Examples for System MTU

This example shows how to set the maximum packet size for a Gigabit Ethernet port to 7500 bytes:

```
Device(config)# system mtu 7500
Device(config)# exit
```

If you enter a value that is outside the allowed range for the specific type of interface, the value is not accepted. This example shows the response when you try to set Gigabit Ethernet interfaces to an out-of-range number:

```
Device(config)# system mtu 25000

### Configuration Examples for System MTU

#### Example: Configuring Protocol-Specific MTU

```
Device# configure terminal
Device(config)# interface gigabitethernet 0/0
Device(config-if)# ip mtu 900
Device(config-if)# ipv6 mtu 1286
Device(config-if)# end
```

#### Example: Configuring the System MTU

```
Device# configure terminal
Device(config)# system mtu 1600
Device(config)# exit
```

Information About the MTU

The default maximum transmission unit (MTU) size for frames received and sent on all device interfaces is 1500 bytes.

Restrictions for System MTU

When configuring the system MTU values, follow these guidelines:

- The device does not support the MTU on a per-interface basis.
- If you enter the `system mtu bytes` global configuration command, the command affects all the switched and routed ports on the switch.
System MTU Value Application

In a switch stack, the MTU values applied to member switches depends upon the stack configuration. The following stack configurations are supported:

The upper limit of the IP or IPv6 MTU value is based on the switch configuration and refers to the currently applied system MTU or the system jumbo MTU value. For more information about setting the MTU sizes, see the `system mtu` global configuration command in the command reference for this release.

How to Configure MTU Sizes

Configuring the System MTU

Follow these steps to change the MTU size for switched packets:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `system mtu bytes`
4. `end`
5. `copy running-config startup-config`
6. `show system mtu`

**DETAILED STEPS**

<table>
<thead>
<tr>

**Step 6** | verifies your settings.
show system mtu | Example:
Device# show system mtu

**Configuring Protocol-Specific MTU**

To override system MTU values on routed interfaces, configure protocol-specific MTU under each routed interface.

Beginning in privileged EXEC mode, follow these steps to change the MTU size for routed ports:

**SUMMARY STEPS**

1. configure terminal
2. interface interface
3. ip mtu bytes
4. ipv6 mtu bytes
5. end
6. copy running-config startup-config
7. show system mtu

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>

<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ipv6 mtu bytes</td>
<td>(Optional) Changes the IPv6 MTU size</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 mtu 1280</td>
<td></td>
</tr>
</tbody>
</table>
### Configuration Examples for System MTU

This example shows how to set the maximum packet size for a Gigabit Ethernet port to 7500 bytes:

```
Device(config)# system mtu 7500
Device(config)# system mtu 1900
Device(config)# exit
```

If you enter a value that is outside the allowed range for the specific type of interface, the value is not accepted. This example shows the response when you try to set Gigabit Ethernet interfaces to an out-of-range number:

```
Device(config)# system mtu 25000

^% Invalid input detected at '^' marker.
```

### Configuration Examples for System MTU

#### Example: Configuring Protocol-Specific MTU

```
Device# configure terminal
Device(config)# interface gigabitethernet 0/0
Device(config-if)# ip mtu 900
Device(config-if)# ipv6 mtu 1286
Device(config-if)# end
```
Example: Configuring the System MTU

Device# configure terminal
Device(config)# system mtu 1600
Device(config)# exit

Information About PoE

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

• a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
• an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Supported Protocols and Standards

The device uses these protocols and standards to support PoE:

• CDP with power consumption—The powered device notifies the device of the amount of power it is consuming. The device does not reply to the power-consumption messages. The device can only supply power to or remove power from the PoE port.

• Cisco intelligent power management—The powered device and the device negotiate through power-negotiation CDP messages for an agreed-upon power-consumption level. The negotiation allows a high-power Cisco powered device, which consumes more than 7 W, to operate at its highest power mode. The powered device first boots up in low-power mode, consumes less than 7 W, and negotiates to obtain enough power to operate in high-power mode. The device changes to high-power mode only when it receives confirmation from the device.

High-power devices can operate in low-power mode on devices that do not support power-negotiation CDP.
Cisco intelligent power management is backward-compatible with CDP with power consumption; the device responds according to the CDP message that it receives. CDP is not supported on third-party powered devices; therefore, the device uses the IEEE classification to determine the power usage of the device.

- IEEE 802.3af—The major features of this standard are powered-device discovery, power administration, disconnect detection, and optional powered-device power classification. For more information, see the standard.
- IEEE 802.3at—The PoE+ standard increases the maximum power that can be drawn by a powered device from 15.4 W per port to 30 W per port.
- The Cisco UPOE feature provides the capability to source up to 60 W of power (2 x 30 W) over both signal and spare pairs of the RJ-45 Ethernet cable by using the Layer-2 power negotiation protocols such as CDP or LLDP. An LLDP and CDP request of 30 W and higher in presence of the 4-wire Cisco Proprietary spare-pair power TLV can provide power on the spare pair.

**Powered-Device Detection and Initial Power Allocation**

The device detects a Cisco pre-standard or an IEEE-compliant powered device when the PoE-capable port is in the no-shutdown state, PoE is enabled (the default), and the connected device is not being powered by an AC adaptor.

After device detection, the device determines the device power requirements based on its type:

- The initial power allocation is the maximum amount of power that a powered device requires. The device initially allocates this amount of power when it detects and powers the powered device. As the device receives CDP messages from the powered device and as the powered device negotiates power levels with the device through CDP power-negotiation messages, the initial power allocation might be adjusted.
- The device classifies the detected IEEE device within a power consumption class. Based on the available power in the power budget, the device determines if a port can be powered. Table 15: IEEE Power Classifications, on page 186 lists these levels.

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum Power Level Required from the Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (class status unknown)</td>
<td>15.4 W</td>
</tr>
<tr>
<td>1</td>
<td>4 W</td>
</tr>
<tr>
<td>2</td>
<td>7 W</td>
</tr>
<tr>
<td>3</td>
<td>15.4 W</td>
</tr>
<tr>
<td>4</td>
<td>30 W (For IEEE 802.3at Type 2 powered devices)</td>
</tr>
</tbody>
</table>

The device monitors and tracks requests for power and grants power only when it is available. The device tracks its power budget (the amount of power available on the device for PoE). The device performs power-accounting calculations when a port is granted or denied power to keep the power budget up to date.

After power is applied to the port, the device uses CDP to determine the CDP-specific power consumption requirement of the connected Cisco powered devices, which is the amount of power to allocate based on the CDP messages. The device adjusts the power budget accordingly. This does not apply to third-party PoE...
devices. The device processes a request and either grants or denies power. If the request is granted, the device
updates the power budget. If the request is denied, the device ensures that power to the port is turned off,
generates a syslog message, and updates the LEDs. Powered devices can also negotiate with the device for
more power.

With PoE+, powered devices use IEEE 802.3at and LLDP power with media dependent interface (MDI) type,
length, and value descriptions (TLVs), Power-via-MDI TLVs, for negotiating power up to 30 W. Cisco
pre-standard devices and Cisco IEEE powered devices can use CDP or the IEEE 802.3at power-via-MDI
power negotiation mechanism to request power levels up to 30 W.

---

**Note**
The initial allocation for Class 0, Class 3, and Class 4 powered devices is 15.4 W. When a device starts up
and uses CDP or LLDP to send a request for more than 15.4 W, it can be allocated up to the maximum of 30
W.

---

**Note**
The CDP-specific power consumption requirement is referred to as the *actual* power consumption requirement
in the software configuration guides and command references.

If the device detects a fault caused by an undervoltage, overvoltage, overtemperature, oscillator-fault, or
short-circuit condition, it turns off power to the port, generates a syslog message, and updates the power
budget and LEDs.

The PoE feature operates the same whether or not the device is a stack member. The power budget is per
device and independent of any other device in the stack. Election of a new active device does not affect PoE
operation. The active device keeps track of the PoE status for all devices and ports in the stack and includes
the status in output displays.

### Power Management Modes

The device supports these PoE modes:

- **auto**—The device automatically detects if the connected device requires power. If the device discovers
  a powered device connected to the port and if the device has enough power, it grants power, updates the
  power budget, turns on power to the port on a first-come, first-served basis, and updates the LEDs. For
  LED information, see the hardware installation guide.

  If the device has enough power for all the powered devices, they all come up. If enough power is available
  for all powered devices connected to the device, power is turned on to all devices. If there is not enough
  available PoE, or if a device is disconnected and reconnected while other devices are waiting for power,
  it cannot be determined which devices are granted or are denied power.

  If granting power would exceed the system power budget, the device denies power, ensures that power
to the port is turned off, generates a syslog message, and updates the LEDs. After power has been denied,
the device periodically rechecks the power budget and continues to attempt to grant the request for power.

  If a device being powered by the device is then connected to wall power, the device might continue to
power the device. The device might continue to report that it is still powering the device whether the
device is being powered by the device or receiving power from an AC power source.

  If a powered device is removed, the device automatically detects the disconnect and removes power from
the port. You can connect a nonpowered device without damaging it.
You can specify the maximum wattage that is allowed on the port. If the IEEE class maximum wattage of the powered device is greater than the configured maximum value, the device does not provide power to the port. If the device powers a powered device, but the powered device later requests through CDP messages more than the configured maximum value, the device removes power to the port. The power that was allocated to the powered device is reclaimed into the global power budget. If you do not specify a wattage, the device delivers the maximum value. Use the auto setting on any PoE port. The auto mode is the default setting.

- **static**—The device pre-allocates power to the port (even when no powered device is connected) and guarantees that power will be available for the port. The device allocates the port configured maximum wattage, and the amount is never adjusted through the IEEE class or by CDP messages from the powered device. Because power is pre-allocated, any powered device that uses less than or equal to the maximum wattage is guaranteed to be powered when it is connected to the static port. The port no longer participates in the first-come, first-served model.

However, if the powered-device IEEE class is greater than the maximum wattage, the device does not supply power to it. If the device learns through CDP messages that the powered device is consuming more than the maximum wattage, the device shuts down the powered device.

If you do not specify a wattage, the device pre-allocates the maximum value. The device powers the port only if it discovers a powered device. Use the static setting on a high-priority interface.

- **never**—The device disables powered-device detection and never powers the PoE port even if an unpowered device is connected. Use this mode only when you want to make sure that power is never applied to a PoE-capable port, making the port a data-only port.

For most situations, the default configuration (auto mode) works well, providing plug-and-play operation. No further configuration is required. However, perform this task to configure a PoE port for a higher priority, to make it data only, or to specify a maximum wattage to disallow high-power powered devices on a port.

**Power Monitoring and Power Policing**

When policing of the real-time power consumption is enabled, the device takes action when a powered device consumes more power than the maximum amount allocated, also referred to as the cutoff-power value.

When PoE is enabled, the device senses the real-time power consumption of the powered device. The device monitors the real-time power consumption of the connected powered device; this is called power monitoring or power sensing. The device also polices the power usage with the power policing feature.

Power monitoring is backward-compatible with Cisco intelligent power management and CDP-based power consumption. It works with these features to ensure that the PoE port can supply power to the powered device.

The device senses the real-time power consumption of the connected device as follows:

1. The device monitors the real-time power consumption on individual ports.
2. The device records the power consumption, including peak power usage. The device reports the information through the CISCO-POWER-ETHERNET-EXT-MIB.
3. If power policing is enabled, the device polices power usage by comparing the real-time power consumption to the maximum power allocated to the device. The maximum power consumption is also referred to as the cutoff power on a PoE port.

If the device uses more than the maximum power allocation on the port, the device can either turn off power to the port, or the device can generate a syslog message and update the LEDs (the port LED is now blinking amber) while still providing power to the device based on the device configuration. By default, power-usage policing is disabled on all PoE ports.
If error recovery from the PoE error-disabled state is enabled, the device automatically takes the PoE port out of the error-disabled state after the specified amount of time.

If error recovery is disabled, you can manually re-enable the PoE port by using the `shutdown` and `no shutdown` interface configuration commands.

4. If policing is disabled, no action occurs when the powered device consumes more than the maximum power allocation on the PoE port, which could adversely affect the device.

**Power Consumption Values**

You can configure the initial power allocation and the maximum power allocation on a port. However, these values are only the configured values that determine when the device should turn on or turn off power on the PoE port. The maximum power allocation is not the same as the actual power consumption of the powered device. The actual cutoff power value that the device uses for power policing is not equal to the configured power value.

When power policing is enabled, the device polices the power usage at the switch port, which is greater than the power consumption of the device. When you manually set the maximum power allocation, you must consider the power loss over the cable from the switch port to the powered device. The cutoff power is the sum of the rated power consumption of the powered device and the worst-case power loss over the cable.

We recommend that you enable power policing when PoE is enabled on your device. For example, if policing is disabled and you set the cutoff-power value by using the `power inline auto max` command, the configured maximum power allocation on the PoE port is 6.3 W (6300 mW). The device provides power to the connected devices on the port if the device needs up to 6.3 W. If the CDP-power negotiated value or the IEEE classification value exceeds the configured cutoff value, the device does not provide power to the connected device. After the device turns on power on the PoE port, the device does not police the real-time power consumption of the device, and the device can consume more power than the maximum allocated amount, which could adversely affect the device and the devices connected to the other PoE ports.

Because a standalone device supports internal power supplies, the total amount of power available for the powered devices varies depending on the power supply configuration.

- If a power supply is removed and replaced by a new power supply with less power and the device does not have enough power for the powered devices, the device denies power to the PoE ports in auto mode in descending order of the port numbers. If the device still does not have enough power, the device then denies power to the PoE ports in static mode in descending order of the port numbers.

- If the new power supply supports more power than the previous one and the device now has more power available, the device grants power to the PoE ports in static mode in ascending order of the port numbers. If it still has power available, the device then grants power to the PoE ports in auto mode in ascending order of the port numbers.

**Cisco Universal Power Over Ethernet**

Cisco Universal Power Over Ethernet (Cisco UPOE) is a Cisco proprietary technology that extends the IEEE 802.3at PoE standard to provide the capability to source up to 60 W of power over standard Ethernet cabling infrastructure (Class D or better) by using the spare pair of an RJ-45 cable (wires 4, 5, 7, 8) with the signal pair (wires 1, 2, 3, 6). Power on the spare pair is enabled when the switch port and end device mutually identify themselves as Cisco UPOE-capable using CDP or LLDP and the end device requests for power to be enabled.
on the spare pair. When the spare pair is powered, the end device can negotiate up to 60 W of power from the switch using CDP or LLDP.

If the end device is PoE-capable on both signal and spare pairs but does not support the CDP or LLDP extensions required for Cisco UPOE, a 4-pair forced mode configuration automatically enables power on both signal and spare pairs from the switch port.

How to Configure PoE

Configuring a Power Management Mode on a PoE Port

When you make PoE configuration changes, the port being configured drops power. Depending on the new configuration, the state of the other PoE ports, and the state of the power budget, the port might not be powered up again. For example, port 1 is in the auto and on state, and you configure it for static mode. The device removes power from port 1, detects the powered device, and repowers the port. If port 1 is in the auto and on state and you configure it with a maximum wattage of 10 W, the device removes power from the port and then redetects the powered device. The device repowers the port only if the powered device is a class 1, class 2, or a Cisco-only powered device.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. power inline {auto [max max-wattage] | never | static [max max-wattage]}
5. end
6. show power inline [interface-id | module switch-number]
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>

<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the physical port to be configured, and enters interface configuration mode.</td>
</tr>
</tbody>
</table>
### Command or Action

**Device(config)# interface gigabitethernet 2/0/1**

### Purpose

Configures the PoE mode on the port. The keywords have these meanings:

- **auto**—Enables powered-device detection. If enough power is available, automatically allocates power to the PoE port after device detection. This is the default setting.
- **max** *max-wattage*—Limits the power allowed on the port. The range for Cisco UPOE ports is 4000 to 60000 mW. If no value is specified, the maximum is allowed.
- **never**—Disables device detection, and disable power to the port.

#### Note

If a port has a Cisco powered device connected to it, do not use the **power inline never** command to configure the port. A false link-up can occur, placing the port into the error-disabled state.

The device allocates power to a port configured in static mode before it allocates power to a port configured in auto mode.

### Step 4

**power inline \{auto \[max \text{max-wattage}\] \text{never} \[static \[max \text{max-wattage}\]\]**

**Example:**

**Device(config-if)# power inline auto**

### Step 5

**end**

**Example:**

**Device(config-if)# end**

### Purpose

Returns to privileged EXEC mode.

### Step 6

**show power inline \[interface-id | module switch-number\]**

**Example:**

**Device# show power inline**

### Purpose

Displays PoE status for a device or a device stack, for the specified interface, or for a specified stack member.

The **module switch-number** keywords are supported only on stacking-capable devices.

### Step 7

**copy running-config startup-config**

**Example:**

**Device# copy running-config startup-config**

(Optional) Saves your entries in the configuration file.
Enabling Power on Signal/Spare Pairs

**Note**
Do not enter this command if the end device cannot source inline power on the spare pair or if the end device supports the CDP or LLDP extensions for Cisco UPOE.

**SUMMARY STEPS**
1. `configure terminal`
2. `interface interface-id`
3. `power inline four-pair forced`
4. `end`

**DETAILED STEPS**

**Configuring Power Policing**

By default, the device monitors the real-time power consumption of connected powered devices. You can configure the device to police the power usage. By default, policing is disabled.

**SUMMARY STEPS**
1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `power inline police [action {log | errdisable}]`
5. `exit`
6. Use one of the following:

Information About EEE

EEE Overview

Energy Efficient Ethernet (EEE) is an IEEE 802.3az standard that is designed to reduce power consumption in Ethernet networks during idle periods.

Default EEE Configuration

EEE is disabled by default.

Restrictions for EEE

EEE has the following restrictions:

• Changing the EEE configuration resets the interface because the device has to restart Layer 1 autonegotiation.

• You might want to enable the Link Layer Discovery Protocol (LLDP) for devices that require longer wakeup times before they are able to accept data on their receive paths. Doing so enables the device to negotiate for extended system wakeup times from the transmitting link partner.
How to Configure EEE

You can enable or disable EEE on an interface that is connected to an EEE-capable link partner.

Enabling or Disabling EEE

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. power efficient-ethernet auto
4. no power efficient-ethernet auto
5. end
6. copy running-config startup-config

DETAILED STEPS

<table>

</table>

Following are examples of the `show eee` commands:

Switch#show eee capabilities interface gigabitEthernet2/0/1
Gi2/0/1
EEE (efficient-ethernet): yes (100-Tx and 1000T auto)
Link Partner : yes (100-Tx and 1000T auto)

ASIC/Interface : EEE Capable/EEE Enabled

Switch#show eee status interface gigabitEthernet2/0/1
Gi2/0/1 is up
EEE (efficient-ethernet): Operational
Rx LPI Status : Low Power
Tx LPI Status : Low Power
Wake Error Count : 0

ASIC EEE STATUS
Rx LPI Status : Receiving LPI
Tx LPI Status : Transmitting LPI
Link Fault Status : Link Up
Sync Status : Code group synchronization with data stream intact

Switch#show eee counters interface gigabitEthernet2/0/1
LP Active Tx Time (10us) : 66649648
LP Transitioning Tx : 462
LP Active Rx Time (10us) : 64911682
LP Transitioning Rx : 153

Examples for Cataylst Digital Building Series Switches

Switch#show eee capabilities interface gig1/0/1
Gi1/0/1
Configuration Examples for Configuring EEE

This example shows how to enable EEE for an interface:

```plaintext
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# power efficient-ethernet auto
```

This example shows how to disable EEE for an interface:

```plaintext
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# no power efficient-ethernet auto
```

Configuring MLD Snooping

This module contains details of configuring MLD snooping

• Information About Configuring IPv6 MLD Snooping, on page 205
• How to Configure IPv6 MLD Snooping, on page 209
• Displaying MLD Snooping Information, on page 217
• Configuration Examples for Configuring MLD Snooping, on page 218

Information About Configuring IPv6 MLD Snooping

Note

To use IPv6 MLD Snooping, the switch must be running the LAN Base image.

You can use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP Version 6 (IPv6) multicast data to clients and routers in a switched network on the switch. Unless otherwise noted, the term switch refers to a standalone switch and to a switch stack.

Note

Stacking is supported only on Catalyst 2960-X switches running the LAN base image.

Note

To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch.

On switches running the LAN Base feature set, the routing template is not supported.

Note

For complete syntax and usage information for the commands used in this chapter, see the command reference for this release or the Cisco IOS documentation referenced in the procedures.
Understanding MLD Snooping

In IP Version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on the links that are directly attached to the routers and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD Version 1 (MLDv1) is equivalent to IGMPv2, and MLD Version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol Version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

Note

The switch does not support MLDv2 enhanced snooping, which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address-based bridging in hardware.

According to IPv6 multicast standards, the switch derives the MAC multicast address by performing a logical-OR of the four low-order octets of the switch MAC address with the MAC address of 33:33:00:00:00:00. For example, the IPv6 MAC address of FF02:DEAD:BEEF:1:3 maps to the Ethernet MAC address of 33:33:00:01:00:03.

A multicast packet is unmatched when the destination IPv6 address does not match the destination MAC address. The switch forwards the unmatched packet in hardware based on the MAC address table. If the destination MAC address is not in the MAC address table, the switch floods the packet to all ports in the same VLAN as the receiving port.

MLD Messages

MLDv1 supports three types of messages:

- Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
- Multicast Listener Reports are the equivalent of IGMPv2 reports
- Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.
MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages. Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

**MLD Queries**

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast group address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

---

**Note**

When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the Catalyst 2960, 2960-S, 2960-C, 2960-X or 2960-CX switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

**Multicast Client Aging Robustness**

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

**Multicast Router Discovery**

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.

- Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether or not MLD snooping is enabled on the switch.
- After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

**MLD Reports**

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address is entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

**MLD Done Messages and Immediate-Leave**

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port. The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the `ipv6 mld snooping last-listener-query count` global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the `ipv6 mld snooping last-listener-query-interval` global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

When Immediate Leave is not enabled and a port receives an MLD Done message, the switch generates MASQs on the port and sends them to the IPv6 multicast address for which the Done message was sent. You can optionally configure the number of MASQs that are sent and the length of time the switch waits for a response before deleting the port from the multicast group.
When you enable MLDv1 Immediate Leave, the switch immediately removes a port from a multicast group when it detects an MLD Done message on that port. You should only use the Immediate-Leave feature when there is a single receiver present on every port in the VLAN. When there are multiple clients for a multicast group on the same port, you should not enable Immediate-Leave in a VLAN.

**Topology Change Notification Processing**

When topology change notification (TCN) solicitation is enabled by using the `ipv6 mld snooping tcn query solicit` global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the `ipv6 mld snooping tcn flood query count` global configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This is same as done in IGMP snooping.

**How to Configure IPv6 MLD Snooping**

**Default MLD Snooping Configuration**

*Table 18: Default MLD Snooping Configuration*

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>MLD snooping (Global)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLD snooping (per VLAN)</td>
<td>Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place.</td>
</tr>
<tr>
<td>IPv6 Multicast addresses</td>
<td>None configured.</td>
</tr>
<tr>
<td>IPv6 Multicast router ports</td>
<td>None configured.</td>
</tr>
<tr>
<td>MLD snooping Immediate Leave</td>
<td>Disabled.</td>
</tr>
</tbody>
</table>
| MLD snooping robustness variable | Global: 2; Per VLAN: 0.  
**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
| Last listener query count      | Global: 2; Per VLAN: 0.  
**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
| Last listener query interval   | Global: 1000 (1 second); VLAN: 0.  
**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global interval. |
### MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the `ipv6 mld snooping` global configuration command for the configuration to take effect.

- When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch.

- The maximum number of multicast entries allowed on the switch or switch stack is determined by the configured SDM template.

- The maximum number of address entries allowed for the switch or switch stack is 4000.

### Enabling or Disabling MLD Snooping on the Switch

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis or for a range of VLANs, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

To globally enable MLD snooping on the switch, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device&gt; enable</code></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Device# configure terminal**

### Purpose

Enables privileged EXEC mode.

**Device# configure terminal**

### Step 3

**ipv6 mld snooping**  
**Example:**  
Device(config)# ipv6 mld snooping

Enables MLD snooping on the switch.

**Example:**  
Device(config)# ipv6 mld snooping

### Step 4

**end**  
**Example:**  
Device(config)# end

Returns to privileged EXEC mode.

**Example:**  
Device(config)# end

### Step 5

**copy running-config startup-config**  
**Example:**  
Device(config)# copy running-config startup-config

(Optional) Save your entries in the configuration file.

**Example:**  
Device(config)# copy running-config startup-config

### Step 6

**reload**  
**Example:**  
Device(config)# reload

Reload the operating system.

**Example:**  
Device(config)# reload

---

### Enabling or Disabling MLD Snooping on a VLAN

To enable MLD snooping on a VLAN, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a Static Multicast Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

To add a Layer 2 port as a member of a multicast group, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  enable          | Enables privileged EXEC mode.  
  Example:
  Device> enable |
| **Step 2**
  configure terminal | Enters global configuration mode.  
  Example:
  Device# configure terminal |
| **Step 3**
  ipv6 mld snooping vlan vlan-id static  
  ipv6_multicast_address interface interface-id | Configures a multicast group with a Layer 2 port as a member of a multicast group:  
  - *vlan-id* is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094.  
  - *ipv6_multicast_address* is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373.  
  Example:
  Device(config)# ipv6 mld snooping vlan 1 static 3333.0000.1111 interface gigabitethernet 0/1 |
### Configuring a Multicast Router Port

**Note**

Static connections to multicast routers are supported only on switch ports.

To add a multicast router port to a VLAN, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ipv6 mld snooping vlan vlan-id mrouter interface interface-id</td>
<td>Specifies the multicast router VLAN ID, and specify the interface to the multicast router.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ipv6 mld snooping vlan 1 mrouter interface gigabitethernet</td>
<td></td>
</tr>
</tbody>
</table>
### Enabling MLD Immediate Leave

To enable MLDv1 immediate leave, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  
  `enable`
  
  **Example:**
  
  Device> `enable`
  |
  |
  Enables privileged EXEC mode.
  
  Enter your password if prompted.
  |
| **Step 2**
  
  `configure terminal`
  
  **Example:**
  
  Device# `configure terminal`
  |
  |
  Enters global configuration mode.
  |
| **Step 3**
  
  `ipv6 mld snooping vlan `vlan-id` immediate-leave`
  
  **Example:**
  
  Device(config)# `ipv6 mld snooping vlan 1 immediate-leave`
  |
  |
  Enables MLD Immediate Leave on the VLAN interface.
  |
| **Step 4**
  
  `end`
  
  **Example:**
  
  Device(config)# `end`
  |
  |
  Returns to privileged EXEC mode.
  |
| **Step 5**
  
  `show ipv6 mld snooping vlan `vlan-id``
  
  **Example:**
  
  Device# `show ipv6 mld snooping vlan 1`
  |
  |
  Verifies that Immediate Leave is enabled on the VLAN interface.
## Configuring MLD Snooping Queries

To configure MLD snooping query characteristics for the switch or for a VLAN, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>ipv6 mld snooping robustness-variable value</code></td>
<td>(Optional) Sets the number of queries that are sent before switch will deletes a listener (port) that does not respond to a general query. The range is 1 to 3; the default is 2.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# ipv6 mld snooping robustness-variable 3</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>ipv6 mld snooping vlan vlan-id robustness-variable value</code></td>
<td>(Optional) Sets the robustness variable on a VLAN basis, which determines the number of general queries that MLD snooping sends before aging out a multicast address when there is no MLD report response. The range is 1 to 3; the default is 0. When set to 0, the number used is the global robustness variable value.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# ipv6 mld snooping vlan 1 robustness-variable 3</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>ipv6 mld snooping last-listener-query-count count</code></td>
<td>(Optional) Sets the number of MASQs that the switch sends before aging out an MLD client. The range is 1 to 7; the default is 2. The queries are sent 1 second apart.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# ipv6 mld snooping last-listener-query-count 7</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>ipv6 mld snooping vlan vlan-id last-listener-query-count count</code></td>
<td>(Optional) Sets the last-listener query count on a VLAN basis. This value overrides the value configured globally. The range is 1 to 7; the default is 0. When set to 0, the global count value is used. Queries are sent 1 second apart.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# ipv6 mld snooping vlan 1 last-listener-query-count 7</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><code>ipv6 mld snooping last-listener-query-interval interval</code></td>
<td>(Optional) Sets the maximum response time that the switch waits after sending out a MASQ before deleting a port from the multicast group. The range is 100 to 32,768 thousands of a second. The default is 1000 (1 second).</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# ipv6 mld snooping last-listener-query-interval 2000</code></td>
<td></td>
</tr>
</tbody>
</table>
### Disabling MLD Listener Message Suppression

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

To disable MLD listener message suppression, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 3</strong> no ipv6 mld snooping listener-message-suppression</td>
<td>Disable MLD message suppression.</td>
</tr>
</tbody>
</table>
| **Example:**  
  Device(config)# no ipv6 mld snooping listener-message-suppression | |
| **Step 4** end | Return to privileged EXEC mode. |
| **Example:**  
  Device(config)# end | |
| **Step 5** show ipv6 mld snooping | Verify that IPv6 MLD snooping report suppression is disabled. |
| **Example:**  
  Device# show ipv6 mld snooping | |

## Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display IPv6 group address multicast entries for a VLAN configured for MLD snooping.

**Table 19: Commands for Displaying MLD Snooping Information**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **show ipv6 mld snooping [ vlan vlan-id ]** | Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN.  
(Optional) Enter `vlan vlan-id` to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| **show ipv6 mld snooping mrouter [ vlan vlan-id ]** | Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces.  
(Optional) Enters `vlan vlan-id` to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| **show ipv6 mld snooping querier [ vlan vlan-id ]** | Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN.  
(Optional) Enters `vlan vlan-id` to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
### Configuration Examples for Configuring MLD Snooping

#### Configuring a Static Multicast Group: Example

This example shows how to statically configure an IPv6 multicast group:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 2 static 3333.0000.1111 interface gigabitethernet1/0/1
Device(config)# end
```

#### Configuring a Multicast Router Port: Example

This example shows how to add a multicast router port to VLAN 200:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet0/2
Device(config)# exit
```

#### Enabling MLD Immediate Leave: Example

This example shows how to enable MLD Immediate Leave on VLAN 130:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 130 immediate-leave
Device(config)# exit
```
Configuring MLD Snooping Queries: Example

This example shows how to set the MLD snooping global robustness variable to 3:

```conf
Device# configure terminal
Device(config)# ipv6 mld snooping robustness-variable 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```conf
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```conf
Device# configure terminal
Device(config)# ipv6 mld snooping last-listener-query-interval 2000
Device(config)# exit
```
CHAPTER 15

Configuring IPv6 Unicast Routing

• Information About Configuring IPv6 Unicast Routing, on page 221
• Configuring DHCP for IPv6 Address Assignment, on page 249
• Configuration Examples for IPv6 Unicast Routing, on page 253

Information About Configuring IPv6 Unicast Routing

This chapter describes how to configure IPv6 unicast routing on the switch.

Note
To use all IPv6 features in this chapter, the switch or stack master must be running the IP services feature set. Switches running the IP base feature set support IPv6 static routing, RIP for IPv6, and OSPF. Switches running the LAN base feature set support only IPv6 host functionality.

Understanding IPv6

IPv4 users can move to IPv6 and receive services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to:

For information about IPv6 and other features in this chapter

• See the Cisco IOS IPv6 Configuration Library.

• Use the Search field on Cisco.com to locate the Cisco IOS software documentation. For example, if you want information about static routes, you can enter Implementing Static Routes for IPv6 in the search field to learn about static routes.

IPv6 Addresses

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses, or anycast addresses.
The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: n:n:n:n:n:n:n:n. This is an example of an IPv6 address:
2031:0000:130F:0000:0000:09C0:080F:130B
For easier implementation, leading zeros in each field are optional. This is the same address without leading zeros:
2031:0:130F:0:0:9C0:80F:130B
You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:
2031:0:130F::09C0:080F:130B
In the “Information About Implementing Basic Connectivity for IPv6” chapter, these sections apply to the switch:
• IPv6 Address Formats
• IPv6 Address Type: Unicast
• IPv6 Address Type: Multicast
• IPv6 Address Output Display
• Simplified IPv6 Packet Header

**Supported IPv6 Unicast Routing Features**

These sections describe the IPv6 protocol features supported by the switch:
The switch provides IPv6 routing capability over Routing Information Protocol (RIP) for IPv6, and Open Shortest Path First (OSPF) Version 3 Protocol. It supports up to 16 equal-cost routes and can simultaneously forward IPv4 and IPv6 frames at line rate.

**128-Bit Wide Unicast Addresses**
The switch supports aggregatable global unicast addresses and link-local unicast addresses. It does not support site-local unicast addresses.

• Aggregatable global unicast addresses are IPv6 addresses from the aggregatable global unicast prefix. The address structure enables strict aggregation of routing prefixes and limits the number of routing table entries in the global routing table. These addresses are used on links that are aggregated through organizations and eventually to the Internet service provider.

These addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). Addresses with a prefix of 2000::/3(001) through E000::/3(111) must have 64-bit interface identifiers in the extended unique identifier (EUI)-64 format.

• Link local unicast addresses can be automatically configured on any interface by using the link-local prefix FE80::/10(1111 1110 10) and the interface identifier in the modified EUI format. Link-local addresses are used in the neighbor discovery protocol (NDP) and the stateless autoconfiguration process.
Nodes on a local link use link-local addresses and do not require globally unique addresses to communicate. IPv6 routers do not forward packets with link-local source or destination addresses to other links.

For more information, see the section about IPv6 unicast addresses in the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**DNS for IPv6**

IPv6 supports Domain Name System (DNS) record types in the DNS name-to-address and address-to-name lookup processes. The DNS AAAA resource record types support IPv6 addresses and are equivalent to an A address record in IPv4. The switch supports DNS resolution for IPv4 and IPv6.

**Path MTU Discovery for IPv6 Unicast**

The switch supports advertising the system maximum transmission unit (MTU) to IPv6 nodes and path MTU discovery. Path MTU discovery allows a host to dynamically discover and adjust to differences in the MTU size of every link along a given data path. In IPv6, if a link along the path is not large enough to accommodate the packet size, the source of the packet handles the fragmentation.

**ICMPv6**

The Internet Control Message Protocol (ICMP) in IPv6 generates error messages, such as ICMP destination unreachable messages, to report errors during processing and other diagnostic functions. In IPv6, ICMP packets are also used in the neighbor discovery protocol and path MTU discovery.

**Neighbor Discovery**

The switch supports NDP for IPv6, a protocol running on top of ICMPv6, and static neighbor entries for IPv6 stations that do not support NDP. The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), to verify the reachability of the neighbor, and to keep track of neighboring routers.

The switch supports ICMPv6 redirect for routes with mask lengths less than 64 bits. ICMP redirect is not supported for host routes or for summarized routes with mask lengths greater than 64 bits.

Neighbor discovery throttling ensures that the switch CPU is not unnecessarily burdened while it is in the process of obtaining the next hop forwarding information to route an IPv6 packet. The switch drops any additional IPv6 packets whose next hop is the same neighbor that the switch is actively trying to resolve. This drop avoids further load on the CPU.

**Default Router Preference**

The switch supports IPv6 default router preference (DRP), an extension in router advertisement messages. DRP improves the ability of a host to select an appropriate router, especially when the host is multihomed and the routers are on different links. The switch does not support the Route Information Option in RFC 4191.

An IPv6 host maintains a default router list from which it selects a router for traffic to offlink destinations. The selected router for a destination is then cached in the destination cache. NDP for IPv6 specifies that routers that are reachable or probably reachable are preferred over routers whose reachability is unknown or suspect. For reachable or probably reachable routers, NDP can either select the same router every time or cycle through the router list. By using DRP, you can configure an IPv6 host to prefer one router over another, provided both are reachable or probably reachable.

For configuring DRP for IPv6, see the Configuring Default Router Preference section.

For more information about DRP for IPv6, see the Cisco IOS IPv6 Configuration Library on Cisco.com.
IPv6 Stateless Autoconfiguration and Duplicate Address Detection

The switch uses stateless autoconfiguration to manage link, subnet, and site addressing changes, such as management of host and mobile IP addresses. A host autonomously configures its own link-local address, and booting nodes send router solicitations to request router advertisements for configuring interfaces.

Beginning from Cisco IOS XE Gibraltar 16.11.1, an autoconfigured IPv6 address will contain interface identifiers that are not part of the reserved interface identifiers range specified in RFC5453.

For more information about autoconfiguration and duplicate address detection, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of Cisco IOS IPv6 Configuration Library on Cisco.com.

IPv6 Applications

The switch has IPv6 support for these applications:

• Ping, traceroute, Telnet, and TFTP
• Secure Shell (SSH) over an IPv6 transport
• HTTP server access over IPv6 transport
• DNS resolver for AAAA over IPv4 transport
• Cisco Discovery Protocol (CDP) support for IPv6 addresses

For more information about managing these applications, see the Cisco IOS IPv6 Configuration Library on Cisco.com.

DHCP for IPv6 Address Assignment

DHCPv6 enables DHCP servers to pass configuration parameters, such as IPv6 network addresses, to IPv6 clients. The address assignment feature manages non-duplicate address assignment in the correct prefix based on the network where the host is connected. Assigned addresses can be from one or multiple prefix pools. Additional options, such as default domain and DNS name-server address, can be passed back to the client. Address pools can be assigned for use on a specific interface, on multiple interfaces, or the server can automatically find the appropriate pool.

For configuring DHCP for IPv6, see the Configuring DHCP for IPv6 Address Assignment section.

For more information about configuring the DHCPv6 client, server, or relay agent functions, see the Cisco IOS IPv6 Configuration Library on Cisco.com.

Static Routes for IPv6

Static routes are manually configured and define an explicit route between two networking devices. Static routes are useful for smaller networks with only one path to an outside network or to provide security for certain types of traffic in a larger network.

For configuring static routes for IPv6, see the Configuring Static Routing for IPv6 section.

For more information about static routes, see the “Implementing Static Routes for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.
Policy-Based Routing for IPv6

Policy-based routing (PBR) gives you a flexible means of routing packets by allowing you to configure a defined policy for traffic flows, which lessens reliance on routes derived from routing protocols. Therefore, PBR gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols. PBR allows you to set the IPv6 precedence. For a simple policy, you can use any one of these tasks; for a complex policy, you can use all of them. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link.

PBR for IPv6 may be applied to both forwarded and originated IPv6 packets. For forwarded packets, PBR for IPv6 will be implemented as an IPv6 input interface feature, supported in the following forwarding paths:

- Process
- Cisco Express Forwarding (formerly known as CEF)
- Distributed Cisco Express Forwarding

Policies can be based on the IPv6 address, port numbers, protocols, or packet size.

PBR allows you to perform the following tasks:

- Classify traffic based on extended access list criteria. Access lists, then, establish the match criteria.
- Set IPv6 precedence bits, giving the network the ability to enable differentiated classes of service.
- Route packets to specific traffic-engineered paths; you might need to route them to allow a specific quality of service (QoS) through the network.

PBR allows you to classify and mark packets at the edge of the network. PBR marks a packet by setting precedence value. The precedence value can be used directly by devices in the network core to apply the appropriate QoS to a packet, which keeps packet classification at your network edge.

For enabling PBR for IPv6, see the Enabling Local PBR for IPv6 section.

For enabling IPv6 PBR for an interface, see the Enabling IPv6 PBR on an Interface section.

RIP for IPv6

Routing Information Protocol (RIP) for IPv6 is a distance-vector protocol that uses hop count as a routing metric. It includes support for IPv6 addresses and prefixes and the all-RIP-routers multicast group address FF02::9 as the destination address for RIP update messages.

For configuring RIP for IPv6, see the Configuring RIP for IPv6 section.

For more information about RIP for IPv6, see the “Implementing RIP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

OSPF for IPv6

The switch running the IP Base feature set supports Open Shortest Path First (OSPF) for IPv6, a link-state protocol for IP. For more information, see Cisco IOS IPv6 Configuration Library on Cisco.com.

Configuring HSRP for IPv6

HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.
An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address. Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

**Note**

When configuring HSRP for IPv6, you must enable HSRP version 2 (HSRIPv2) on the interface.

**EIGRP IPv6**

Switches support the Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address. Switches running IP Lite only support EIGRPv6 stub routing.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv6 address, so any IPv6 node always has an available router ID. However, EIGRP IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv6 router ID.

For more information about EIGRP for IPv6, see the “Implementing EIGRP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

**EIGRPv6 Stub Routing**

The EIGRPv6 stub routing feature, reduces resource utilization by moving routed traffic closer to the end user.

In a network using EIGRPv6 stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with EIGRPv6 stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRPv6 stub routing, you need to configure the distribution and remote routers to use EIGRPv6 and to configure only the switch as a stub. Only specified routes are propagated from the switch. The switch responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In the figure given below, switch B is configured as an EIGRPv6 stub router. Switches A and C are connected to the rest of the WAN. Switch B advertises connected, static, redistribution, and summary routes to switch A and C. Switch B does not advertise any routes learned from switch A (and the reverse).
For more information about EIGRPv6 stub routing, see “Implementing EIGRP for IPv6” section of the *Cisco IOS IP Configuration Guide, Volume 2 of 3: Routing Protocols, Release 12.4*.

**SNMP and Syslog Over IPv6**

To support both IPv4 and IPv6, IPv6 network management requires both IPv6 and IPv4 transports. Syslog over IPv6 supports address data types for these transports.

Simple Network Management Protocol (SNMP) and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and to modify the SNMP agent to support traps for an IPv6 host
- SNMP- and syslog-related MIBs to support IPv6 addressing
- Configuration of IPv6 hosts as trap receivers

For support over IPv6, SNMP modifies the existing IP transport mapping to simultaneously support IPv4 and IPv6. These SNMP actions support IPv6 transport management:

- Opens User Datagram Protocol (UDP) SNMP socket with default settings
- Provides a new transport mechanism called *SR_IPV6_TRANSPORT*
- Sends SNMP notifications over IPv6 transport
- Supports SNMP-named access lists for IPv6 transport
- Supports SNMP proxy forwarding using IPv6 transport
- Verifies SNMP Manager feature works with IPv6 transport

For information on SNMP over IPv6, including configuration procedures, see the “Managing Cisco IOS Applications over IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

For information about syslog over IPv6, including configuration procedures, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.
HTTP(S) Over IPv6

The HTTP client sends requests to both IPv4 and IPv6 HTTP servers, which respond to requests from both IPv4 and IPv6 HTTP clients. URLs with literal IPv6 addresses must be specified in hexadecimal using 16-bit values between colons.

The accept socket call chooses an IPv4 or IPv6 address family. The accept socket is either an IPv4 or IPv6 socket. The listening socket continues to listen for both IPv4 and IPv6 signals that indicate a connection. The IPv6 listening socket is bound to an IPv6 wildcard address.

The underlying TCP/IP stack supports a dual-stack environment. HTTP relies on the TCP/IP stack and the sockets for processing network-layer interactions.

Basic network connectivity (ping) must exist between the client and the server hosts before HTTP connections can be made.

For more information, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

Unsupported IPv6 Unicast Routing Features

The switch does not support these IPv6 features:

- IPv6 packets destined to site-local addresses
- Tunneling protocols, such as IPv4-to-IPv6 or IPv6-to-IPv4
- The switch as a tunnel endpoint supporting IPv4-to-IPv6 or IPv6-to-IPv4 tunneling protocols
- IPv6 Web Cache Communication Protocol (WCCP)

IPv6 Feature Limitations

Because IPv6 is implemented in switch hardware, some limitations occur due to the IPv6 compressed addresses in the hardware memory. These hardware limitations result in some loss of functionality and limits some features.

These are feature limitations.

- The switch cannot forward SNAP-encapsulated IPv6 packets in hardware. They are forwarded in software.
- The switch cannot apply QoS classification on source-routed IPv6 packets in hardware.

IPv6 and Switch Stacks

The switch supports IPv6 forwarding across the stack and IPv6 host functionality on the stack master. The stack master runs the IPv6 unicast routing protocols and computes the routing tables. They receive the tables and create hardware IPv6 routes for forwarding. The stack master also runs all IPv6 applications.

Note

To route IPv6 packets in a stack, all switches in the stack should be running the IP Base feature set.

If a new switch becomes the stack master, it recomputes the IPv6 routing tables and distributes them to the member switches. While the new stack master is being elected and is resetting, the switch stack does not forward IPv6 packets. The stack MAC address changes, which also changes the IPv6 address. When you
specify the stack IPv6 address with an extended unique identifier (EUI) by using the `ipv6 address ipv6-prefix/prefix-length eui-64` interface configuration command, the address is based on the interface MAC address. See the Configuring IPv6 Addressing and Enabling IPv6 Routing.

If you configure the persistent MAC address feature on the stack and the stack master changes, the stack MAC address does not change for approximately 4 minutes.

These are the functions of IPv6 stack master and members:

- **Stack master:**
  - runs IPv6 routing protocols
  - generates routing tables
  - distributes routing tables to stack members that use distributed Cisco Express Forwarding for IPv6
  - runs IPv6 host functionality and IPv6 applications

- **Stack member (must be running the IP services feature set):**
  - receives Cisco Express Forwarding for IPv6 routing tables from the stack master
  - programs the routes into hardware

**Note**
IPv6 packets are routed in hardware across the stack if the packet does not have exceptions (IPv6 Options) and the switches in the stack have not run out of hardware resources.

- flushes the Cisco Express Forwarding for IPv6 tables on master re-election

### Default IPv6 Configuration

Configuring IPv6 Addressing and Enabling IPv6 Routing

This section describes how to assign IPv6 addresses to individual Layer 3 interfaces and to globally forward IPv6 traffic on the switch.

Before configuring IPv6 on the switch, consider these guidelines:

• Not all features discussed in this chapter are supported by the switch. See the Unsupported IPv6 Unicast Routing Features, on page 228.

• In the `ipv6 address` interface configuration command, you must enter the `ipv6-address` and `ipv6-prefix` variables with the address specified in hexadecimal using 16-bit values between colons. The `prefix-length` variable (preceded by a slash `/`) is a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address).

To forward IPv6 traffic on an interface, you must configure a global IPv6 address on that interface. Configuring an IPv6 address on an interface automatically configures a link-local address and activates IPv6 for the interface. The configured interface automatically joins these required multicast groups for that link:

• solicited-node multicast group FF02::1:ff00::/104 for each unicast address assigned to the interface (this address is used in the neighbor discovery process.)

• all-nodes link-local multicast group FF02::1

• all-routers link-local multicast group FF02::2

To remove an IPv6 address from an interface, use the `no ipv6 address ipv6-prefix/prefix length eui-64` or `no ipv6 address ipv6-address link-local` interface configuration command. To remove all manually configured IPv6 addresses from an interface, use the `no ipv6 address` interface configuration command without arguments. To disable IPv6 processing on an interface that has not been explicitly configured with an IPv6 address, use the `no ipv6 enable` interface configuration command. To globally disable IPv6 routing, use the `no ipv6 unicast-routing` global configuration command.

For more information about configuring IPv6 routing, see the “Implementing Addressing and Basic Connectivity for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to assign an IPv6 address to a Layer 3 interface and enable IPv6 routing:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>`sdm prefer dual-ipv4-and-ipv6 { advanced</td>
<td>vlan}`</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# sdm prefer dual-ipv4-and-ipv6 default</td>
<td>- Sets the switch to the default template to balance system resources.</td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>• vlan—Maximizes VLAN configuration on the switch with no routing supported in hardware.</td>
<td>• vlan</td>
</tr>
<tr>
<td>Note Advanced is available at all license levels. VLAN template is available only in LAN Base license.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 3

**Example:**

Device(config)# end

### Step 4

**Example:**

Device# reload

### Step 5

**Example:**

Device# configure terminal

### Step 6

**Example:**

Device(config)# interface gigabitethernet 1/0/1

### Step 7

**Example:**

Device(config-if)# no switchport

### Step 8

**Example:**

Device(config)# interface gigabitethernet 1/0/1

**Use one of the following:**

• ipv6 address ipv6-prefix/prefix length eui-64
• ipv6 address ipv6-address/prefix length
• ipv6 address ipv6-address link-local
• ipv6 enable
• ipv6 address WORD
• ipv6 address autoconfig
• ipv6 address dhcp

• Specifies a global IPv6 address with an extended unique identifier (EUI) in the low-order 64 bits of the IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address. This enables IPv6 processing on the interface.

• Manually configures an IPv6 address on the interface.

• Specifies a link-local address on the interface to be used instead of the link-local address that is automatically configured when IPv6 is enabled on
### Command or Action

- **Device(config-if)# ipv6 address**
  - `2001:0DB8:c18:1::/64 eui 64`

- **Device(config-if)# ipv6 enable**

### Purpose

- Enables IPv6 processing on the interface.
- **Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link.**

### Step 9

- **exit**
  - **Example:**
    
    Device(config-if)# exit

### Step 10

- **ip routing**
  - **Example:**
    
    Device(config)# ip routing

### Step 11

- **ipv6 unicast-routing**
  - **Example:**
    
    Device(config)# ipv6 unicast-routing

### Step 12

- **end**
  - **Example:**
    
    Device(config)# end

### Step 13

- **show ipv6 interface interface-id**
  - **Example:**
    
    Device# show ipv6 interface gigabitethernet 1/0/1

### Step 14

- **copy running-config startup-config**
  - **Example:**
    
    Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
Configuring IPv4 and IPv6 Protocol Stacks

To configure a Layer 3 interface to support both IPv4 and IPv6 and to enable IPv6 routing, perform this procedure:

1. **enable**
2. **configure terminal**
3. **ip routing**
4. **ipv6 unicast-routing**
5. **interface interface-id**
6. **no switchport**
7. **ip address ip-address mask** [secondary]
8. Use one of the following:
   - **ipv6 address ipv6-prefix/prefix-length eui-64**
   - **ipv6 address ipv6-address/prefix-length**
   - **ipv6 address ipv6-address link-local**
   - **ipv6 enable**
   - **ipv6 address WORD**
   - **ipv6 address autoconfig**
   - **ipv6 address dhcp**
9. **end**
10. Use one of the following:
    - **show interface interface-id**
    - **show ip interface interface-id**
    - **show ipv6 interface interface-id**
11. **copy running-config startup-config**

**Note**
To disable IPv6 processing on an interface that has not been configured with an IPv6 address, use the `no ipv6 enable` interface configuration command.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip routing**
4. **ipv6 unicast-routing**
5. **interface interface-id**
6. **no switchport**
7. **ip address ip-address mask** [secondary]
8. Use one of the following:
   - **ipv6 address ipv6-prefix/prefix-length eui-64**
   - **ipv6 address ipv6-address/prefix-length**
   - **ipv6 address ipv6-address link-local**
   - **ipv6 enable**
   - **ipv6 address WORD**
   - **ipv6 address autoconfig**
   - **ipv6 address dhcp**
9. **end**
10. Use one of the following:
    - **show interface interface-id**
    - **show ip interface interface-id**
    - **show ipv6 interface interface-id**
11. **copy running-config startup-config**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Device# configure terminal</strong></td>
<td>Enables routing on the switch.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Device(config)# ip routing</strong></td>
</tr>
</tbody>
</table>

### Example:

```
Device(config)# ip routing
```

**Purpose:** Enables forwarding of IPv6 data packets on the switch.

**Step 4**

**Device(config)# ipv6 unicast-routing**

### Example:

```
Device(config)# ipv6 unicast-routing
```

**Purpose:** Enters interface configuration mode, and specifies the Layer 3 interface to configure.

**Step 5**

**Device(config)# interface gigabitethernet 1/0/1**

**Purpose:** Removes the interface from Layer 2 configuration mode (if it is a physical interface).

**Step 6**

**Device(config-if)# no switchport**

### Example:

```
Device(config-if)# no switchport
```

**Purpose:** Specifies a primary or secondary IPv4 address for the interface.

**Step 7**

**Device(config-if)# ip address 10.1.2.3 255.255.255.255**

### Example:

```
Device(config-if)# ip address 10.1.2.3 255.255.255.255
```

**Purpose:**
- Specifies a global IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address.
- Specifies a link-local address on the interface to be used instead of the automatically configured link-local address when IPv6 is enabled on the interface.
- Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link.

**Note**

To remove all manually configured IPv6 addresses from an interface, use the **no ipv6 address** interface configuration command without arguments.
**Configuring Default Router Preference**

Router advertisement messages are sent with the default router preference (DRP) configured by the `ipv6 nd router-preference` interface configuration command. If no DRP is configured, RAs are sent with a medium preference.

A DRP is useful when two routers on a link might provide equivalent, but not equal-cost routing, and policy might dictate that hosts should prefer one of the routers.

For more information about configuring DRP for IPv6, see the “Implementing IPv6 Addresses and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

To configure a DRP for a router on an interface, perform this procedure:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>interface interface-id</td>
<td>Enters interface configuration mode and identifies the Layer 3 interface on which you want to specify the DRP.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
</tbody>
</table>
**Configuring IPv6 ICMP Rate Limiting**

ICMP rate limiting is enabled by default with a default interval between error messages of 100 milliseconds and a bucket size (maximum number of tokens to be stored in a bucket) of 10.

To change the ICMP rate-limiting parameters, perform this procedure:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Purpose**: Configuring IPv6 ICMP Rate Limiting

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong> ipv6 nd router-preference {high</td>
<td>Specifies a DRP for the router on the switch</td>
</tr>
<tr>
<td>medium</td>
<td>low}</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# ipv6 nd router-preference</td>
</tr>
<tr>
<td></td>
<td>medium</td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
</tr>
<tr>
<td><strong>Step 6</strong> show ipv6 interface</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show ipv6 interface</td>
</tr>
<tr>
<td><strong>Step 7</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the config</td>
</tr>
</tbody>
</table>
IPv6

Configuring Cisco Express Forwarding and distributed Cisco Express Forwarding for IPv6

Cisco Express Forwarding is a Layer 3 IP switching technology to improve network performance. Cisco Express Forwarding implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. It is less CPU-intensive than fast-switching route-caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed Cisco Express Forwarding in the stack. IPv4 Cisco Express Forwarding and distributed Cisco Express Forwarding are enabled by default. IPv6 Cisco Express Forwarding and distributed Cisco Express Forwarding are disabled by default, but automatically enabled when you configure IPv6 routing.

IPv6 Cisco Express Forwarding and distributed Cisco Express Forwarding are automatically disabled when IPv6 routing is unconfigured. IPv6 Cisco Express Forwarding and distributed Cisco Express Forwarding cannot be disabled through configuration. You can verify the IPv6 state by entering the `show ipv6 cef` privileged EXEC command.

To route IPv6 unicast packets, you must first globally configure forwarding of IPv6 unicast packets by using the `ipv6 unicast-routing` global configuration command, and you must configure an IPv6 address and IPv6 processing on an interface by using the `ipv6 address` interface configuration command.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td>Configure the interval and bucket size for IPv6 ICMP error messages:</td>
</tr>
<tr>
<td><code>ipv6 icmp error-interval interval [bucketsize]</code></td>
<td>- <code>interval</code>—The interval (in milliseconds) between tokens being added to the bucket. The range is from 0 to 2147483647 milliseconds.</td>
</tr>
<tr>
<td>Example:</td>
<td>- <code>bucketsize</code>—(Optional) The maximum number of tokens stored in the bucket. The range is from 1 to 200.</td>
</tr>
<tr>
<td><code>Device(config)# ipv6 icmp error-interval 50 20</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 4**        | Returns to privileged EXEC mode. |
| `end`             | Example: |
| `Device(config)# end` | |

| **Step 5**        | Verifies your entries. |
| `show ipv6 interface [interface-id]` | Example: |
| `Device# show ipv6 interface gigabitethernet0/1` | |

| **Step 6**        | (Optional) Saves your entries in the configuration file. |
| `copy running-config startup-config` | Example: |
| `Device# copy running-config startup-config` | |
For more information about configuring Cisco Express Forwarding and distributed Cisco Express Forwarding, see Cisco IOS IPv6 Configuration Library on Cisco.com.

## Configuring Static Routing for IPv6

For more information about configuring static IPv6 routing, see the “Implementing Static Routes for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

To configure static IPv6 routing, perform this procedure:

### Before you begin

You must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on at least one Layer 3 interface by configuring an IPv6 address on the interface.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
- `enable`  
  **Example:** Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
- `configure terminal`  
  **Example:** Device# configure terminal | Enters global configuration mode. |
| **Step 3**
- `ipv6 route`  
  **Example:** Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130 | Configures a static IPv6 route.  
  - `ipv6-prefix`—The IPv6 network that is the destination of the static route. It can also be a hostname when static host routes are configured.  
  - `/prefix length`—The length of the IPv6 prefix. A decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark must precede the decimal value.  
  - `ipv6-address`—The IPv6 address of the next hop that can be used to reach the specified network. The IPv6 address of the next hop need not be directly connected; recursion is done to find the IPv6 address of the directly connected next hop. The address must be in the form documented in RFC 2373, specified in hexadecimal using 16-bit values between colons.  
  - `interface-id`—Specifies direct static routes from point-to-point and broadcast interfaces. With |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>point-to-point interfaces, there is no need to specify the IPv6 address of the next hop. With broadcast interfaces, you should always specify the IPv6 address of the next hop, or ensure that the specified prefix is assigned to the link, specifying a link-local address as the next hop. You can optionally specify the IPv6 address of the next hop to which packets are sent.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong> You must specify an interface-id when using a link-local address as the next hop (the link-local next hop must also be an adjacent router).</td>
<td></td>
</tr>
<tr>
<td>administrative distance—(Optional) An administrative distance. The range is 1 to 254; the default value is 1, which gives static routes precedence over any other type of route except connected routes. To configure a floating static route, use an administrative distance greater than that of the dynamic routing protocol.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 5**

Use one of the following:

- `show ipv6 static [ ipv6-address | ipv6-prefix/prefix length ] [ interface interface-id ] [ detail ] [ recursive ]`
- `show ipv6 route static [ updated ]`

**Example:**

```
Device# show ipv6 static 2001:0DB8::/32 interface gigabitethernet2/0/1
```

* or *

```
Device# show ipv6 route static
```

Verifies your entries by displaying the contents of the IPv6 routing table.

- `interface interface-id`—(Optional) Displays only those static routes with the specified interface as an egress interface.
- `recursive`—(Optional) Displays only recursive static routes. The `recursive` keyword is mutually exclusive with the `interface` keyword, but it can be used with or without the IPv6 prefix included in the command syntax.
- `detail`—(Optional) Displays this additional information:
  - For valid recursive routes, the output path set, and maximum resolution depth.
  - For invalid routes, the reason why the route is not valid.

**Step 6**

**Example:**

```
 copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
Enabling IPv6 PBR on an Interface

To enable Policy-Based Routing (PBR) for IPv6, you must create a route map that specifies the packet match criteria and desired policy-route action. Then you associate the route map on the required interface. All packets arriving on the specified interface that match the match clauses will be subject to PBR.

In PBR, the `set vrf` command decouples the virtual routing and forwarding (VRF) instance and interface association and allows the selection of a VRF based on access control list (ACL)-based classification using existing PBR or route-map configurations. It provides a single router with multiple routing tables and the ability to select routes based on ACL classification. The router classifies packets based on ACL, selects a routing table, looks up the destination address, and then routes the packet.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. route-map map-tag [permit | deny] [sequence-number]
4. Do one of the following:
   - match length minimum-length maximum-length
   - match ipv6 address [prefix-list prefix-list-name | access-list-name]
5. Do one of the following:
   - set ipv6 precedence precedence-value
   - set ipv6 next-hop global-ipv6-address [global-ipv6-address...]
   - set interface type number [...type number]
   - set ipv6 default next-hop global-ipv6-address [global-ipv6-address...]
   - set default interface type number [...type number]
   - set vrf vrf-name
6. exit
7. interface type number
8. ipv6 policy route-map route-map-name
9. end

**DETAILED STEPS**

</tbody>
</table>
Enabling Local PBR for IPv6

Packets that are generated by the device are not normally policy routed. Perform this task to enable local IPv6 policy-based routing (PBR) for such packets, indicating which route map the device should use.

To enable Local PBR for IPv6, perform this procedure:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ipv6 local policy route-map route-map-name`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
### Command or Action

**Example:**

```
Device> enable
```

**Purpose**

Enter your password if prompted.

<table>
<thead>

### Configuring RIP for IPv6

For more information about configuring RIP routing for IPv6, see the “Implementing RIP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

To configure RIP routing for IPv6, perform this procedure:

**Before you begin**

Before configuring the switch to run IPv6 RIP, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on any Layer 3 interfaces on which IPv6 RIP is to be enabled.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ipv6 router rip name</td>
<td>Configures an IPv6 RIP routing process, and enters router configuration mode for the process.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring RIP for IPv6

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)# ipv6 router rip cisco</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>maximum-paths number-paths</td>
<td>(Optional) Define the maximum number of equal-cost routes that IPv6 RIP can support. The range is from 1 to 32, and the default is 16 routes.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# maximum-paths 6</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# exit</td>
<td></td>
</tr>
</tbody>
</table>

**Step 6**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>interface interface-id</td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
</tbody>
</table>

**Step 7**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv6 rip name enable</td>
<td>Enables the specified IPv6 RIP routing process on the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ipv6 rip cisco enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 8**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv6 rip name default-information {only</td>
<td>originate}</td>
</tr>
<tr>
<td>Note</td>
<td>To avoid routing loops after the IPv6 default route (::/0) is originated from any interface, the routing process ignores all default routes received on any interface.</td>
</tr>
<tr>
<td>• only—Select to originate the default route, but suppress all other routes in the updates sent on this interface.</td>
<td></td>
</tr>
<tr>
<td>• originate—Select to originate the default route in addition to all other routes in the updates sent on this interface.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# ipv6 rip cisco default-information only</td>
<td></td>
</tr>
</tbody>
</table>

**Step 9**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
Use one of the following:

• `show ipv6 rip [name] [ interface interface-id] [ database ] [ next-hops ]`
• `show ipv6 rip`

Example:

```
Device# show ipv6 rip cisco interface
gigabitethernet 2/0/1
```

or

```
Device# show ipv6 rip
```

(Optional) Saves your entries in the configuration file.

Example:

```
Device# copy running-config startup-config
```

### Configuring OSPF for IPv6

For more information about configuring OSPF routing for IPv6, see the “Implementing OSPF for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

To configure OSPF routing for IPv6, perform this procedure:

#### Before you begin

You can customize OSPF for IPv6 for your network. However, the defaults for OSPF in IPv6 are set to meet the requirements of most customers and features.

Follow these guidelines:

• Be careful when changing the defaults for IPv6 commands. Changing the defaults might adversely affect OSPF for the IPv6 network.

• Before you enable IPv6 OSPF on an interface, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on Layer 3 interfaces on which you are enabling IPv6 OSPF.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td>3</td>
<td>ipv6 router ospf process-id</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>Device(config)# ipv6 router ospf 21</td>
</tr>
<tr>
<td>4</td>
<td>area area-id range {ipv6-prefix/prefix length} [advertise</td>
</tr>
<tr>
<td></td>
<td>[not-advertise] [cost cost]</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>Device(config)# area .3 range 2001:0DB8::/32 not-advertise</td>
</tr>
<tr>
<td>5</td>
<td>maximum paths number-paths</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>Device(config)# maximum paths 16</td>
</tr>
<tr>
<td>6</td>
<td>exit</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# exit</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 7</strong></td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# <code>interface gigabitethernet 1/0/1</code></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Enables OSPF for IPv6 on the interface.</td>
</tr>
<tr>
<td><code>ipv6 ospf process-id area area-id [instance instance-id]</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-if)# <code>ipv6 ospf 21 area .3</code></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# <code>end</code></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Displays information about OSPF interfaces.</td>
</tr>
<tr>
<td>Use one of the following:</td>
<td></td>
</tr>
<tr>
<td>• <code>show ipv6 ospf [process-id] [area-id] interface [interface-id]</code></td>
<td></td>
</tr>
<tr>
<td>• <code>show ipv6 ospf [process-id] [area-id]</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# <code>show ipv6 ospf 21 interface gigabitethernet2/0/1</code></td>
</tr>
<tr>
<td>or</td>
<td>Device# <code>show ipv6 ospf 21</code></td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# <code>copy running-config startup-config</code></td>
</tr>
</tbody>
</table>

## Configuring EIGRP for IPv6

Before configuring the switch to run IPv6 EIGRP, enable routing by entering the **ip routing global configuration** command, enable the forwarding of IPv6 packets by entering the **ipv6 unicast-routing global configuration** command, and enable IPv6 on any Layer 3 interfaces on which you want to enable IPv6 EIGRP.

To set an explicit router ID, use the **show ipv6 eigrp** command to see the configured router IDs, and then use the **router-id** command.

As with EIGRP IPv4, you can use EIGRPv6 to specify your EIGRP IPv6 interfaces and to select a subset of those as passive interfaces. Use the **passive-interface** command to make an interface passive, and then use...
the `no passive-interface` command on selected interfaces to make them active. EIGRP IPv6 does not need to be configured on a passive interface.

For more configuration procedures, see the “Implementing EIGRP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

## Configuring IPv6 Unicast Reverse Path Forwarding

The unicast Reverse Path Forwarding (unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

**Note**

- Unicast RPF is supported only in IP services.
- Do not configure Unicast RPF if the switch is in a mixed hardware stack combining more than one switch type.

For detailed IP unicast RPF configuration information, see the *Other Security Features* chapter in the *Cisco IOS Security Configuration Guide, Release 12.4*.

## Displaying IPv6

For complete syntax and usage information on these commands, see the Cisco IOS command reference publications.

**Table 21: Command for Monitoring IPv6**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ipv6 access-list</code></td>
<td>Displays a summary of access lists.</td>
</tr>
<tr>
<td><code>show ipv6 cef</code></td>
<td>Displays Cisco Express Forwarding for IPv6.</td>
</tr>
<tr>
<td><code>show ipv6 interface interface-id</code></td>
<td>Displays IPv6 interface status and configuration.</td>

</table>
### Configuring DHCP for IPv6 Address Assignment

This section describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### Default DHCPv6 Address Assignment Configuration

By default, no DHCPv6 features are configured on the switch.

### DHCPv6 Address Assignment Configuration Guidelines

When configuring DHCPv6 address assignment, consider these guidelines:

- In the procedures, the specified interface must be one of these Layer 3 interfaces:
  - DHCPv6 IPv6 routing must be enabled on a Layer 3 interface.
  - SVI: a VLAN interface created by using the `interface vlan vlan_id` command.
  - EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the `interface port-channel port-channel-number` command.
• The switch can act as a DHCPv6 client, server, or relay agent. The DHCPv6 client, server, and relay function are mutually exclusive on an interface.

• The DHCPv6 client, server, or relay agent runs only on the master switch. When there is a stack master re-election, the new master switch retains the DHCPv6 configuration. However, the local RAM copy of the DHCP server database lease information is not retained.

• Beginning from Cisco IOS XE Gibraltar 16.11.1, an autoconfigured IPv6 address will contain interface identifiers that are not part of the reserved interface identifiers range specified in RFC5453.

### Enabling DHCPv6 Server Function (CLI)

Use the no form of the DHCP pool configuration mode commands to change the DHCPv6 pool characteristics. To disable the DHCPv6 server function on an interface, use the no ipv6 dhcp server interface configuration command.

To enable the DHCPv6 server function on an interface, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ipv6 dhcp pool poolname</td>
<td>Enters DHCP pool configuration mode, and define the name for the IPv6 DHCP pool. The pool name can be a symbolic string (such as Engineering) or an integer (such as 0).</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ipv6 dhcp pool 7</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>address prefix IPv6-prefix {lifetime} {t1 t1}</td>
<td>(Optional) Specifies an address prefix for address assignment.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-dhcpv6)# address prefix 2001:1000::0/64 lifetime 3600</td>
<td>This address must be in hexadecimal, using 16-bit values between colons.</td>
</tr>
<tr>
<td></td>
<td>lifetime t1 t1—Specifies a time interval (in seconds) that an IPv6 address prefix remains in the valid state. The range is 5 to 4294967295 seconds. Specify infinite for no time interval.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>link-address IPv6-prefix</td>
<td>(Optional) Specifies a link-address IPv6 prefix.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>( \text{Device(config-dhcpv6)} # \text{link-address} \ 2001:1002::0/64 )</td>
<td>When an address on the incoming interface or a link-address in the packet matches the specified IPv6 prefix, the server uses the configuration information pool. This address must be in hexadecimal, using 16-bit values between colons.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ( \text{vendor-specific vendor-id} ) ( \text{Example:} ) ( \text{Device(config-dhcpv6)} # \text{vendor-specific 9} )</td>
<td>(Optional) Enters vendor-specific configuration mode and specifies a vendor-specific identification number. This number is the vendor IANA Private Enterprise Number. The range is 1 to 4294967295.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> ( \text{suboption number} \ {\text{[address IPv6-address</td>
<td>ascii ASCII-string</td>
<td>hex hex-string]}} ) ( \text{Example:} ) ( \text{Device(config-dhcpv6-vs)} # \text{suboption 1 address 1000:235D::}} )</td>
</tr>
<tr>
<td><strong>Step 8</strong> ( \text{exit} ) ( \text{Example:} ) ( \text{Device(config-dhcpv6-vs)} # \text{exit} )</td>
<td>Returns to DHCP pool configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> ( \text{exit} ) ( \text{Example:} ) ( \text{Device(config-dhcpv6)} # \text{exit} )</td>
<td>Returns to global configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> ( \text{interface interface-id} ) ( \text{Example:} ) ( \text{Device(config)} # \text{interface gigabitethernet 1/0/1} )</td>
<td>Enters interface configuration mode, and specifies the interface to configure.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong> ( \text{ipv6 dhcp server [poolname</td>
<td>automatic] [rapid-commit] [preference value] [allow-hint]} ) ( \text{Example:} ) ( \text{Device(config-if)} # \text{ipv6 dhcp server automatic} )</td>
<td>Enables DHCPv6 server function on an interface.</td>
</tr>
<tr>
<td>( \cdot \text{poolname} ) — (Optional) User-defined name for the IPv6 DHCP pool. The pool name can be a symbolic string (such as Engineering) or an integer (such as 0).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>( \cdot \text{automatic} ) — (Optional) Enables the system to automatically determine which pool to use when allocating addresses for a client.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>( \cdot \text{rapid-commit} ) — (Optional) Allows two-message exchange method.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Enabling DHCPv6 Client Function

To enable the DHCPv6 client on an interface, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Enters interface configuration mode, and specifies the interface to configure.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ipv6 address dhcp [rapid-commit]</td>
<td>Enables the interface to acquire an IPv6 address from the DHCPv6 server.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 address dhcp rapid-commit</td>
<td>rapid-commit—(Optional) Allow two-message exchange method for address assignment.</td>
</tr>
<tr>
<td><strong>Step 5</strong> ipv6 dhcp client request [vendor-specific]</td>
<td>(Optional) Enables the interface to request the vendor-specific option.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 dhcp client request vendor-specific</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> show ipv6 dhcp interface</td>
<td>Verifies that the DHCPv6 client is enabled on an interface.</td>
</tr>
<tr>
<td>Example: Device# show ipv6 dhcp interface</td>
<td></td>
</tr>
</tbody>
</table>

**Configuration Examples for IPv6 Unicast Routing**

**Configuring IPv6 Addressing and Enabling IPv6 Routing: Example**

This example shows how to enable IPv6 with both a link-local address and a global address based on the IPv6 prefix 2001:0DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the `show ipv6 interface` EXEC command is included to show how the interface ID (20B:46FF:FE2F:D940) is appended to the link-local prefix FE80::/64 of the interface.

```
Device(config)# ipv6 unicast-routing
Device(config)# interface gigabitethernet0/11
Device(config-if)# no switchport
```
IPv6

Configuring Default Router Preference: Example

This example shows how to configure a DRP of high for the router on an interface.

```
Device(config-if)# configure terminal
Device(config)# interface gigabitethernet/1/0/1
Device(config-if)# ipv6 nd router-preference high
Device(config-if)# end
```

Configuring IPv4 and IPv6 Protocol Stacks: Example

This example shows how to enable IPv4 and IPv6 routing on an interface.

```
Device(config)# ip routing
Device(config)# ipv6 unicast-routing
Device(config)# interface fastethernet/1/0/11
Device(config-if)# no switchport
Device(config-if)# ip address 192.168.99.1 255.255.255.0
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
```

Enabling DHCPv6 Server Function: Example

This example shows how to configure a pool called engineering with an IPv6 address prefix:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool engineering
Device(config-dhcpv6)# address prefix 2001:1000::0/64
Device(config-dhcpv6)# end
```
This example shows how to configure a pool called testgroup with three link-addresses and an IPv6 address prefix:

Device# configure terminal
Device(config)# ipv6 dhcp pool testgroup
Device(config-dhcpv6)# link-address 2001:1001::0/64
Device(config-dhcpv6)# link-address 2001:1002::0/64
Device(config-dhcpv6)# link-address 2001:2000::0/48
Device(config-dhcpv6)# address prefix 2001:1003::0/64
Device(config-dhcpv6)# end

This example shows how to configure a pool called 350 with vendor-specific options:

Device# configure terminal
Device(config)# ipv6 dhcp pool 350
Device(config-dhcpv6)# address prefix 2001:1005::0/48
Device(config-dhcpv6)# vendor-specific 9
Device(config-dhcpv6-vs)# suboption 1 address 1000:235D::1
Device(config-dhcpv6-vs)# suboption 2 ascii "IP-Phone"
Device(config-dhcpv6-vs)# end

Enabling DHCPv6 Client Function: Example

This example shows how to acquire an IPv6 address and to enable the rapid-commit option:

Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ipv6 address dhcp rapid-commit

Configuring IPv6 ICMP Rate Limiting: Example

This example shows how to configure an IPv6 ICMP error message interval of 50 milliseconds and a bucket size of 20 tokens.

Device(config)# ipv6 icmp error-interval 50 20

Configuring Static Routing for IPv6: Example

This example shows how to configure a floating static route to an interface with an administrative distance of 130:

Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet 1/0/1 130

Example: Enabling PBR on an Interface

In the following example, a route map named pbr-dest-1 is created and configured, specifying packet match criteria and desired policy-route action. PBR is then enabled on GigabitEthernet interface 0/0/1.
IPv6 access-list match-dest-1
   permit ipv6 any 2001:DB8:2001:1760::/32
route-map pbr-dest-1 permit 10
   match ipv6 address match-dest-1
   set interface GigabitEthernet 0/0/0
interface GigabitEthernet0/0/1
   ipv6 policy-route-map interactive

Example: Enabling Local PBR for IPv6

In the following example, packets with a destination IPv6 address that match the IPv6 address range allowed by access list pbr-src-90 are sent to the device at IPv6 address 2001:DB8:2003:1::95:

ipv6 access-list src-90
   permit ipv6 host 2001:DB8:2003::90 2001:DB8:2001:1000::/64
route-map pbr-src-90 permit 10
   match ipv6 address src-90
   set ipv6 next-hop 2001:DB8:2003:1::95
ipv6 local policy route-map pbr-src-90

Configuring RIP for IPv6: Example

This example shows how to enable the RIP routing process cisco with a maximum of eight equal-cost routes and to enable it on an interface:

Device(config)# ipv6 router rip cisco
Device(config-router)# maximum-paths 8
Device(config)# exit
Device(config)# interface gigabitethernet2/0/11
Device(config-if)# ipv6 rip cisco enable

Displaying IPv6: Example

This is an example of the output from the show ipv6 interface privileged EXEC command:

Device# show ipv6 interface
Vlan1 is up, line protocol is up
   IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
   Global unicast address(es):
      3FFE:C000:0:1:20B:46FF:FE2F:D940, subnet is 3FFE:C000:0:1::/64 [EUI]
   Joined group address(es):
      FF02::1
      FF02::2
      FF02::1:FF2F:D940
   MTU is 1500 bytes
   ICMP error messages limited to one every 100 milliseconds
   ICMP redirects are enabled
   ND DAD is enabled, number of DAD attempts: 1
   ND reachable time is 30000 milliseconds
   ND advertised reachable time is 0 milliseconds
   ND advertised retransmit interval is 0 milliseconds
   ND router advertisements are sent every 200 seconds
   ND router advertisements live for 1800 seconds

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)

Displaying IPv6: Example
Implementing IPv6 Multicast

Information About Implementing IPv6 Multicast Routing

This chapter describes how to implement IPv6 multicast routing on the switch.

Traditional IP communication allows a host to send packets to a single host (unicast transmission) or to all hosts (broadcast transmission). IPv6 multicast provides a third scheme, allowing a host to send a single data stream to a subset of all hosts (group transmission) simultaneously.

IPv6 Multicast Overview

An IPv6 multicast group is an arbitrary group of receivers that want to receive a particular data stream. This group has no physical or geographical boundaries—receivers can be located anywhere on the Internet or in any private network. Receivers that are interested in receiving data flowing to a particular group must join the group by signaling their local switch. This signaling is achieved with the MLD protocol.

Switches use the MLD protocol to learn whether members of a group are present on their directly attached subnets. Hosts join multicast groups by sending MLD report messages. The network then delivers data to a potentially unlimited number of receivers, using only one copy of the multicast data on each subnet. IPv6 hosts that wish to receive the traffic are known as group members.

Packets delivered to group members are identified by a single multicast group address. Multicast packets are delivered to a group using best-effort reliability, just like IPv6 unicast packets.

The multicast environment consists of senders and receivers. Any host, regardless of whether it is a member of a group, can send to a group. However, only members of a group can listen to and receive the message.

A multicast address is chosen for the receivers in a multicast group. Senders use that address as the destination address of a datagram to reach all members of the group.

Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time.

How active a multicast group is, its duration, and its membership can vary from group to group and from time to time. A group that has members may have no activity.
IPv6 Multicast Routing Implementation

The Cisco IOS software supports the following protocols to implement IPv6 multicast routing:

- **MLD** is used by IPv6 switches to discover multicast listeners (nodes that want to receive multicast packets destined for specific multicast addresses) on directly attached links. There are two versions of MLD: MLD version 1 is based on version 2 of the Internet Group Management Protocol (IGMP) for IPv4, and MLD version 2 is based on version 3 of the IGMP for IPv4. IPv6 multicast for Cisco IOS software uses both MLD version 2 and MLD version 1. MLD version 2 is fully backward-compatible with MLD version 1 (described in RFC 2710). Hosts that support only MLD version 1 will interoperate with a switch running MLD version 2. Mixed LANs with both MLD version 1 and MLD version 2 hosts are likewise supported.

- **PIM-SM** is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs.

- **PIM in Source Specific Multicast (PIM-SSM)** is similar to PIM-SM with the additional ability to report interest in receiving packets from specific source addresses (or from all but the specific source addresses) to an IP multicast address.

IPv6 Multicast Listener Discovery Protocol

To start implementing multicasting in the campus network, users must first define who receives the multicast. The MLD protocol is used by IPv6 switches to discover the presence of multicast listeners (for example, nodes that want to receive multicast packets) on their directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes. It is used for discovering local group and source-specific group membership.

The MLD protocol provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

Multicast Queriers and Hosts

A multicast querier is a network device, such as a switch, that sends query messages to discover which network devices are members of a given multicast group.

A multicast host is a receiver, including switches, that send report messages to inform the querier of a host membership.

A set of queriers and hosts that receive multicast data streams from the same source is called a multicast group. Queriers and hosts use MLD reports to join and leave multicast groups and to begin receiving group traffic.

MLD uses the Internet Control Message Protocol (ICMP) to carry its messages. All MLD messages are link-local with a hop limit of 1, and they all have the switch alert option set. The switch alert option implies an implementation of the hop-by-hop option header.

MLD Access Group

The MLD access group provides receiver access control in Cisco IOS IPv6 multicast switches. This feature limits the list of groups a receiver can join, and it allows or denies sources used to join SSM channels.

Explicit Tracking of Receivers

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network. This feature also enables the fast leave mechanism to be used with MLD version 2 host reports.
Protocol Independent Multicast

Protocol Independent Multicast (PIM) is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs. PIM works independently of the unicast routing protocol to perform send or receive multicast route updates like other protocols. Regardless of which unicast routing protocols are being used in the LAN to populate the unicast routing table, Cisco IOS PIM uses the existing unicast table content to perform the Reverse Path Forwarding (RPF) check instead of building and maintaining its own separate routing table.

You can configure IPv6 multicast to use either PIM-SM or PIM-SSM operation, or you can use both PIM-SM and PIM-SSM together in your network.

PIM-Sparse Mode

IPv6 multicast provides support for intradomain multicast routing using PIM-SM. PIM-SM uses unicast routing to provide reverse-path information for multicast tree building, but it is not dependent on any particular unicast routing protocol.

PIM-SM is used in a multicast network when relatively few switches are involved in each multicast and these switches do not forward multicast packets for a group, unless there is an explicit request for the traffic. PIM-SM distributes information about active sources by forwarding data packets on the shared tree. PIM-SM initially uses shared trees, which requires the use of an RP.

Requests are accomplished via PIM joins, which are sent hop by hop toward the root node of the tree. The root node of a tree in PIM-SM is the RP in the case of a shared tree or the first-hop switch that is directly connected to the multicast source in the case of a shortest path tree (SPT). The RP keeps track of multicast groups and the hosts that send multicast packets are registered with the RP by that host's first-hop switch.

As a PIM join travels up the tree, switches along the path set up multicast forwarding state so that the requested multicast traffic will be forwarded back down the tree. When multicast traffic is no longer needed, a switch sends a PIM prune up the tree toward the root node to prune (or remove) the unnecessary traffic. As this PIM prune travels hop by hop up the tree, each switch updates its forwarding state appropriately. Ultimately, the forwarding state associated with a multicast group or source is removed.

A multicast data sender sends data destined for a multicast group. The designated switch (DR) of the sender takes those data packets, unicast-encapsulates them, and sends them directly to the RP. The RP receives these encapsulated data packets, de-encapsulates them, and forwards them onto the shared tree. The packets then follow the (*, G) multicast tree state in the switches on the RP tree, being replicated wherever the RP tree branches, and eventually reaching all the receivers for that multicast group. The process of encapsulating data packets to the RP is called registering, and the encapsulation packets are called PIM register packets.

IPv6 BSR: Configure RP Mapping

PIM switches in a domain must be able to map each multicast group to the correct RP address. The BSR protocol for PIM-SM provides a dynamic, adaptive mechanism to distribute group-to-RP mapping information rapidly throughout a domain. With the IPv6 BSR feature, if an RP becomes unreachable, it will be detected and the mapping tables will be modified so that the unreachable RP is no longer used, and the new tables will be rapidly distributed throughout the domain.

Every PIM-SM multicast group needs to be associated with the IP or IPv6 address of an RP. When a new multicast sender starts sending, its local DR will encapsulate these data packets in a PIM register message and send them to the RP for that multicast group. When a new multicast receiver joins, its local DR will send a PIM join message to the RP for that multicast group. When any PIM switch sends a (*, G) join message, the PIM switch needs to know which is the next switch toward the RP so that G (Group) can send a message
to that switch. Also, when a PIM switch is forwarding data packets using (*, G) state, the PIM switch needs to know which is the correct incoming interface for packets destined for G, because it needs to reject any packets that arrive on other interfaces.

A small set of switches from a domain are configured as candidate bootstrap switches (C-BSRs) and a single BSR is selected for that domain. A set of switches within a domain are also configured as candidate RPs (C-RPs); typically, these switches are the same switches that are configured as C-BSRs. Candidate RPs periodically unicast candidate-RP-advertisement (C-RP-Adv) messages to the BSR of that domain, advertising their willingness to be an RP. A C-RP-Adv message includes the address of the advertising C-RP, and an optional list of group addresses and mask length fields, indicating the group prefixes for which the candidacy is advertised. The BSR then includes a set of these C-RPs, along with their corresponding group prefixes, in bootstrap messages (BSMs) it periodically originates. BSMs are distributed hop-by-hop throughout the domain.

Bidirectional BSR support allows bidirectional RPs to be advertised in C-RP messages and bidirectional ranges in the BSM. All switches in a system must be able to use the bidirectional range in the BSM; otherwise, the bidirectional RP feature will not function.

**PIM-Source Specific Multicast**

PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM-SM. However, unlike PIM-SM where data from all multicast sources are sent when there is a PIM join, the SSM feature forwards datagram traffic to receivers from only those multicast sources that the receivers have explicitly joined, thus optimizing bandwidth utilization and denying unwanted Internet broadcast traffic. Further, instead of the use of RP and shared trees, SSM uses information found on source addresses for a multicast group. This information is provided by receivers through the source addresses relayed to the last-hop switches by MLD membership reports, resulting in shortest-path trees directly to the sources.

In SSM, delivery of datagrams is based on (S, G) channels. Traffic for one (S, G) channel consists of datagrams with an IPv6 unicast source address S and the multicast group address G as the IPv6 destination address. Systems will receive this traffic by becoming members of the (S, G) channel. Signaling is not required, but receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources.

MLD version 2 is required for SSM to operate. MLD allows the host to provide source information. Before SSM can run with MLD, SSM must be supported in the Cisco IOS IPv6 switch, the host where the application is running, and the application itself.

** Routable Address Hello Option**

When an IPv6 interior gateway protocol is used to build the unicast routing table, the procedure to detect the upstream switch address assumes the address of a PIM neighbor is always same as the address of the next-hop switch, as long as they refer to the same switch. However, it may not be the case when a switch has multiple addresses on a link.

Two typical situations can lead to this situation for IPv6. The first situation can occur when the unicast routing table is not built by an IPv6 interior gateway protocol such as multicast BGP. The second situation occurs when the address of an RP shares a subnet prefix with downstream switches (note that the RP switch address has to be domain-wide and therefore cannot be a link-local address).

The routable address hello option allows the PIM protocol to avoid such situations by adding a PIM hello message option that includes all the addresses on the interface on which the PIM hello message is advertised. When a PIM switch finds an upstream switch for some address, the result of RPF calculation is compared with the addresses in this option, in addition to the PIM neighbor's address itself. Because this option includes all the possible addresses of a PIM switch on that link, it always includes the RPF calculation result if it refers to the PIM switch supporting this option.
Because of size restrictions on PIM messages and the requirement that a routable address hello option fits within a single PIM hello message, a limit of 16 addresses can be configured on the interface.

**PIM IPv6 Stub Routing**

The PIM stub routing feature reduces resource usage by moving routed traffic closer to the end user. In a network using PIM stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IPv6 multicast routing and configure only the switch as a PIM stub router. The switch does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the switch. The switch uplink port cannot be used with SVIs.

You must also configure EIGRP stub routing when configuring PIM stub routing on the switch.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM assert and designated router election mechanisms are not supported on the PIM passive interfaces. Only the non-redundant access router topology is supported by the PIM stub feature. By using a non-redundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

In the figure shown below, Switch A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source.

*Figure 10: PIM Stub Router Configuration*

**Static Mroutes**

IPv6 static mroutes behave much in the same way as IPv4 static mroutes used to influence the RPF check. IPv6 static mroutes share the same database as IPv6 static routes and are implemented by extending static route support for RPF checks. Static mroutes support equal-cost multipath mroutes, and they also support unicast-only static routes.
The Multicast Routing Information Base (MRIB) is a protocol-independent repository of multicast routing entries instantiated by multicast routing protocols (routing clients). Its main function is to provide independence between routing protocols and the Multicast Forwarding Information Base (MFIB). It also acts as a coordination and communication point among its clients.

Routing clients use the services provided by the MRIB to instantiate routing entries and retrieve changes made to routing entries by other clients. Besides routing clients, MRIB also has forwarding clients (MFIB instances) and special clients such as MLD. MFIB retrieves its forwarding entries from MRIB and notifies the MRIB of any events related to packet reception. These notifications can either be explicitly requested by routing clients or spontaneously generated by the MFIB.

Another important function of the MRIB is to allow for the coordination of multiple routing clients in establishing multicast connectivity within the same multicast session. MRIB also allows for the coordination between MLD and routing protocols.

The MFIB is a platform-independent and routing-protocol-independent library for IPv6 software. Its main purpose is to provide a Cisco IOS platform with an interface with which to read the IPv6 multicast forwarding table and notifications when the forwarding table changes. The information provided by the MFIB has clearly defined forwarding semantics and is designed to make it easy for the platform to translate to its specific hardware or software forwarding mechanisms.

When routing or topology changes occur in the network, the IPv6 routing table is updated, and those changes are reflected in the MFIB. The MFIB maintains next-hop address information based on the information in the IPv6 routing table. Because there is a one-to-one correlation between MFIB entries and routing table entries, the MFIB contains all known routes and eliminates the need for route cache maintenance that is associated with switching paths such as fast switching and optimum switching.

Distributed MFIB has its significance only in a stacked environment where the Master distributes the MFIB information to the other stack members. In the following section the line cards are nothing but the member switches in the stack.

MFIB (MFIB) is used to switch multicast IPv6 packets on distributed platforms. MFIB may also contain platform-specific information on replication across line cards. The basic MFIB routines that implement the core of the forwarding logic are common to all forwarding environments.

MFIB implements the following functions:

- Relays data-driven protocol events generated in the line cards to PIM.
- Provides an MFIB platform application program interface (API) to propagate MFIB changes to platform-specific code responsible for programming the hardware acceleration engine. This API also includes entry points to switch a packet in software (necessary if the packet is triggering a data-driven event) and to upload traffic statistics to the software.
The combination of MFIB and MRIB subsystems also allows the switch to have a "customized" copy of the MFIB database in each line card and to transport MFIB-related platform-specific information from the RP to the line cards.

**IPv6 Multicast Process Switching and Fast Switching**

A unified MFIB is used to provide both fast switching and process switching support for PIM-SM and PIM-SSM in IPv6 multicast. In process switching, the IOS daemon must examine, rewrite, and forward each packet. The packet is first received and copied into the system memory. The switch then looks up the Layer 3 network address in the routing table. The Layer 2 frame is then rewritten with the next-hop destination address and sent to the outgoing interface. The IOSd also computes the cyclic redundancy check (CRC). This switching method is the least scalable method for switching IPv6 packets.

IPv6 multicast fast switching allows switches to provide better packet forwarding performance than process switching. Information conventionally stored in a route cache is stored in several data structures for IPv6 multicast switching. The data structures provide optimized lookup for efficient packet forwarding.

In IPv6 multicast forwarding, the first packet is fast-switched if the PIM protocol logic allows it. In IPv6 multicast fast switching, the MAC encapsulation header is precomputed. IPv6 multicast fast switching uses the MFIB to make IPv6 destination prefix-based switching decisions. In addition to the MFIB, IPv6 multicast fast switching uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all MFIB entries.

The adjacency table is populated as adjacencies are discovered. Each time an adjacency entry is created (such as through ARP), a link-layer header for that adjacent node is precomputed and stored in the adjacency table. Once a route is determined, it points to a next hop and corresponding adjacency entry. It is subsequently used for encapsulation during switching of packets.

A route might have several paths to a destination prefix, such as when a switch is configured for simultaneous load balancing and redundancy. For each resolved path, a pointer is added for the adjacency corresponding to the next-hop interface for that path. This mechanism is used for load balancing across several paths.

**Multiprotocol BGP for the IPv6 Multicast Address Family**

The multiprotocol BGP for the IPv6 multicast address family feature provides multicast BGP extensions for IPv6 and supports the same features and functionality as IPv4 BGP. IPv6 enhancements to multicast BGP include support for an IPv6 multicast address family and network layer reachability information (NLRI) and next hop (the next switch in the path to the destination) attributes that use IPv6 addresses.

Multicast BGP is an enhanced BGP that allows the deployment of interdomain IPv6 multicast. Multiprotocol BGP carries routing information for multiple network layer protocol address families; for example, IPv6 address family and for IPv6 multicast routes. The IPv6 multicast address family contains routes used for RPF lookup by the IPv6 PIM protocol, and multicast BGP IPv6 provides for interdomain transport of the same. Users must use multiprotocol BGP for IPv6 multicast when using IPv6 multicast with BGP because the unicast BGP learned routes will not be used for IPv6 multicast.

Multicast BGP functionality is provided through a separate address family context. A subsequent address family identifier (SAFI) provides information about the type of the network layer reachability information that is carried in the attribute. Multiprotocol BGP unicast uses SAFI 1 messages, and multiprotocol BGP multicast uses SAFI 2 messages. SAFI 1 messages indicate that the routes are only usable for IP unicast, but not IP multicast. Because of this functionality, BGP routes in the IPv6 unicast RIB must be ignored in the IPv6 multicast RPF lookup.
A separate BGP routing table is maintained to configure incongruent policies and topologies (for example, IPv6 unicast and multicast) by using IPv6 multicast RPF lookup. Multicast RPF lookup is very similar to the IP unicast route lookup.

No MRIB is associated with the IPv6 multicast BGP table. However, IPv6 multicast BGP operates on the unicast IPv6 RIB when needed. Multicast BGP does not insert or update routes into the IPv6 unicast RIB.

### Implementing IPv6 Multicast

#### Enabling IPv6 Multicast Routing

To enable IPv6 multicast routing, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
</tr>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
</tr>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td>ipv6 multicast-routing</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Device(config)# ipv6 multicast-routing</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
</tr>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

(Optional) Save your entries in the configuration file.

### Customizing and Verifying the MLD Protocol

#### Customizing and Verifying MLD on an Interface

To customize and verify MLD on an interface, perform this procedure:

<table>
<thead>
<tr>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
</tr>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td>configure terminal</td>
</tr>
</tbody>
</table>

Enters global configuration mode.
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 3 | interface type number  
Example:  
Device(config)# interface GigabitEthernet 1/0/1 | Specifies an interface type and number, and places the switch in interface configuration mode. |
| Step 4 | ipv6 mld join-group [group-address] [include | exclude] 
{source-address | source-list [acl]}  
Example:  
Device(config-if)# ipv6 mld join-group FF04::10 | Configures MLD reporting for a specified group and source. |
| Step 5 | ipv6 mld access-group access-list-name  
Example:  
Device(config-if)# ipv6 access-list acc-grp-1 | Allows the user to perform IPv6 multicast receiver access control. |
| Step 6 | ipv6 mld static-group [group-address] [include | exclude] 
{source-address | source-list [acl]}  
Example:  
Device(config-if)# ipv6 mld static-group ff04::10 include 100::1 | Statically forwards traffic for the multicast group onto a specified interface and cause the interface to behave as if a MLD joiner were present on the interface. |
| Step 7 | ipv6 mld query-max-response-time seconds  
Example:  
Device(config-if)# ipv6 mld query-timeout 130 | Configures the timeout value before the switch takes over as the querier for the interface. |
| Step 8 | exit  
Example:  
Device(config-if)# exit | Enter this command twice to exit interface configuration mode and enter privileged EXEC mode. |
| Step 9 | show ipv6 mld groups [link-local] [group-name | group-address] [interface-type interface-number] [detail | explicit]  
Example:  
Device# show ipv6 mld groups GigabitEthernet 1/0/1 | Displays the multicast groups that are directly connected to the switch and that were learned through MLD. |
| Step 10 | show ipv6 mld groups summary  
Example:  
Device# show ipv6 mld groups summary | Displays the number of (*, G) and (S, G) membership reports present in the MLD cache. |
### Implementing MLD Group Limits

Per-interface and global MLD limits operate independently of each other. Both per-interface and global MLD limits can be configured on the same switch. The number of MLD limits, globally or per interface, is not configured by default; the limits must be configured by the user. A membership report that exceeds either the per-interface or the global state limit is ignored.

### Implementing MLD Group Limits Globally

To implement MLD group limits globally, perform this procedure:

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. `ipv6 mld [vrf vrf-name] state-limit number`
4. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Implementing MLD Group Limits per Interface

To implement MLD group limits per interface, perform this procedure:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ipv6 mld limit number [except]access-list`
5. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>interface type number</code></td>
<td>Specifies an interface type and number, and places the switch in</td>
</tr>
<tr>
<td>Example:</td>
<td>interface configuration mode.</td>
</tr>
<tr>
<td><code>Device(config)# interface GigabitEthernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>ipv6 mld limit number [except]access-list</code></td>
<td>Limits the number of MLD states on a per-interface basis.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# ipv6 mld limit 100</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>copy running-config startup-config</code></td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
Configuring Explicit Tracking of Receivers to Track Host Behavior

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network and enables the fast leave mechanism to be used with MLD version 2 host reports.

To configuring explicit tracking of receivers to track host behavior, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable&lt;br&gt;Example: Device&gt; enable</td>
<td>Enables privileged EXEC mode.&lt;br&gt;Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>interface type number&lt;br&gt;Example: Device(config)# interface GigabitEthernet 1/0/1</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>ipv6 mld explicit-tracking access-list-name&lt;br&gt;Example: Device(config-if)# ipv6 mld explicit-tracking list1</td>
<td>Enables explicit tracking of hosts.</td>
</tr>
<tr>
<td>Step 5</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Resetting the MLD Traffic Counters

To reset the MLD traffic counters, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable&lt;br&gt;Example: Device&gt; enable</td>
<td>Enables privileged EXEC mode.&lt;br&gt;Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal&lt;br&gt;Example: Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>clear ipv6 mld traffic&lt;br&gt;Example:</td>
<td>Resets all MLD traffic counters.</td>
</tr>
</tbody>
</table>
### Clearing the MLD Interface Counters

To clearing the MLD interface counters, perform this procedure.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device# enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> clear ipv6 mld counters interface-type</td>
<td>Clears the MLD interface counters.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# clear ipv6 mld counters Ethernet1/0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring PIM

This section explains how to configure PIM.

#### Configuring PIM-SM and Displaying PIM-SM Information for a Group Range

To configuring PIM-SM and view PIM-SM information for a group range, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ipv6 pim rp-address ipv6-address[group-access-list]</td>
<td>Configures the address of a PIM RP for a particular group range.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>ipv6 pim rp-address 2001:DB8::01:800:200E:8C6C acc-grp-1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> exit</td>
<td>Exits global configuration mode, and returns the switch to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>exit</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show ipv6 pim interface [state-on] [state-off] [type-number]</td>
<td>Displays information about interfaces configured for PIM.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ipv6 pim interface</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> show ipv6 pim group-map [group-name</td>
<td>group-address] [group-range</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ipv6 pim group-map</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> show ipv6 pim neighbor [detail] [interface-type interface-number</td>
<td>count]</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ipv6 pim neighbor</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> show ipv6 pim range-list [config] [rp-address</td>
<td>rp-name]</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ipv6 pim range-list</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> show ipv6 pim tunnel [interface-type interface-number]</td>
<td>Displays information about the PIM register encapsulation and de-encapsulation tunnels on an interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
---|---
Device# show ipv6 pim tunnel | Enables debugging on PIM protocol activity.

**Step 10**

**Command or Action**

```
Device# debug ipv6 pim [group-name | group-address | interface interface-type | bsr | group | mvpn | neighbor]
```

**Example:**

```
Device# debug ipv6 pim
```

### Step 11

**Command or Action**

```
copy running-config startup-config
```

(Optional) Save your entries in the configuration file.

---

## Configuring PIM Options

To configure PIM options, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** Device# configure terminal | |

| **Step 3** ipv6 pim spt-threshold infinity [group-list access-list-name] | Configures when a PIM leaf switch joins the SPT for the specified groups. |
| **Example:** Device(config)# ipv6 pim spt-threshold infinity group-list acc-grp-1 | |

| **Step 4** ipv6 pim accept-register {list access-list | route-map map-name} | Accepts or rejects registers at the RP. |
| **Example:** Device(config)# ipv6 pim accept-register route-map reg-filter | |

<p>| <strong>Step 5</strong> interface type number | Specifies an interface type and number, and places the switch in interface configuration mode. |
| <strong>Example:</strong> Device(config)# interface GigabitEthernet 1/0/1 | |</p>
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>ipv6 pim dr-priority <em>value</em></td>
<td>Configures the DR priority on a PIM switch.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# ipv6 pim dr-priority 3</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>ipv6 pim hello-interval <em>seconds</em></td>
<td>Configures the frequency of PIM hello messages on an interface.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# ipv6 pim hello-interval 45</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>ipv6 pim join-prune-interval <em>seconds</em></td>
<td>Configures periodic join and prune announcement intervals for a specified interface.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# ipv6 pim join-prune-interval 75</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>exit</td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>ipv6 pim join-prune statistic [interface-type]</td>
<td>Displays the average join-prune aggregation for the most recently aggregated packets for each interface.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# show ipv6 pim join-prune statistic</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

**Resetting the PIM Traffic Counters**

If PIM malfunctions or in order to verify that the expected number of PIM packets are received and sent, the user can clear PIM traffic counters. Once the traffic counters are cleared, the user can enter the show ipv6 pim traffic command to verify that PIM is functioning correctly and that PIM packets are being received and sent correctly.

To resetting the PIM traffic counters, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### IPv6

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> clear ipv6 pim traffic</td>
<td>Resets the PIM traffic counters.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# clear ipv6 pim traffic</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> show ipv6 pim traffic</td>
<td>Displays the PIM traffic counters.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show ipv6 pim traffic</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Clearing the PIM Topology Table to Reset the MRIB Connection

No configuration is necessary to use the MRIB. However, users may in certain situations want to clear the PIM topology table in order to reset the MRIB connection and verify MRIB information.

To clear the PIM topology table to reset the MRIB connection, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Enter your password if prompted.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> clear ipv6 pim topology [group-name</td>
<td>group-address]</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# clear ipv6 pim topology FF04::10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> show ipv6 mrrib client [filter] [name {client-name</td>
<td>client-name : client-id}]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# <code>show ipv6 mrib client</code></td>
<td>Clearing the PIM Topology Table to Reset the MRIB Connection</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>show ipv6 mrib route</code> [link-local</td>
<td>summary</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ipv6 mrib route</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> <code>show ipv6 pim topology</code> [groupname-or-address</td>
<td>[sourceaddress-or-name]</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ipv6 pim topology</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> <code>debug ipv6 mrib client</code></td>
<td>Enables debugging on MRIB client management activity.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>debug ipv6 mrib client</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> <code>debug ipv6 mrib io</code></td>
<td>Enables debugging on MRIB I/O events.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>debug ipv6 mrib io</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> <code>debug ipv6 mrib proxy</code></td>
<td>Enables debugging on MRIB proxy activity between the switch processor and line cards on distributed switch platforms.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>debug ipv6 mrib proxy</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> <code>debug ipv6 mrib route</code> [group-name</td>

<tr>
<td><strong>Step 11</strong> <code>debug ipv6 mrib table</code></td>
<td>Enables debugging on MRIB table management activity.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>debug ipv6 mrib table</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong> <code>copy running-config startup-config</code></td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Configuring PIM IPv6 Stub Routing

The PIM Stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards MLD traffic.

PIM IPv6 Stub Routing Configuration Guidelines

- Before configuring PIM stub routing, you must have IPv6 multicast routing configured on both the stub router and the central router. You must also have PIM mode (sparse-mode) configured on the uplink interface of the stub router.
- The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior. For more information, see the EIGRP Stub Routing section.
- Only directly connected multicast (MLD) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- The redundant PIM stub router topology is not supported.

Default IPv6 PIM Routing Configuration

This table displays the default IPv6 PIM routing configuration for the Device.

Table 23: Default Multicast Routing Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multicast routing</td>
<td>Disabled on all interfaces.</td>
</tr>
<tr>
<td>PIM version</td>
<td>Version 2.</td>
</tr>
<tr>
<td>PIM mode</td>
<td>No mode is defined.</td>
</tr>
<tr>
<td>PIM stub routing</td>
<td>None configured.</td>
</tr>
<tr>

<td>30 seconds.</td>
</tr>
</tbody>
</table>

Enabling IPV6 PIM Stub Routing

To enable IPV6 PIM stub routing, perform this procedure:
**Before you begin**

PIM stub routing is disabled in IPv6 by default.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ipv6 multicast pim-passive-enable`
4. `interface interface-id`
5. `ipv6 pim`
6. `ipv6 pim {bsr} | {dr-priority | value} | {hello-interval | seconds} | {join-prune-interval | seconds} | {passive}`
7. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** |         |
| `configure terminal` | Enters global configuration mode. |
| **Example:** |         |
| `Device# configure terminal` | |

| **Step 3** | Enables IPv6 Multicast PIM routing on the switch. |
| `ipv6 multicast pim-passive-enable` | |
| **Example:** |         |
| `Device(config-if)# ipv6 multicast pim-passive-enable` | |

| **Step 4** | Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode. The specified interface must be one of the following: |
| `interface interface-id` | |
| **Example:** |         |
| `Device(config)# interface gigabitethernet 9/0/6` |   |

- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse mode on the interface, and join the interface as a statically connected member to an MLD static group.
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse mode on the VLAN, join the VLAN as a statically connected member to an MLD static group.
Purpose

Command or Action | Purpose
---|---
membertoanMLDstaticgroup,andthenenableMLD snoopingontheVLAN, theMLDstaticgroup,and physical interface.

<tbody>
<tr>
<td>show ipv6 pim interface</td>
<td>Displays the PIM stub that is enabled on each interface.</td>
</tr>
</tbody>
</table>

Device# show ipv6 pim interface

| show ipv6 mld groups | Displays the interested clients that have joined the specific multicast source group. |

Device# show ipv6 mld groups

| show ipv6 mroute | Verifies that the multicast stream forwards from the source to the interested clients. |

Device# show ipv6 mroute
Configuring a BSR

The tasks included here are described below.

### Configuring a BSR and Verifying BSR Information

To configure and verify BSR Information, perform this procedure:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ipv6 pim bsr candidate bsr ipv6-address[hash-mask-length] [priority priority-value]</td>
<td>Configures a switch to be a candidate BSR.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# ipv6 pim bsr candidate bsr 2001:DB8:3000:3000::42 124 priority 10</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>ipv6 pim bsr border</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# ipv6 pim bsr border</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>exit</td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>show ipv6 pim bsr {election</td>
<td>rp-cache</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# show ipv6 pim bsr election</td>
<td></td>
</tr>
</tbody>
</table>
Sending PIM RP Advertisements to the BSR

To sending PIM RP advertisements to the BSR, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  
  `enable`
  
  **Example:**
  
  `Device> enable`

  Enables privileged EXEC mode.

  Enter your password if prompted.

| **Step 2**
  
  `configure terminal`
  
  **Example:**
  
  `Device# configure terminal`

  Enters global configuration mode.

| **Step 3**
  
  `ipv6 pim bsr candidate rp ipv6-address [group-list access-list-name] [priority priority-value] [interval seconds]`
  
  **Example:**
  
  `Device(config)# ipv6 pim bsr candidate rp 2001:DB8:3000:3000::42 priority 0`

  Sends PIM RP advertisements to the BSR.

| **Step 4**
  
  `interface type number`
  
  **Example:**
  
  `Device(config)# interface GigabitEthernet 1/0/1`

  Specifies an interface type and number, and places the switch in interface configuration mode.

| **Step 5**
  
  `ipv6 pim bsr border`
  
  **Example:**
  
  `Device(config-if)# ipv6 pim bsr border`

  Configures a border for all BSMs of any scope on a specified interface.

| **Step 6**
  
  `copy running-config startup-config`
  
  **(Optional)** Save your entries in the configuration file.

### Configuring BSR for Use Within Scoped Zones

To configure BSR for use within scoped zones, perform this procedure:
### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ipv6 pim bsr candidate rp <code>ipv6-address</code> [hash-mask-length] [priority priority-value]</td>
<td>Configures a switch to be a candidate BSR.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>ipv6 pim bsr candidate bsr 2001:DB8:1:1:4</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ipv6 pim bsr candidate rp <code>ipv6-address</code> [group-list access-list-name] [priority priority-value] [interval seconds]</td>
<td>Configures the candidate RP to send PIM RP advertisements to the BSR.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>ipv6 pim bsr candidate rp 2001:DB8:1:1:1 group-list list scope 6</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# <code>interface GigabitEthernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ipv6 multicast boundary scope <code>scope-value</code></td>
<td>Configures a multicast boundary on the interface for a specified scope.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# <code>ipv6 multicast boundary scope 6</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Configuring BSR Switches to Announce Scope-to-RP Mappings

IPv6 BSR switches can be statically configured to announce scope-to-RP mappings directly instead of learning them from candidate-RP messages. A user might want to configure a BSR switch to announce scope-to-RP mappings so that an RP that does not support BSR is imported into the BSR. Enabling this feature also allows an RP positioned outside the enterprise's BSR domain to be learned by the known remote RP on the local candidate BSR switch.
To configure BSR switches to announce Scope-to-RP mappings, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ipv6 pim bsr announced rp ipv6-address [group-list access-list-name] [priority priority-value]</td>
<td>Announces scope-to-RP mappings directly from the BSR for the specified candidate RP.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# ipv6 pim bsr announced rp 2001:DB8:3000:3000::42 priority 0</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Configuring SSM Mapping

When the SSM mapping feature is enabled, DNS-based SSM mapping is automatically enabled, which means that the switch will look up the source of a multicast MLD version 1 report from a DNS server.

You can use either DNS-based or static SSM mapping, depending on your switch configuration. If you choose to use static SSM mapping, you can configure multiple static SSM mappings. If multiple static SSM mappings are configured, the source addresses of all matching access lists will be used.

#### Note

To use DNS-based SSM mapping, the switch needs to find at least one correctly configured DNS server, to which the switch may be directly attached.

To configuring SSM mapping, perform this procedure:

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Static Mroutes

Static multicast routes (mroutes) in IPv6 can be implemented as an extension of IPv6 static routes. You can configure your switch to use a static route for unicast routing only, to use a static multicast route for multicast RPF selection only, or to use a static route for both unicast routing and multicast RPF selection.

To configure static mroutes, perform this procedure:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>

Prerequisites for IPv6 Client Address Learning

Before configuring IPv6 client address learning, configure the wireless clients to support IPv6.

Information About IPv6 Client Address Learning

Client Address Learning is configured on device to learn the wireless client's IPv4 and IPv6 address and clients transition state maintained by the device on an association, re-association, de-authentication and timeout.

There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLACC)
• Stateful DHCPv6
• Static Configuration

For all of these methods, the IPv6 client always sends neighbor solicitation DAD (Duplicate Address Detection) request to ensure there is no duplicate IP address on the network. The device snoops the client's NDP and DHCPv6 packets to learn about its client IP addresses.

### SLAAC Address Assignment

The most common method for IPv6 client address assignment is Stateless Address Auto-Configuration (SLAAC). SLAAC provides simple plug-and-play connectivity where clients self-assign an address based on the IPv6 prefix. This process is achieved Stateless Address Auto-Configuration (SLAAC) is configured as follows:

- Host sends a router solicitation message.
- Hosts wait for a Router Advertisement message.
- Hosts take the first 64 bits of the IPv6 prefix from the Router Advertisement message and combines it with the 64 bit EUI-64 address (in the case of ethernet, this is created from the MAC Address) to create a global unicast message. The host also uses the source IP address, in the IP header, of the Router Advertisement message, as its default gateway.
- Duplicate Address Detection is performed by IPv6 clients in order to ensure that random addresses that are picked do not collide with other clients.
- The choice of algorithm is up to the client and is often configurable.

The last 64 bits of the IPv6 address can be learned based on the following 2 algorithms:

- EUI-64 which is based on the MAC address of the interface, or
- Private addresses that are randomly generated.

### Figure 11: SLAAC Address Assignment

The following Cisco IOS configuration commands from a Cisco-capable IPv6 router are used to enable SLAAC addressing and router advertisements:

```
ipv6 unicast-routing
interface Vlan20
description IPv6-SLAAC
ip address 192.168.20.1 255.255.255.0
ipv6 address FE80:DB8:0:20::1 linklocal
```
The use of DHCPv6 is not required for IPv6 client connectivity if SLAAC is already deployed. There are two modes of operation for DHCPv6 called Stateless and Stateful.

The DHCPv6 Stateless mode is used to provide clients with additional network information that is not available in the router advertisement, but not an IPv6 address as this is already provided by SLAAC. This information can include the DNS domain name, DNS server(s), and other DHCP vendor-specific options. This interface configuration is for a Cisco IOS IPv6 router implementing stateless DHCPv6 with SLAAC enabled:

```
ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPv6-DHCP-Stateless
ip address 192.168.20.1 255.255.255.0
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPPOOL
ipv6 address 2001:DB8:0:20::1/64
end
```

The DHCPv6 Stateful option, also known as managed mode, operates similarly to DHCPv4 in that it assigns unique addresses to each client instead of the client generating the last 64 bits of the address as in SLAAC. This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on a local Device:

```
ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPv6-DHCP-Stateful
ip address 192.168.20.1 255.255.255.0
ipv6 address 2001:DB8:0:20::1/64
ipv6 nd prefix 2001:db8:0:20::/64 no-advertise
ipv6 nd managed-config-flag
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPPOOL
end
```

This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on an external DHCP server:

```
ipv6 unicast-routing
domain-name cisco.com
```
Static IP Address Assignment

Statically configured address on a client.

Router Solicitation

A Router Solicitation message is issued by a host controller to facilitate local routers to transmit Router Advertisement from which it can obtain information about local routing or perform Stateless Auto-configuration. RouterAdvertisements are transmitted periodically and the host prompts with an immediate Router Advertisement using a Router Solicitation such as - when it boots or following a restart operation.

Router Advertisement

A Router Advertisement message is issued periodically by a router or in response to a Router Solicitation message from a host. The information contained in these messages is used by hosts to perform Stateless Auto-configuration and to modify its routing table.

Neighbor Discovery

IPv6 Neighbor Discovery is a set of messages and processes that determine relationships between neighboring nodes. Neighbor Discovery replaces ARP, ICMP Router Discovery, and ICMP Redirect used in IPv4.

IPv6 Neighbor Discovery inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery packets that do not comply are dropped. The neighbor binding table in the switch tracks each IPv6 address and its associated MAC address. Clients are expired from the table according to Neighbor Binding timers.

Neighbor Discovery Suppression

The IPv6 addresses of wireless clients are cached by the device. When the device receives an NS multicast looking for an IPv6 address, and if the target address is known to the device and belongs to one of its clients, the device will reply with an NA message on behalf of the client. The result of this process generates the equivalent of the Address Resolution Protocol (ARP) table of IPv4 but is more efficient - uses generally fewer messages.

Note
The device acts like proxy and respond with NA, only when the `ipv6 nd suppress` command is configured.
If the device does not have the IPv6 address of a wireless client, the device will not respond with NA and forward the NS packet to the wireless side. To resolve this, an NS Multicast Forwarding knob is provided. If this knob is enabled, the device gets the NS packet for the IPv6 address that it does not have (cache miss) and forwards it to the wireless side. This packet reaches the intended wireless client and the client replies with NA.

This cache miss scenario occurs rarely, and only very few clients which do not implement complete IPv6 stack may not advertise their IPv6 address during NDP.

RA Guard

IPv6 clients configure IPv6 addresses and populate their router tables based on IPv6 router advertisement (RA) packets. The RA guard feature is similar to the RA guard feature of wired networks. RA guard increases the security of the IPv6 network by dropping the unwanted or rogue RA packets that come from wireless clients. If this feature is not configured, malicious IPv6 wireless clients announce themselves as the router for the network often with high priority, which would take higher precedence over legitimate IPv6 routers.

RA-Guard also examines the incoming RA's and decides whether to switch or block them based solely on information found in the message or in the switch configuration. The information available in the frames received is useful for RA validation:

- Port on which the frame is received
- IPv6 source address
- Prefix list

The following configuration information created on the switch is available to RA-Guard to validate against the information found in the received RA frame:

- Trusted/Untrusted ports for receiving RA-guard messages
- Trusted/Untrusted IPv6 source addresses of RA-sender
- Trusted/Untrusted Prefix list and Prefix ranges
- Router Preference

RA guard occurs at the device. You can configure the device to drop RA messages at the device. All IPv6 RA messages are dropped, which protects other wireless clients and upstream wired network from malicious IPv6 clients.

//Create a policy for RA Guard//
ipv6 nd raguard policy raguard-router
trusted-port
device-role router

//Applying the RA Guard Policy on port/interface//
interface tengigabitethernet1/0/1 (Katana)
interface gigabitethernet1/0/1 (Edison)

ipv6 nd raguard attach-policy raguard-router

RA Throttling

RA throttling allows the controller to enforce limits to RA packets headed toward the wireless network. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will...
still maintain an IPv6 client connectivity. If a client sends an RS packet, an RA is sent back to the client. This RA is allowed through the controller and unicast to the client. This process ensures that the new clients or roaming clients are not affected by the RA throttling.

**Configuring IPv6 Unicast**

IPv6 unicasting must always be enabled on the switch and the controller. IPv6 unicast routing is disabled.

To configure IPv6 unicast, perform this procedure:

**Before you begin**

To enable the forwarding of IPv6 unicast datagrams, use the `ipv6 unicast-routing` command in global configuration mode. To disable the forwarding of IPv6 unicast datagrams, use the `no` form of this command.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ipv6 unicast-routing`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ipv6 unicast routing</td>
<td>enable the forwarding of IPv6 unicast datagrams</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ipv6 unicast routing</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring RA Guard Policy**

Configure RA Guard policy on the device to add IPv6 client addresses and populate the router table based on IPv6 router advertisement packets.

To configuring RA guard policy, perform this procedure:
SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 nd raguard policy raguard-router
4. trustedport
5. device-role router
6. exit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Defines the RA guard policy name and enters RA guard policy configuration mode.</td>
</tr>
<tr>
<td>ipv6 nd raguard policy raguard-router</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 nd raguard policy raguard-router</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>(Optional) Specifies that this policy is being applied to trusted ports.</td>
</tr>
<tr>
<td>trustedport</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-ra-guard)# trustedport</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>Specifies the role of the device attached to the port.</td>
</tr>
<tr>
<td>device-role router</td>
<td></td>
</tr>
<tr>

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
### How to Configure IPv6 Neighbor Probing

For IPv6 Neighbor Probing to work, the binding table needs to be populated. To provide fine tuning for the life cycle of an entry in the binding table, perform this task.

A single IPv6 client can have multiple IPv6 addresses at any given time. When you execute the command `show ipv6 neighbor binding mac mac_address`, these addresses display the state as REACHABLE in the IPv6 neighbor binding table for that client's MAC address. If there is no control activity on these addresses for 300 seconds, they move to STALE state and become unusable by the client thereafter.

The `device-tracking tracking` command is used to send periodic probes (default time period is 300 seconds) to all IPv6 clients to ensure that the client's IPv6 address(s) do not age out and move to STALE state. These probes are sent from the switch with a source IP address of all zeros which is a Duplicate address detection (DAD) probe. There are a few clients which do not respond to DAD probes and hence age out after 300 seconds.

You should enable IPv6 Neighbor Probing only if there is a network issue with respect to hosts having difficulty to obtain or keep their IP addresses. Specifically, if a DAD probe is issued to a host during the timing window when the host is negotiating its IP lease renewal, the DAD challenge can result in the host giving up its IP address. Enabling IPv6 Neighbor Probing gratuitously can cause unexpected host behavior.

For Cisco IOS 15.2(5)E release and earlier, you need to remove the IPv6 Snooping policy at the interface level and attach the policy at the VLAN level. Perform step 8 and step 9 to attach the IPv6 Snooping policy at the VLAN level.

If IPv6 Neighbor Probing is enabled on a VLAN, additional configuration must be done to prevent learning and hosts over trunk ports. To disable learning over trunk ports, you must configure a policy with a trusted-port and device-role switch. This configuration requires that other access switches connected to trunk ports have policies to provide first hop security for their own connected hosts. Each switch should provide security for their hosts. Perform step 10 to step 12 to configure a policy with these attributes.

Follow the steps below to configure IPv6 Neighbor Probing.

---

### Configuration Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td><code>vlan configuration 1</code></td>
<td>Configures a VLAN or a collection of VLANs and enters VLAN configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device(config)# <code>vlan configuration 1</code></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><code>ipv6 nd ra throttler attach-policy ra-throttler1</code></td>
<td>Attaches an IPv6 RA throttler policy to a VLAN or a collection of VLANs.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device(config-vlan)# <code>ipv6 nd ra throttler attach-policy ra-throttler1</code></td>
<td></td>
</tr>
</tbody>
</table>

---

**Note:**

For Cisco IOS 15.2(5)E release and earlier, you need to remove the IPv6 Snooping policy at the interface level and attach the policy at the VLAN level. Perform step 8 and step 9 to attach the IPv6 Snooping policy at the VLAN level.

If IPv6 Neighbor Probing is enabled on a VLAN, additional configuration must be done to prevent learning and hosts over trunk ports. To disable learning over trunk ports, you must configure a policy with a trusted-port and device-role switch. This configuration requires that other access switches connected to trunk ports have policies to provide first hop security for their own connected hosts. Each switch should provide security for their hosts. Perform step 10 to step 12 to configure a policy with these attributes.

---

Follow the steps below to configure IPv6 Neighbor Probing.
### SUMMARY STEPS

1. enable
2. configure terminal
3. device-tracking tracking
4. interface vlan vlan-id
5. ipv6 enable
6. no shutdown
7. exit
8. vlan configuration vlan_list
9. ipv6 snooping [attach-policy policy_name]
10. ipv6 snooping policy policy_name
11. trusted-port
12. device-role switch
13. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>device-tracking tracking</td>
<td>Enables IPv6 neighbor probing.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>To disable IPv6 neighbor probing, use the no form of this command.</td>
</tr>
<tr>
<td></td>
<td>Device(config)# device-tracking tracking</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>interface vlan vlan-id</td>
<td>Enters interface configuration mode, and enters the VLAN to which the IP information is assigned. The range is 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# interface vlan 1810</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>ipv6 enable</td>
<td>Enables IPv6 processing on an interface that has not been configured with an explicit IPv6 address.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# ipv6 enable</code></td>
<td><strong>Note</strong> When you create an SVI on VLAN with <code>ipv6 enable</code> configured on it, it results in the link local address of the SVI being used as the probe source address. Hence, probing is performed as an NS message rather than a DAD message. This configuration results in a higher probe response rate. Certain hosts may ignore DAD requests. However, all hosts respond to an NS message.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Enables the interface.</td>
<td></td>
</tr>
<tr>
<td><code>no shutdown</code></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# no shutdown</code></td>
<td>If <code>dot1x</code> is enabled for IPv4, the policies on the interfaces where <code>dot1x</code> is enabled will automatically be configured and tracking will be enabled specifically for IPv6 Neighbor Probing. In this case, changing the tracking behavior at a global configuration level will have no impact on the tracking for these automatically configured policies. Tracking will always be enabled on all the interfaces.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Exits interface configuration mode.</td>
<td></td>
</tr>
<tr>
<td><code>exit</code></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# exit</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Specifies the VLANs to which the IPv6 Snooping policy will be attached; enters the VLAN interface configuration mode.</td>
<td></td>
</tr>
<tr>
<td><code>vlan configuration vlan_list</code></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# vlan configuration 1815</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Attaches the IPv6 Snooping policy to the specified VLANs across all switch and stack interfaces. The default policy is attached if the attach-policy option is not used. The default policy is, security-level guard, device-role node, protocol ndp and dhcp.</td>
<td></td>
</tr>
<tr>
<td><code>ipv6 snooping [attach-policy policy_name]</code></td>
<td><strong>Note</strong> If the same user-defined policy is configured on all interfaces, then this policy can be configured on the VLAN, and it can be removed from the interfaces. If different policies are configured on the interfaces, the policies configured on the interfaces should not be removed and the above default policy should be applied at the VLAN level.</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-vlan-config)# ipv6 snooping attach-policy example_policy</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Configures an IPv6 snooping policy and enters IPv6 snooping configuration mode.</td>
<td></td>
</tr>
<tr>
<td><code>ipv6 snooping policy policy_name</code></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-vlan-config)# ipv6 snooping policy example_policy</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Configuring IPv6 Snooping**

IPv6 snooping must always be enabled on the switch and the controller.

To configuring IPv6 snooping, perform this procedure:

**Before you begin**
Enable IPv6 on the client machine.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. vlan configuration 1
4. ipv6 snooping
5. ipv6 nd suppress
6. exit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
Device# configure terminal | Enters VLAN configuration mode.

**Step 3**

**vlan configuration 1**

*Example:**

Device(config)# vlan configuration 1

**Step 4**

ipv6 snooping

*Example:*

Device(config-vlan)# ipv6 snooping

**Step 5**

ipv6 nd suppress

*Example:*

Device(config-vlan-config)# ipv6 nd suppress

**Step 6**

exit

*Example:*

Device(config-vlan-config)# exit

### Configuring IPv6 ND Suppress Policy

The IPv6 neighbor discovery (ND) multicast suppress feature stops as many ND multicast neighbor solicit (NS) messages as possible by dropping them (and responding to solicitations on behalf of the targets) or converting them into unicast traffic. This feature runs on a layer 2 switch or a wireless controller and is used to reduce the amount of control traffic necessary for proper link operations.

When an address is inserted into the binding table, an address resolution request sent to a multicast address is intercepted, and the device either responds on behalf of the address owner or, at layer 2, converts the request into a unicast message and forwards it to its destination.

To configure IPv6 ND suppress policy, perform this procedure:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ipv6 nd suppress policy

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
</tbody>
</table>
**Purpose**

**Command or Action**

Device> enable

| Step 2 | configure terminal
| Example:
| Device# configure terminal |

| Step 3 | ipv6 nd suppress policy
| Example:
| Device(config)# ipv6 nd suppress policy |

**Configuring IPv6 Snooping on VLAN/PortChannel**

Neighbor Discover (ND) suppress can be enabled or disabled on either the VLAN or a switchport.

To configure IPv6 snooping on VLAN/PortChannel, perform this procedure:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. vlan config901
4. ipv6 nd suppress
5. end
6. interface gi1/0/1
7. ipv6 nd suppress
8. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
Configuring Stateless Auto Address Configuration With DHCP

Follow the procedure given below to configure stateless auto address configuration with DHCP:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface vlan 1
4. ip address fe80::1 link-local
5. ipv6 enable
6. no ipv6 nd managed-config-flag
7. ipv6 nd other-config-flag
8. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 8</strong></td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

---

Example:

Device(config)# end

Enters global configuration mode.

**Step 2**

configure terminal

**Example:**

Device# configure terminal

Creates a interface and enters interface configuration mode.

**Step 3**

interface vlan 1

**Example:**

Device(config)# interface vlan 1

Configures IPv6 address on the interface using the link-local option.

**Step 4**

ip address fe80::1 link-local

**Example:**

Device(config-if)# ip address 198.51.100.1 255.255.255.0

Device(config-if)# ipv6 address fe80::1 link-local

Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::5/64
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Device(config-if)# ipv6 address**
2001:DB8:0:0:EO00::F/64 |

**Step 5**

**ipv6 enable**

**Example:**

Device(config)# ipv6 enable

(Optional) Enables IPv6 on the interface.

**Step 6**

**no ipv6 nd managed-config-flag**

**Example:**

Device(config)# interface vlan 1
Device(config-if)# no ipv6 nd managed-config-flag

Ensures the attached hosts do not use stateful autoconfiguration to obtain addresses.

**Step 7**

**ipv6 nd other-config-flag**

**Example:**

Device(config-if)# no ipv6 nd other-config-flag

Ensures the attached hosts do not use stateful autoconfiguration to obtain non-address options from DHCP (domain etc).

**Step 8**

**end**

**Example:**

Device(config)# end

Exits from the interface mode.

---

## Configuring Stateful DHCP Locally

This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on a local Device.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 unicast-routing
4. ipv6 dhcp pool IPv6_DHCPPOOL
5. address prefix 2001:DB8:0:1:FFFF:1234::/64
6. dns-server 2001:100:0:1::1
7. domain-name example.com
8. exit
9. interface vlan1
10. description IPv6-DHCP-Stateful
11. ipv6 address 2001:DB8:0:20::1/64
12. ip address 192.168.20.1 255.255.255.0
13. ipv6 nd prefix 2001:db8::/64 no-advertise
14. ipv6 nd managed-config-flag
15. ipv6 nd other-config-flag
16. ipv6 dhcp server IPv6_DHCPPOOL
## DETAILED STEPS

</table>
Verifying IPv6 Address Learning Configuration

This example displays the output of the `show ipv6 dhcp pool` command. This command displays the IPv6 service configuration on the device. The vlan 21 configured pool detail displays 6 clients that are currently using addresses from the pool.

**SUMMARY STEPS**

1. `show ipv6 dhcp pool`

**DETAILED STEPS**

<table>

Configuring IPv6 WLAN Security

- Prerequisites for IPv6 WLAN Security, on page 317
- Restrictions for IPv6 WLAN Security, on page 317
- Information About IPv6 WLAN Security, on page 317
- How to Configure IPv6 WLAN Security, on page 320
- Additional References, on page 336
- Feature Information for IPv6 WLAN Security, on page 337

Prerequisites for IPv6 WLAN Security

A client VLAN must be mapped to the WLAN configured on the device

Restrictions for IPv6 WLAN Security

RADIUS Server Support

- If multiple RADIUS servers are configured for redundancy, the user database must be identical in all the servers for the backup to work properly.

Radius ACS Support

- You must configure RADIUS on both your Cisco Secure Access Control Server (ACS) and your device
- RADIUS is supported on Cisco Secure ACS version 3.2 and later releases.

Information About IPv6 WLAN Security

Information About RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a client/server protocol that provides centralized security for users attempting to gain management access to a network. It serves as a back-end database similar to Local EAP and provides authentication and accounting services.
• Authentication—The process of verifying users when they attempt to log into the device

Users must enter a valid username and password for the device to authenticate users to the RADIUS server. If multiple databases are configured, then specify the sequence in which the backend database must be tried.

• Accounting—The process of recording user actions and changes.

Whenever a user successfully executes an action, the RADIUS accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided. If the RADIUS accounting server is unreachable, the users can continue their sessions uninterrupted.

User Datagram Protocol—RADIUS uses User Datagram Protocol (UDP) for its transport. It maintains a database and listens on UDP port 1812 for incoming authentication requests and UDP port 1813 for incoming accounting requests. The device, which requires access control, acts as the client and requests AAA services from the server. The traffic between the device and the server is encrypted by an algorithm defined in the protocol and a shared secret key configured on both devices.

Configures multiple RADIUS accounting and authentication servers. For example, you can have one central RADIUS authentication server but several RADIUS accounting servers in different regions. If you configure multiple servers of the same type and the first one fails or becomes unreachable, the controller automatically tries the second one, then the third one if necessary, and so on.

When RADIUS method is configured for the WLAN, the device will use the RADIUS method configured for the WLAN. When the WLAN is configured to use local EAP, the RADIUS method configured on the WLAN points to Local. The WLAN must also be configured with the name of the local EAP profile to use.

If no RADIUS method is configured in the WLAN, the device will use the default RADIUS method defined in global mode.

Information About Local EAP

Local EAP is an authentication method that allows users and wireless clients to be authenticated locally. It is designed for use in remote offices that maintain connectivity to wireless clients when the back-end system is disrupted or the external authentication server goes down. When you enable local EAP, the device serves as the authentication server and the local user database, which removes dependence on an external authentication server. Local EAP retrieves user credentials from the local user database or the LDAP back-end database to authenticate users. Local EAP supports LEAP, EAP-FAST, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC authentication between the controller and wireless clients.

Without an EAP profile name being provided, or if a name was provided for an EAP profile that does not exist, then EAP by default allows no EAP method for local authentication.

Note

The LDAP back-end database supports these local EAP methods: EAP-TLS, EAP-FAST/GTC, and PEAPv1/GTC. LEAP, EAP-FAST/MSCHAPv2, and PEAPv0. MSCHAPv2 is supported only if the LDAP server is set up to return a clear-text password.
Device support Local EAP authentication against external LDAP databases such as Microsoft Active Directory and Novell’s eDirectory. For more information about configuring the controller for Local EAP authentication against Novell’s eDirectory, see the Configure Unified Wireless Network for Authentication Against Novell’s eDirectory Database whitepaper.

<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
**Step 7**: `exit` | Exits from the interface mode.

**Example:**
```
Device (config-if)# exit
```

---

### Purpose

**Creating WLAN for WPA2+AES**

Create a WLAN and map it to the client VLAN created for WPA2+AES.

#### SUMMARY STEPS

1. `configure terminal`
2. `wlan wpas2-aes-wlan 1 wpas2-aes-wlan`
3. `client vlan 105`
4. `local-auth wcm_eap_profile`
5. `security dot1x authentication-list default`
6. `no shutdown`
7. `end`

#### DETAILED STEPS

**Example:**
```
Device# configure terminal
```

| **Step 2** `wlan wpas2-aes-wlan 1 wpas2-aes-wlan` | Creates a WLAN. |

**Example:**
```
Device(config)# wlan wpas2-aes-wlan 1 wpas2-aes-wlan
```

| **Step 3** `client vlan 105` | Maps the WLAN to the client VLAN. |

**Example:**
```
Device(config-wlan)# client vlan 105
```

| **Step 4** `local-auth wcm_eap_profile` | Creates and sets the EAP profile on the WLAN. |

**Example:**
```
Device(config-wlan)# local-auth wcm_eap_profile
```
**Purpose**

Command or Action | Purpose
--- | ---
**Step 5** | security dot1x authentication-list default
Example: Device(config-wlan)#security dot1x authentication-list default
Uses the default dot1x authentication list.

**Step 6** | no shutdown
Example: Device(config-wlan)#no shutdown
Enables the WLAN.

**Step 7** | end
Example: Device(config)# end
Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

**Step 3**  
**aaa group server radius wcm_rad**  
**Example:**  
`Device(config)# aaa group server radius wcm_rad`  
`Device(config-sg-radius)#`  
- Creates a radius server-group.

**Step 4**  
**server <ip address> auth-port 1812 acct-port 1813**  
**Example:**  
`Device(config-sg-radius)# server One auth-port 1812 acct-port 1813`  
`Device(config-sg-radius)# server Two auth-port 1812 acct-port 1813`  
`Device(config-sg-radius)# server Three auth-port 1812 acct-port 1813`  
- Adds servers to the radius group created in Step 3.  
- Configures the UDP port for RADIUS accounting server and authentication server.

**Step 5**  
**aaa authentication dot1x method_list group wcm_rad**  
**Example:**  
`Device(config)# aaa authentication dot1x method_list group wcm_rad`  
- Maps the method list to the radius group.

**Step 6**  
**dot1x system-auth-control**  
**Example:**  
`Device(config)# dot1x system-auth-control`  
- Enables the system authorization control for the radius group.

**Step 7**  
**aaa session-id common**  
**Example:**  
`Device(config)# aaa session-id common`  
- Ensures that all session IDs information sent out, from the radius group, for a given call are identical.

Configuring IPv6 ACL

Prerequisites for Configuring IPv6 ACL

You can filter IP Version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP Version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic when the switch is running the IP base feature set.

Restrictions for Configuring IPv6 ACL

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs.

The device supports most of the Cisco IOS-supported IPv6 ACLs with some exceptions:

- The device does not support matching on these keywords: flowlabel, routing header, and undetermined-transport.
- The device does not support reflexive ACLs (the reflect keyword).
- The device does not apply MAC-based ACLs on IPv6 frames.
- When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the device checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.
• If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the device does not allow the ACE to be added to the ACL that is currently attached to the interface.

**Information About IPv6 ACL**

An access control list (ACL) is a set of rules used to limit access to a particular interface (for example, if you want to restrict a wireless client from pinging the management interface of the controller). ACLs are configured on the device and applied to the management interface, the AP-manager interface, any of the dynamic interfaces, or a WLAN to control data traffic to and from wireless clients or to the controller central processing unit (CPU) to control all traffic destined for the CPU.

An access control list (ACL) is a set of rules used to limit access to a particular interface. ACLs are configured on the device and applied to the management interface and to any of the dynamic interfaces.

You can also create a preauthentication ACL for web authentication. Such an ACL is used to allow certain types of traffic before authentication is complete.

IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source and destination ports.

---

**Note**

You can enable only IPv4 traffic in your network by blocking IPv6 traffic. That is, you can configure an IPv6 ACL to deny all IPv6 traffic and apply it on specific or all WLANs.

**Understanding IPv6 ACLs**

A switch supports two types of IPv6 ACLs:

- IPv6 router ACLs are supported on outbound or inbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. IPv6 router ACLs apply only to IPv6 packets that are routed.

- IPv6 port ACLs are supported on inbound traffic on Layer 2 interfaces only. IPv6 port ACLs are applied to all IPv6 packets entering the interface.

A switch running the IP base feature set supports only input router IPv6 ACLs. It does not support port ACLs or output IPv6 router ACLs.

---

**Note**

If you configure unsupported IPv6 ACLs, an error message appears and the configuration does not take affect.

The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.

You can apply both IPv4 and IPv6 ACLs to an interface. As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs:

- When an input router ACL and input port ACL exist in an SVI, packets received on ports to which a port ACL is applied are filtered by the port ACL. Routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.
• When an output router ACL and input port ACL exist in an SVI, packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IPv6 packets are filtered by the router ACL. Other packets are not filtered.

**Note**

If any port ACL (IPv4, IPv6, or MAC) is applied to an interface, that port ACL is used to filter packets, and any router ACLs attached to the SVI of the port VLAN are ignored.

### Types of ACL

#### Per User IPv6 ACL

For the per-user ACL, the full access control entries (ACE) as the text strings are configured on the ACS. The ACE is not configured on the Controller. The ACE is sent to the device in the **ACCESS-Accept** attribute and applies it directly for the client. When a wireless client roams into an foreign device, the ACEs are sent to the foreign device as an AAA attribute in the mobility Handoff message. Output direction, using per-user ACL is not supported.

#### Filter ID IPv6 ACL

For the filter-Id ACL, the full ACEs and the `acl name(filter-id)` is configured on the device and only the `filter-id` is configured on the ACS.

The `filter-id` is sent to the device in the **ACCESS-Accept** attribute, and the device looks up the `filter-id` for the ACEs, and then applies the ACEs to the client. When the client L2 roams to the foreign device, only the `filter-id` is sent to the foreign device in the mobility Handoff message. Output filtered ACL, using per-user ACL is not supported. The foreign device has to configure the `filter-id` and ACEs beforehand.

### IPv6 ACLs and Switch Stacks

The stack master supports IPv6 ACLs in hardware and distributes the IPv6 ACLs to the stack members.

**Note**

For full IPv6 functionality in a switch stack, all stack members must be running the IP services feature set.

If a new switch takes over as stack master, it distributes the ACL configuration to all stack members. The member switches sync up the configuration distributed by the new stack master and flush out entries that member switches sync up the configuration distributed by the new stack master and flush out entries that are not required.

When an ACL is modified, attached to, or detached from an interface, the stack master distributes the change to all stack members.

### Configuring IPv6 ACLs

Follow the procedure given below to filter IPv6 traffic:
1. Create an IPv6 ACL, and enter IPv6 access list configuration mode.

2. Configure the IPv6 ACL to block (deny) or pass (permit) traffic.

3. Apply the IPv6 ACL to the interface where the traffic needs to be filtered.

4. Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.

**Default IPv6 ACL Configuration**

There are no IPv6 ACLs configured or applied.

**Interaction with Other Features and Switches**

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.

- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.

- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

  You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.

- If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.

| Note | Only packets of the same type as the ACL that could not be added (ipv4, ipv6, MAC) will be dropped on the interface. |

**How To Configure an IPv6 ACL**

**Creating an IPv6 ACL**

**SUMMARY STEPS**

1. `enable`

2. `configure terminal`

3. `ipv6 access-list acl_name`
IPv6

Creating an IPv6 ACL

4. `{deny|permit} protocol
5. `{deny|permit} tcp
6. `{deny|permit} udp
7. `{deny|permit} icmp
8. end
9. show ipv6 access-list
10. copy running-config startup-config

<td></td>
</tr>
</tbody>
</table>
| `{deny | permit} protocol
{source-ipv6-prefix/prefix-length | any | host source-ipv6-address}
{destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address}
{operator [port-number]} {dscp value}
{fragments | log | log-input | routing | sequence value}
{time-range name} | • For protocol, enter the name or number of an Internet protocol: ahp, esp, icmp, ipv6, pcp, step, tcp, or udp, or an integer in the range 0 to 255 representing an IPv6 protocol number. |
| | • The source-ipv6-prefix/prefix-length or destination-ipv6-prefix/ prefix-length is the source or destination IPv6 network or class of networks for which to set deny or permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373). |
| | • Enter any as an abbreviation for the IPv6 prefix ::/0. |
| | • For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) For operator, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range. If the operator follows the source-ipv6-prefix/prefix-length argument, it must match the source port. If the operator follows the destination-ipv6-prefix/prefix-length argument, it must match the destination port.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter log to cause a logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter routing to specify that IPv6 packets be routed.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement.</td>
<td></td>
</tr>
</tbody>
</table>

Step 5  
{deny|permit} tcp  
Example:
{deny | permit} tcp  
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}  
[operator  
[port-number]]|destination-ipv6-prefix/prefix-length  
| any |hostdestination-ipv6-address]  
[operator [port-number]]|ack| [dscp  
value]established] |fin|  
[log]|log-input| [neq |port |protocol]| |psh|  
[range|port |protocol]| |rst][routing] |sequence |  
(Optional) Define a TCP access list and the access conditions.  
Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:  
• ack—Acknowledgment bit set.  
• established—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set.

<tbody>
<tr>
<td>value</td>
<td>• fin—Finished bit set; no more data from sender.</td>
</tr>
<tr>
<td>[syn] [time-range name] [urg]</td>
<td>• neq {port</td>
</tr>
<tr>
<td></td>
<td>• psh—Push function bit set.</td>
</tr>
<tr>
<td></td>
<td>• range {port</td>
</tr>
<tr>
<td></td>
<td>• rst—Reset bit set.</td>
</tr>
<tr>
<td></td>
<td>• syn—Synchronize bit set.</td>
</tr>
<tr>
<td></td>
<td>• urg—Urgent pointer bit set.</td>
</tr>
</tbody>
</table>

### Step 6

**{deny|permit} udp**

**Example:**

```plaintext
{deny | permit} udp
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}
[operator {port-number}]
{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}
[operator {port-number}]
[dscp value]
[log]
[log-input]
[neq {port | protocol}]
[range {port | protocol}]
[routing]
[sequence value]
[time-range name]
```

(Optional) Define a UDP access list and the access conditions.

Enter udp for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the operator [port] port number or name must be a UDP port number or name, and the established parameter is not valid for UDP.

### Step 7

**{deny|permit} icmp**

**Example:**

```plaintext
{deny | permit} icmp
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}
{operator [port-number]}
{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}
{operator [port-number]}
[icmp-type [icmp-code]]
[icmp-message] [dscp value]
[log]
[log-input]
[routing]
[sequence value]
[time-range name]
```

(Optional) Define an ICMP access list and the access conditions.

Enter icmp for Internet Control Message Protocol. The ICMP parameters are the same as those described for most IP protocols in Step 3a, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:

- **icmp-type**—Enter to filter by ICMP message type, a number from 0 to 255.
- **icmp-code**—Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255.
- **icmp-message**—Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name. To see a list of ICMP message type names and code names, use the ? key or see command reference for this release.

### Step 8

**end**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
Applying an IPv6 to an Interface

This section describes how to apply IPv6 ACLs to network interfaces. You can apply an IPv6 ACL to outbound or inbound traffic on layer 2 and Layer 3 interfaces. You can apply IPv6 ACLs only to inbound management traffic on Layer 3 interfaces.

To control access to an interface, perform this procedure:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface_id`
4. `no switchport`
5. `ipv6 address ipv6_address`
6. `ipv6 traffic-filter acl_name`
7. `end`
8. `show running-config interface tenGigabitEthernet 1/0/3`
9. `copy running-config startup-config`

**DETAILED STEPS**

### Creating WLAN IPv6 ACL

**SUMMARY STEPS**

1. ipv6 traffic-filter acl *acl_name*
2. ipv6 traffic-filter acl web
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv6 traffic-filter acl acl_name</td>
<td>Creates a named WLAN ACL.</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**
```
Device(config-wlan)# ipv6 traffic-filter acl testacl
```

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv6 traffic-filter acl web</td>
<td>Creates a pre-authentication for WLAN ACL.</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**
```
Device(config-wlan)# ipv6 traffic-filter acl web testacl
```

## Verifying IPv6 ACL

### Displaying IPv6 ACLs

To display IPv6 ACLs, perform this procedure:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device> enable
```

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**
```
Device# configure terminal
```

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show access-list</td>
<td>Displays all access lists configured on the device</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**
```
Device# show access-list
```

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 access-list acl_name</td>
<td>Displays all configured IPv6 access list or the access list specified by name.</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**
```
Device# show ipv6 access-list [access-list-name]
```
Configuration Examples for IPv6 ACL

Example: Creating an IPv6 ACL

This example configures the IPv6 access list named CISCO. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny-all condition is at the end of each IPv6 access list.

Note

Logging is supported only on Layer 3 interfaces.

```
Device(config)# ipv6 access-list CISCO
Device(config-ipv6-acl)# deny tcp any any gt 5000
Device (config-ipv6-acl)# deny ::/0 lt 5000 ::/0 log
Device(config-ipv6-acl)# permit icmp any any
Device(config-ipv6-acl)# permit any any
```

Example: Applying IPv6 ACLs

This example shows how to apply the access list Cisco to outbound traffic on a Layer 3 interface.

```
Device(config)# interface TenGigabitEthernet 1/0/3
Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001::/64 eui-64
Device(config-if)# ipv6 traffic-filter CISCO out
```

Example: Displaying IPv6 ACLs

This is an example of the output from the show access-lists privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

```
Device #show access-lists
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10
```

This is an example of the output from the show ipv6 access-lists privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

```
Device# show ipv6 access-list
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30
IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20
```
Example: Configuring RA Throttling and NS Suppression

This task describes how to create an RA throttle policy in order to help the power-saving wireless clients from being disturbed by frequent unsolicited periodic RA's. The unsolicited multicast RA is throttled by the controller.

Before you begin
Enable IPv6 on the client machine.

SUMMARY STEPS

1. configure terminal
2. ipv6 nd ra-throttler policy Mythrottle
3. throttle-period 20
4. max-through 5
5. allow at-least 3 at-most 5
6. switch (config)# vlan configuration 100
7. ipv6 nd suppress
8. ipv6 nd ra-th attach-policy attach-policy_name
9. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# configure terminal</td>
</tr>
</tbody>
</table>

Enters global configuration mode.

| **Step 2** | ipv6 nd ra-throttler policy Mythrottle |
| Example: | Device (config)# ipv6 nd ra-throttler policy Mythrottle |

Creates a RA throttler policy called Mythrottle.

| **Step 3** | throttle-period 20 |
| Example: | Device (config-nd-ra-throttle)# throttle-period 20 |

Determines the time interval segment during which throttling applies.

| **Step 4** | max-through 5 |
| Example: | Device (config-nd-ra-throttle)# max-through 5 |

Determines how many initial RA's are allowed.

| **Step 5** | allow at-least 3 at-most 5 |
| Example: | Device (config-nd-ra-throttle)# allow at-least 3 at-most 5 |

Determines how many RA's are allowed after the initial RAs have been transmitted, until the end of the interval segment.
### Configuring RA Guard Policy

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ipv6 nd raguard policy `policy name`
4. trusted-port
5. device-role router
6. interface `interface-id`
7. ipv6 nd raguard attach-policy `policy name`
8. vlan `vlan-id`
9. ipv6 nd suppress
10. ipv6 snooping
11. ipv6 nd raguard attach-policy `policy name`
12. ipv6 nd ra-throttler attach-policy `policy name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable use</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: <code>Device&gt;</code> <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>

10. ipv6 snooping
11. ipv6 nd raguard attach-policy `policy name`
12. ipv6 nd ra-throttler attach-policy `policy name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 6** switch (config)# vlan configuration 100  
Example: `Device (config)# vlan configuration 100` | Creates a per vlan configuration. |
| **Step 7** ipv6 nd suppress  
Example: `Device (config)# ipv6 nd suppress` | Disables the neighbor discovery on the Vlan. |
| **Step 8** ipv6 nd ra-th attach-policy `attach-policy_name`  
Example: `Device (config)# ipv6 nd ra-throttle attach-policy `attach-policy_name` | Enables the router advertisement throttling. |
| **Step 9** end  
Example: `Device (config)# end` | Returns to privileged EXEC mode. Alternatively, you can also press `Ctrl-Z` to exit global configuration mode. |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

#### Step 3

**ipv6 nd rarguard policy** *policy name*

**Example:**

Device(config)# ipv6 nd rarguard policy MyPolicy

#### Step 4

**trusted-port**

**Example:**

Device(config-nd-raguard)# trusted-port

Configures the trusted port for the policy created above.

#### Step 5

**device-role router**

**Example:**

Device(config-nd-raguard)# device-role [host|monitor|router|switch] device-role router

 Defines the trusted device that can send RAs to the trusted port created above.

#### Step 6

**interface** *interface-id*

**Example:**

Device(config)# interface tenGigabitEthernet 1/0/1

Configures the interface to the trusted device.

#### Step 7

**ipv6 nd rarguard attach-policy** *policy name*

**Example:**

Device(config-if)# ipv6 nd rarguard attach-policy MyPolicy

Configures and attaches the policy to trust the RA's received from the port.

#### Step 8

**vlan** *vlan-id*

**Example:**

Device(config)# vlan configuration 19-21,23

Configures the wireless client vlans.

#### Step 9

**ipv6 nd suppress**

**Example:**

Device(config-vlan-config)# ipv6 nd suppress

Suppresses the ND messages over wireless.

#### Step 10

**ipv6 snooping**

**Example:**

Device(config-vlan-config)# ipv6 snooping

Captures IPv6 traffic.

#### Step 11

**ipv6 nd rarguard attach-policy** *policy name*

**Example:**

Device(config-vlan-config)# ipv6 nd rarguard attach-policy MyPolicy

Attaches the RA Guard policy to the wireless client vlans.

#### Step 12

**ipv6 nd ra-throttler attach-policy** *policy name*

**Example:**

Attaches the RA throttling policy to the wireless client vlans.
Configuring IPv6 Neighbor Binding

SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 neighbor binding [vlan] 19 2001:db8::25:4 interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc

DETAILED STEPS

<table>

Prerequisites for IPv6 Web Authentication

The following configurations must be in place before you start with IPv6 Web Authentication:

- IPv6 Device Tracking.
- IPv6 DHCP Snooping.
- Disable security of type 802.1x on the wlan.
- Each WLAN must have a vlan associated to it.
- Change the default wlan setting from shutdown to no shutdown.

Related Topics
- Enabling Security on the WLAN, on page 358

Restrictions for IPv6 Web Authentication

The following restrictions are implied when using IPv6 web authentication:

Related Topics

Information About IPv6 Web Authentication

Web authentication is a Layer 3 security feature and the device disallows IP traffic (except DHCP and DNS-related packets) from a particular client until it supplies a valid username and password. It is a simple authentication method without the need for a supplicant or client utility. Web authentication is typically used by customers who deploy a guest-access network. Traffic from both, HTTP and HTTPS, page is allowed to display the login page.

Note
Web authentication does not provide data encryption and is typically used as simple guest access for either a hot spot or campus atmosphere, where connectivity is always a factor.

A WLAN is configured as security weauth for web based authentication. The device supports the following types of web based authentication:

• Web Authentication – The client enters the credentials in a web page which is then validated by the Wlan controller.

• Web Consent – The Wlan controller presents a policy page with Accept/Deny buttons. Click Accept button to access the network.

Note
Maximum consecutive Web Auth sessions supported in device is 40 per second.

A Wlan is typically configured for open authentication, that is without Layer 2 authentication, when web-based authentication mechanism is used.

Web Authentication Process

The following events occur when a WLAN is configured for web authentication:

• The user opens a web browser and enters a URL address, for example, http://www.example.com. The client sends out a DNS request for this URL to get the IP address for the destination. The device bypasses the DNS request to the DNS server, which in turn responds with a DNS reply that contains the IP address of the destination www.example.com. This, in turn, is forwarded to the wireless clients.

• The client then tries to open a TCP connection with the destination IP address. It sends out a TCP SYN packet destined to the IP address of www.example.com.

• The device has rules configured for the client and cannot act as a proxy for www.example.com. It sends back a TCP SYN-ACK packet to the client with source as the IP address of www.example.com. The client sends back a TCP ACK packet in order to complete the three-way TCP handshake and the TCP connection is fully established.

• The client sends an HTTP GET packet destined to www.example.com. The device intercepts this packet and sends it for redirection handling. The HTTP application gateway prepares an HTML body and sends it back as the reply to the HTTP GET requested by the client. This HTML makes the client go to the default web-page of the device, for example, http://<Virtual-Server-IP>/login.html.

• The client closes the TCP connection with the IP address, for example, www.example.com.
• If the client wants to go to virtual IP, the client tries to open a TCP connection with the virtual IP address of the device. It sends a TCP SYN packet for virtual IP to the device.

• The device responds back with a TCP SYN-ACK and the client sends back a TCP ACK to the device in order to complete the handshake.

• The client sends an HTTP GET for /login.html destined to virtual IP in order to request for the login page.

• This request is allowed to the web server of the device, and the server responds with the default login page. The client receives the login page in the browser window where the user can log in.

Configuring the WLAN

Before you begin

- The WLAN must have a Vlan associated with it. By default, a new Wlan is always associated with Vlan 1, which can be changed as per the configuration requirements.
- Configure and enable the WLAN to no shutdown. By default, the Wlan is configured with the shutdown parameter and is disabled.

SUMMARY STEPS

1. wlan 1
2. client vlan interface ID
3. security web-auth authentication list weauthlistlocal
4. security web-auth parameter-map global
5. no security wpa
6. no shutdown
7. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
<th>Example</th>
</tr>
</thead>
</table>
| **Step 1** wlan 1  
Example: Device(config-wlan)# wlan 1 name vicweb ssid vicweb | Creates a wlan and assign an SSID to it. | |
| **Step 2** client vlan interface ID  
Example: Device(config-wlan)# client vlan VLAN0136 | Assigns the client to vlan interface. | |
| **Step 3** security web-auth authentication list webauthlistlocal  
Example: Device(config-wlan)# security web-auth authentication-list webauthlistlocal | Configures web authentication for the wlan. | |
| **Step 4** security web-auth parameter-map global  
Example: Device(config-wlan)# security web-auth parameter-map global | Configures the parameter map on the wlan. | |
| **Step 5** no security wpa  
Example: Device(config-wlan)# no security wpa | Configures the security policy for a wlan. This enables the wlan. | |
| **Step 6** no shutdown  
Example: Device(config-wlan)# no shutdown | Configures and enables the Wlan. | |
| **Step 7** end  
Example: Device(config)# end | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. | |

Prerequisites for IPv6 Client Mobility

To enable wireless IPv6 client connectivity, the underlying wired network must support IPv6 routing and an address assignment mechanism such as SLAAC or DHCPv6. The device must have L2 adjacency to the IPv6 router, and the VLAN needs to be tagged when the packets enter the device. APs do not require connectivity on an IPv6 network, as all traffic is encapsulated inside the IPv4 CAPWAP tunnel between the AP and device.

Restrictions For IPv6 Client Mobility

When using the IPv6 Client Mobility, clients must support IPv6 with either static stateless auto configuration (such as Windows XP clients) or stateful DHCPv6 IP addressing (such as Windows 7 clients).

To allow smooth operation of stateful DHCPv6 IP addressing, you must have a switch or router that supports the DHCP for IPv6 feature (such as the device) that is configured to act like a DHCPv6 server, or you need a dedicated server such as a Windows 2008 server with a built-in DHCPv6 server.

Information About IPv6 Client Mobility

The Device supports IPv6 mobility for IPv6-only or dual-stack nodes. The IPv6 Client Mobility is divided into:

- Link Layer and
• Network Layer

The link layer is handled by the 802.11 protocol which enables the client to roam to any AP in the same BSS (basic service set) identified by the same SSID without losing the link layer connectivity.

However, link layer mobility is not enough to make wireless client Layer 3 applications continue to work seamlessly while roaming. Cisco IOSd’s wireless mobility module uses mobility tunneling to retain seamless connectivity for the client’s Layer 3 PoP (point of presence) when the client roams across different subnets on different switches.

IPv6 is the next-generation network layer Internet protocol intended to replace IPv4 in the TCP/IP suite of protocols. This new version increases the internet global address space to accommodate users and applications that require unique global IP addresses. IPv6 incorporates 128-bit source and destination addresses, which provide significantly more addresses than the 32-bit IPv4 addresses.

To support IPv6 clients across controllers, ICMPv6 messages must be dealt with specially to ensure the IPv6 client remains on the same Layer 3 network. The device keeps track of IPv6 clients by intercepting the ICMPv6 messages to provide seamless mobility and protect the network from network attacks. The NDP (neighbor discovery packets) packets are converted from multicast to unicast and delivered individually per client. This unique solution ensures that Neighbor Discovery and Router Advertisement packets are not leaked across VLANs. Clients can receive specific Neighbor Discovery and Router Advertisement packets ensuring correct IPv6 addressing to avoid unnecessary multicast traffic.

The configuration for IPv6 mobility is the same as IPv4 mobility and requires no separate software on the client side to achieve seamless roaming. The device must be part of the same mobility group. Both IPv4 and IPv6 client mobility are enabled by default.

IPv6 client mobility is used for the following:

• Retaining the client IPv6 multiple addresses in Layer-2 and Layer-3 roaming.

• IPv6 Neighbor Discovery Protocol (NDP) packet management.

• Client IPv6 addresses learning.

---

**Note**

The configuration for IPv6 mobility in SDA wireless and Local mode is the same as of IPv4 mobility and requires no different software configuration on the client side to achieve seamless roaming. Refer to IPv4 mobility section for configuration information.

---

**Using Router Advertisement**

The Neighbor Discovery Protocol (NDP) operates in the link-layer and is responsible for the discovery of other nodes on the link. It determines the link-layer addresses of other nodes, finds the available routers, and maintains reachability information about the paths to other active neighbor nodes.

Router Advertisement (RA) is one of the IPv6 Neighbor Discovery Protocol (NDP) packets that is used by the hosts to discover available routers, acquire the network prefix to generate the IPv6 addresses, link MTU, and so on. The routers send RA on a regular basis, or in response to hosts Router Solicitation messages.

IPv6 wireless client mobility manages the IPv6 RA packet. The converged access device forwards the link-local all-nodes multicast RA packets to the local and roaming wireless nodes mapped on same VLAN the RA was received on.
Figure 1 illustrates the link-local all-nodes mcast RA forwarding issue in the wireless node mobility.

**Figure 14: Roaming Client Receiving Invalid RA from Router 2**

Figure 2 illustrates how a roaming client “MN” receives RA from VLAN 200 in a foreign switch and how it acquires a new IP address and breaks into L3 mobility’s point of presence.

**Figure 15: Roaming Client Receives Valid RA from Router 1**

---

**RA Throttling and NS suppression**

To safeguard the power-saving wireless clients from being disturbed by frequent unsolicited periodic RAs, the controller can throttle the unsolicited multicast RA.

**IPv6 Address Learning**

There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static configuration

For these methods, the IPv6 client always sends NS DAD (duplicate address detection) to ensure that there is no duplicated IP address on the network. The device snoops the clients NDP and DHCPv6 packets to learn about its client IP addresses and then updates the controllers database. The database then informs the controller for the clients new IP address.
Handling Multiple IP Addresses

In the case when the new IP address is received after RUN state, whether an addition or removal, the controller updates the new IP addresses on its local database for display purposes. Essentially, the IPv6 uses the existing or same PEM state machine code flow as in IPv4. When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller will include all the available IP addresses, IPv4 and IPv6, in the API/SPI interface to the external entities.

An IPv6 client can acquire multiple IP addresses from stack for different purposes. For example, a link-local address for link local traffic, and a routable unique local or global address.

When the client is in the DHCP request state and the controller receives the first IP address notification from the database for either an IPv4 or IPv6 address, the PEM moves the client into the RUN state.

When a new IP address is received after the RUN state, either for addition or removal, the controller updates the new IP addresses on its local database for display purposes.

When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller provides the available IP addresses, both IPv4 and IPv6, to the external entities.

IPv6 Configuration

The device supports IPv6 client as seamlessly as the IPv4 clients. The administrator must manually configure the VLANs to enable the IPv6, IPv6's snooping and throttling functionality. This will enable the NDP packets to throttle between the device and its various clients.

High Availability

The switch will sync with the wireless clients when the clients IP address is hard to learn. When a switchover happens, the IPv6 neighbor binding table is synched to standby state. However, the wireless client will itself disassociate and reassociate to a new active state once the switchover is complete and the neighbor binding table is updated with latest information for that client.

If, during the reassociation, the client moves to another AP then the original entry in the binding table is marked as down for sometime and will be aged-out.

For the new entries joining the switch from another AP, the new IP address is learned and notified to the controller's database.

Note

This feature is available only for the Cisco Catalyst 3850 Switch.

Verifying IPv6 Client Mobility

The commands listed in the Table 1 applies to the IPv6 client mobility.

Pre-requisites for IPv6 Mobility

The mobility and its related infrastructure must be configured and ready for use.

Information About IPv6 Mobility

Mobility, or roaming, is a wireless LAN client's ability to maintain its association seamlessly from one access point to another securely and with as little latency as possible. This section explains how mobility works when device are included in a wireless network.

When a wireless client associates and authenticates to an access point, the access point's device places an entry for that client in its client database. This entry includes the client's MAC and IP addresses, security context and associations, quality of service (QoS) contexts, the WLAN, and the associated access point. The device uses this information to forward frames and manage traffic to and from the wireless client.

When the wireless client moves its association from one access point to another, the device simply updates the client database with the newly associated access point. If necessary, new security context and associations are established as well. The process becomes more complicated, however, when a client roams from an access point joined to one device to an access point joined to a different device. It also varies based on whether the device are operating on the same subnet.

Inter Controller Roaming

When the client associates to an access point joined to a new device, the new device exchanges mobility messages with the original device, and the client database entry is moved to the new device if sticky anchoring is disabled.
Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming

Inter-subnet roaming is similar to inter-controller roaming in that the device exchange mobility messages on the client roam. However, instead of moving the client database entry to the new device, the original device marks the client with an "Anchor" entry in its own client database. The database entry is copied to the new device client database and marked with a "Foreign" entry in the new device. The roam remains transparent to the wireless client, and the client maintains its original IP address.

In inter-subnet roaming, WLANs on both anchor and foreign device need to have the same network access privileges and no source-based routing or source-based firewalls in place. Otherwise, the clients may have network connectivity issues after the handoff.

For more information on configuring mobility see, the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE, Release 3.2SE.

How to Configure IPv6 Mobility

Monitoring IPv6 Mobility

This chapter displays the mobility related IPv6 configuration. To see the mobility related configurations refer to the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE 3.2SE.

SUMMARY STEPS

1. `show ipv6 neighbors binding mac C0C1.C06B.C4E2`

DETAILED STEPS

CHAPTER 23

Configuring HSRP

• Configuring HSRP, on page 381

Configuring HSRP

This chapter describes how to use Hot Standby Router Protocol (HSRP) to provide routing redundancy for routing IP traffic without being dependent on the availability of any single router.

You can also use a version of HSRP in Layer 2 mode to configure a redundant command switch to take over cluster management if the cluster command switch fails.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring HSRP

HSRP Overview

HSRP is Cisco's standard method of providing high network availability by providing first-hop redundancy for IP hosts on an IEEE 802 LAN configured with a default gateway IP address. HSRP routes IP traffic without relying on the availability of any single router. It enables a set of router interfaces to work together to present the appearance of a single virtual router or default gateway to the hosts on a LAN. When HSRP is configured on a network or segment, it provides a virtual Media Access Control (MAC) address and an IP address that is shared among a group of configured routers. HSRP allows two or more HSRP-configured routers to use the MAC address and IP network address of a virtual router. The virtual router does not exist; it represents the common target for routers that are configured to provide backup to each other. One of the routers is selected to be the active router and another to be the standby router, which assumes control of the group MAC address and IP address should the designated active router fail.
Routers in an HSRP group can be any router interface that supports HSRP, including routed ports and switch virtual interfaces (SVIs).

**Note**

HSRP provides high network availability by providing redundancy for IP traffic from hosts on networks. In a group of router interfaces, the active router is the router of choice for routing packets; the standby router is the router that takes over the routing duties when an active router fails or when preset conditions are met.

HSRP is useful for hosts that do not support a router discovery protocol and cannot switch to a new router when their selected router reloads or loses power. When HSRP is configured on a network segment, it provides a virtual MAC address and an IP address that is shared among router interfaces in a group of router interfaces running HSRP. The router selected by the protocol to be the active router receives and routes packets destined for the group’s MAC address. For n routers running HSRP, there are n + 1 IP and MAC addresses assigned.

HSRP detects when the designated active router fails, and a selected standby router assumes control of the Hot Standby group’s MAC and IP addresses. A new standby router is also selected at that time. Devices running HSRP send and receive multicast UDP-based hello packets to detect router failure and to designate active and standby routers. When HSRP is configured on an interface, Internet Control Message Protocol (ICMP) redirect messages are automatically enabled for the interface.

You can configure multiple Hot Standby groups among switches and switch stacks that are operating in Layer 3 to make more use of the redundant routers.

To do so, specify a group number for each Hot Standby command group you configure for an interface. For example, you might configure an interface on switch 1 as an active router and one on switch 2 as a standby router and also configure another interface on switch 2 as an active router with another interface on switch 1 as its standby router.

The following figure shows a segment of a network configured for HSRP. Each router is configured with the MAC address and IP network address of the virtual router. Instead of configuring hosts on the network with the IP address of Router A, you configure them with the IP address of the virtual router as their default router. When Host C sends packets to Host B, it sends them to the MAC address of the virtual router. If for any reason, Router A stops transferring packets, Router B responds to the virtual IP address and virtual MAC address and becomes the active router, assuming the active router duties. Host C continues to use the IP address of the virtual router to address packets destined for Host B, which Router B now receives and sends to Host B. Until Router A resumes operation, HSRP allows Router B to provide uninterrupted service to users on Host C’s segment that need to communicate with users on Host B’s segment and also continues to perform its normal function of handling packets between the Host A segment and Host B.
HSRP Versions

Cisco IOS XE 3.3SE and later support these Hot Standby Router Protocol (HSRP) versions:

The switch supports these HSRP versions:

- **HSRPv1** - Version 1 of the HSRP, the default version of HSRP. It has these features:
  - The HSRP group number can be from 0 to 255.
  - HSRPv1 uses the multicast address 224.0.0.2 to send hello packets, which can conflict with Cisco Group Management Protocol (CGMP) leave processing. You cannot enable HSRPv1 and CGMP at the same time; they are mutually exclusive.

- **HSRPv2** - Version 2 of the HSRP has these features:
  - HSRPv2 uses the multicast address 224.0.0.102 to send hello packets. HSRPv2 and CGMP leave processing are no longer mutually exclusive, and both can be enabled at the same time.
  - HSRPv2 has a different packet format than HSRPv1.

A switch running HSRPv1 cannot identify the physical router that sent a hello packet because the source MAC address of the router is the virtual MAC address.

HSRPv2 has a different packet format than HSRPv1. A HSRPv2 packet uses the type-length-value (TLV) format and has a 6-byte identifier field with the MAC address of the physical router that sent the packet.

If an interface running HSRPv1 gets an HSRPv2 packet, the type field is ignored.
**Multiple HSRP**

The switch supports Multiple HSRP (MHSRP), an extension of HSRP that allows load sharing between two or more HSRP groups. You can configure MHSRP to achieve load-balancing and to use two or more standby groups (and paths) from a host network to a server network.

In the figure below, half the clients are configured for Router A, and half the clients are configured for Router B. Together, the configuration for Routers A and B establishes two HSRP groups. For group 1, Router A is the default active router because it has the assigned highest priority, and Router B is the standby router. For group 2, Router B is the default active router because it has the assigned highest priority, and Router A is the standby router. During normal operation, the two routers share the IP traffic load. When either router becomes unavailable, the other router becomes active and assumes the packet-transfer functions of the router that is unavailable.

---

**Note**

For MHSRP, you need to enter the `standby preempt` interface configuration command on the HSRP interfaces so that if a router fails and then comes back up, preemption restores load sharing.

---

**Figure 17: MHSRP Load Sharing**

---

**SSO HSRP**

SSO HSRP alters the behavior of HSRP when a device with redundant Route Processors (RPs) is configured for stateful switchover (SSO) redundancy mode. When an RP is active and the other RP is standby, SSO enables the standby RP to take over if the active RP fails.

With this functionality, HSRP SSO information is synchronized to the standby RP, allowing traffic that is sent using the HSRP virtual IP address to be continuously forwarded during a switchover without a loss of data or a path change. Additionally, if both RPs fail on the active HSRP device, then the standby HSRP device takes over as the active HSRP device.

The feature is enabled by default when the redundancy mode of operation is set to SSO.
HSRP and Switch Stacks

HSRP messages are generated by the stack master. If an HSRP-active stack master fails, a flap in the HSRP active state might occur. This is because HSRP messages are not generated while a new stack master is elected and initialized, and the standby router might become active after the stack master fails.

Configuring HSRP for IPv6

Switches running the IP Services and IP Base feature set support the Hot Standby Router Protocol (HSRP) for IPv6. HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.

An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address.

Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

Note

When configuring HSRP for IPv6, you must enable HSRP version 2 (HSRPv2) on the interface.

</tbody>
</table>

HSRP Configuration Guidelines

- HSRPv2 and HSRPv1 are mutually exclusive. HSRPv2 is not interoperable with HSRPv1 on an interface and the reverse.
• In the procedures, the specified interface must be one of these Layer 3 interfaces:
  • Routed port: A physical port configured as a Layer 3 port by entering the `no switchport` command in interface configuration mode.
  • SVI: A VLAN interface created by using the `interface vlan vlan_id` in global configuration mode, and by default a Layer 3 interface.
  • Etherchannel port channel in Layer 3 mode: A port-channel logical interface created by using the `interface port-channel port-channel-number` in global configuration mode, and binding the Ethernet interface into the channel group.

• All Layer 3 interfaces must have IP addresses assigned to them.
  • If you change the HSRP version on an interface, each HSRP group resets because it now has a new virtual MAC address.
  • Examples of valid and invalid group numbers:
    • If you configure groups with the numbers 2, 150, and 225, you cannot configure another group with the number 3850. It is not in the range of 0 to 255.
    • If you configure groups with the numbers 520, 600, and 700, you cannot configure another group with the number 900. It is not in the range of 512 to 767.

Enabling HSRP

The `standby ip` interface configuration command activates HSRP on the configured interface. If an IP address is specified, that address is used as the designated address for the Hot Standby group. If no IP address is specified, the address is learned through the standby function. You must configure at least one Layer 3 port on the LAN with the designated address. Configuring an IP address always overrides another designated address currently in use.

When the `standby ip` command is enabled on an interface and proxy ARP is enabled, if the interface's Hot Standby state is active, proxy ARP requests are answered using the Hot Standby group MAC address. If the interface is in a different state, proxy ARP responses are suppressed.

SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `standby version { 1 | 2 }`
4. `standby [group-number] ip [ip-address [secondary]]`
5. `end`
6. `show standby [interface-id [group]]`
7. `copy running-config startup-config`

DETAILED STEPS

### Enabling HSRP

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config)# configure terminal</code></td>
<td>Enters interface configuration mode, and enter the Layer 3 interface on which you want to enable HSRP.</td>
</tr>
</tbody>
</table>

**Step 2**
- **interface interface-id**
  - **Example:**
    ```
    Switch(config)# interface gigabitethernet1/0/1
    ```

  - **Purpose:** (Optional) Configures the HSRP version on the interface.
    - 1- Selects HSRPv1.
    - 2- Selects HSRPv2.

  - **Example:**
    ```
    Switch(config-if)# standby version 1
    ```

**Step 3**
- **standby version [ 1 | 2 ]**
  - **Example:**
    ```
    Switch(config-if)# standby version 1
    ```

**Step 4**
- **standby [group-number] ip [ip-address [secondary]]**
  - **Example:**
    ```
    Switch(config-if)# standby 1 ip
    ```

  - **Purpose:** Creates (or enable) the HSRP group using its number and virtual IP address.
    - (Optional) group-number- The group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number.
    - (Optional on all but one interface) ip-address- The virtual IP address of the hot standby router interface. You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces.
    - (Optional) secondary- The IP address is a secondary hot standby router interface. If neither router is designated as a secondary or standby router and no priorities are set, the primary IP addresses are compared and the higher IP address is the active router, with the next highest as the standby router.

**Step 5**
- **end**
  - **Example:**
    ```
    Switch(config-if)# end
    ```

  - **Purpose:** Returns to privileged EXEC mode

**Step 6**
- **show standby [interface-id [group]]**
  - **Example:**
    ```
    Switch # show standby
    ```

**Step 7**
- **copy running-config startup-config**
  - **Example:**
    ```
    Switch# copy running-config startup-config
    ```

  - **Purpose:** (Optional) Saves your entries in the configuration file.
Configuring HSRP Priority

The **standby priority**, **standby preempt**, and **standby track** interface configuration commands are all used to set characteristics for finding active and standby routers and behavior regarding when a new active router takes over.

When configuring HSRP priority, follow these guidelines:

- Assigning a priority allows you to select the active and standby routers. If preemption is enabled, the router with the highest priority becomes the active router. If priorities are equal, the current active router does not change.
- The highest number (1 to 255) represents the highest priority (most likely to become the active router).
- When setting the priority, preempt, or both, you must specify at least one keyword (**priority**, **preempt**, or both)
- The priority of the device can change dynamically if an interface is configured with the **standby track** command and another interface on the router goes down.
- The **standby track** interface configuration command ties the router hot standby priority to the availability of its interfaces and is useful for tracking interfaces that are not configured for HSRP. When a tracked interface fails, the hot standby priority on the device on which tracking has been configured decreases by 10. If an interface is not tracked, its state changes do not affect the hot standby priority of the configured device. For each interface configured for hot standby, you can configure a separate list of interfaces to be tracked.
- The **standby track interface-priority** interface configuration command specifies how much to decrement the hot standby priority when a tracked interface goes down. When the interface comes back up, the priority is incremented by the same amount.
- When multiple tracked interfaces are down and **interface-priority** values have been configured, the configured priority decrements are cumulative. If tracked interfaces that were not configured with priority values fail, the default decrement is 10, and it is noncumulative.
- When routing is first enabled for the interface, it does not have a complete routing table. If it is configured to preempt, it becomes the active router, even though it is unable to provide adequate routing services. To solve this problem, configure a delay time to allow the router to update its routing table.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP priority characteristics on an interface:

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. standby [group-number] priority priority
4. standby [group-number] preempt [delay [minimumseconds] [reloadseconds] [syncseconds]]
5. standby [group-number] track type number [interface-priority]
6. end
7. show running-config
8. copy running-config startup-config

</tr>
</tbody>
</table>
### Configuring MHSRP

To enable MHSRP and load-balancing, you configure two routers as active routers for their groups, with virtual routers as standby routers as shown in the MHSRP Load Sharing figure in the Multiple HSRP section. You need to enter the `standby preempt` interface configuration command on each HSRP interface so that if a router fails and comes back up, the preemption occurs and restores load-balancing.

Router A is configured as the active router for group 1, and Router B is configured as the active router for group 2. The HSRP interface for Router A has an IP address of 10.0.0.1 with a group 1 standby priority of 110 (the default is 100). The HSRP interface for Router B has an IP address of 10.0.0.2 with a group 2 standby priority of 110.

Group 1 uses a virtual IP address of 10.0.0.3 and group 2 uses a virtual IP address of 10.0.0.4.

#### Configuring Router A

**SUMMARY STEPS**

1. `configure terminal`
2. `interface type number`
3. `no switchport`
4. `ip address ip-address mask`
5. `standby [group-number] ip [ip-address [secondary]]`
6. `standby [group-number] priority priority`
7. `standby [group-number] preempt [delay [minimum seconds] [reload seconds] [sync seconds]]`
8. `standby [group-number] ip [ip-address [secondary]]`
9. `standby [group-number] preempt [delay [minimum seconds] [reload seconds] [sync seconds]]`
10. `end`
11. `show running-config`
12. `copy running-config startup-config`

```

Verifies the configuration of the standby groups.

**Step 12**
```
copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

### Configuring HSRP Authentication and Timers

You can optionally configure an HSRP authentication string or change the hello-time interval and holdtime.

When configuring these attributes, follow these guidelines:

- The authentication string is sent unencrypted in all HSRP messages. You must configure the same authentication string on all routers and access servers on a cable to ensure interoperability. Authentication mismatch prevents a device from learning the designated Hot Standby IP address and timer values from other routers configured with HSRP.
- Routers or access servers on which standby timer values are not configured can learn timer values from the active or standby router. The timers configured on an active router always override any other timer settings.
- All routers in a Hot Standby group should use the same timer values. Normally, the holdtime is greater than or equal to 3 times the helotime.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP authentication and timers on an interface:

**SUMMARY STEPS**

1. **configure terminal**
2. **interface interface-id**
3. `standby [group-number] authentication string`
4. `standby [group-number] timers helotime holdtime`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

Enabling HSRP Support for ICMP Redirect Messages

ICMP redirect messages are automatically enabled on interfaces configured with HSRP. ICMP is a network layer Internet protocol that provides message packets to report errors and other information relevant to IP processing. ICMP provides diagnostic functions, such as sending and directing error packets to the host. This feature filters outgoing ICMP redirect messages through HSRP, in which the next hop IP address might be changed to an HSRP virtual IP address. For more information, see the Cisco IOS IP Configuration Guide, Release 12.4.

Configuring HSRP Groups and Clustering

When a device is participating in an HSRP standby routing and clustering is enabled, you can use the same standby group for command switch redundancy and HSRP redundancy. Use the `cluster standby-group HSRP-group-name [routing-redundancy]` global configuration command to enable the same HSRP standby group to be used for command switch and routing redundancy. If you create a cluster with the same HSRP standby group name without entering the `routing-redundancy` keyword, HSRP standby routing is disabled for the group.

Verifying HSRP

Verifying HSRP Configurations

From privileged EXEC mode, use this command to display HSRP settings:

```
show standby [interface-id [group]] [brief] [detail]
```

You can display HSRP information for the whole switch, for a specific interface, for an HSRP group, or for an HSRP group on an interface. You can also specify whether to display a concise overview of HSRP information or detailed HSRP information. The default display is `detail`. If there are a large number of HSRP groups, using the `show standby` command without qualifiers can result in an unwieldy display.

Example

```
Switch # show standby
VLAN1 - Group 1
Local state is Standby, priority 105, may preempt
Hello time 3 holdtime 10
Next hello sent in 00:00:02.182
Hot standby IP address is 172.20.128.3 configured
Active router is 172.20.128.1 expires in 00:00:09
Standby router is local
Standby virtual mac address is 0000.0c07.ac01
Name is bbb

VLAN1 - Group 100
Local state is Standby, priority 105, may preempt
Hello time 3 holdtime 10
Next hello sent in 00:00:02.262
Hot standby IP address is 172.20.138.51 configured
Active router is 172.20.128.1 expires in 00:00:09
Active router is local
Standby router is unknown expired
Standby virtual mac address is 0000.0c07.ac64
Name is test
```
Configuration Examples for Configuring HSRP

Enabling HSRP: Example

This example shows how to activate HSRP for group 1 on an interface. The IP address used by the hot standby group is learned by using HSRP.

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# standby 1 ip
Switch(config-if)# end
Switch # show standby
```

**Note**

This procedure is the minimum number of steps required to enable HSRP. Other configurations are optional.

Configuring HSRP Priority: Example

This example activates a port, sets an IP address and a priority of 120 (higher than the default value), and waits for 300 seconds (5 minutes) before attempting to become the active router:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# standby ip 172.20.128.3
Switch(config-if)# standby priority 120 preempt delay 300
Switch(config-if)# end
Switch # show standby
```

Configuring MHSRP: Example

This example shows how to enable the MHSRP configuration shown in the figure *MHSRP Load Sharing*.

**Router A Configuration**

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# ip address 10.0.0.1 255.255.255.0
Switch(config-if)# standby ip 10.0.0.3
Switch(config-if)# standby 1 priority 110
Switch(config-if)# standby 1 preempt
Switch(config-if)# standby 2 ip 10.0.0.4
Switch(config-if)# standby 2 preempt
Switch(config-if)# end
```

**Router B Configuration**

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
```
Switch(config-if)# ip address 10.0.0.2 255.255.255.0
Switch(config-if)# standby ip 10.0.0.3
Switch(config-if)#  standby 1 preempt
Switch(config-if)#  standby 2 ip 10.0.0.4
Switch(config-if)#  standby 1 priority 110
Switch(config-if)#  standby 2 preempt
Switch(config-if)#  end

Configuring HSRP Authentication and Timer: Example

This example shows how to configure word as the authentication string required to allow Hot Standby routers in group 1 to interoperate:

Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 authentication word
Switch(config-if) # end

This example shows how to set the timers on standby group 1 with the time between hello packets at 5 seconds and the time after which a router is considered down to be 15 seconds:

Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 ip
Switch(config-if) # standby 1 timers 5 15
Switch(config-if) # end

Configuring HSRP Groups and Clustering: Example

This example shows how to bind standby group my_hsrp to the cluster and enable the same HSRP group to be used for command switch redundancy and router redundancy. The command can only be executed on the cluster command switch. If the standby group name or number does not exist, or if the switch is a cluster member switch, an error message appears.

Switch # configure terminal
Switch(config) # cluster standby-group my_hsrp routing-redundancy
Switch(config-if) # end

Feature Information for Configuring HSRP
Configuring NHRP

The Next Hop Resolution Protocol (NHRP) is an Address Resolution Protocol (ARP)-like protocol that dynamically maps a nonbroadcast multiaccess (NBMA) network, instead of manually configuring all the tunnel end points. With NHRP, systems attached to an NBMA network can dynamically learn the NBMA (physical) address of the other systems that are part of that network, allowing these systems to directly communicate. This protocol provides an ARP-like solution which allows stations’ data-link addresses to be dynamically determined.

NHRP is a client and server protocol where the hub is the Next Hop Server (NHS) and the spokes are the Next Hop Clients (NHCs). The hub maintains an NHRP database of the public interface addresses of each spoke. Each spoke registers its non-NBMA (real) address when it boots and queries the NHRP database for addresses of the destination spokes to build direct tunnels.

This module explains how to configure NHRP with generic routing encapsulation (GRE). In Cisco IOS XE Denali 16.3.1, the NHRP supports only spoke configurations.

- Information About Configuring NHRP, on page 403
- How to Configure NHRP, on page 404
- Configuration Examples for NHRP, on page 408

Information About Configuring NHRP

NHRP and NBMA Network Interaction

Most WAN networks are a collection of point-to-point links. Virtual tunnel networks (for example Generic Routing Encapsulation [GRE] tunnels) are also a collection of point-to-point links. To effectively scale the connectivity of these point-to-point links, they are usually grouped into a single or multilayer hub-and-spoke network. Multipoint interfaces (for example, GRE tunnel interfaces) can be used to reduce the configuration on a hub router in such a network. This resulting network is a NBMA network.

Because there are multiple tunnel endpoints that are reachable through a single multipoint interface, there needs to be a mapping from the logical tunnel endpoint IP address to the physical tunnel endpoint IP address, to forward packets out of the tunnel interfaces over this NBMA network. This mapping could be statically configured, but it is preferable if the mapping can be discovered or learned dynamically.
NHRP is an ARP-like protocol that alleviates these NBMA network problems. With NHRP, systems attached to an NBMA network dynamically learn the NBMA address of other systems that are part of the network, allowing these systems to directly communicate without requiring traffic to use an intermediate hop.

Routers, access servers, and hosts can use NHRP to discover the addresses of other routers and hosts connected to an NBMA network. Partially-meshed NBMA networks typically have multiple logical networks behind the NBMA network. In such configurations, packets traversing the NBMA network might have to make several hops over the NBMA network before arriving at the exit router (the router nearest the destination network).

NHRP Registration helps support these NBMA networks:

- **NHRP Registration**—NHRP allows Next Hop Clients (NHCs) to dynamically register with Next Hop Servers (NHSs). This registration function allows the NHCs to join the NBMA network without configuration changes on the NHSs, especially in cases where the NHC has a dynamic physical IP address or is behind a Network Address Translation (NAT) router that dynamically changes the physical IP address. In these cases, it would be impossible to preconfigure the logical (VPN IP address) to physical (NBMA IP) mapping for the NHC on the NHS.

### Dynamically Built Hub-and-Spoke Networks

With NHRP, the NBMA network is initially laid out as a hub-and-spoke network that can have multiple hierarchical layers of NHCs as spokes and NHSs as hubs. The NHCs are configured with static mapping information to reach their NHSs and will connect to their NHS and send an NHRP registration to the NHS. This configuration allows the NHS to dynamically learn the mapping information for the spoke, reducing the configuration needed on the hub and allowing the spoke to obtain a dynamic NBMA (physical) IP address.

### How to Configure NHRP

#### Enabling NHRP on an Interface

Perform this task to enable NHRP for an interface on a switch. In general, all NHRP stations within a logical NBMA network should be configured with the same network identifier.

The NHRP network ID is used to define the NHRP domain for an NHRP interface and differentiate between multiple NHRP domains or networks, when two or more NHRP domains (GRE tunnel interfaces) are available on the same NHRP node (switch). The NHRP network ID helps keep two NHRP networks (clouds) separate when both are configured on the same switch.

The NHRP network ID is a local-only parameter. It is significant only to the local switch and is not transmitted in NHRP packets to other NHRP nodes. For this reason the actual value of the NHRP network ID configured on a switch need not match the same NHRP network ID on another switch where both of these switches are in the same NHRP domain. As NHRP packets arrive on a GRE interface, they are assigned to the local NHRP domain in the NHRP network ID that is configured on that interface.

We recommend that the same NHRP network ID be used on the GRE interfaces on all switches that are in the same NHRP network. It is then easier to track which GRE interfaces are members of which NHRP network.

NHRP domains (network IDs) can be unique on each GRE tunnel interface on a switch. NHRP domains can span across GRE tunnel interfaces on a route. In this case the effect of using the same NHRP network ID on the GRE tunnel interfaces is to merge the two GRE interfaces into a single NHRP network.
### SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. ip address ip-address network-mask
5. ip nhrp network-id number
6. end

### DETAILED STEPS

</table>

### Configuring a GRE Tunnel for Multipoint Operation

Perform this task to configure a GRE tunnel for multipoint (NMBA) operation.
A tunnel network of multipoint tunnel interfaces can be considered as an NBMA network. When multiple GRE tunnels are configured on the same switch, they must either have unique tunnel ID keys or unique tunnel source addresses.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip address ip-address`
5. `ip mtu bytes`
6. `ip pim sparse-dense-mode`
7. `ip nhrp map ip-address nbma-address`
8. `ip nhrp map multicast nbma-address`
9. `ip nhrp network-id number`
10. `ip nhrp nhs nhs-address`
11. `tunnel source vlan interface-number`
12. `tunnel destination ip-address`
13. `end`

<tr>
<td><strong>Step 6</strong></td>
<td>ip pim sparse-dense-mode&lt;br&gt;Example: Switch(config-if)# ip pim sparse-dense-mode</td>
<td>Enables Protocol Independent Multicast (PIM) on an interface and treats the interface in either sparse mode or dense mode of operation, depending on which mode the multicast group operates in.</td>
</tr>
</tbody>
</table>
| **Step 7** | ip nhrp map *ip-address nbma-address*<br>Example: Switch(config-if)# ip nhrp map 172.16.1.2 10.10.10.2 | Statically configures the IP-to-nonbroadcast multiaccess (NBMA) address mapping of IP destinations connected to an NBMA network.  
- *ip-address*—IP address of the destinations reachable through the NBMA network. This address is mapped to the NBMA address.  
- *nbma-address*—NBMA address that is directly reachable through the NBMA network. The address format varies depending on the medium used. For example, ATM has a Network Service Access Point (NSAP) address, Ethernet has a MAC address, and Switched Multimegabit Data Service (SMDS) has an E.164 address. This address is mapped to the IP address. |
| **Step 8** | ip nhrp map multicast *nbma-address*<br>Example: Switch(config-if)# ip nhrp map multicast 10.10.10.2 | Configures nonbroadcast multiaccess (NBMA) addresses used as destinations for broadcast or multicast packets to be sent over a tunnel network. |
| **Step 9** | ip nhrp network-id *number*<br>Example: Switch(config-if)# ip nhrp network-id 1 | Enable the Next Hop Resolution Protocol (NHRP) on an interface.  
- *number*—Globally unique, 32-bit network ID from a nonbroadcast multiaccess (NBMA) network. The range is from 1 to 4294967295. |
| **Step 10** | ip nhrp nhs *nhs-address*<br>Example: Switch(config-if)# ip nhrp nhs 172.16.1.2 | Specifies the address of one or more NHRP servers.  
- *nhs-address*—Address of the next-hop server being specified. |
| **Step 11** | tunnel source vlan *interface-number*<br>Example: Switch(config-if)# tunnel source vlan 1 | Sets the source address for a tunnel interface |
| **Step 12** | tunnel destination *ip-address*<br>Example: Switch(config-if)# tunnel destination 10.10.10.2 | Sets the destination address for a tunnel interface. |
### Configuration Examples for NHRP

#### Physical Network Designs for Logical NBMA Examples

A logical NBMA network is considered the group of interfaces and hosts participating in NHRP and having the same network identifier. The figure below illustrates two logical NBMA networks (shown as circles) configured over a single physical NBMA network. Router A can communicate with routers B and C because they share the same network identifier (2). Router C can also communicate with routers D and E because they share network identifier 7. After address resolution is complete, router A can send IP packets to router C in one hop, and router C can send them to router E in one hop, as shown by the dotted lines.

*Figure 18: Two Logical NBMA Networks over One Physical NBMA Network*

The physical configuration of the five routers in the figure above might actually be as shown in the figure below. The source host is connected to router A and the destination host is connected to router E. The same switch serves all five routers, making one physical NBMA network.
Refer again to the first figure above. Initially, before NHRP has resolved any NBMA addresses, IP packets from the source host to the destination host travel through all five routers connected to the switch before reaching the destination. When router A first forwards the IP packet toward the destination host, router A also generates an NHRP request for the IP address of the destination host. The request is forwarded to router C, whereupon a reply is generated. Router C replies because it is the egress router between the two logical NBMA networks.

Similarly, router C generates an NHRP request of its own, to which router E replies. In this example, subsequent IP traffic between the source and the destination still requires two hops to traverse the NBMA network, because the IP traffic must be forwarded between the two logical NBMA networks. Only one hop would be required if the NBMA network were not logically divided.

Example: GRE Tunnel for Multipoint Operation

With multipoint tunnels, a single tunnel interface may be connected to multiple neighboring switches. Unlike point-to-point tunnels, a tunnel destination need not be configured. In fact, if configured, the tunnel destination must correspond to an IP multicast address.

In the following example, switches A and B share an Ethernet segment. Minimal connectivity over the multipoint tunnel network is configured, thus creating a network that can be treated as a partially meshed NBMA network. Due to the static NHRP map entries, switch A knows how to reach switch B and vice versa.

The following example shows how to configure a GRE multipoint tunnel:

**Switch A Configuration**

```plaintext
Switch(config)# interface tunnel 100 !Tunnel interface configured for PIM traffic
Switch(config-if)# no ip redirects
Switch(config-if)# ip address 192.168.24.1 255.255.255.252
```
Switch(config-if)# ip mtu 1400
Switch(config-if)# ip pim sparse-dense-mode
Switch(config-if)# ip nhrp map 192.168.24.3 172.16.0.1 !NHRP may optionally be configured
to dynamically discover tunnel end points.
Switch(config-if)# ip nhrp map multicast 172.16.0.1
Switch(config-if)# ip nhrp network-id 1
Switch(config-if)# ip nhrp nhs 192.168.24.3
Switch(config-if)# tunnel source vlan 1
Switch(config-if)# tunnel destination 172.16.0.1
Switch(config-if)# end

Switch B Configuration

Switch(config)# interface tunnel 100
Switch(config-if)# no ip redirects
Switch(config-if)# ip address 192.168.24.2 255.255.255.252
Switch(config-if)# ip mtu 1400
Switch(config-if)# ip pim sparse-dense-mode
Switch(config-if)# ip nhrp map 192.168.24.4 10.10.0.3
Switch(config-if)# ip nhrp map multicast 10.10.0.3
Switch(config-if)# ip nhrp network-id 1
Switch(config-if)# ip nhrp nhs 192.168.24.4
Switch(config-if)# tunnel source vlan 1
Switch(config-if)# tunnel destination 10.10.10.3
Switch(config-if)# end

Feature Information for Configuring NHRP

The following table provides release information about the feature or features described in this module. This
table lists only the software release that introduced support for a given feature in a given software release
train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support.
To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

VRRPv3 Protocol Support

Virtual Router Redundancy Protocol (VRRP) enables a group of devices to form a single virtual device to provide redundancy. The LAN clients can then be configured with the virtual device as their default gateway. The virtual device, representing a group of devices, is also known as a VRRP group. The VRRP version 3 (v3) Protocol Support feature provides the capability to support IPv4 and IPv6 addresses while VRRP version 2 (v2) only supports IPv4 addresses. This module explains concepts related to VRRPv3 and describes how to create and customize a VRRP group in a network. Benefits of using VRRPv3 Protocol Support include the following:

- Interoperability in multi-vendor environments.
- VRRPv3 supports usage of IPv4 and IPv6 addresses while VRRPv2 only supports IPv4 addresses
- Improved scalability through the use of VRRS Pathways.

Note

In this module, VRRP and VRRPv3 are used interchangeably.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.
Restrictions for VRRPv3 Protocol Support

- VRRPv3 is not intended as a replacement for existing dynamic protocols. VRRPv3 is designed for use over multi-access, multicast, or broadcast capable Ethernet LANs.

- VRRPv3 is supported on Ethernet, Fast Ethernet, Bridge Group Virtual Interface (BVI), and Gigabit Ethernet interfaces, and on Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs), VRF-aware MPLS VPNs and VLANs.

- Because of the forwarding delay that is associated with the initialization of a BVI interface, you must not configure the VRRPv3 advertise timer to a value lesser than the forwarding delay on the BVI interface. If you configure the VRRPv3 advertise timer to a value equal to or greater than the forwarding delay on the BVI interface, the setting prevents a VRRP device on a recently initialized BVI interface from unconditionally taking over the master role. Use the `bridge forward-time` command to set the forwarding delay on the BVI interface. Use the `vrrp timers advertise` command to set the VRRP advertisement timer.

- VRRPv3 does not support Stateful Switchover (SSO).

- Full network redundancy can only be achieved if VRRP operates over the same network path as the VRRS Pathway redundant interfaces. For full redundancy, the following restrictions apply:
  - VRRS pathways should not share a different physical interface as the parent VRRP group or be configured on a sub-interface having a different physical interface as the parent VRRP group.
  - VRRS pathways should not be configured on Switch Virtual Interface (SVI) interfaces as long as the associated VLAN does not share the same trunk as the VLAN on which the parent VRRP group is configured.

Information About VRRPv3 Protocol Support

VRRPv3 Benefits

Support for IPv4 and IPv6

VRRPv3 supports IPv4 and IPv6 address families while VRRPv2 only supports IPv4 addresses.

---

Note

When VRRPv3 is in use, VRRPv2 is unavailable. For VRRPv3 to be configurable, the `fhrp version vrrp v3` command must be used in global configuration mode.

Redundancy

VRRP enables you to configure multiple devices as the default gateway device, which reduces the possibility of a single point of failure in a network.

Load Sharing

You can configure VRRP in such a way that traffic to and from LAN clients can be shared by multiple devices, thereby sharing the traffic load more equitably between available devices.
Multiple Virtual Devices

VRRP supports up to 255 virtual devices (VRRP groups) on a device physical interface, subject to restrictions in scaling. Multiple virtual device support enables you to implement redundancy and load sharing in your LAN topology. In scaled environments, VRRS Pathways should be used in combination with VRRP control groups.

Multiple IP Addresses

The virtual device can manage multiple IP addresses, including secondary IP addresses. Therefore, if you have multiple subnets configured on an Ethernet interface, you can configure VRRP on each subnet.

Note

To utilize secondary IP addresses in a VRRP group, a primary address must be configured on the same group.

Preemption

The redundancy scheme of VRRP enables you to preempt a virtual device backup that has taken over for a failing virtual device master with a higher priority virtual device backup that has become available.

Note

Preemption of a lower priority master device is enabled with an optional delay.

Advertisement Protocol

VRRP uses a dedicated Internet Assigned Numbers Authority (IANA) standard multicast address for VRRP advertisements. For IPv4, the multicast address is 224.0.0.18. For IPv6, the multicast address is FF02:0:0:0:0:0:12. This addressing scheme minimizes the number of devices that must service the multicasts and allows test equipment to accurately identify VRRP packets on a segment. The IANA has assigned VRRP the IP protocol number 112.

VRRP Device Priority and Preemption

An important aspect of the VRRP redundancy scheme is VRRP device priority. Priority determines the role that each VRRP device plays and what happens if the virtual device master fails.

If a VRRP device owns the IP address of the virtual device and the IP address of the physical interface, this device will function as a virtual device master.

Priority also determines if a VRRP device functions as a virtual device backup and the order of ascendancy to becoming a virtual device master if the virtual device master fails. You can configure the priority of each virtual device backup with a value of 1 through 254 using the priority command (use the vrrp address-family command to enter the VRRP configuration mode and access the priority option).

For example, if device A, the virtual device master in a LAN topology, fails, an election process takes place to determine if virtual device backups B or C should take over. If devices B and C are configured with the priorities of 101 and 100, respectively, device B is elected to become virtual device master because it has the higher priority. If devices B and C are both configured with the priority of 100, the virtual device backup with the higher IP address is elected to become the virtual device master.

By default, a preemptive scheme is enabled whereby a higher priority virtual device backup that becomes available takes over from the virtual device backup that was elected to become virtual device master. You
can disable this preemptive scheme using the `no preempt` command (use the `vrp address-family` command to enter the VRRP configuration mode, and enter the `no preempt` command). If preemption is disabled, the virtual device backup that is elected to become virtual device master remains the master until the original virtual device master recovers and becomes master again.

---

**Note**

Preemption of a lower priority master device is enabled with an optional delay.

---

### VRRP Advertisements

The virtual device master sends VRRP advertisements to other VRRP devices in the same group. The advertisements communicate the priority and state of the virtual device master. The VRRP advertisements are encapsulated into either IPv4 or IPv6 packets (based on the VRRP group configuration) and sent to the appropriate multicast address assigned to the VRRP group. For IPv4, the multicast address is 224.0.0.18. For IPv6, the multicast address is FF02:0:0:0:0:0:0:12. The advertisements are sent every second by default and the interval is configurable.

Cisco devices allow you to configure millisecond timers, which is a change from VRRPv2. You need to manually configure the millisecond timer values on both the primary and the backup devices. The master advertisement value displayed in the `show vrrp` command output on the backup devices is always 1 second because the packets on the backup devices do not accept millisecond values.

You must use millisecond timers where absolutely necessary and with careful consideration and testing. Millisecond values work only under favorable circumstances. The use of the millisecond timer values is compatible with third party vendors, as long as they also support VRRPv3. You can specify a timer value between 100 milliseconds and 40000 milliseconds.

### Information About VRRPv3 Protocol Support

#### VRRPv3 Benefits

**Support for IPv4 and IPv6**

VRRPv3 supports IPv4 and IPv6 address families while VRRPv2 only supports IPv4 addresses.

**Note**

When VRRPv3 is in use, VRRPv2 is unavailable. For VRRPv3 to be configurable, the `fhrp version vrrp v3` command must be used in global configuration mode.

**Redundancy**

VRRP enables you to configure multiple devices as the default gateway device, which reduces the possibility of a single point of failure in a network.

**Load Sharing**

You can configure VRRP in such a way that traffic to and from LAN clients can be shared by multiple devices, thereby sharing the traffic load more equitably between available devices.
Multiple Virtual Devices

VRRP supports up to 255 virtual devices (VRRP groups) on a device physical interface, subject to restrictions in scaling. Multiple virtual device support enables you to implement redundancy and load sharing in your LAN topology. In scaled environments, VRRS Pathways should be used in combination with VRRP control groups.

Multiple IP Addresses

The virtual device can manage multiple IP addresses, including secondary IP addresses. Therefore, if you have multiple subnets configured on an Ethernet interface, you can configure VRRP on each subnet.

Note

To utilize secondary IP addresses in a VRRP group, a primary address must be configured on the same group.

Preemption

The redundancy scheme of VRRP enables you to preempt a virtual device backup that has taken over for a failing virtual device master with a higher priority virtual device backup that has become available.

Note

Preemption of a lower priority master device is enabled with an optional delay.

Advertisement Protocol

VRRP uses a dedicated Internet Assigned Numbers Authority (IANA) standard multicast address for VRRP advertisements. For IPv4, the multicast address is 224.0.0.18. For IPv6, the multicast address is FF02::0:0:0:0:0:12. This addressing scheme minimizes the number of devices that must service the multicasts and allows test equipment to accurately identify VRRP packets on a segment. The IANA has assigned VRRP the IP protocol number 112.

VRRP Device Priority and Preemption

An important aspect of the VRRP redundancy scheme is VRRP device priority. Priority determines the role that each VRRP device plays and what happens if the virtual device master fails.

If a VRRP device owns the IP address of the virtual device and the IP address of the physical interface, this device will function as a virtual device master.

Priority also determines if a VRRP device functions as a virtual device backup and the order of ascendancy to becoming a virtual device master if the virtual device master fails. You can configure the priority of each virtual device backup with a value of 1 through 254 using the priority command (use the vrrp address-family command to enter the VRRP configuration mode and access the priority option).

For example, if device A, the virtual device master in a LAN topology, fails, an election process takes place to determine if virtual device backups B or C should take over. If devices B and C are configured with the priorities of 101 and 100, respectively, device B is elected to become virtual device master because it has the higher priority. If devices B and C are both configured with the priority of 100, the virtual device backup with the higher IP address is elected to become the virtual device master.

By default, a preemptive scheme is enabled whereby a higher priority virtual device backup that becomes available takes over from the virtual device backup that was elected to become virtual device master. You
can disable this preemptive scheme using the `no preempt` command (use the `vrrp address-family` command to enter the VRRP configuration mode, and enter the `no preempt` command). If preemption is disabled, the virtual device backup that is elected to become virtual device master remains the master until the original virtual device master recovers and becomes master again.

---

**Note**

Preemption of a lower priority master device is enabled with an optional delay.

---

**VRRP Advertisements**

The virtual device master sends VRRP advertisements to other VRRP devices in the same group. The advertisements communicate the priority and state of the virtual device master. The VRRP advertisements are encapsulated into either IPv4 or IPv6 packets (based on the VRRP group configuration) and sent to the appropriate multicast address assigned to the VRRP group. For IPv4, the multicast address is 224.0.0.18. For IPv6, the multicast address is FF02:0:0:0:0:0:0:12. The advertisements are sent every second by default and the interval is configurable.

Cisco devices allow you to configure millisecond timers, which is a change from VRRPv2. You need to manually configure the millisecond timer values on both the primary and the backup devices. The master advertisement value displayed in the `show vrrp` command output on the backup devices is always 1 second because the packets on the backup devices do not accept millisecond values.

You must use millisecond timers where absolutely necessary and with careful consideration and testing. Millisecond values work only under favorable circumstances. The use of the millisecond timer values is compatible with third party vendors, as long as they also support VRRPv3. You can specify a timer value between 100 milliseconds and 40000 milliseconds.

**How to Configure VRRPv3 Protocol Support**

**Enabling and Verifying GLBP**

Perform this task to enable GLBP on an interface and verify its configuration and operation. GLBP is designed to be easy to configure. Each gateway in a GLBP group must be configured with the same group number, and at least one gateway in the GLBP group must be configured with the virtual IP address to be used by the group. All other required parameters can be learned.

**Before you begin**

If VLANs are in use on an interface, the GLBP group number must be different for each VLAN.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface type number
4. ip address ip-address mask [secondary]
5. glbp group ip [ip-address [secondary]]
6. end
7. show glbp [interface-type interface-number] [group] [state] [brief]
## Enabling and Verifying GLBP

## Configuration Examples for VRRPv3 Protocol Support

### Example: Enabling VRRPv3 on a Device

The following example shows how to enable VRRPv3 on a device:

```
Device> enable  
Device# configure terminal  
Device(config)# fhrp version vrrp v3  
Device(config-if-vrrp)# end  
```

### Example: Creating and Customizing a VRRP Group

The following example shows how to create and customize a VRRP group:
Example: Configuring the Delay Period Before FHRP Client Initialization

The following example shows how to configure the delay period before FHRP client initialization:

```
Device> enable
Device# configure terminal
Device(config)# fhrp version vrrp v3
Device(config)# interface GigabitEthernet 1/0/1
Device(config-if)# vrrp 3 address-family ipv4
Device(config-if-vrrp)# address 100.0.1.10 primary
Device(config-if-vrrp)# description group 3
Device(config-if-vrrp)# preempt delay minimum 5
Device(config-if-vrrp)# end
```

Note: In the above example, a five-second delay period is specified for the initialization of FHRP clients after the interface comes up. You can specify a delay period between 0 and 3600 seconds.

Example: VRRP Status, Configuration, and Statistics Details

The following is a sample output of the status, configuration and statistics details for a VRRP group:

```
Device> enable
Device# show vrrp detail

GigabitEthernet1/0/1 - Group 3 - Address-Family IPv4
Description is "group 3"
State is MASTER
State duration 53.901 secs
Virtual IP address is 100.0.1.10
Virtual MAC address is 0000.5E00.0103
Advertisement interval is 1000 msec
Preemption enabled, delay min 30 secs (0 msec remaining)
Priority is 100
Master Router is 10.21.0.1 (local), priority is 100
Master Advertisement interval is 1000 msec (expires in 832 msec)
Master Down interval is unknown
VRRPv3 Advertisements: sent 61 (errors 0) - rcvd 0
VRRPv2 Advertisements: sent 0 (errors 0) - rcvd 0
Group Discarded Packets: 0
VRRPv2 incompatibility: 0
IP Address Owner conflicts: 0
```

Feature Information for VRRPv3 Protocol Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

This feature was introduced.

Glossary

Virtual IP address owner—The VRRP device that owns the IP address of the virtual device. The owner is the device that has the virtual device address as its physical interface address.

Virtual device—One or more VRRP devices that form a group. The virtual device acts as the default gateway device for LAN clients. The virtual device is also known as a VRRP group.

Virtual device backup—One or more VRRP devices that are available to assume the role of forwarding packets if the virtual device master fails.

Virtual device master—The VRRP device that is currently responsible for forwarding packets sent to the IP addresses of the virtual device. Usually, the virtual device master also functions as the IP address owner.

VRRP device—A device that is running VRRP.
Configuring GLBP

Gateway Load Balancing Protocol (GLBP) protects data traffic from a failed device or circuit, like Hot Standby Router Protocol (HSRP) and Virtual Router Redundancy Protocol (VRRP), while allowing packet load sharing between a group of redundant devices.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for GLBP

Enhanced Object Tracking (EOT) is not stateful switchover (SSO)-aware and cannot be used with GLBP in SSO mode.

Prerequisites for GLBP

Before configuring GLBP, ensure that the devices can support multiple MAC addresses on the physical interfaces. For each GLBP forwarder to be configured, an additional MAC address is used.
Information About GLBP

GLBP Overview

GLBP provides automatic device backup for IP hosts configured with a single default gateway on an IEEE 802.3 LAN. Multiple first-hop devices on the LAN combine to offer a single virtual first-hop IP device while sharing the IP packet forwarding load. Other devices on the LAN act as redundant GLBP devices that will become active if any of the existing forwarding devices fail.

GLBP performs a similar function for the user as HSRP and VRRP. HSRP and VRRP allow multiple devices to participate in a virtual device group configured with a virtual IP address. One member is elected to be the active device to forward packets sent to the virtual IP address for the group. The other devices in the group are redundant until the active device fails. These standby devices have unused bandwidth that the protocol is not using. Although multiple virtual device groups can be configured for the same set of devices, the hosts must be configured for different default gateways, which results in an extra administrative burden. The advantage of GLBP is that it additionally provides load balancing over multiple devices (gateways) using a single virtual IP address and multiple virtual MAC addresses. The forwarding load is shared among all devices in a GLBP group rather than being handled by a single device while the other devices stand idle. Each host is configured with the same virtual IP address, and all devices in the virtual device group participate in forwarding packets. GLBP members communicate between each other through hello messages sent every 3 seconds to the multicast address 224.0.0.102, UDP port 3222 (source and destination).

GLBP Packet Types

GLBP uses 3 different packet types to operate. The packet types are Hello, Request, and Reply. The Hello packet is used to advertise protocol information. Hello packets are multicast, and are sent when any virtual gateway or virtual forwarder is in Speak, Standby or Active state. Request and Reply packets are used for virtual MAC assignment. They are both unicast messages to and from the active virtual gateway (AVG).

GLBP Active Virtual Gateway

Members of a GLBP group elect one gateway to be the active virtual gateway (AVG) for that group. Other group members provide backup for the AVG if the AVG becomes unavailable. The AVG assigns a virtual MAC address to each member of the GLBP group. Each gateway assumes responsibility for forwarding packets sent to the virtual MAC address assigned to it by the AVG. These gateways are known as active virtual forwarders (AVFs) for their virtual MAC address.

The AVG is also responsible for answering Address Resolution Protocol (ARP) requests for the virtual IP address. Load sharing is achieved by the AVG replying to the ARP requests with different virtual MAC addresses.

When the no glbp load-balancing command is configured, if the AVG does not have an AVF, it preferentially responds to ARP requests with the MAC address of the first listening virtual forwarder (VF), which will causes traffic to route via another gateway until that VF migrates back to being the current AVG.

In the figure below, Router A (or Device A) is the AVG for a GLBP group, and is responsible for the virtual IP address 10.21.8.10. Router A is also an AVF for the virtual MAC address 0007.b400.0101. Router B (or Device B) is a member of the same GLBP group and is designated as the AVF for the virtual MAC address 0007.b400.0102. Client 1 has a default gateway IP address of 10.21.8.10 and a gateway MAC address of 0007.b400.0101. Client 2 shares the same default gateway IP address but receives the gateway MAC address 0007.b400.0102 because Router B is sharing the traffic load with Router A.
If Router A becomes unavailable, Client 1 will not lose access to the WAN because Router B will assume responsibility for forwarding packets sent to the virtual MAC address of Router A, and for responding to packets sent to its own virtual MAC address. Router B will also assume the role of the AVG for the entire GLBP group. Communication for the GLBP members continues despite the failure of a device in the GLBP group.

GLBP Virtual MAC Address Assignment

A GLBP group allows up to four virtual MAC addresses per group. The AVG is responsible for assigning the virtual MAC addresses to each member of the group. Other group members request a virtual MAC address after they discover the AVG through hello messages. Gateways are assigned the next MAC address in sequence. A virtual forwarder that is assigned a virtual MAC address by the AVG is known as a primary virtual forwarder. Other members of the GLBP group learn the virtual MAC addresses from hello messages. A virtual forwarder that has learned the virtual MAC address is referred to as a secondary virtual forwarder.

GLBP Virtual Gateway Redundancy

GLBP operates virtual gateway redundancy in the same way as HSRP. One gateway is elected as the AVG, another gateway is elected as the standby virtual gateway, and the remaining gateways are placed in a listen state.

If an AVG fails, the standby virtual gateway will assume responsibility for the virtual IP address. A new standby virtual gateway is then elected from the gateways in the listen state.

GLBP Virtual Forwarder Redundancy

Virtual forwarder redundancy is similar to virtual gateway redundancy with an AVF. If the AVF fails, one of the secondary virtual forwarders in the listen state assumes responsibility for the virtual MAC address.

The new AVF is also a primary virtual forwarder for a different forwarder number. GLBP migrates hosts away from the old forwarder number using two timers that start as soon as the gateway changes to the active virtual forwarder state. GLBP uses the hello messages to communicate the current state of the timers.

The redirect time is the interval during which the AVG continues to redirect hosts to the old virtual forwarder MAC address. When the redirect time expires, the AVG stops using the old virtual forwarder MAC address.
in ARP replies, although the virtual forwarder will continue to forward packets that were sent to the old virtual forwarder MAC address.

The secondary holdtime is the interval during which the virtual forwarder is valid. When the secondary holdtime expires, the virtual forwarder is removed from all gateways in the GLBP group. The expired virtual forwarder number becomes eligible for reassignment by the AVG.

**GLBP Gateway Priority**

GLBP gateway priority determines the role that each GLBP gateway plays and what happens if the AVG fails. Priority also determines if a GLBP device functions as a backup virtual gateway and the order of ascendency to becoming an AVG if the current AVG fails. You can configure the priority of each backup virtual gateway with a value of 1 through 255 using the `glbp priority` command.

In the "GLBP Topology" figure, if Router A (or Device A)—the AVG in a LAN topology—fails, an election process takes place to determine which backup virtual gateway should take over. In this example, Router B (or Device B) is the only other member in the group so it will automatically become the new AVG. If another device existed in the same GLBP group with a higher priority, then the device with the higher priority would be elected. If both devices have the same priority, the backup virtual gateway with the higher IP address would be elected to become the active virtual gateway.

By default, the GLBP virtual gateway preemptive scheme is disabled. A backup virtual gateway can become the AVG only if the current AVG fails, regardless of the priorities assigned to the virtual gateways. You can enable the GLBP virtual gateway preemptive scheme using the `glbp preempt` command. Preemption allows a backup virtual gateway to become the AVG, if the backup virtual gateway is assigned a higher priority than the current AVG.

**GLBP Gateway Weighting and Tracking**

GLBP uses a weighting scheme to determine the forwarding capacity of each device in the GLBP group. The weighting assigned to a device in the GLBP group can be used to determine whether it will forward packets and, if so, the proportion of hosts in the LAN for which it will forward packets. Thresholds can be set to disable forwarding when the weighting for a GLBP group falls below a certain value, and when it rises above another threshold, forwarding is automatically reenabled.

The GLBP group weighting can be automatically adjusted by tracking the state of an interface within the device. If a tracked interface goes down, the GLBP group weighting is reduced by a specified value. Different interfaces can be tracked to decrement the GLBP weighting by varying amounts.

By default, the GLBP virtual forwarder preemptive scheme is enabled with a delay of 30 seconds. A backup virtual forwarder can become the AVF if the current AVF weighting falls below the low weighting threshold for 30 seconds. You can disable the GLBP forwarder preemptive scheme using the `no glbp forwarder preempt` command or change the delay using the `glbp forwarder preempt delay minimum` command.

**GLBP MD5 Authentication**

GLBP MD5 authentication uses the industry-standard MD5 algorithm for improved reliability and security. MD5 authentication provides greater security than the alternative plain text authentication scheme and protects against spoofing software.

MD5 authentication allows each GLBP group member to use a secret key to generate a keyed MD5 hash that is part of the outgoing packet. A keyed hash of an incoming packet is generated and, if the hash within the incoming packet does not match the generated hash, the packet is ignored.
The key for the MD5 hash can either be given directly in the configuration using a key string or supplied indirectly through a key chain. The key string cannot exceed 100 characters in length.

A device will ignore incoming GLBP packets from devices that do not have the same authentication configuration for a GLBP group. GLBP has three authentication schemes:

- No authentication
- Plain text authentication
- MD5 authentication

GLBP packets will be rejected in any of the following cases:

- The authentication schemes differ on the device and in the incoming packet.
- MD5 digests differ on the device and in the incoming packet.
- Text authentication strings differ on the device and in the incoming packet.

**ISSU-GLBP**

This feature is not supported on the C9500-12Q, C9500-16X, C9500-24Q, C9500-40X models of the Cisco Catalyst 9500 Series Switches. GLBP supports In Service Software Upgrade (ISSU). ISSU allows a high-availability (HA) system to run in Stateful Switchover (SSO) mode even when different versions of Cisco IOS software are running on the active and standby Route Processors (RPs) or line cards.

ISSU provides the ability to upgrade or downgrade from one supported Cisco IOS release to another while continuing to forward packets and maintain sessions, thereby reducing planned outage time. The ability to upgrade or downgrade is achieved by running different software versions on the active RP and standby RP for a short period of time to maintain state information between RPs. This feature allows the system to switch over to a secondary RP running upgraded (or downgraded) software and continue forwarding packets without session loss and with minimal or no packet loss. This feature is enabled by default.

**GLBP SSO**

This feature is not supported on the C9500-12Q, C9500-16X, C9500-24Q, C9500-40X models of the Cisco Catalyst 9500 Series Switches. With the introduction of the GLBP SSO functionality, GLBP is stateful switchover (SSO) aware. GLBP can detect when a device is failing over to the secondary router processor (RP) and continue in its current group state.

SSO functions in networking devices (usually edge devices) that support dual RPs. SSO provides RP redundancy by establishing one of the RPs as the active processor and the other RP as the standby processor. SSO also synchronizes critical state information between the RPs so that network state information is dynamically maintained between RPs.

Without SSO-awareness, if GLBP is deployed on a device with redundant RPs, a switchover of roles between the active RP and the standby RP results in the device relinquishing its activity as a GLBP group member and then rejoining the group as if it had been reloaded. The GLBP SSO feature enables GLBP to continue its activities as a group member during a switchover. GLBP state information between redundant RPs is maintained so that the standby RP can continue the device’s activities within the GLBP during and after a switchover.

This feature is enabled by default. To disable this feature, use the command `no glbp sso` in global configuration mode.
GLBP Benefits

Load Sharing
You can configure GLBP in such a way that traffic from LAN clients can be shared by multiple devices, thereby sharing the traffic load more equitably among available devices.

Multiple Virtual Devices
GLBP supports up to 1024 virtual devices (GLBP groups) on each physical interface of a device and up to four virtual forwarders per group.

Preemption
The redundancy scheme of GLBP enables you to preempt an active virtual gateway (AVG) with a higher priority backup virtual gateway that has become available. Forwarder preemption works in a similar way, except that forwarder preemption uses weighting instead of priority and is enabled by default.

Authentication
GLBP supports the industry-standard message digest 5 (MD5) algorithm for improved reliability, security, and protection against GLBP-spoofing software. A device within a GLBP group with a different authentication string than other devices will be ignored by other group members. You can alternatively use a simple text password authentication scheme between GLBP group members to detect configuration errors.

How to Configure GLBP

Customizing GLBP
Customizing the behavior of GLBP is optional. Be aware that as soon as you enable a GLBP group, that group is operating. It is possible that if you first enable a GLBP group before customizing GLBP, the device could take over control of the group and become the AVG before you have finished customizing the feature. Therefore, if you plan to customize GLBP, it is a good idea to do so before enabling GLBP.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface type number**
4. **ip address ip-address mask [secondary]**
5. **glbp group timers [msec] hellotime [msec] holdtime**
6. **glbp group timers redirect redirect timeout**
7. **glbp group load-balancing [host-dependent | round-robin | weighted]**
8. **glbp group priority level**
9. **glbp group preempt [delay minimum seconds]**
10. **glbp group client-cache maximum number [timeout minutes]**
11. **glbp group name redundancy-name**
12. **exit**
13. **no glbp sso**
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable<br>**Example:**<br>Device> enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Step 2** | configure terminal<br>**Example:**<br>Device# configure terminal | Enters global configuration mode. |
| **Step 3** | interface type number<br>**Example:**<br>Device(config)# interface GigabitEthernet 1/0/1 | Specifies an interface type and number, and enters interface configuration mode. |
| **Step 4** | ip address ip-address mask [secondary]<br>**Example:**<br>Device(config-if)# ip address 10.21.8.32 255.255.255.0 | Specifies a primary or secondary IP address for an interface. |
| **Step 5** | glbp group timers [msec] hellotime [msec] holdtime<br>**Example:**<br>Device(config-if)# glbp 10 timers 5 18 | Configures the interval between successive hello packets sent by the AVG in a GLBP group.  
  • The `holdtime` argument specifies the interval in seconds before the virtual gateway and virtual forwarder information in the hello packet is considered invalid.  
  • The optional `msec` keyword specifies that the following argument will be expressed in milliseconds, instead of the default seconds. |
| **Step 6** | glbp group timers redirect redirect timeout<br>**Example:**<br>Device(config-if)# glbp 10 timers redirect 1800 28800 | Configures the time interval during which the AVG continues to redirect clients to an AVF. The default is 600 seconds (10 minutes).  
  • The `timeout` argument specifies the interval in seconds before a secondary virtual forwarder becomes invalid. The default is 14,400 seconds (4 hours). |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>The zero value for the <em>redirect</em> argument cannot be removed from the range of acceptable values because preexisting configurations of Cisco IOS software already using the zero value could be negatively affected during an upgrade. However, a zero setting is not recommended and, if used, results in a redirect timer that never expires. If the redirect timer does not expire, and the device fails, new hosts continue to be assigned to the failed device instead of being redirected to the backup.</td>
<td></td>
</tr>
</tbody>
</table>

### Note

**glbp**

**group**

**load-balancing**

[host-dependent | round-robin | weighted]

**Example:**

Device(config-if)# glbp 10 load-balancing host-dependent

**Step 7**

**glbp group load-balancing [host-dependent | round-robin | weighted]**

Specifies the method of load balancing used by the GLBP AVG.

**Example:**

Device(config-if)# glbp 10 load-balancing host-dependent

**Step 8**

**glbp group priority level**

Sets the priority level of the gateway within a GLBP group.

- The default value is 100.

**Example:**

Device(config-if)# glbp 10 priority 254

**Step 9**

**glbp group preempt [delay minimum seconds]**

Configures the device to take over as AVG for a GLBP group if it has a higher priority than the current AVG.

- This command is disabled by default.
- Use the optional *delay* and *minimum* keywords and the *seconds* argument to specify a minimum delay interval in seconds before preemption of the AVG takes place.

**Example:**

Device(config-if)# glbp 10 preempt delay minimum 60

**Step 10**

**glbp group client-cache maximum number [timeout minutes]**

(Optional) Enables the GLBP client cache.

- This command is disabled by default.
- Use the *number* argument to specify the maximum number of clients the cache will hold for this GLBP group. The range is from 8 to 2000.
- Use the optional *timeout minutes* keyword and argument pair to configure the maximum amount of time a client entry can stay in the GLBP client cache after the client information was last updated. The range is from 1 to 1440 minutes (one day).

**Example:**

Device(config-if)# glbp 10 client-cache maximum 1200 timeout 245
For IPv4 networks, Cisco recommends setting a GLBP client cache timeout value that is slightly longer than the maximum expected end-host Address Resolution Protocol (ARP) cache timeout value.

**Step 11**

`glbp group name redundancy-name`

**Example:**

```bash
Device(config-if)# glbp 10 name abc123
```

Enables IP redundancy by assigning a name to the GLBP group.

- The GLBP redundancy client must be configured with the same GLBP group name so the redundancy client and the GLBP group can be connected.

**Step 12**

`exit`

**Example:**

```bash
Device(config-if)# exit
```

Exits interface configuration mode, and returns the device to global configuration mode.

**Step 13**

`no glbp sso`

**Example:**

```bash
Device(config)# no glbp sso
```

(Optional) Disables GLBP support of SSO.

---

**Configuring GLBP MD5 Authentication Using a Key String**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip address ip-address mask [secondary]`
5. `glbp group-number authentication md5 key-string [ 0 | 7 ] key`
6. `glbp group-number ip [ip-address [secondary]]`
7. Repeat Steps 1 through 6 on each device that will communicate.
8. `end`
9. `show glbp`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
</tr>
</thead>
</table>
| **Step 2** | configure terminal  
**Example:**
Device# configure terminal |
| **Purpose** | Enters global configuration mode. |
| **Step 3** | interface type number  
**Example:**
Device(config)# interface GigabitEthernet 1/0/1 |
| **Purpose** | Configures an interface type and enters interface configuration mode. |
| **Step 4** | ip address ip-address mask [secondary]  
**Example:**
Device(config-if)# ip address 10.0.0.1 255.255.255.0 |
| **Purpose** | Specifies a primary or secondary IP address for an interface. |
| **Step 5** | glbp group-number authentication md5 key-string [0 | 7] key  
**Example:**
Device(config-if)# glbp 1 authentication md5 key-string d00b4r987654321a |
| **Purpose** | Configures an authentication key for GLBP MD5 authentication.  
- The key string cannot exceed 100 characters in length.  
- No prefix to the key argument or specifying 0 means the key is unencrypted.  
- Specifying 7 means the key is encrypted. The key-string authentication key will automatically be encrypted if the **service password-encryption** global configuration command is enabled. |
| **Step 6** | glbp group-number ip [ip-address [secondary]]  
**Example:**
Device(config-if)# glbp 1 ip 10.0.0.10 |
| **Purpose** | Enables GLBP on an interface and identifies the primary IP address of the virtual gateway. |
| **Step 7** | Repeat Steps 1 through 6 on each device that will communicate. |
| **Step 8** | end  
**Example:**
Device(config-if)# end |
| **Purpose** | Returns to privileged EXEC mode. |
| **Step 9** | show glbp  
**Example:**
Device# show glbp |
| **Purpose** | (Optional) Displays GLBP information.  
- Use this command to verify your configuration. The key string and authentication type will be displayed if configured. |
Configuring GLBP MD5 Authentication Using a Key Chain

Perform this task to configure GLBP MD5 authentication using a key chain. Key chains allow a different key string to be used at different times according to the key chain configuration. GLBP will query the appropriate key chain to obtain the current live key and key ID for the specified key chain.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. key chain name-of-chain
4. key key-id
5. key-string string
6. exit
7. exit
8. interface type number
9. ip address ip-address mask [secondary]
10. glbp group-number authentication md5 key-chain name-of-chain
11. glbp group-number ip [ip-address [secondary]]
12. Repeat Steps 1 through 10 on each device that will communicate.
13. end
14. show glbp
15. show key chain

**DETAILED STEPS**

### Configuring GLBP Text Authentication

Text authentication provides minimal security. Use MD5 authentication if security is required.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip address ip-address mask [secondary]`
5. `glbp group-number authentication text string`
6. `glbp group-number ip [ip-address [secondary]]`
7. Repeat Steps 1 through 6 on each device that will communicate.
8. `end`
9. `show glbp`

#### DETAILED STEPS

### Configuring GLBP Weighting Values and Object Tracking

GLBP weighting is used to determine whether a GLBP group can act as a virtual forwarder. Initial weighting values can be set and optional thresholds specified. Interface states can be tracked and a decrement value set to reduce the weighting value if the interface goes down. When the GLBP group weighting drops below a specified value, the group will no longer be an active virtual forwarder. When the weighting rises above a specified value, the group can resume its role as an active virtual forwarder.

### SUMMARY STEPS

1. enable
2. configure terminal
3. track object-number interface type number [line-protocol | [ip | ipv6] routing]
4. exit
5. interface type number
6. glbp group weighting maximum [lower lower] [upper upper]
7. glbp group weighting track object-number [decrement value]
8. glbp group forwarder preempt [delay minimum seconds]
9. exit
10. show track [object-number | brief] [interface [brief]] [ip route [brief]] [resolution | timers]
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | **enable** | Enables privileged EXEC mode.  
- Enter your password if prompted.  
**Example:**  
Device> enable |
| **Step 2** | **configure terminal** | Enters global configuration mode.  
**Example:**  
Device# configure terminal |
| **Step 3** | **track object-number interface type number [line-protocol [ip | ipv6] routing]** | Configures an interface to be tracked where changes in the state of the interface affect the weighting of a GLBP gateway, and enters tracking configuration mode.  
- This command configures the interface and corresponding object number to be used with the **glbp weighting track** command.  
- The **line-protocol** keyword tracks whether the interface is up. The **ip routing** keywords also check that IP routing is enabled on the interface, and an IP address is configured.  
**Example:**  
Device(config)# track 2 interface GigabitEthernet 1/0/1 ip routing |
| **Step 4** | **exit** | Returns to global configuration mode.  
**Example:**  
Device(config-track)# exit |
| **Step 5** | **interface type number** | Enters interface configuration mode.  
**Example:**  
Device(config)# interface GigabitEthernet 1/0/1 |
| **Step 6** | **glbp group weighting maximum [lower lower] [upper upper]** | Specifies the initial weighting value, and the upper and lower thresholds, for a GLBP gateway.  
**Example:**  
Device(config-if)# glbp 10 weighting 110 lower 95 upper 105 |
| **Step 7** | **glbp group weighting track object-number [decrement value]** | Specifies an object to be tracked that affects the weighting of a GLBP gateway.  
- The **value** argument specifies a reduction in the weighting of a GLBP gateway when a tracked object fails.  
**Example:**  
Device(config-if)# glbp 10 weighting track 2 decrement 5 |
<table>
<thead>
<tr>
<th>Command or Action</th>

</tbody>
</table>

**Troubleshooting GLBP**

GLBP introduces five privileged EXEC mode commands to enable display of diagnostic output concerning various events relating to the operation of GLBP. The `debug condition glbp`, `debug glbp errors`, `debug glbp events`, `debug glbp packets`, and `debug glbp terse` commands are intended only for troubleshooting purposes because the volume of output generated by the software can result in severe performance degradation on the device. Perform this task to minimize the impact of using the `debug glbp` commands.

This procedure will minimize the load on the device created by the `debug condition glbp` or `debug glbp` command because the console port is no longer generating character-by-character processor interrupts. If you cannot connect to a console directly, you can run this procedure via a terminal server. If you must break the Telnet connection, however, you may not be able to reconnect because the device may be unable to respond due to the processor load of generating the debugging output.

**Before you begin**

This task requires a device running GLBP to be attached directly to a console.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no logging console
4. Use Telnet to access a device port and repeat Steps 1 and 2.
5. end
6. terminal monitor

---

**IP**

Troubleshooting GLBP

</table>
| **Step 1**  
**Example:**  
Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Step 2**  
**Example:**  
Device# configure terminal | Enters global configuration mode. |
| **Step 3**  
**Example:**  
Device(config)# no logging console | Disables all logging to the console terminal.  
• To reenable logging to the console, use the `logging console` command in global configuration mode. |
| **Step 4** | Enters global configuration mode in a recursive Telnet session, which allows the output to be redirected away from the console port. |
| **Step 5**  
**Example:**  
Device(config)# end | Exits to privileged EXEC mode. |
| **Step 6**  
**Example:**  
Device# terminal monitor | Enables logging output on the virtual terminal. |
| **Step 7**  
**Example:**  
Device# debug condition glbp GigabitEthernet 0/0/0 1 | Displays debugging messages about GLBP conditions.  
• Try to enter only specific `debug condition glbp` or `debug glbp` commands to isolate the output to a certain subcomponent and minimize the load on the processor. Use appropriate arguments and keywords to generate more detailed debug information on specified subcomponents.  
• Enter the specific `no debug condition glbp` or `no debug glbp` command when you are finished. |
| **Step 8**  
**Example:** | Disables logging on the virtual terminal. |
### Configuration Examples for GLBP

#### Example: Customizing GLBP Configuration

```
Device(config)# interface GigabitEthernet 1/0/1
Device(config-if)# ip address 10.21.8.32 255.255.255.0
Device(config-if)# glbp 10 timers 5 18
Device(config-if)# glbp 10 timers redirect 1800 28800
Device(config-if)# glbp 10 load-balancing host-dependent
Device(config-if)# glbp 10 priority 254
Device(config-if)# glbp 10 preempt delay minimum 60
Device(config-if)# glbp 10 client-cache maximum 1200 timeout 245
```

#### Example: Configuring GLBP MD5 Authentication Using Key Strings

The following example shows how to configure GLBP MD5 authentication using a key string:

```
Device(config)# interface GigabitEthernet 1/0/1
Device(config-if)# ip address 10.0.0.1 255.255.255.0
Device(config-if)# glbp 2 authentication md5 key-string ThisStringIsTheSecretKey
Device(config-if)# glbp 2 ip 10.0.0.10
```

#### Example: Configuring GLBP MD5 Authentication Using Key Chains

In the following example, GLBP queries the key chain “AuthenticateGLBP” to obtain the current live key and key ID for the specified key chain:

```
Device(config)# key chain AuthenticateGLBP
Device(config-keychain)# key 1
Device(config-keychain-key)# key-string ThisIsASecretKey
Device(config-keychain-key)# exit
Device(config)# interface GigabitEthernet 1/0/1
Device(config-if)# ip address 10.0.0.1 255.255.255.0
Device(config-if)# glbp 2 authentication md5 key-chain AuthenticateGLBP
Device(config-if)# glbp 2 ip 10.0.0.10
```

#### Example: Configuring GLBP Text Authentication

```
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 10.21.8.32 255.255.255.0
Device(config-if)# glbp 10 authentication text stringxyz
Device(config-if)# glbp 10 ip 10.21.8.10
```
Example: Configuring GLBP Weighting

In the following example, the device is configured to track the IP routing state of the POS interface 5/0/0 and 6/0/0, an initial GLBP weighting with upper and lower thresholds is set, and a weighting decrement value of 10 is set. If POS interface 5/0/0 and 6/0/0 go down, the weighting value of the device is reduced.

```
Device(config)# track 1 interface GigabitEthernet 1/0/1 line-protocol
Device(config)# track 2 interface GigabitEthernet 1/0/3 line-protocol
Device(config-if)# interface TenGigabitEthernet 0/0/1
Device(config-if)# ip address 10.21.8.32 255.255.255.0
Device(config-if)# glbp 10 weighting 110 lower 95 upper 105
Device(config-if)# glbp 10 weighting track 1 decrement 10
Device(config-if)# glbp 10 weighting track 2 decrement 10
```

Example: Enabling GLBP Configuration

In the following example, the device is configured to enable GLBP, and the virtual IP address of 10.21.8.10 is specified for GLBP group 10:

```
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 10.21.8.32 255.255.255.0
Device(config-if)# glbp 10 ip 10.21.8.10
```

Feature Information for GLBP

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 31: Feature Information for GLBP

<table>
<thead>
<tr>
<th>Feature Name</th>

<th>Feature Configuration Information</th>
</tr>
</thead>
</table>
| Gateway Load Balancing Protocol | Cisco IOS XE 3.6E | GLBP protects data traffic from a failed router or circuit, like HSRP and VRRP, while allowing packet load sharing between a group of redundant routers. In Cisco IOS Release Cisco IOS XE Release 3.6E, this feature is supported on the following platforms:  
  • Cisco 5760 Wireless LAN Controller  

The following commands were introduced or modified by this feature: `glbp forwarder preempt, glbp ip, glbp load-balancing, glbp name, glbp preempt, glbp priority, glbp sso, glbp timers, glbp timers redirect, glbp weighting, glbp weighting track, show glbp.` |

| GLBP MD5 Authentication | Cisco IOS XE 3.6E | MD5 authentication provides greater security than the alternative plain text authentication scheme. MD5 authentication allows each GLBP group member to use a secret key to generate a keyed MD5 hash that is part of the outgoing packet. A keyed hash of an incoming packet is generated and, if the hash within the incoming packet does not match the generated hash, the packet is ignored. In Cisco IOS Release Cisco IOS XE Release 3.6E, this feature is supported on the following platforms:  
  • Cisco 5760 Wireless LAN Controller  

The following commands were modified by this feature: `glbp authentication, show glbp.` |

</thead>
<tbody>
<tr>
<td>ISSU—GLBP</td>
<td></td>
<td>GLBP supports In Service Software Upgrade (ISSU). ISSU allows a high-availability (HA) system to run in Stateful Switchover (SSO) mode even when different versions of Cisco IOS software are running on the active and standby Route Processors (RPs) or line cards. This feature provides customers with the same level of HA functionality for planned outages due to software upgrades as is available with SSO for unplanned outages. That is, the system can switch over to a secondary RP and continue forwarding packets without session loss and with minimal or no packet loss. This feature is enabled by default. There are no new or modified commands for this feature.</td>
</tr>
<tr>
<td>SSO—GLBP</td>
<td></td>
<td>GLBP is now SSO aware. GLBP can detect when a router is failing over to the secondary RP and continue in its current GLBP group state. Prior to being SSO aware, GLBP was not able to detect that a second RP was installed and configured to take over in the event that the primary RP failed. When the primary failed, the GLBP device would stop participating in the GLBP group and, depending on its role, could trigger another router in the group to take over as the active router. With this enhancement, GLBP detects the failover to the secondary RP and no change occurs to the GLBP group. If the secondary RP fails and the primary is still not available, then the GLBP group detects this and re-elects a new active GLBP router. This feature is enabled by default. The following commands were introduced or modified by this feature: <code>debug glbp events</code>, <code>glbp sso</code>, <code>show glbp</code>.</td>
</tr>
</tbody>
</table>

### Glossary

**active RP**—The Route Processor (RP) controls the system, provides network services, runs routing protocols and presents the system management interface.

**AVF**—active virtual forwarder. One virtual forwarder within a GLBP group is elected as active virtual forwarder for a specified virtual MAC address, and it is responsible for forwarding packets sent to that MAC address. Multiple active virtual forwarders can exist for each GLBP group.

**AVG**—active virtual gateway. One virtual gateway within a GLBP group is elected as the active virtual gateway, and is responsible for the operation of the protocol.

**GLBP gateway**—Gateway Load Balancing Protocol gateway. A router or gateway running GLBP. Each GLBP gateway may participate in one or more GLBP groups.

**GLBP group**—Gateway Load Balancing Protocol group. One or more GLBP gateways configured with the same GLBP group number on connected Ethernet interfaces.

**ISSU**—In Service Software Upgrade. A process that allows Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades are a significant cause of downtime. ISSU allows software to be modified while packet forwarding continues, which increases network availability and reduces downtime caused by planned software upgrades.
NSF—nonstop forwarding. The ability of a router to continue to forward traffic to a router that may be recovering from a failure. Also, the ability of a router recovering from a failure to continue to correctly forward traffic sent to it by a peer.

RP—Route Processor. A generic term for the centralized control unit in a chassis. Platforms usually use a platform-specific term, such as RSP on the Cisco 7500, the PRE on the Cisco 10000, or the SUP+MSFC on the Cisco 7600.

RPR—Route Processor Redundancy. RPR provides an alternative to the High System Availability (HSA) feature. HSA enables a system to reset and use a standby Route Processor (RP) if the active RP fails. Using RPR, you can reduce unplanned downtime because RPR enables a quicker switchover between an active and standby RP if the active RP experiences a fatal error.

RPR+—An enhancement to RPR in which the standby RP is fully initialized.

SSO—Stateful Switchover. Enables applications and features to maintain state information between an active and standby unit.

standby RP—An RP that has been fully initialized and is ready to assume control from the active RP should a manual or fault-induced switchover occur.

switchover—An event in which system control and routing protocol execution are transferred from the active RP to the standby RP. Switchover may be a manual operation or may be induced by a hardware or software fault. Switchover may include transfer of the packet forwarding function in systems that combine system control and packet forwarding in an indivisible unit.

vIP—virtual IP address. An IPv4 address. There must be only one virtual IP address for each configured GLBP group. The virtual IP address must be configured on at least one GLBP group member. Other GLBP group members can learn the virtual IP address from hello messages.

IP Multicast Routing Technology Overview

Information About IP Multicast Technology

Role of IP Multicast in Information Delivery

IP multicast is a bandwidth-conserving technology that reduces traffic by delivering a single stream of information simultaneously to potentially thousands of businesses and homes. Applications that take advantage of multicast include video conferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address. The sending host inserts the multicast group address into the IP destination address field of the packet and IP multicast routers and multilayer switches forward incoming IP multicast packets out all interfaces that lead to the members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

IP Multicast Routing Protocols

The software supports the following protocols to implement IP multicast routing:

- IGMP is used between hosts on a LAN and the routers (and multilayer devices) on that LAN to track the multicast groups of which hosts are members. To participate in IP multicasting, multicast hosts, routers, and multilayer devices must have the Internet Group Management Protocol (IGMP) operating.

- Protocol Independent Multicast (PIM) is used between routers so that they can track which multicast packets to forward to each other and to their directly connected LANs.

- IGMP Snooping is used for multicasting in a Layer 2 switching environment. It helps reduce the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices.

This figure shows where these protocols operate within the IP multicast environment.
According to IPv4 multicast standards, the MAC destination multicast address begins with 0100:5e and is appended by the last 23 bits of the IP address. For example, if the IP destination address is 239.1.1.39, the MAC destination address is 0100:5e01:0127.

A multicast packet is unmatched when the destination IPv4 address does not match the destination MAC address. The device forwards the unmatched packet in hardware based upon the MAC address table. If the destination MAC address is not in the MAC address table, the device floods the packet to the all port in the same VLAN as the receiving port.

### Multicast Group Transmission Scheme

IP communication consists of hosts that act as senders and receivers of traffic as shown in the first figure. Senders are called sources. Traditional IP communication is accomplished by a single host source sending packets to another single host (unicast transmission) or to all hosts (broadcast transmission). IP multicast provides a third scheme, allowing a host to send packets to a subset of all hosts (multicast transmission). This subset of receiving hosts is called a multicast group. The hosts that belong to a multicast group are called group members.

Multicast is based on this group concept. A multicast group is an arbitrary number of receivers that join a group in order to receive a particular data stream. This multicast group has no physical or geographical boundaries—the hosts can be located anywhere on the Internet or on any private internetwork. Hosts that are interested in receiving data from a source to a particular group must join that group. Joining a group is accomplished by a host receiver by way of the Internet Group Management Protocol (IGMP).

In a multicast environment, any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group can receive packets sent to that group. Multicast packets are delivered to a group using best-effort reliability, just like IP unicast packets.
In the next figure, the receivers (the designated multicast group) are interested in receiving the video data stream from the source. The receivers indicate their interest by sending an IGMP host report to the routers in the network. The routers are then responsible for delivering the data from the source to the receivers. The routers use Protocol Independent Multicast (PIM) to dynamically create a multicast distribution tree. The video data stream will then be delivered only to the network segments that are in the path between the source and the receivers.
IP Multicast Boundary

As shown in the figure, address scoping defines domain boundaries so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

Figure 22: Address Scoping at Boundaries

You can set up an administratively scoped boundary on an interface for multicast group addresses using the `ip multicast boundary` command with the `access-list` argument. A standard access list defines the range of addresses affected. When a boundary is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The Internet Assigned Numbers Authority (IANA) has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. They would be considered local, not globally unique.
You can configure the `filter-autorp` keyword to examine and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

### IP Multicast Group Addressing

A multicast group is identified by its multicast group address. Multicast packets are delivered to that multicast group address. Unlike unicast addresses that uniquely identify a single host, multicast IP addresses do not identify a particular host. To receive the data sent to a multicast address, a host must join the group that address identifies. The data is sent to the multicast address and received by all the hosts that have joined the group indicating that they wish to receive traffic sent to that group. The multicast group address is assigned to a group at the source. Network administrators who assign multicast group addresses must make sure the addresses conform to the multicast address range assignments reserved by the Internet Assigned Numbers Authority (IANA).

### IP Class D Addresses

IP multicast addresses have been assigned to the IPv4 Class D address space by IANA. The high-order four bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 to 239.255.255.255. A multicast address is chosen at the source (sender) for the receivers in a multicast group.

---

**Note**

The Class D address range is used only for the group address or destination address of IP multicast traffic. The source address for multicast datagrams is always the unicast source address.

### IP Multicast Address Scoping

The multicast address range is subdivided to provide predictable behavior for various address ranges and for address reuse within smaller domains. The table provides a summary of the multicast address ranges. A brief summary description of each range follows.

#### Table 32: Multicast Address Range Assignments

<table>
<thead>
<tr>
<th>Name</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved Link-Local Addresses</td>
<td>224.0.0.0 to 224.0.0.255</td>
<td>Reserved for use by network protocols on a local network segment.</td>
</tr>
<tr>
<td>Globally Scoped Addresses</td>
<td>224.0.1.0 to 238.255.255.255</td>
<td>Reserved to send multicast data between organizations and across the Internet.</td>
</tr>
<tr>
<td>Source Specific Multicast</td>
<td>232.0.0.0 to 232.255.255.255</td>
<td>Reserved for use with the SSM datagram delivery model where data is forwarded only to receivers that have explicitly joined the group.</td>
</tr>
</tbody>
</table>
### Reserved Link-Local Addresses

The IANA has reserved the range 224.0.0.0 to 224.0.0.255 for use by network protocols on a local network segment. Packets with an address in this range are local in scope and are not forwarded by IP routers. Packets with link local destination addresses are typically sent with a time-to-live (TTL) value of 1 and are not forwarded by a router.

Within this range, reserved link-local addresses provide network protocol functions for which they are reserved. Network protocols use these addresses for automatic router discovery and to communicate important routing information. For example, Open Shortest Path First (OSPF) uses the IP addresses 224.0.0.5 and 224.0.0.6 to exchange link-state information.

IANA assigns single multicast address requests for network protocols or network applications out of the 224.0.1.xxx address range. Multicast routers forward these multicast addresses.

---

**Note**

All the packets with reserved link-local addresses are punted to CPU by default in the ASR 903 RSP2 Module.

### Globally Scoped Addresses

Addresses in the range 224.0.1.0 to 238.255.255.255 are called globally scoped addresses. These addresses are used to send multicast data between organizations across the Internet. Some of these addresses have been reserved by IANA for use by multicast applications. For example, the IP address 224.0.1.1 is reserved for Network Time Protocol (NTP).

### Source Specific Multicast Addresses

Addresses in the range 232.0.0.0/8 are reserved for Source Specific Multicast (SSM) by IANA. In Cisco IOS software, you can use the `ip pim ssm` command to configure SSM for arbitrary IP multicast addresses also. SSM is an extension of Protocol Independent Multicast (PIM) that allows for an efficient data delivery mechanism in one-to-many communications. SSM is described in the IP Multicast Delivery Modes, on page 457 section.

### GLOP Addresses

GLOP addressing (as proposed by RFC 2770, GLOP Addressing in 233/8) proposes that the 233.0.0.0/8 range be reserved for statically defined addresses by organizations that already have an AS number reserved. This practice is called GLOP addressing. The AS number of the domain is embedded into the second and third octets of the 233.0.0.0/8 address range. For example, AS 62010 is written in hexadecimal format as F23A. Separating the two octets F2 and 3A results in 242 and 58 in decimal format. These values result in a subnet of 233.242.58.0/24 that would be globally reserved for AS 62010 to use.
Limited Scope Addresses

The range 239.0.0.0 to 239.255.255.255 is reserved as administratively or limited scoped addresses for use in private multicast domains. These addresses are constrained to a local group or organization. Companies, universities, and other organizations can use limited scope addresses to have local multicast applications that will not be forwarded outside their domain. Routers typically are configured with filters to prevent multicast traffic in this address range from flowing outside an autonomous system (AS) or any user-defined domain. Within an AS or domain, the limited scope address range can be further subdivided so that local multicast boundaries can be defined.

Note

Network administrators may use multicast addresses in this range, inside a domain, without conflicting with others elsewhere in the Internet.

Layer 2 Multicast Addresses

Historically, network interface cards (NICs) on a LAN segment could receive only packets destined for their burned-in MAC address or the broadcast MAC address. In IP multicast, several hosts need to be able to receive a single data stream with a common destination MAC address. Some means had to be devised so that multiple hosts could receive the same packet and still be able to differentiate between several multicast groups. One method to accomplish this is to map IP multicast Class D addresses directly to a MAC address. Using this method, NICs can receive packets destined to many different MAC addresses.

Cisco Group Management Protocol (CGMP) is used on routers connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary for those Catalyst switches that cannot distinguish between IP multicast data packets and IGMP report messages, both of which are addressed to the same group address at the MAC level.

IP Multicast Delivery Modes

IP multicast delivery modes differ only for the receiver hosts, not for the source hosts. A source host sends IP multicast packets with its own IP address as the IP source address of the packet and a group address as the IP destination address of the packet.

Source Specific Multicast

Source Specific Multicast (SSM) is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core network technology for the Cisco implementation of IP multicast targeted for audio and video broadcast application environments.

For the SSM delivery mode, an IP multicast receiver host must use IGMP Version 3 (IGMPv3) to subscribe to channel (S,G). By subscribing to this channel, the receiver host is indicating that it wants to receive IP multicast traffic sent by source host S to group G. The network will deliver IP multicast packets from source host S to group G to all hosts in the network that have subscribed to the channel (S, G).

SSM does not require group address allocation within the network, only within each source host. Different applications running on the same source host must use different SSM groups. Different applications running on different source hosts can arbitrarily reuse SSM group addresses without causing any excess traffic on the network.
Configuring IGMP

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IGMP and IGMP Snooping

Prerequisites for IGMP

- Before performing the tasks in this module, you should be familiar with the concepts explained in the "IP Multicast Routing Technology Overview" module.

- The tasks in this module assume that IP multicast has been enabled and that the Protocol Independent Multicast (PIM) interfaces have been configured using the tasks described in the "Configuring Basic IP Multicast Routing" module.
Prerequisites for IGMP Snooping

Observe these guidelines when configuring the IGMP snooping querier:

- Configure the VLAN in global configuration mode.

- Configure an IP address on the VLAN interface. When enabled, the IGMP snooping querier uses the IP address as the query source address.

- If there is no IP address configured on the VLAN interface, the IGMP snooping querier tries to use the configured global IP address for the IGMP querier. If there is no global IP address specified, the IGMP querier tries to use the VLAN device virtual interface (SVI) IP address (if one exists). If there is no SVI IP address, the device uses the first available IP address configured on the device. The first IP address available appears in the output of the `show ip interface` privileged EXEC command. The IGMP snooping querier does not generate an IGMP general query if it cannot find an available IP address on the device.

- The IGMP snooping querier supports IGMP Versions 1 and 2.

- When administratively enabled, the IGMP snooping querier moves to the nonquerier state if it detects the presence of a multicast router in the network.

- When it is administratively enabled, the IGMP snooping querier moves to the operationally disabled state under these conditions:
  - IGMP snooping is disabled in the VLAN.
  - PIM is enabled on the SVI of the corresponding VLAN.

Restrictions for IGMP and IGMP Snooping

Restrictions for Configuring IGMP

The following are the restrictions for configuring IGMP:

- The device supports IGMP Versions 1, 2, and 3.

  Note: For IGMP Version 3, only IGMP Version 3 BISS (Basic IGMPv3 Snooping Support) is supported.

- IGMP Version 3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.

- IGMPv3 can operate with both ISM and SSM. In ISM, both exclude and include mode reports are applicable. In SSM, only include mode reports are accepted by the last-hop router. Exclude mode reports are ignored.

- IGMP filtering and throttling is not supported under the WLAN.
• You cannot have a device stack containing a mix of Catalyst 3850 and Catalyst 3650 devices.

**Restrictions for IGMP Snooping**

The following are the restrictions for IGMP snooping:

• The device supports IGMPv3 snooping based only on the destination multicast IP address. It does not support snooping based on a source IP address or proxy report.

• IGMPv3 join and leave messages are not supported on devices running IGMP filtering or Multicast VLAN registration (MVR).

• IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

• The IGMP configurable leave time is only supported on hosts running IGMP Version 2. IGMP version 2 is the default version for the device.

The actual leave latency in the network is usually the configured leave time. However, the leave time might vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

• The IGMP throttling action restriction can be applied only to Layer 2 ports. You can use **ip igmp max-groups action replace** interface configuration command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

When the maximum group limitation is set to the default (no maximum), entering the **ip igmp max-groups action {deny | replace}** command has no effect.

If you configure the throttling action and set the maximum group limitation after an interface has added multicast entries to the forwarding table, the forwarding-table entries are either aged out or removed, depending on the throttling action.

**Information About IGMP**

**Role of the Internet Group Management Protocol**

IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Enabling PIM on an interface also enables IGMP. IGMP provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

• A querier is a network device, such as a router, that sends query messages to discover which network devices are members of a given multicast group.

• A host is a receiver, including routers, that sends report messages (in response to query messages) to inform the querier of a host membership. Hosts use IGMP messages to join and leave multicast groups.

Hosts identify group memberships by sending IGMP messages to their local multicast device. Under IGMP, devices listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.
IGMP Multicast Addresses

IPv4 multicast traffic uses group addresses, which are Class D IP addresses. The high-order four bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 to 239.255.255.255.

Multicast addresses in the range 224.0.0.0 to 224.0.0.255 are reserved for use by routing protocols and other network control traffic. The address 224.0.0.0 is guaranteed not to be assigned to any group.

IGMP packets are transmitted using IP multicast group addresses as follows:

- IGMP general queries are destined to the address 224.0.0.1 (all systems on a subnet).
- IGMP group-specific queries are destined to the group IP address for which the device is querying.
- IGMP group membership reports are destined to the group IP address for which the device is reporting.
- IGMPv2 leave-group messages are destined to the address 224.0.0.2 (all devices on a subnet).
- IGMPv3 membership reports are destined to the address 224.0.0.22; all IGMPv3-capable multicast devices must listen to this address.

IGMP Versions

The device supports IGMP version 1, IGMP version 2, and IGMP version 3. These versions are interoperable on the device. For example, if IGMP snooping is enabled and the querier's version is IGMPv2, and the device receives an IGMPv3 report from a host, then the device can forward the IGMPv3 report to the multicast router.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

IGMP Version 1

IGMP version 1 (IGMPv1) primarily uses a query-response model that enables the multicast router and multilayer device to find which multicast groups are active (have one or more hosts interested in a multicast group) on the local subnet. IGMPv1 has other processes that enable a host to join and leave a multicast group. For more information, see RFC 1112.

IGMP Version 2

IGMPv2 extends IGMP functionality by providing such features as the IGMP leave process to reduce leave latency, group-specific queries, and an explicit maximum query response time. IGMPv2 also adds the capability for routers to elect the IGMP querier without depending on the multicast protocol to perform this task. For more information, see RFC 2236.

Note

IGMP version 2 is the default version for the device.

IGMP Version 3

The device supports IGMP version 3.

An IGMPv3 device supports Basic IGMPv3 Snooping Support (BISS), which includes support for the snooping features on IGMPv1 and IGMPv2 switches and for IGMPv3 membership report messages. BISS constrains
the flooding of multicast traffic when your network includes IGMPv3 hosts. It constrains traffic to approximately
the same set of ports as the IGMP snooping feature on IGMPv2 or IGMPv1 hosts.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific
Multicast (SSM) feature.

**IGMPv3 Host Signaling**

IGMPv3 is the third version of the IETF standards track protocol in which hosts signal membership to last-hop
devices of multicast groups. IGMPv3 introduces the ability for hosts to signal group membership that allows
filtering capabilities with respect to sources. A host can signal either that it wants to receive traffic from all
sources sending to a group except for some specific sources (a mode called EXCLUDE) or that it wants to
receive traffic only from some specific sources sending to the group (a mode called INCLUDE).

IGMPv3 can operate with both ISM and SSM. In ISM, both EXCLUDE and INCLUDE mode reports are
accepted by the last-hop router. In SSM, only INCLUDE mode reports are accepted by the last-hop router.

**IGMP Versions Differences**

There are three versions of IGMP, as defined by Request for Comments (RFC) documents of the Internet
Engineering Task Force (IETF). IGMPv2 improves over IGMPv1 by adding the ability for a host to signal
desire to leave a multicast group and IGMPv3 improves over IGMPv2 mainly by adding the ability to listen
to multicast originating from a set of source IP addresses only.

<table>
<thead>
<tr>
<th>IGMP Version</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGMPv1</td>
<td>Provides the basic query-response mechanism that allows the multicast device to determine which multicast groups are active and other processes that enable hosts to join and leave a multicast group. RFC 1112 defines the IGMPv1 host extensions for IP multicasting.</td>
</tr>
<tr>
<td>IGMPv2</td>
<td>Extends IGMP, allowing such capabilities as the IGMP leave process, group-specific queries, and an explicit maximum response time field. IGMPv2 also adds the capability for devices to elect the IGMP querier without dependence on the multicast protocol to perform this task. RFC 2236 defines IGMPv2.</td>
</tr>
</tbody>
</table>

*Note* By default, enabling a PIM on an interface enables IGMPv2 on that device. IGMPv2 was designed to be as backward compatible with IGMPv1 as possible. To accomplish this backward compatibility, RFC 2236 defined special interoperability rules. If your network contains legacy IGMPv1 hosts, you should be familiar with these operability rules. For more information about IGMPv1 and IGMPv2 interoperability, see RFC 2236, Internet Group Management Protocol, Version 2.

**Devices That Run IGMPv1**

IGMPv1 devices send IGMP queries to the “all-hosts” multicast address of 224.0.0.1 to solicit multicast
groups with active multicast receivers. The multicast receivers also can send IGMP reports to the device to notify it that they are interested in receiving a particular multicast stream. Hosts can send the report
asynchronously or in response to the IGMP queries sent by the device. If more than one multicast receiver exists for the same multicast group, only one of these hosts sends an IGMP report message; the other hosts suppress their report messages.

In IGMPv1, there is no election of an IGMP querier. If more than one device on the segment exists, all the devices send periodic IGMP queries. IGMPv1 has no special mechanism by which the hosts can leave the group. If the hosts are no longer interested in receiving multicast packets for a particular group, they simply do not reply to the IGMP query packets sent from the device. The device continues sending query packets. If the device does not hear a response in three IGMP queries, the group times out and the device stops sending multicast packets on the segment for the group. If the host later wants to receive multicast packets after the timeout period, the host simply sends a new IGMP join to the device, and the device begins to forward the multicast packet again.

If there are multiple devices on a LAN, a designated router (DR) must be elected to avoid duplicating multicast traffic for connected hosts. PIM devices follow an election process to select a DR. The PIM device with the highest IP address becomes the DR.

The DR is responsible for the following tasks:

- Sending PIM register and PIM Join and Prune messages toward the rendezvous point (RP) to inform it about host group membership.
- Sending IGMP host-query messages.
- Sending host-query messages by default every 60 seconds in order to keep the IGMP overhead on hosts and networks very low.

**Devices That Run IGMPv2**

IGMPv2 improves the query messaging capabilities of IGMPv1.

The query and membership report messages in IGMPv2 are identical to the IGMPv1 messages with two exceptions:

- IGMPv2 query messages are broken into two categories: general queries (identical to IGMPv1 queries) and group-specific queries.
- IGMPv1 membership reports and IGMPv2 membership reports have different IGMP type codes.

IGMPv2 also enhances IGMP by providing support for the following capabilities:

- Querier election process—Provides the capability for IGMPv2 devices to elect the IGMP querier without having to rely on the multicast routing protocol to perform the process.
- Maximum Response Time field—A new field in query messages permits the IGMP querier to specify the maximum query-response time. This field permits the tuning of the query-response process to control response burstiness and to fine-tune leave latencies.
- Group-Specific Query messages—Permits the IGMP querier to perform the query operation on a specific group instead of all groups.
- Leave-Group messages—Provides hosts with a method of notifying devices on the network that they wish to leave the group.

Unlike IGMPv1, in which the DR and the IGMP querier are typically the same device, in IGMPv2 the two functions are decoupled. The DR and the IGMP querier are selected based on different criteria and may be
different devices on the same subnet. The DR is the device with the highest IP address on the subnet, whereas
the IGMP querier is the device with the lowest IP address.

Query messages are used to elect the IGMP querier as follows:
1. When IGMPv2 devices start, they each multicast a general query message to the all-systems group address
   of 224.0.0.1 with their interface address in the source IP address field of the message.
2. When an IGMPv2 device receives a general query message, the device compares the source IP address
   in the message with its own interface address. The device with the lowest IP address on the subnet is
   elected the IGMP querier.
3. All devices (excluding the querier) start the query timer, which is reset whenever a general query message
   is received from the IGMP querier. If the query timer expires, it is assumed that the IGMP querier has
gone down, and the election process is performed again to elect a new IGMP querier.

By default, the timer is two times the query interval.

IGMP Join and Leave Process

IGMP Join Process

When a host wants to join a multicast group, the host sends one or more unsolicited membership reports for
the multicast group it wants to join. The IGMP join process is the same for IGMPv1 and IGMPv2 hosts.

In IGMPv3, the join process for hosts proceeds as follows:

- When a host wants to join a group, it sends an IGMPv3 membership report to 224.0.0.22 with an empty
  EXCLUDE list.
- When a host wants to join a specific channel, it sends an IGMPv3 membership report to 224.0.0.22 with
  the address of the specific source included in the INCLUDE list.
- When a host wants to join a group excluding particular sources, it sends an IGMPv3 membership report
  to 224.0.0.22 excluding those sources in the EXCLUDE list.

Note

If some IGMPv3 hosts on a LAN wish to exclude a source and others wish to include the source, then the
device will send traffic for the source on the LAN (that is, inclusion trumps exclusion in this situation).

IGMP Leave Process

The method that hosts use to leave a group varies depending on the version of IGMP in operation.

IGMPv1 Leave Process

There is no leave-group message in IGMPv1 to notify the devices on the subnet that a host no longer wants
to receive the multicast traffic from a specific group. The host simply stops processing traffic for the multicast
group and ceases responding to IGMP queries with IGMP membership reports for the group. As a result, the
only way IGMPv1 devices know that there are no longer any active receivers for a particular multicast group
on a subnet is when the devices stop receiving membership reports. To facilitate this process, IGMPv1 devices
associate a countdown timer with an IGMP group on a subnet. When a membership report is received for the
group on the subnet, the timer is reset. For IGMPv1 devices, this timeout interval is typically three times the query interval (3 minutes). This timeout interval means that the device may continue to forward multicast traffic onto the subnet for up to 3 minutes after all hosts have left the multicast group.

**IGMPv2 Leave Process**

IGMPv2 incorporates a leave-group message that provides the means for a host to indicate that it wishes to stop receiving multicast traffic for a specific group. When an IGMPv2 host leaves a multicast group, if it was the last host to respond to a query with a membership report for that group, it sends a leave-group message to the all-devices multicast group (224.0.0.2).

**IGMPv3 Leave Process**

IGMPv3 enhances the leave process by introducing the capability for a host to stop receiving traffic from a particular group, source, or channel in IGMP by including or excluding sources, groups, or channels in IGMPv3 membership reports.

**IGMP Snooping**

Layer 2 devices can use IGMP snooping to constrain the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. As the name implies, IGMP snooping requires the LAN device to snoop on the IGMP transmissions between the host and the router and to keep track of multicast groups and member ports. When the device receives an IGMP report from a host for a particular multicast group, the device adds the host port number to the forwarding table entry; when it receives an IGMP Leave Group message from a host, it removes the host port from the table entry. It also periodically deletes entries if it does not receive IGMP membership reports from the multicast clients.

---

**Note**

For more information on IP multicast and IGMP, see RFC 1112 and RFC 2236.

The multicast router (which could be a device with the IP services feature) set on the active device sends out periodic general queries to all VLANs. All hosts interested in this multicast traffic send join requests and are added to the forwarding table entry. The device creates one entry per VLAN in the IGMP snooping IP multicast forwarding table for each group from which it receives an IGMP join request.

The device supports IP multicast group-based bridging, instead of MAC-addressed based groups. With multicast MAC address-based groups, if an IP address being configured translates (aliases) to a previously configured MAC address or to any reserved multicast MAC addresses (in the range 224.0.0.xxx), the command fails. Because the device uses IP multicast groups, there are no address aliasing issues.

The IP multicast groups learned through IGMP snooping are dynamic. However, you can statically configure multicast groups by using the `ip igmp snooping vlan` `vlan-id static ip_address interface` `interface-id` global configuration command. If you specify group membership for a multicast group address statically, your setting supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can consist of both user-defined and IGMP snooping-learned settings.

You can configure an IGMP snooping querier to support IGMP snooping in subnets without multicast interfaces because the multicast traffic does not need to be routed.

If a port spanning-tree, a port group, or a VLAN ID change occurs, the IGMP snooping-learned multicast groups from this port on the VLAN are deleted.
These sections describe IGMP snooping characteristics:

**Joining a Multicast Group**

*Figure 23: Initial IGMP Join Message*

When a host connected to the device wants to join an IP multicast group and it is an IGMP version 2 client, it sends an unsolicited IGMP join message, specifying the IP multicast group to join. Alternatively, when the device receives a general query from the router, it forwards the query to all ports in the VLAN. IGMP version 1 or version 2 hosts wanting to join the multicast group respond by sending a join message to the device. The device CPU creates a multicast forwarding-table entry for the group if it is not already present. The CPU also adds the interface where the join message was received to the forwarding-table entry. The host associated with that interface receives multicast traffic for that multicast group.

Router A sends a general query to the device, which forwards the query to ports 2 through 5, all of which are members of the same VLAN. Host 1 wants to join multicast group 224.1.2.3 and multicasts an IGMP membership report (IGMP join message) to the group. The device CPU uses the information in the IGMP report to set up a forwarding-table entry that includes the port numbers connected to Host 1 and to the router.

*Table 34: IGMP Snooping Forwarding Table*

<table>
<thead>
<tr>
<th>Destination Address</th>
<th>Type of Packet</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>224.1.2.3</td>
<td>IGMP</td>
<td>1, 2</td>
</tr>
</tbody>
</table>

The device hardware can distinguish IGMP information packets from other packets for the multicast group. The information in the table tells the switching engine to send frames addressed to the 224.1.2.3 multicast IP address that are not IGMP packets to the router and to the host that has joined the group.

*Figure 24: Second Host Joining a Multicast Group*

If another host (for example, Host 4) sends an unsolicited IGMP join message for the same group, the CPU receives that message and adds the port number of Host 4 to the forwarding table. Because the forwarding table directs IGMP messages only to the CPU, the message is not flooded to other ports on the device. Any
known multicast traffic is forwarded to the group and not to the CPU.

</tr>
</tbody>
</table>

Leaving a Multicast Group

The router sends periodic multicast general queries, and the device forwards these queries through all ports in the VLAN. Interested hosts respond to the queries. If at least one host in the VLAN wants to receive multicast traffic, the router continues forwarding the multicast traffic to the VLAN. The device forwards multicast group traffic only to those hosts listed in the forwarding table for that IP multicast group maintained by IGMP snooping.

When hosts want to leave a multicast group, they can silently leave, or they can send a leave message. When the device receives a leave message from a host, it sends a group-specific query to learn if any other devices connected to that interface are interested in traffic for the specific multicast group. The device then updates the forwarding table for that MAC group so that only those hosts interested in receiving multicast traffic for the group are listed in the forwarding table. If the router receives no reports from a VLAN, it removes the group for the VLAN from its IGMP cache.

Immediate Leave

The device uses IGMP snooping Immediate Leave to remove from the forwarding table an interface that sends a leave message without the device sending group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original leave message. Immediate Leave ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are simultaneously in use.

Immediate Leave is only supported on IGMP version 2 hosts. IGMP version 2 is the default version for the device.
You should use the Immediate Leave feature only on VLANs where a single host is connected to each port. If Immediate Leave is enabled on VLANs where more than one host is connected to a port, some hosts may be dropped inadvertently.

**IGMP Configurable-Leave Timer**

You can configure the time that the device waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 32767 milliseconds.

**IGMP Report Suppression**

**Note**

IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

The device uses IGMP report suppression to forward only one IGMP report per multicast router query to multicast devices. When IGMP report suppression is enabled (the default), the device sends the first IGMP report from all hosts for a group to all the multicast routers. The device does not send the remaining IGMP reports for the group to the multicast routers. This feature prevents duplicate reports from being sent to the multicast devices.

If the multicast router query includes requests only for IGMPv1 and IGMPv2 reports, the device forwards only the first IGMPv1 or IGMPv2 report from all hosts for a group to all the multicast routers.

If the multicast router query also includes requests for IGMPv3 reports, the device forwards all IGMPv1, IGMPv2, and IGMPv3 reports for a group to the multicast devices.

If you disable IGMP report suppression, all IGMP reports are forwarded to the multicast routers.

**IGMP Snooping and Device Stacks**

IGMP snooping functions across the device stack; that is, IGMP control information from one device is distributed to all devices in the stack. Regardless of the stack member through which IGMP multicast data enters the stack, the data reaches the hosts that have registered for that group.

If a device in the stack fails or is removed from the stack, only the members of the multicast group that are on that device will not receive the multicast data. All other members of a multicast group on other devices in the stack continue to receive multicast data streams. However, multicast groups that are common for both Layer 2 and Layer 3 (IP multicast routing) might take longer to converge if the active device is removed.

**IGMP Filtering and Throttling**

In some environments, for example, metropolitan or multiple-dwelling unit (MDU) installations, you might want to control the set of multicast groups to which a user on a device port can belong. You can control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan. You might also want to limit the number of multicast groups to which a user on a device port can belong.

With the IGMP filtering feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual device ports. An IGMP profile can contain one or more multicast
groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a device port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing. You can also set the maximum number of IGMP groups that a Layer 2 interface can join.

IGMP filtering controls only group-specific query and membership reports, including join and leave reports. It does not control general IGMP queries. IGMP filtering has no relationship with the function that directs the forwarding of IP multicast traffic. The filtering feature operates in the same manner whether CGMP or MVR is used to forward the multicast traffic.

IGMP filtering applies only to the dynamic learning of IP multicast group addresses, not static configuration. With the IGMP throttling feature, you can set the maximum number of IGMP groups that a Layer 2 interface can join. If the maximum number of IGMP groups is set, the IGMP snooping forwarding table contains the maximum number of entries, and the interface receives an IGMP join report, you can configure an interface to drop the IGMP report or to replace the randomly selected multicast entry with the received IGMP report.

Note
IGMPv3 join and leave messages are not supported on devices running IGMP filtering.

Default IGMP Configuration

This table displays the default IGMP configuration for the device.

Table 36: Default IGMP Configuration

### How to Configure IGMP

#### Configuring the Device as a Member of a Group (CLI)

You can configure the device as a member of a multicast group and discover multicast reachability in a network. If all the multicast-capable routers and multilayer devices that you administer are members of a multicast group, pinging that group causes all of these devices to respond. The devices respond to ICMP echo-request packets addressed to a group of which they are members. Another example is the multicast trace-route tools provided in the software.
Performing this procedure might impact the CPU performance because the CPU will receive all data traffic for the group address.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp join-group group-address
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip igmp join-group group-address</td>
<td>Configures the device to join a multicast group.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ip igmp</td>
<td></td>
</tr>
</tbody>
</table>

By default, no group memberships are defined.

For group-address, specify the multicast IP address in dotted decimal notation.

- A routed port—A physical port that has been configured as a Layer 3 port by entering the no switchport interface configuration command.
- An SVI—A VLAN interface created by using the interface vlan vlan-id global configuration command.

These interfaces must have IP addresses assigned to them.
Controlling Access to IP Multicast Group (CLI)

The device sends IGMP host-query messages to find which multicast groups have members on attached local networks. The device then forwards to these group members all packets addressed to the multicast group. You can place a filter on each interface to restrict the multicast groups that hosts on the subnet serviced by the interface can join.

To limit the number of joins on the interface, configure the port for the filter which associates with the IGMP profile.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp profile
4. permit
5. exit
6. interface interface-id
7. ip igmp filter filter_number
8. end
9. show ip igmp interface [interface-id]
10. copy running-config startup-config

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>join-group 225.2.2.2</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
</tr>
<tr>

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
   *Example:*  
   Device> enable |
| **Step 2** | `configure terminal` | Enters global configuration mode.  
   *Example:*  
   Device# configure terminal |
| **Step 3** | `ip igmp profile` | Enters an IGMP filter profile number from 1 to 4294967295.  
   *Example:*  
   Device(config)# ip igmp profile 10  
   Device(config-igmp-profile)# ?  
   For additional information about configuring IGMP filter profiles, see Configuring IGMP Profiles (CLI), on page 483. |
| **Step 4** | `permit` | Enters an IGMP profile configuration action. The following IGMP profile configuration actions are supported:  
   *Example:*  
   Device(config-igmp-profile)# permit 229.9.9.0  
   • `deny`—Matching IP addresses are denied.  
   • `exit`—Exits from the IGMP profile configuration mode.  
   • `no`—Negates a command or set its defaults.  
   • `permit`—Matching addresses are permitted.  
   • `range`—adds a range to the set. |
| **Step 5** | `exit` | Returns to global configuration mode.  
   *Example:*  
   Device(config-igmp-profile)# exit |
| **Step 6** | `interface interface-id` | Specifies the interface to be configured, and enters interface configuration mode.  
   *Example:*  
   Device(config)# interface gigabitethernet 1/0/1 |
| **Step 7** | `ip igmp filter filter_number` | Specifies the IGMP filter profile number.  
   *Example:*  
   For additional information about applying IGMP filter profiles, see Applying IGMP Profiles (CLI), on page 485.
Changing the IGMP Version (CLI)

By default, the switch uses IGMP Version 2, which provides features such as the IGMP query timeout and the maximum query response time.

All systems on the subnet must support the same version. The switch does not automatically detect Version 1 systems and switch to Version 1. You can mix Version 1 and Version 2 hosts on the subnet because Version 2 routers or switches always work correctly with IGMPv1 hosts.

Configure the switch for Version 1 if your hosts do not support Version 2.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp version {1 | 2 | 3 }
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

DETAILED STEPS

<table>

</tbody>
</table>
### Modifying the IGMP Host-Query Message Interval (CLI)

The device periodically sends IGMP host-query messages to discover which multicast groups are present on attached networks. These messages are sent to the all-hosts multicast group (224.0.0.1) with a time-to-live
(TTL) of 1. The device sends host-query messages to refresh its knowledge of memberships present on the network. If, after some number of queries, the software discovers that no local hosts are members of a multicast group, the software stops forwarding multicast packets to the local network from remote origins for that group and sends a prune message upstream toward the source.

The device elects a PIM designated router (DR) for the LAN (subnet). The designated router is responsible for sending IGMP host-query messages to all hosts on the LAN. In sparse mode, the designated router also sends PIM register and PIM join messages toward the RP router. With IGMPv2, the DR is the router or multilayer device with the highest IP address. With IGMPv1, the DR is elected according to the multicast routing protocol that runs on the LAN.

This procedure is optional.

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. interface interface-id  
4. ip igmp query-interval seconds  
5. end  
6. show ip igmp interface [interface-id]  
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<table>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>interface interface-id</td>
<td>Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>The specified interface must be one of the following:</td>
</tr>
<tr>
<td></td>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td>• A routed port—A physical port that has been configured as a Layer 3 port by entering the no switchport interface configuration command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• An SVI—A VLAN interface created by using the interface vlan vlan-id global configuration command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>These interfaces must have IP addresses assigned to them.</td>
</tr>
</tbody>
</table>
**Command or Action**

**Step 4**

`ip igmp query-interval seconds`

*Example:*

```
Device(config-if)# ip igmp query-interval 75
```

Purpose:

Configures the frequency at which the designated router sends IGMP host-query messages.

By default, the designated router sends IGMP host-query messages every 60 seconds to keep the IGMP overhead very low on hosts and networks.

The range is 1 to 65535.

**Step 5**

`end`

*Example:*

```
Device(config)# end
```

Purpose:

Returns to privileged EXEC mode.

**Step 6**

`show ip igmp interface [interface-id]`

*Example:*

```
Device# show ip igmp interface
```

Purpose:

Verifies your entries.

**Step 7**

`copy running-config startup-config`

*Example:*

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

### Changing the IGMP Query Timeout for IGMPv2 (CLI)

If you are using IGMPv2, you can specify the period of time before the device takes over as the querier for the interface. By default, the device waits twice the query interval period controlled by the `ip igmp query-interval` interface configuration command. After that time, if the device has received no queries, it becomes the querier.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp querier-timeout seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config
## DETAILED STEPS

<table>

<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
Changing the Maximum Query Response Time for IGMPv2 (CLI)

If you are using IGMPv2, you can change the maximum query response time advertised in IGMP queries. The maximum query response time enables the device to quickly detect that there are no more directly connected group members on a LAN. Decreasing the value enables the device to prune groups faster. This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp query-max-response-time seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

DETAILED STEPS

<table>

</table>
### Configuring the Device as a Statically Connected Member (CLI)

At various times, either there is not a group member on a network segment or a host that cannot report its group membership by using IGMP. However, you may want multicast traffic to be sent to that network segment. The following commands are used to pull multicast traffic down to a network segment:

- **ip igmp join-group**—The device accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the device from fast switching.

- **ip igmp static-group**—The device does not accept the packets itself, but only forwards them. This method enables fast switching. The outgoing interface appears in the IGMP cache, but the device itself is not a member, as evidenced by lack of an L (local) flag in the multicast route entry.

This procedure is optional.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp static-group group-address`
5. `end`
6. `show ip igmp interface [interface-id]`
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

</tbody>
</table>
### Configuring IGMP Profiles (CLI)

Follow these steps to create an IGMP profile:

This task is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp profile profile number`
4. `permit | deny`
5. `range ip multicast address`
6. `end`
7. `show ip igmp profile profile number`
8. `show running-config`
9. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Example:** | Device> enable |
| **Step 2** | `configure terminal` | Enters global configuration mode. |
| **Example:** | Device# configure terminal |
| **Step 3** | `ip igmp profile profile number` | Assigns a number to the profile you are configuring, and enters IGMP profile configuration mode. The profile number range is 1 to 4294967295. When you are in IGMP profile configuration mode, you can create the profile by using these commands:  
- `deny`—Specifies that matching addresses are denied; this is the default. |
<p>| <strong>Example:</strong> | Device(config)# ip igmp profile 3 |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| • exit — Exits from igmp-profile configuration mode.  
• no — Negates a command or returns to its defaults.  
• permit — Specifies that matching addresses are permitted.  
• range — Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with a start and an end address. | |

The default is for the device to have no IGMP profiles configured.

**Note** To delete a profile, use the `no ip igmp profile profile number` global configuration command.

**Step 4**  
**permit | deny**  
**Example:**

Device(config-igmp-profile)# permit

(Optional) Sets the action to permit or deny access to the IP multicast address. If no action is configured, the default for the profile is to deny access.

**Step 5**  
**range ip multicast address**  
**Example:**

Device(config-igmp-profile)# range 229.9.9.0

Enters the IP multicast address or range of IP multicast addresses to which access is being controlled. If entering a range, enter the low IP multicast address, a space, and the high IP multicast address.

You can use the `range` command multiple times to enter multiple addresses or ranges of addresses.

**Note** To delete an IP multicast address or range of IP multicast addresses, use the `no range ip multicast address` IGMP profile configuration command.

**Step 6**  
**end**  
**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 7**  
**show ip igmp profile profile number**  
**Example:**

Device# show ip igmp profile 3

Verifies the profile configuration.

**Step 8**  
**show running-config**  
**Example:**

Verifies your entries.
Applying IGMP Profiles (CLI)

To control access as defined in an IGMP profile, you have to apply the profile to the appropriate interfaces. You can apply IGMP profiles only to Layer 2 access ports; you cannot apply IGMP profiles to routed ports or SVIs. You cannot apply profiles to ports that belong to an EtherChannel port group. You can apply a profile to multiple interfaces, but each interface can have only one profile applied to it.

Follow these steps to apply an IGMP profile to a switch port:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp filter profile number
5. end
6. show running-config
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| enable
| Example:
| Device> enable | Enables privileged EXEC mode.
| • Enter your password if prompted. |
| **Step 2**
| configure terminal
| Example:
| Device# configure terminal | Enters global configuration mode. |
Purpose

Command or Action | Purpose
--- | ---
Step 3 | **interface interface-id**
Example: | Specifies the physical interface, and enters interface configuration mode. The interface must be a Layer 2 port that does not belong to an EtherChannel port group.
Device(config)# interface gigabitethernet1/0/1

Step 4 | **ip igmp filter profile number**
Example: | Applies the specified IGMP profile to the interface. The range is 1 to 4294967295.
Device(config-if)# ip igmp filter 321

**Note** To remove a profile from an interface, use the **no ip igmp filter profile number** interface configuration command.

Step 5 | **end**
Example: | Returns to privileged EXEC mode.
Device(config-if)# end

Step 6 | **show running-config**
Example: | Verifies your entries.
Device# show running-config

Step 7 | **copy running-config startup-config**
Example: | (Optional) Saves your entries in the configuration file.
Device# copy running-config startup-config

---

**Setting the Maximum Number of IGMP Groups (CLI)**

Follow these steps to set the maximum number of IGMP groups that a Layer 2 interface can join:

**Before you begin**

This restriction can be applied to Layer 2 ports only; you cannot set a maximum number of IGMP groups on routed ports or SVIs. You also can use this command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp max-groups number
5. end

---

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
6. `show running-config interface interface-id`
7. `copy running-config startup-config`

## Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
*Example:*  
`Device> enable` |
| **Step 2** | `configure terminal` | Enters global configuration mode.  
*Example:*  
`Device# configure terminal` |
| **Step 3** | `interface interface-id` | Specifies the interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or a EtherChannel interface.  
*Example:*  
`Device(config)# interface gigabitethernet1/0/2` |
| **Step 4** | `ip igmp max-groups number` | Sets the maximum number of IGMP groups that the interface can join. The range is 0 to 4294967294. The default is to have no maximum set.  
*Example:*  
`Device(config-if)# ip igmp max-groups 20`  
**Note:** The device supports a maximum number of 4096 Layer 2 IGMP groups and 2048 Layer 3 IGMP groups. |
| **Step 5** | `end` | Returns to privileged EXEC mode.  
*Example:*  
`Device(config)# end` |
| **Step 6** | `show running-config interface interface-id` | Verifies your entries.  
*Example:*  
`Device# interface gigabitethernet1/0/1` |
| **Step 7** | `copy running-config startup-config` | (Optional) Saves your entries in the configuration file.  
*Example:*  
`Device# copy running-config startup-config` |
Configuring the IGMP Throttling Action (CLI)

After you set the maximum number of IGMP groups that a Layer 2 interface can join, you can configure an interface to replace the existing group with the new group for which the IGMP report was received.

Follow these steps to configure the throttling action when the maximum number of entries is in the forwarding table:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp max-groups action {deny | replace}`
5. `end`
6. `show running-config interface interface-id`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td>Specifies the physical interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or an EtherChannel interface. The interface cannot be a trunk port.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td>When an interface receives an IGMP report and the maximum number of entries is in the forwarding table, specifies the action that the interface takes:</td>
</tr>
<tr>
<td><code>Step 2</code></td>
<td><code>configure terminal</code></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td>`ip igmp max-groups action {deny</td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td><code>Device(config-if)# ip igmp max-groups action replace</code></td>
</tr>
<tr>
<td><code>Step 3</code></td>
<td><code>interface interface-id</code></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td><code>deny</code>—Drops the report. If you configure this throttling action, the entries that were previously in the forwarding table are not removed but are aged out. After these entries are aged out and the maximum number of entries is in the forwarding table, the device drops the next IGMP report received on the interface.</td>
</tr>
<tr>
<td><code>Device(config)# interface gigabitethernet1/0/1</code></td>
<td><code>replace</code></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>replace</strong>—Replaces the existing group with the new group for which the IGMP report was received. If you configure this throttling action, the entries that were previously in the forwarding table are removed. When the maximum number of entries is in the forwarding table, the device replaces a randomly selected entry with the received IGMP report.</td>
<td></td>
</tr>
</tbody>
</table>

To prevent the device from removing the forwarding-table entries, you can configure the IGMP throttling action before an interface adds entries to the forwarding table.  

**Note** To return to the default action of dropping the report, use the `no ip igmp max-groups action` interface configuration command.

<table>
<thead>
<tr>
<th>Step 5</th>
<th>end</th>
<th>Returns to privileged EXEC mode.</th>
</tr>
</thead>
<tbody>
<tr>

### Configuring the Device to Forward Multicast Traffic in the Absence of Directly Connected IGMP Hosts

Perform this optional task to configure the device to forward multicast traffic in the absence of directly connected IGMP hosts.

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. interface type number  
4. Do one of the following:
### Configuring the Device to Forward Multicast Traffic in the Absence of Directly Connected IGMP Hosts

- **ip igmp join-group** `group-address`
- **ip igmp static-group** `{* | `group-address` [source `source-address`]}`

5. **end**
6. **show ip igmp interface** `[interface-type interface-number]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable<br>**Example:**<br>Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Step 2** | `configure terminal`<br>**Example:**<br>device# configure terminal | Enters global configuration mode. |
| **Step 3** | `interface type number`<br>**Example:**<br>device(config)# interface gigabitethernet 1 | Enters interface configuration mode.  
• For the `type` and `number` arguments, specify an interface that is connected to hosts. |
| **Step 4** | Do one of the following:  
• **ip igmp join-group** `group-address`  
• **ip igmp static-group** `{* | `group-address` [source `source-address`]}`<br>**Example:**<br>device(config-if)# ip igmp join-group 225.2.2.2  
**Example:**<br>device(config-if)# ip igmp static-group 225.2.2.2 | The first sample shows how to configure an interface on the device to join the specified group.  
With this method, the device accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the device from fast switching.  
The second example shows how to configure static group membership entries on an interface. With this method, the device does not accept the packets itself, but only forwards them. Hence, this method allows fast switching.  
The outgoing interface appears in the IGMP cache, but the device itself is not a member, as evidenced by lack of an “L” (local) flag in the multicast route entry. |
| **Step 5** | **end**<br>**Example:**<br>device#(config-if)# end | Returns to privileged EXEC mode. |
| **Step 6** | **show ip igmp interface** `[interface-type interface-number]`<br>**Example:**<br>device# show ip igmp interface | (Optional) Displays multicast-related information about an interface. |
### Controlling Access to an SSM Network Using IGMP Extended Access Lists

Perform this optional task to control access to an SSM network by using an IGMP extended access list that filters SSM traffic based on source address, group address, or both.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast-routing [distributed]`
4. `ip pim ssm {default | range access-list}`
5. `ip access-list extended access-list -name`
6. `deny igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
7. `permit igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
8. `exit`
9. `interface type number`
10. `ip igmp access-group access-list`
11. `ip pim sparse-mode`
12. Repeat Steps 1 through 11 on all interfaces that require access control of SSM channel membership.
13. `ip igmp version 3`
14. Repeat Step 13 on all host-facing interfaces.
15. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example</strong>: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example</strong>: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip multicast-routing [distributed]</td>
<td>Enables IP multicast routing.</td>
</tr>
<tr>
<td><strong>Example</strong>: Device(config)# ip multicast-routing distributed</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip pim ssm {default</td>
<td>range access-list}</td>
</tr>
<tr>
<td><strong>Example</strong>: Device(config)# ip pim ssm default</td>
<td></td>
</tr>
</tbody>
</table>

- The `distributed` keyword is required for IPv4 multicast.
- The `default` keyword defines the SSM range access list as 232/8.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td><code>ip access-list extended access-list-name</code></td>
<td>The <code>range</code> keyword specifies the standard IP access list number or name that defines the SSM range.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Specifies an extended named IP access list.</td>
</tr>
<tr>
<td><code>Device(config)# ip access-list extended mygroup</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 6** | **Purpose** |
| `deny igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]` | (Optional) Filters the specified source address or group address from the IGMP report, thereby restricting hosts on a subnet from membership to the (S, G) channel. |
| **Example:** | Repeat this step to restrict hosts on a subnet membership to other (S, G) channels. (These sources should be more specific than a subsequent `permit` statement because any sources or groups not specifically permitted are denied.) |
| `Device(config-ext-nacl)# deny igmp host 10.1.2.3 any` | Remember that the access list ends in an implicit `deny` statement. |
| | This example shows how to create a deny statement that filters all groups for source 10.1.2.3, which effectively denies the source. |

| **Step 7** | **Purpose** |
| `permit igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]` | Allows a source address or group address in an IGMP report to pass the IP access list. |
| **Example:** | You must have at least one `permit` statement in an access list. |
| `Device(config-ext-nacl)# permit igmp any any` | Repeat this step to allow other sources to pass the IP access list. |
| | This example shows how to allow group membership to sources and groups not denied by prior `deny` statements. |

| **Step 8** | **Purpose** |
| `exit` | Exits the current configuration session and returns to global configuration mode. |
| **Example:** | |
| `Device(config-ext-nacl)# exit` | |

| **Step 9** | **Purpose** |
| `interface type number` | Selects an interface that is connected to hosts on which IGMPv3 can be enabled. |
| **Example:** | |
| `Device(config)# interface ethernet 0` | |

| **Step 10** | **Purpose** |
| `ip igmp access-group access-list` | Applies the specified access list to IGMP reports. |
| **Example:** | |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config-if)# ip igmp access-group mygroup</code></td>
<td>Enables PIM-SM on the interface.</td>
</tr>
</tbody>
</table>

**Step 11**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip pim sparse-mode</code></td>
<td>Enables PIM-SM on the interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>You must use sparse mode.</td>
</tr>
<tr>
<td><code>Device(config-if)# ip pim sparse-mode</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 12**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeat Steps 1 through 11 on all interfaces that require access control of SSM channel membership.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 13**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip igmp version 3</code></td>
<td>Enables IGMPv3 on this interface. The default version of IGMP is IGMP version 2. Version 3 is required by SSM.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# ip igmp version 3</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 14**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeat Step 13 on all host-facing interfaces.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 15**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

---

### How to Configure IGMP Snooping

#### Enabling IGMP Snooping

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping
4. bridge-domain **bridge-id**
5. ip igmp snooping
6. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| `enable` | Enables privileged EXEC mode. |
| **Example:** | |
| `Device> enable` | |
| **Step 2**
| `configure terminal` | Enters global configuration mode. |
| **Example:** | |
| | | | | |
Enabling or Disabling IGMP Snooping on a VLAN Interface (CLI)

Follow these steps to enable IGMP snooping on a VLAN interface:

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. ip igmp snooping vlan vlan-id  
4. end  
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  enable
  Example:
  Device> enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Step 2**
  configure terminal
  Example: | Enters global configuration mode. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Enables IGMP snooping on the VLAN interface. The VLAN ID range is 1 to 1001 and 1006 to 4094. IGMP snooping must be globally enabled before you can enable VLAN snooping.</td>
</tr>
</tbody>
</table>

**Step 3**  
ip igmp snooping vlan *vlan-id*  
Example:  
Device(config)# ip igmp snooping vlan 7

**Note**  
To disable IGMP snooping on a VLAN interface, use the `no ip igmp snooping vlan *vlan-id*` global configuration command for the specified VLAN number.

**Step 4**  
end

Example:  
Device(config)# end

**Step 5**  
copy running-config startup-config  
Example:  
Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

### Setting the Snooping Method (CLI)

Multicast-capable router ports are added to the forwarding table for every Layer 2 multicast entry. The device learns of the ports through one of these methods:

- Snooping on IGMP queries, Protocol-Independent Multicast (PIM) packets
- Statically connecting to a multicast router port using the `ip igmp snooping mrouter` global configuration command

Beginning in privileged EXEC mode, follow these steps to alter the method in which a VLAN interface accesses a multicast router:

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. ip igmp snooping vlan *vlan-id* mrouter interface {GigabitEthernet | Port-Channel | TenGigabitEthernet}  
4. end  
5. show ip igmp snooping  
6. copy running-config startup-config
### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password, if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><em>Device</em> &gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><em>Device</em># <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>`ip igmp snooping vlan vlan-id mrouter interface {GigabitEthernet</td>
<td>Port-Channel</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>*Device(config)# <code>ip igmp snooping vlan 1 mrouter interface GigabitEthernet1/0/3</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>*Device(config)# <code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>show ip igmp snooping</code></td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>*Device# <code>show ip igmp snooping</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>*Device# <code>copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

### Configuring a Multicast Router Port (CLI)

Perform these steps to add a multicast router port (enable a static connection to a multicast router) on the device.

**Note**

Static connections to multicast routers are supported only on device ports.
**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping vlan *vlan-id* mrouter interface *interface-id*
4. end
5. show ip igmp snooping mrouter [vlan *vlan-id*]
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
Example:  
Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal |
| **Step 3** ip igmp snooping vlan *vlan-id* mrouter interface *interface-id* | Specifies the multicast router VLAN ID and the interface to the multicast router.  
Example:  
Device(config)# ip igmp snooping vlan 5 mrouter interface gigabitethernet1/0/1 |
| **Step 4** end | Returns to privileged EXEC mode.  
Example:  
Device(config)# end |
| **Step 5** show ip igmp snooping mrouter [vlan *vlan-id*] | Verifies that IGMP snooping is enabled on the VLAN interface.  
Example:  
Device# show ip igmp snooping mrouter vlan 5 |
Configuring a Host Statically to Join a Group (CLI)

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure a host on an interface.

Follow these steps to add a Layer 2 port as a member of a multicast group:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id static ip_address interface interface-id`
4. `end`
5. `show ip igmp snooping groups`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip igmp snooping vlan vlan-id static ip_address interface interface-id</code></td>
<td>Statically configures a Layer 2 port as a member of a multicast group:</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# ip igmp snooping vlan 105 static 230.0.0.1 interface gigabitethernet1/0/1</code></td>
<td></td>
</tr>
</tbody>
</table>

**Purpose**

(Optional) Saves your entries in the configuration file.
Enabling IGMP Immediate Leave (CLI)

When you enable IGMP Immediate Leave, the device immediately removes a port when it detects an IGMP Version 2 leave message on that port. You should use the Immediate-Leave feature only when there is a single receiver present on every port in the VLAN.

Note
Immediate Leave is supported only on IGMP Version 2 hosts. IGMP Version 2 is the default version for the device.

SUMMARY STEPS
1. enable
2. configure terminal
3. ip igmp snooping vlan vlan-id immediate-leave
4. end
5. show ip igmp snooping vlan vlan-id
6. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
### Configuring the IGMP Leave Timer (CLI)

You can configure the leave time globally or on a per-VLAN basis. Follow these steps to enable the IGMP configurable-leave timer:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping last-member-query-interval time`
4. `ip igmp snooping vlan vlan-id last-member-query-interval time`
5. `end`
6. `show ip igmp snooping`

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip igmp snooping vlan vlan-id immediate-leave</code></td>
<td>Enables IGMP Immediate Leave on the VLAN interface.</td>
</tr>
<tr>
<td><strong>Note</strong> To disable IGMP Immediate Leave on a VLAN, use the no <code>ip igmp snooping vlan vlan-id immediate-leave</code> global configuration command.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>show ip igmp snooping vlan vlan-id</code></td>
<td>Verifies that Immediate Leave is enabled on the VLAN interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>show ip igmp snooping vlan 21</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> <code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>end</code></td>
<td></td>
</tr>
</tbody>
</table>
### DETAILED STEPS

<table>

<tr>
<td></td>
<td>Device# show ip igmp snooping</td>
<td></td>
</tr>
</tbody>
</table>
Configuring the IGMP Robustness-Variable (CLI)

Use the following procedure to configure the IGMP robustness variable on the device.

The robustness variable is the integer used by IGMP snooping during calculations for IGMP messages. The robustness variable provides fine tuning to allow for expected packet loss.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping robustness-variable count`
4. `ip igmp snooping vlan vlan-id robustness-variable count`
5. `end`
6. `show ip igmp snooping`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password, if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**                                             |                                                                         |
| configure terminal                                     | Enters global configuration mode.                                       |
| Example:                                               |                                                                         |
| `Device# configure terminal`                           |                                                                         |

| **Step 3**                                             |                                                                         |
| ip igmp snooping robustness-variable `count`            | Configures the IGMP robustness variable. The range is 1 to 3 times.    |
| Example:                                               | The recommended value for the robustness variable is 2.                |
| `Device(config)# ip igmp snooping robustness-variable 3`| Use this command to change the value of the robustness variable for IGMP snooping from the default (2) to a specified value. |
### Configuring the IGMP Last Member Query Count (CLI)

To configure the number of times the device sends IGMP group-specific or group-source-specific (with IGMP version 3) query messages in response to receiving a group-specific or group-source-specific leave message, use this command.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping last-member-query-count count
4. ip igmp snooping vlan *vlan-id* last-member-query-count count
5. end
6. show ip igmp snooping
7. copy running-config startup-config

### DETAILED STEPS

</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td>show ip igmp snooping</td>
<td>(Optional) Displays the configured IGMP last member query count.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ip igmp snooping</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

---

**Note**

Configuring the last member query count on a VLAN overrides the globally configured timer.
1 general query. If you set the count to 7, the flooding continues until 7 general queries are received. Groups are relearned based on the general queries received during the TCN event.

Some examples of TCN events are when the client location is changed and the receiver is on same port that was blocked but is now forwarding, and when a port goes down without sending a leave message.

Follow these steps to configure the TCN flood query count:

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip igmp snooping tcn flood query count** *count*
4. **end**
5. **show ip igmp snooping**
6. **copy running-config startup-config**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| Example: Device> enable |
| **Step 2** configure terminal | Enters global configuration mode. |
| Example: Device# configure terminal |
| **Step 3** ip igmp snooping tcn flood query count *count* | Specifies the number of IGMP general queries for which the multicast traffic is flooded.  
The range is 1 to 10. The default, the flooding query count is 2. |
| Example: Device(config)# ip igmp snooping tcn flood query count 3 |
| **Note**  
To return to the default flooding query count, use the **no ip igmp snooping tcn flood query count** global configuration command. |
| **Step 4** end | Returns to privileged EXEC mode. |
| Example: Device(config)# end |
| **Step 5** show ip igmp snooping | Verifies the TCN settings. |
| Example: | |

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
Recovering from Flood Mode (CLI)

When a topology change occurs, the spanning-tree root sends a special IGMP leave message (also known as global leave) with the group multicast address 0.0.0.0. However, you can enable the device to send the global leave message whether it is the spanning-tree root or not. When the router receives this special leave, it immediately sends general queries, which expedite the process of recovering from the flood mode during the TCN event. Leaves are always sent if the device is the spanning-tree root regardless of this configuration.

Follow these steps to enable sending of leave messages:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping tcn query solicit
4. end
5. show ip igmp snooping
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# show ip igmp snooping</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>

<td><strong>Example:</strong> Device(config)# ip igmp snooping tcn query solicit</td>
<td></td>
</tr>
</tbody>
</table>
Disabling Multicast Flooding During a TCN Event (CLI)

When the device receives a TCN, multicast traffic is flooded to all the ports until 2 general queries are received. If the device has many ports with attached hosts that are subscribed to different multicast groups, this flooding might exceed the capacity of the link and cause packet loss. Follow these steps to control TCN flooding:

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. no ip igmp snooping tcn flood
5. end
6. show ip igmp snooping
7. copy running-config startup-config

DETAILED STEPS

<table>

### Disabling IGMP Report Suppression (CLI)

Follow these steps to disable IGMP report suppression:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no ip igmp snooping report-suppression
4. end
5. show ip igmp snooping
6. copy running-config startup-config
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
*enable*  
*Example:*  
Device> enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Step 2**  
*configure terminal*  
*Example:*  
Device# configure terminal | Enters global configuration mode. |
| **Step 3**  
*no ip igmp snooping report-suppression*  
*Example:*  
Device(config)# no ip igmp snooping report-suppression | Disables IGMP report suppression. When report suppression is disabled, all IGMP reports are forwarded to the multicast routers.  
IGMP report suppression is enabled by default.  
When IGMP report supression is enabled, the device forwards only one IGMP report per multicast router query.  
**Note** To re-enable IGMP report suppression, use the *ip igmp snooping report-suppression* global configuration command. |
| **Step 4**  
*end*  
*Example:*  
Device(config)# end | Returns to privileged EXEC mode. |
| **Step 5**  
*show ip igmp snooping*  
*Example:*  
Device# show ip igmp snooping | Verifies that IGMP report suppression is disabled. |
| **Step 6**  
*copy running-config startup-config*  
*Example:*  
Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Monitoring IGMP

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.
This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

### Table 39: Commands for Displaying System and Network Statistics

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ping [group-name</td>
<td>group-address]</td>
</tr>
<tr>
<td>show ip igmp filter</td>
<td>Displays IGMP filter information.</td>
</tr>
<tr>
<td>show ip igmp groups [type-number</td>
<td>detail ]</td>
</tr>
<tr>
<td>show ip igmp interface [type-number]</td>
<td>Displays multicast-related information about an interface.</td>
</tr>
<tr>
<td>show ip igmp membership [ name/group address</td>
<td>all</td>
</tr>
<tr>
<td>show ip igmp profile [profile_number]</td>
<td>Displays IGMP profile information.</td>
</tr>
<tr>
<td>show ip igmp ssm-mapping [hostname/IP address ]</td>
<td>Displays IGMP SSM mapping information.</td>
</tr>
<tr>
<td>show ip igmp static-group {class-map [ interface [ type ] ]}</td>
<td>Displays static group information.</td>
</tr>
<tr>
<td>show ip igmp vrf</td>
<td>Displays the selected VPN routing/forwarding instance by name.</td>
</tr>
</tbody>
</table>

### Monitoring IGMP Snooping Information

You can display IGMP snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display MAC address multicast entries for a VLAN configured for IGMP snooping.

### Table 40: Commands for Displaying IGMP Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip igmp snooping detail</td>
<td>Displays the operational state information.</td>

<td>Displays the snooping configuration information for all VLANs on the device or for a specified VLAN.</td>
</tr>
<tr>
<td></td>
<td><code>vlan-id</code></td>
</tr>
<tr>
<td><code>show ip igmp snooping wireless mgid</code></td>
<td>Displays wireless-related events.</td>
</tr>
</tbody>
</table>

### Monitoring IGMP Filtering and Throttling Configuration

You can display IGMP profile characteristics, and you can display the IGMP profile and maximum group configuration for all interfaces on the device or for a specified interface. You can also display the IGMP throttling configuration for all interfaces on the device or for a specified interface.
### Configuration Examples for IGMP

#### Example: Configuring the Device as a Member of a Multicast Group

This example shows how to enable the device to join multicast group 255.2.2.2:

```
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip igmp join-group 255.2.2.2
Device(config-if)#
```

#### Example: Controlling Access to Multicast Groups

To limit the number of joins on the interface, configure the port for filter which associates with the IGMP profile.

```
Device# configure terminal
Device(config)# ip igmp profile 10
Device(config-igmp-profile)# ?
IGMP profile configuration commands:
deny matching addresses are denied
exit Exit from igmp profile configuration mode
no Negate a command or set its defaults
permit matching addresses are permitted
range add a range to the set

Device(config-igmp-profile)# range 172.16.5.1
Device(config-igmp-profile)# exit
Device(config)#
Device(config)# interface gigabitEthernet 2/0/10
Device(config-if)# ip igmp filter 10
```

#### Examples: Configuring IGMP Snooping

This example shows how to enable a static connection to a multicast router:

```
Device(config)# interface gigabitEthernet 2/0/10
Device(config-if)# ip igmp snooping enable
```

---

**Table 41: Commands for Displaying IGMP Filtering and Throttling Configuration**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip igmp profile [profile number]</code></td>
<td>Displays the specified IGMP profile or all the IGMP profiles defined on the device.</td>
</tr>
<tr>
<td><code>show running-config [interface interface-id]</code></td>
<td>Displays the configuration of the specified interface or the configuration of all interfaces on the device, including (if configured) the maximum number of IGMP groups to which an interface can belong and the IGMP profile applied to the interface.</td>
</tr>
</tbody>
</table>
Example: Configuring IGMP Profiles

This example shows how to statically configure a host on a port:

Device# configure terminal
Device(config)# ip igmp snooping vlan 200 mrouter interface gigabitethernet1/0/2
Device(config)# end

This example shows how to enable IGMP Immediate Leave on VLAN 130:

Device# configure terminal
Device(config)# ip igmp snooping vlan 130 immediate-leave
Device(config)# end

This example shows how to set the IGMP snooping querier source address to 10.0.0.64:

Device# configure terminal
Device(config)# ip igmp snooping querier 10.0.0.64
Device(config)# end

This example shows how to set the IGMP snooping querier maximum response time to 25 seconds:

Device# configure terminal
Device(config)# ip igmp snooping querier query-interval 25
Device(config)# end

This example shows how to set the IGMP snooping querier timeout to 60 seconds:

Device# configure terminal
Device(config)# ip igmp snooping querier timer expiry 60
Device(config)# end

This example shows how to set the IGMP snooping querier feature to Version 2:

Device# configure terminal
Device(config)# no ip igmp snooping querier version 2
Device(config)# end

Example: Configuring IGMP Profiles

This example shows how to create IGMP profile 4 allowing access to the single IP multicast address and how to verify the configuration. If the action was to deny (the default), it would not appear in the show ip igmp profile output display.

Device(config)# ip igmp profile 4
Device(config-igmp-profile)# permit
Device(config-igmp-profile)# range 229.9.9.0
Device(config-igmp-profile)# end
Example: Applying IGMP Profile

This example shows how to apply IGMP profile 4 to a port:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp filter 4
Device(config-if)# end
```

Example: Setting the Maximum Number of IGMP Groups

This example shows how to limit to 25 the number of IGMP groups that a port can join:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp max-groups 25
Device(config-if)# end
```

Example: Interface Configuration as a Routed Port

This example shows how to configure an interface on the device as a routed port. This configuration is required on the interface for several IP multicast routing configuration procedures that require running the `no switchport` command.

```
Device configure terminal
Device(config)# interface GigabitEthernet1/0/9
Device(config-if)# description interface to be use as routed port
Device(config-if)# no switchport
Device(config-if)# ip address 10.20.20.1 255.255.255.0
Device(config-if)# ip pim sparse-mode
Device(config-if)# ip igmp join-group 224.1.2.3 source 15.15.15.2
Device(config-if)# end
Device# configure terminal
Device# show run interface gigabitEthernet 1/0/9
```

Example: Interface Configuration as an SVI

This example shows how to configure an interface on the device as an SVI. This configuration is required on the interface for several IP multicast routing configuration procedures that require running the `no switchport` command.

```
Device# show ip igmp profile 4
IGMP Profile 4
   permit
       range 229.9.9.0 229.9.9.0
```
Example: Configuring the Device to Forward Multicast Traffic in the Absence of Directly Connected IGMP Hosts

The following example shows how to configure a device to forward multicast traffic in the absence of directly connected IGMP hosts using the `ip igmp join-group` command. With this method, the device accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the device from fast switching.

In this example, Fast Ethernet interface 0/0/0 on the device is configured to join the group 225.2.2.2:

```
interface FastEthernet0/0/0
  ip igmp join-group 225.2.2.2
```

The following example shows how to configure a device to forward multicast traffic in the absence of directly connected IGMP hosts using the `ip igmp static-group` command. With this method, the device does not accept the packets itself, but only forwards them. Hence, this method allows fast switching. The outgoing interface appears in the IGMP cache, but the device itself is not a member, as evidenced by lack of an “L” (local) flag in the multicast route entry.

In this example, static group membership entries for group 225.2.2.2 are configured on Fast Ethernet interface 0/1/0:

```
interface FastEthernet0/1/0
  ip igmp static-group 225.2.2.2
```

Controlling Access to an SSM Network Using IGMP Extended Access Lists

This section contains the following configuration examples for controlling access to an SSM network using IGMP extended access lists:
Keep in mind that access lists are very flexible: there are many combinations of permit and deny statements one could use in an access list to filter multicast traffic. The examples in this section simply provide a few examples of how it can be done.

**Example: Denying All States for a Group G**

The following example shows how to deny all states for a group G. In this example, Fast Ethernet interface 0/0/0 is configured to filter all sources for SSM group 232.2.2.2 in IGMPv3 reports, which effectively denies this group.

```
ip access-list extended test1
deny igmp any host 232.2.2.2
permit igmp any any
!
interface FastEthernet0/0/0
ip igmp access-group test1
```

**Example: Denying All States for a Source S**

The following example shows how to deny all states for a source S. In this example, Gigabit Ethernet interface 1/1/0 is configured to filter all groups for source 10.2.1.32 in IGMPv3 reports, which effectively denies this source.

```
ip access-list extended test2
deny igmp host 10.2.1.32 any
permit igmp any any
!
interface GigabitEthernet1/1/0
ip igmp access-group test2
```

**Example: Permitting All States for a Group G**

The following example shows how to permit all states for a group G. In this example, Gigabit Ethernet interface 1/2/0 is configured to accept all sources for SSM group 232.1.1.10 in IGMPv3 reports, which effectively accepts this group altogether.

```
ip access-list extended test3
permit igmp any host 232.1.1.10
!
interface GigabitEthernet1/2/0
ip igmp access-group test3
```

**Example: Permitting All States for a Source S**

The following example shows how to permit all states for a source S. In this example, Gigabit Ethernet interface 1/2 is configured to accept all groups for source 10.6.23.32 in IGMPv3 reports, which effectively accepts this source altogether.

```
ip access-list extended test4
permit igmp host 10.6.23.32 any
!
```
Example: Filtering a Source S for a Group G

The following example shows how to filter a particular source S for a group G. In this example, Gigabit Ethernet interface 0/3/0 is configured to filter source 232.2.2.2 for SSM group 232.2.30.30 in IGMPv3 reports.

```
ip access-list extended test5
deny igmp host 10.4.4.4 host 232.2.30.30
permit igmp any any
!
interface GigabitEthernet0/3/0
ip igmp access-group test5
```

Prerequisites for IGMP Proxy

- All devices on the IGMP UDL have the same subnet address. If all devices on the UDL cannot have the same subnet address, the upstream device must be configured with secondary addresses to match all of the subnets to which the downstream devices are attached.
- IP multicast is enabled and the PIM interfaces are configured.

Note

Use the following guidelines when configuring PIM interfaces for IGMP proxy:

- Use PIM sparse mode (PIM-SM) when the interface is operating in a sparse-mode region and you are running static RP, bootstrap (BSR), or Auto-RP with the Auto-RP listener capability.

Information about IGMP Proxy

IGMP Proxy

An IGMP proxy enables hosts in a unidirectional link routing (UDLR) environment that are not directly connected to a downstream router to join a multicast group sourced from an upstream network.

The figure below illustrates a sample topology that shows two UDLR scenarios:

- Traditional UDL routing scenario--A UDL device with directly connected receivers.
- IGMP proxy scenario--UDL device without directly connected receivers.
Note IGMP UDLs are needed on the upstream and downstream devices.

Note Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

---

**Scenario 1—Traditional UDLR Scenario (UDL Device with Directly Connected Receivers)**

For scenario 1, no IGMP proxy mechanism is needed. In this scenario, the following sequence of events occurs:

1. User 2 sends an IGMP membership report requesting interest in group G.
2. Router B receives the IGMP membership report, adds a forwarding entry for group G on LAN B, and proxies the IGMP report to Router A, which is the UDLR upstream device.
3. The IGMP report is then proxied across the Internet link.
4. Router A receives the IGMP proxy and maintains a forwarding entry on the unidirectional link.

**Scenario 2—IGMP Proxy Scenario (UDL Device without Directly Connected Receivers)**

For scenario 2, the IGMP proxy mechanism is needed to enable hosts that are not directly connected to a downstream device to join a multicast group sourced from an upstream network. In this scenario, the following sequence of events occurs:

1. User 1 sends an IGMP membership report requesting interest in group G.
2. Router C sends a PIM Join message hop-by-hop to the RP (Router B).
3. Router B receives the PIM Join message and adds a forwarding entry for group G on LAN B.
4. Router B periodically checks its mroutetable and proxies the IGMP membership report to its upstream UDL device across the Internet link.
5. Router A creates and maintains a forwarding entry on the unidirectional link (UDL).

In an enterprise network, it is desirable to be able to receive IP multicast traffic via satellite and forward the traffic throughout the network. With unidirectional link routing (UDLR) alone, scenario 2 would not be possible because receiving hosts must be directly connected to the downstream device, Router B. The IGMP proxy mechanism overcomes this limitation by creating an IGMP report for (\textbf{*}, G) entries in the multicast forwarding table. To make this scenario functional, therefore, you must enable IGMP report forwarding of proxied (\textbf{*}, G) multicast static route (mroute) entries (using the \texttt{ip igmp mroute-proxy} command) and enable the mroute proxy service (using the \texttt{ip igmp proxy-service} command) on interfaces leading to PIM-enabled networks with potential members.

---

**How to Configure IGMP Proxy**

**Configuring the Upstream UDL Device for IGMP UDLR**

Perform this task to configure the upstream UDL device for IGMP UDLR.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface type number
4. ip igmp unidirectional-link
5. end

**DETAILED STEPS**

<tr>
<td><strong>Step 7</strong></td>
<td>Enables IGMP report forwarding of proxied (*, G) multicast static route (mroute) entries.</td>
</tr>
<tr>
<td>ip igmp mroute-proxy type number</td>
<td>• This step is performed to enable the forwarding of IGMP reports to a proxy service interface for all (*, G) forwarding entries in the multicast forwarding table.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• In this example, the <code>ip igmp mroute-proxy</code> command is configured on Gigabit Ethernet interface 1/0/0 to request that IGMP reports be sent to loopback interface 0 for all groups in the mroute table that are forwarded to Gigabit Ethernet interface 1/0/0.</td>
</tr>
<tr>
<td>Device(config-if)# ip igmp mroute-proxy loopback 0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Exits interface configuration mode and returns to global configuration mode.</td>
</tr>
<tr>
<td>exit</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------------</td>
</tr>
</tbody>
</table>
| 9      | interface  
Example:  
Device(config)# interface loopback 0 | Enters interface configuration mode for the specified interface.  
• In this example, loopback interface 0 is specified. |
| 10     | ip igmp helper-address udl 
interface-type 
interface-number  
Example:  
Device(config-if)# ip igmp helper-address udl 
gigabitethernet 0/0/0 | Configures IGMP helping for UDLR.  
• This step allows the downstream device to helper IGMP reports received from hosts to an upstream device connected to a UDL associated with the interface specified for the `interface-type` and `interface-number` arguments.  
• In the example topology, IGMP helping is configured over loopback interface 0 on the downstream device. Loopback interface 0, thus, is configured to help IGMP reports from hosts to an upstream device connected to Gigabit Ethernet interface 0/0/0. |
| 11     | ip igmp proxy-service  
Example:  
Device(config-if)# ip igmp proxy-service | Enables the mroute proxy service.  
• When the mroute proxy service is enabled, the device periodically checks the static mroute table for (*, G) forwarding entries that match interfaces configured with the `ip igmp mroute-proxy` command (see Step 7) based on the IGMP query interval. Where there is a match, one IGMP report is created and received on this interface.  
**Note**  
The `ip igmp proxy-service` command is intended to be used with the `ip igmp helper-address` (UDL) command.  
• In this example, the `ip igmp proxy-service` command is configured on loopback interface 0 to enable the forwarding of IGMP reports out the interface for all groups on interfaces registered through the `ip igmp mroute-proxy` command (see Step 7). |
| 12     | end  
Example:  
Device(config-if)# end | Ends the current configuration session and returns to privileged EXEC mode. |
| 13     | show ip igmp interface  
Example:  
Device# show ip igmp interface | (Optional) Displays multicast-related information about an interface. |
### Configuration Examples for IGMP Proxy

#### Example: IGMP Proxy Configuration

The following example shows how to configure the upstream UDL device for IGMP UDLR and the downstream UDL device for IGMP UDLR with IGMP proxy support.

**Upstream Device Configuration**

```plaintext
interface gigabitethernet 0/0/0
ip address 10.1.1.1 255.255.255.0
ip pim sparse-mode
!
interface gigabitethernet 1/0/0
ip address 10.2.1.1 255.255.255.0
ip pim sparse-mode
ip igmp unidirectional-link
!
interface gigabitethernet 2/0/0
ip address 10.3.1.1 255.255.255.0
```

**Downstream Device Configuration**

```plaintext
ip pim rp-address 10.5.1.1 5
access-list 5 permit 239.0.0.0 0.0.0.255
!
interface loopback 0
ip address 10.7.1.1 255.255.255.0
ip pim sparse-mode
ip igmp helper-address udl ethernet 0
ip igmp proxy-service
!
interface gigabitethernet 0/0/0
ip address 10.2.1.2 255.255.255.0
ip pim sparse-mode
ip igmp unidirectional-link
!
interface gigabitethernet 1/0/0
ip address 10.5.1.1 255.255.255.0
ip pim sparse-mode
ip igmp mroute-proxy loopback 0
!
interface gigabitethernet 2/0/0
ip address 10.6.1.1 255.255.255.0
```

Feature History and Information for IGMP Proxy
Prerequisites for Constraining IP Multicast in a Switched Ethernet Network

Before using the tasks in this module, you should be familiar with the concepts described in the “IP Multicast Technology Overview” module.

Information About IP Multicast in a Switched Ethernet Network

IP Multicast Traffic and Layer 2 Switches

The default behavior for a Layer 2 switch is to forward all multicast traffic to every port that belongs to the destination LAN on the switch. This behavior reduces the efficiency of the switch, whose purpose is to limit traffic to the ports that need to receive the data. This behavior requires a constraining mechanism to reduce unnecessary multicast traffic, which improves switch performance.

Cisco Group Management Protocol (CGMP), Router Group Management Protocol (RGMP), and IGMP snooping efficiently constrain IP multicast in a Layer 2 switching environment.

- CGMP and IGMP snooping are used on subnets that include end users or receiver clients.
- RGMP is used on routed segments that contain only routers, such as in a collapsed backbone.
- RGMP and CGMP cannot interoperate. However, Internet Group Management Protocol (IGMP) can interoperate with CGMP and RGMP snooping.
CGMP on Catalyst Switches for IP Multicast

CGMP is a Cisco-developed protocol used on device connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary for those Catalyst switches that do not distinguish between IP multicast data packets and IGMP report messages, both of which are addressed to the same group address at the MAC level. The switch can distinguish IGMP packets, but would need to use software on the switch, greatly impacting its performance.

You must configure CGMP on the multicast device and the Layer 2 switches. The result is that, with CGMP, IP multicast traffic is delivered only to those Catalyst switch ports that are attached to interested receivers. All other ports that have not explicitly requested the traffic will not receive it unless these ports are connected to a multicast router. Multicast router ports must receive every IP multicast data packet.

Using CGMP, when a host joins a multicast group, it multicasts an unsolicited IGMP membership report message to the target group. The IGMP report is passed through the switch to the router for normal IGMP processing. The router (which must have CGMP enabled on this interface) receives the IGMP report and processes it as it normally would, but also creates a CGMP Join message and sends it to the switch. The Join message includes the MAC address of the end station and the MAC address of the group it has joined.

The switch receives this CGMP Join message and then adds the port to its content-addressable memory (CAM) table for that multicast group. All subsequent traffic directed to this multicast group is then forwarded out the port for that host.

The Layer 2 switches are designed so that several destination MAC addresses could be assigned to a single physical port. This design allows switches to be connected in a hierarchy and also allows many multicast destination addresses to be forwarded out a single port.

The device port also is added to the entry for the multicast group. Multicast device must listen to all multicast traffic for every group because IGMP control messages are also sent as multicast traffic. The rest of the multicast traffic is forwarded using the CAM table with the new entries created by CGMP.

IGMP Snooping

IGMP snooping is an IP multicast constraining mechanism that runs on a Layer 2 LAN switch. IGMP snooping requires the LAN switch to examine, or “snoop,” some Layer 3 information (IGMP Join/Leave messages) in the IGMP packets sent between the hosts and the router. When the switch receives the IGMP host report from a host for a particular multicast group, the switch adds the port number of the host to the associated multicast table entry. When the switch hears the IGMP Leave group message from a host, the switch removes the table entry of the host.

Because IGMP control messages are sent as multicast packets, they are indistinguishable from multicast data at Layer 2. A switch running IGMP snooping must examine every multicast data packet to determine if it contains any pertinent IGMP control information. IGMP snooping implemented on a low-end switch with a slow CPU could have a severe performance impact when data is sent at high rates. The solution is to implement IGMP snooping on high-end switches with special application-specific integrated circuits (ASICs) that can perform the IGMP checks in hardware. CGMP is a better option for low-end switches without special hardware.

Router-Port Group Management Protocol (RGMP)

CGMP and IGMP snooping are IP multicast constraining mechanisms designed to work on routed network segments that have active receivers. They both depend on IGMP control messages that are sent between the hosts and the routers to determine which switch ports are connected to interested receivers.
Switched Ethernet backbone network segments typically consist of several routers connected to a switch without any hosts on that segment. Because routers do not generate IGMP host reports, CGMP and IGMP snooping will not be able to constrain the multicast traffic, which will be flooded to every port on the VLAN. Routers instead generate Protocol Independent Multicast (PIM) messages to Join and Prune multicast traffic flows at a Layer 3 level.

Router-Port Group Management Protocol (RGMP) is an IP multicast constraining mechanism for router-only network segments. RGMP must be enabled on the routers and on the Layer 2 switches. A multicast router indicates that it is interested in receiving a data flow by sending an RGMP Join message for a particular group. The switch then adds the appropriate port to its forwarding table for that multicast group—similar to the way it handles a CGMP Join message. IP multicast data flows will be forwarded only to the interested router ports. When the router no longer is interested in that data flow, it sends an RGMP Leave message and the switch removes the forwarding entry.

If there are any routers that are not RGMP-enabled, they will continue to receive all multicast data.

How to Constrain Multicast in a Switched Ethernet Network

Configuring Switches for IP Multicast

If you have switching in your multicast network, consult the documentation for the switch you are working with for information about how to configure IP multicast.

Configuring IGMP Snooping

No configuration is required on the router. Consult the documentation for the switch you are working with to determine how to enable IGMP snooping and follow the provided instructions.

Enabling CGMP

CGMP is a protocol used on devices connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary because the Catalyst switch cannot distinguish between IP multicast data packets and IGMP report messages, which are both at the MAC level and are addressed to the same group address.

Note

- CGMP should be enabled only on 802 or ATM media, or LAN emulation (LANE) over ATM.
- CGMP should be enabled only on devices connected to Catalyst switches.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. ip cgmp [proxy | router-only]
5. end
6. `clear ip cgmp [interface-type interface-number]`

### DETAILED STEPS

Configuration Examples for Constraining IP Multicast in a Switched Ethernet Network

Example: CGMP Configuration

The following example is for a basic network environment where multicast source(s) and multicast receivers are in the same VLAN. The desired behavior is that the switch will constrain the multicast forwarding to those ports that request the multicast stream.

A 4908G-L3 router is connected to the Catalyst 4003 on port 3/1 in VLAN 50. The following configuration is applied on the GigabitEthernet1 interface. Note that there is no `ip multicast-routing` command configured because the router is not routing multicast traffic across its interfaces.

RGMP Configuration Example

The following example shows how to configure RGMP on a router:

```
ip multicast-routing
ip pim sparse-mode
interface ethernet 0
ip rgmp
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for PIM

- Before you begin the PIM configuration process, decide which PIM mode to use. This is based on the applications you intend to support on your network. Use the following guidelines:
  - In general, if the application is one-to-many or many-to-many in nature, then PIM-SM can be used successfully.
  - For optimal one-to-many application performance, SSM is appropriate but requires IGMP version 3 support.

- Before you configure PIM stub routing, check that you have met these conditions:
• You must have IP multicast routing configured on both the stub router and the central router. You must also have PIM mode configured on the uplink interface of the stub router.

• You must also configure either Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing or Open Shortest Path First (OSPF) stub routing on the device.

• The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior.

Restrictions for PIM

The following are the restrictions for configuring PIM:

• PIM is not supported when running the LAN Base feature set.

PIMv1 and PIMv2 Interoperability

To avoid misconfiguring multicast routing on your device, review the information in this section.

The Cisco PIMv2 implementation provides interoperability and transition between Version 1 and Version 2, although there might be some minor problems.

You can upgrade to PIMv2 incrementally. PIM Versions 1 and 2 can be configured on different routers and multilayer devices within one network. Internally, all routers and multilayer devices on a shared media network must run the same PIM version. Therefore, if a PIMv2 device detects a PIMv1 device, the Version 2 device downgrades itself to Version 1 until all Version 1 devices have been shut down or upgraded.

PIMv2 uses the BSR to discover and announce RP-set information for each group prefix to all the routers and multilayer devices within a PIM domain. PIMv1, together with the Auto-RP feature, can perform the same tasks as the PIMv2 BSR. However, Auto-RP is a standalone protocol, separate from PIMv1, and is a proprietary Cisco protocol. PIMv2 is a standards-track protocol in the IETF.

Note

We recommend that you use PIMv2. The BSR function interoperates with Auto-RP on Cisco routers and multilayer devices.

When PIMv2 devices interoperate with PIMv1 devices, Auto-RP should have already been deployed. A PIMv2 BSR that is also an Auto-RP mapping agent automatically advertises the RP elected by Auto-RP. That is, Auto-RP sets its single RP on every router or multilayer device in the group. Not all routers and devices in the domain use the PIMv2 hash function to select multiple RPs.

Sparse-mode groups in a mixed PIMv1 and PIMv2 region are possible because the Auto-RP feature in PIMv1 interoperates with the PIMv2 RP feature. Although all PIMv2 devices can also use PIMv1, we recommend that the RPs be upgraded to PIMv2. To ease the transition to PIMv2, we recommend:

• Using Auto-RP throughout the region.

If Auto-RP is not already configured in the PIMv1 regions, configure Auto-RP.
Restrictions for Configuring PIM Stub Routing

- The IP services image contains complete multicast routing.
- Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing.
- The redundant PIM stub router topology is not supported. Only the nonredundant access router topology is supported by the PIM stub feature.
- PIM stub routing is supported when running the IP Base and IP Services feature sets.

Restrictions for Configuring Auto-RP and BSR

Take into consideration your network configuration, and the following restrictions when configuring Auto-RP and BSR:

Restrictions for Configuring Auto-RP

The following are restrictions for configuring Auto-RP (if used in your network configuration):

- Auto-RP is not supported when running the LAN Base feature set.
- If routed interfaces are configured in sparse mode, Auto-RP can still be used if all devices are configured with a manual RP address for the Auto-RP groups.
- If routed interfaces are configured in sparse mode and you enter the `ip pim autorp listener` global configuration command, Auto-RP can still be used even if all devices are not configured with a manual RP address for the Auto-RP groups.

Restrictions for Configuring BSR

The following are the restrictions for configuring BSR (if used in your network configuration):

- Configure the candidate BSRS as the RP-mapping agents for Auto-RP.
- For group prefixes advertised through Auto-RP, the PIMv2 BSR mechanism should not advertise a subrange of these group prefixes served by a different set of RPs. In a mixed PIMv1 and PIMv2 domain, have backup RPs serve the same group prefixes. This prevents the PIMv2 DRs from selecting a different RP from those PIMv1 DRs, due to the longest match lookup in the RP-mapping database.
Restrictions and Guidelines for Configuring Auto-RP and BSR

The following are restrictions for configuring Auto-RP and BSR (if used in your network configuration):

- If your network is all Cisco routers and multilayer devices, you can use either Auto-RP or BSR.
- If you have non-Cisco routers in your network, you must use BSR.
- If you have Cisco PIMv1 and PIMv2 routers and multilayer devices and non-Cisco routers, you must use both Auto-RP and BSR. If your network includes routers from other vendors, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 device. Ensure that no PIMv1 device is located in the path a between the BSR and a non-Cisco PIMv2 device.

Note
There are two approaches to using PIMv2. You can use Version 2 exclusively in your network or migrate to Version 2 by employing a mixed PIM version environment.

- Because bootstrap messages are sent hop-by-hop, a PIMv1 device prevents these messages from reaching all routers and multilayer devices in your network. Therefore, if your network has a PIMv1 device in it and only Cisco routers and multilayer devices, it is best to use Auto-RP.
- If you have a network that includes non-Cisco routers, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 router or multilayer device. Ensure that no PIMv1 device is on the path between the BSR and a non-Cisco PIMv2 router.
- If you have non-Cisco PIMv2 routers that need to interoperate with Cisco PIMv1 routers and multilayer devices, both Auto-RP and a BSR are required. We recommend that a Cisco PIMv2 device be both the Auto-RP mapping agent and the BSR.

Information About PIM

Protocol Independent Multicast Overview

The Protocol Independent Multicast (PIM) protocol maintains the current IP multicast service mode of receiver-initiated membership. PIM is not dependent on a specific unicast routing protocol; it is IP routing protocol independent and can leverage whichever unicast routing protocols are used to populate the unicast routing table, including Enhanced Interior Gateway Routing Protocol (EIGRP), Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and static routes. PIM uses unicast routing information to perform the multicast forwarding function.

Although PIM is called a multicast routing protocol, it actually uses the unicast routing table to perform the reverse path forwarding (RPF) check function instead of building up a completely independent multicast routing table. Unlike other routing protocols, PIM does not send and receive routing updates between routers.

PIM is defined in RFC 4601, Protocol Independent Multicast - Sparse Mode (PIM-SM)

For information about PIM forwarding (interface) modes, see the following sections:

PIM Dense Mode

PIM dense mode (PIM-DM) uses a push model to flood multicast traffic to every corner of the network. This push model is a method for delivering data to the receivers without the receivers requesting the data. This method is efficient in certain deployments in which there are active receivers on every subnet in the network.

In dense mode, a router assumes that all other routers want to forward multicast packets for a group. If a router receives a multicast packet and has no directly connected members or PIM neighbors present, a prune message is sent back to the source. Subsequent multicast packets are not flooded to this router on this pruned branch. PIM builds source-based multicast distribution trees.

PIM-DM initially floods multicast traffic throughout the network. Routers that have no downstream neighbors prune back the unwanted traffic. This process repeats every 3 minutes.

Routers accumulate state information by receiving data streams through the flood and prune mechanism. These data streams contain the source and group information so that downstream routers can build up their multicast forwarding table. PIM-DM supports only source trees--that is, (S,G) entries--and cannot be used to build a shared distribution tree.

Note

Dense mode is not often used and its use is not recommended. For this reason it is not specified in the configuration tasks in related modules.

PIM Sparse Mode

PIM sparse mode (PIM-SM) uses a pull model to deliver multicast traffic. Only network segments with active receivers that have explicitly requested the data will receive the traffic.

Sparse mode interfaces are added to the multicast routing table only when periodic Join messages are received from downstream routers, or when a directly connected member is on the interface. When forwarding from a LAN, sparse mode operation occurs if an RP is known for the group. If so, the packets are encapsulated and
sent toward the RP. If the multicast traffic from a specific source is sufficient, the first hop router of the receiver may send Join messages toward the source to build a source-based distribution tree.

PIM-SM distributes information about active sources by forwarding data packets on the shared tree. Because PIM-SM uses shared trees (at least, initially), it requires the use of a rendezvous point (RP). The RP must be administratively configured in the network. See the Rendezvous Points, on page 547 section for more information.

In sparse mode, a router assumes that other routers do not want to forward multicast packets for a group, unless there is an explicit request for the traffic. When hosts join a multicast group, the directly connected routers send PIM Join messages toward the RP. The RP keeps track of multicast groups. Hosts that send multicast packets are registered with the RP by the first hop router of that host. The RP then sends Join messages toward the source. At this point, packets are forwarded on a shared distribution tree. If the multicast traffic from a specific source is sufficient, the first hop router of the host may send Join messages toward the source to build a source-based distribution tree.

Sources register with the RP and then data is forwarded down the shared tree to the receivers. The edge routers learn about a particular source when they receive data packets on the shared tree from that source through the RP. The edge router then sends PIM (S,G) Join messages toward that source. Each router along the reverse path compares the unicast routing metric of the RP address to the metric of the source address. If the metric for the source address is better, it will forward a PIM (S,G) Join message toward the source. If the metric for the RP is the same or better, then the PIM (S,G) Join message will be sent in the same direction as the RP. In this case, the shared tree and the source tree would be considered congruent.

If the shared tree is not an optimal path between the source and the receiver, the routers dynamically create a source tree and stop traffic from flowing down the shared tree. This behavior is the default behavior in software. Network administrators can force traffic to stay on the shared tree by using the `ip pim spt-threshold infinity` command.

PIM-SM scales well to a network of any size, including those with WAN links. The explicit join mechanism prevents unwanted traffic from flooding the WAN links.

**Multicast Source Discovery Protocol (MSDP)**

Multicast Source Discovery Protocol (MSDP) is used for inter-domain source discovery when PIM SM is used. Each PIM administrative domain has its own RP. In order for the RP in one domain to signal new sources to the RP in the other domain, MSDP is used.

When RP in a domain receives a PIM register message for a new source, with MSDP configured it sends a new source-active (SA) message to all its MSDP peers in other domains. Each intermediate MSDP peer floods this SA message away from the originating RP. The MSDP peers install this SA message in their MSDP sa-cache. If the RPs in other domains have any join requests for the group in the SA message (indicated by the presence of a (*,G) entry with non empty outgoing interface list), the domain is interested in the group, and the RP triggers an (S,G) join toward the source.

**Sparse-Dense Mode**

If you configure either sparse mode or dense mode on an interface, then sparseness or denseness is applied to the interface as a whole. However, some environments might require PIM to run in a single region in sparse mode for some groups and in dense mode for other groups.

An alternative to enabling only dense mode or only sparse mode is to enable sparse-dense mode. In this case, the interface is treated as dense mode if the group is in dense mode; the interface is treated in sparse mode if the group is in sparse mode. You must have an RP if the interface is in sparse-dense mode and you want to treat the group as a sparse group.
If you configure sparse-dense mode, the idea of sparseness or denseness is applied to the groups for which the router is a member.

Another benefit of sparse-dense mode is that Auto-RP information can be distributed in a dense mode; yet, multicast groups for user groups can be used in a sparse mode manner. Therefore there is no need to configure a default RP at the leaf routers.

When an interface is treated in dense mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

- Members or DVMRP neighbors are on the interface.
- There are PIM neighbors and the group has not been pruned.

When an interface is treated in sparse mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

- Members or DVMRP neighbors are on the interface.
- An explicit Join message has been received by a PIM neighbor on the interface.

**PIM Versions**

PIMv2 includes these improvements over PIMv1:

- A single, active rendezvous point (RP) exists per multicast group, with multiple backup RPs. This single RP compares to multiple active RPs for the same group in PIMv1.
- A bootstrap router (BSR) provides a fault-tolerant, automated RP discovery and distribution function that enables routers and multilayer devices to dynamically learn the group-to-RP mappings.
- PIM join and prune messages have more flexible encoding for multiple address families.
- A more flexible hello packet format replaces the query packet to encode current and future capability options.
- Register messages sent to an RP specify whether they are sent by a border router or a designated router.
- PIM packets are no longer inside IGMP packets; they are standalone packets.

**Related Topics**

Troubleshooting PIMv1 and PIMv2 Interoperability Problems, on page 595
PIMv1 and PIMv2 Interoperability, on page 540

**PIM Stub Routing**

The PIM stub routing feature, available in all of the device software images, reduces resource usage by moving routed traffic closer to the end user.

The PIM stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards IGMP traffic.

In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains,
such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IP multicast routing and configure only the device as a PIM stub router. The device does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the device. The device uplink port cannot be used with SVIs. If you need PIM for an SVI uplink port, you should upgrade to the IP Services feature set.

**Note**

You must also configure EIGRP stub routing when configuring PIM stub routing on the device.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM asset and designated router election mechanisms are not supported on the PIM passive interfaces. Only the nonredundant access router topology is supported by the PIM stub feature. By using a nonredundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

**Figure 25: PIM Stub Router Configuration**

In the following figure, the Device A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source 200.1.1.3.

**Related Topics**

- Enabling PIM Stub Routing (CLI), on page 558
- Example: Enabling PIM Stub Routing, on page 595
- Example: Verifying PIM Stub Routing, on page 596
- Restrictions for Configuring PIM Stub Routing, on page 541

**IGMP Helper**

PIM stub routing moves routed traffic closer to the end user and reduces network traffic. You can also reduce traffic by configuring a stub router (switch) with the IGMP helper feature.
You can configure a stub router (switch) with the `ip igmp helper-address ip-address` interface configuration command to enable the switch to send reports to the next-hop interface. Hosts that are not directly connected to a downstream router can then join a multicast group sourced from an upstream network. The IGMP packets from a host wanting to join a multicast stream are forwarded upstream to the next-hop device when this feature is configured. When the upstream central router receives the helper IGMP reports or leaves, it adds or removes the interfaces from its outgoing interface list for that group.

**Rendezvous Points**

A rendezvous point (RP) is a role that a device performs when operating in Protocol Independent Multicast (PIM) Sparse Mode (SM). An RP is required only in networks running PIM SM. In the PIM-SM model, only network segments with active receivers that have explicitly requested multicast data will be forwarded the traffic.

An RP acts as the meeting place for sources and receivers of multicast data. In a PIM-SM network, sources must send their traffic to the RP. This traffic is then forwarded to receivers down a shared distribution tree. By default, when the first hop device of the receiver learns about the source, it will send a Join message directly to the source, creating a source-based distribution tree from the source to the receiver. This source tree does not include the RP unless the RP is located within the shortest path between the source and receiver.

In most cases, the placement of the RP in the network is not a complex decision. By default, the RP is needed only to start new sessions with sources and receivers. Consequently, the RP experiences little overhead from traffic flow or processing. In PIM version 2, the RP performs less processing than in PIM version 1 because sources must only periodically register with the RP to create state.

**Related Topics**

- Configuring the Candidate RPs (CLI), on page 576
- Configuring a Rendezvous Point, on page 560
- Example: Configuring Candidate RPs, on page 598

**Auto-RP**

In the first version of PIM-SM, all leaf routers (routers directly connected to sources or receivers) were required to be manually configured with the IP address of the RP. This type of configuration is also known as static RP configuration. Configuring static RPs is relatively easy in a small network, but it can be laborious in a large, complex network.

Following the introduction of PIM-SM version 1, Cisco implemented a version of PIM-SM with the Auto-RP feature. Auto-RP automates the distribution of group-to-RP mappings in a PIM network. Auto-RP has the following benefits:

- Configuring the use of multiple RPs within a network to serve different groups is easy.
- Auto-RP allows load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Auto-RP avoids inconsistent, manual RP configurations that can cause connectivity problems.

Multiple RPs can be used to serve different group ranges or serve as backups to each other. For Auto-RP to work, a router must be designated as an RP-mapping agent, which receives the RP-announcement messages from the RPs and arbitrates conflicts. The RP-mapping agent then sends the consistent group-to-RP mappings to all other routers. Thus, all routers automatically discover which RP to use for the groups they support.
If router interfaces are configured in sparse mode, Auto-RP can still be used if all routers are configured with a static RP address for the Auto-RP groups.

To make Auto-RP work, a router must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP. One advantage of Auto-RP is that any change to the RP designation must be configured only on the routers that are RPs and not on the leaf routers. Another advantage of Auto-RP is that it offers the ability to scope the RP address within a domain. Scoping can be achieved by defining the time-to-live (TTL) value allowed for the Auto-RP advertisements.

Each method for configuring an RP has its own strengths, weaknesses, and level of complexity. In conventional IP multicast network scenarios, we recommend using Auto-RP to configure RPs because it is easy to configure, well-tested, and stable. The alternative ways to configure an RP are static RP, Auto-RP, and bootstrap router.

**Related Topics**
- Setting Up Auto-RP in a New Internetwork (CLI), on page 563
- Example: Configuring Auto-RP, on page 596
- Example: Sparse Mode with Auto-RP, on page 596
- Restrictions for Configuring Auto-RP and BSR, on page 541
- Restrictions for Auto-RP Enhancement, on page 542

**The Role of Auto-RP in a PIM Network**

Auto-RP automates the distribution of group-to-rendezvous point (RP) mappings in a PIM network. To make Auto-RP work, a device must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts.

Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP.

The mapping agent receives announcements of intention to become the RP from Candidate-RPs. The mapping agent then announces the winner of the RP election. This announcement is made independently of the decisions by the other mapping agents.

**Multicast Boundaries**

Administratively-scoped boundaries can be used to limit the forwarding of multicast traffic outside of a domain or subdomain. This approach uses a special range of multicast addresses, called administratively-scoped addresses, as the boundary mechanism. If you configure an administratively-scoped boundary on a routed interface, multicast traffic whose multicast group addresses fall in this range cannot enter or exit this interface, which provides a firewall for multicast traffic in this address range.

**Note**

Multicast boundaries and TTL thresholds control the scoping of multicast domains; however, TTL thresholds are not supported by the device. You should use multicast boundaries instead of TTL thresholds to limit the forwarding of multicast traffic outside of a domain or a subdomain.
The following figure shows that Company XYZ has an administratively-scoped boundary set for the multicast address range 239.0.0.0/8 on all routed interfaces at the perimeter of its network. This boundary prevents any multicast traffic in the range 239.0.0.0 through 239.255.255.255 from entering or leaving the network. Similarly, the engineering and marketing departments have an administratively-scoped boundary of 239.128.0.0/16 around the perimeter of their networks. This boundary prevents multicast traffic in the range of 239.128.0.0 through 239.128.255.255 from entering or leaving their respective networks.

You can define an administratively-scoped boundary on a routed interface for multicast group addresses. A standard access list defines the range of addresses affected. When a boundary is defined, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The IANA has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively-scoped addresses. This range of addresses can then be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

You can configure the `filter-autorp` keyword to examine and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

**Sparse-Dense Mode for Auto-RP**

A prerequisite of Auto-RP is that all interfaces must be configured in sparse-dense mode using the `ip pim sparse-dense-mode` interface configuration command. An interface configured in sparse-dense mode is treated in either sparse mode or dense mode of operation, depending on which mode the multicast group operates. If a multicast group has a known RP, the interface is treated in sparse mode. If a group has no known RP, by default the interface is treated in dense mode and data will be flooded over this interface. (You can prevent dense-mode fallback; see the module “Configuring Basic IP Multicast.”)

To successfully implement Auto-RP and prevent any groups other than 224.0.1.39 and 224.0.1.40 from operating in dense mode, we recommend configuring a “sink RP” (also known as “RP of last resort”). A sink RP is a statically configured RP that may or may not actually exist in the network. Configuring a sink RP does not interfere with Auto-RP operation because, by default, Auto-RP messages supersede static RP
configurations. We recommend configuring a sink RP for all possible multicast groups in your network, because it is possible for an unknown or unexpected source to become active. If no RP is configured to limit source registration, the group may revert to dense mode operation and be flooded with data.

Adding Auto-RP to an Existing Sparse-Mode Cloud (CLI), on page 565

Auto-RP Benefits

Auto-RP uses IP multicast to automate the distribution of group-to-RP mappings to all Cisco routers and multilayer devices in a PIM network. Auto-RP has these benefits:

- Easy to use multiple RPs within a network to serve different group ranges.
- Provides load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Avoids inconsistent, manual RP configurations on every router and multilayer device in a PIM network, which can cause connectivity problems.

Benefits of Auto-RP in a PIM Network

- Auto-RP allows any change to the RP designation to be configured only on the devices that are RPs, not on the leaf routers.
- Auto-RP offers the ability to scope the RP address within a domain.

PIMv2 Bootstrap Router

PIMv2 Bootstrap Router (BSR) is another method to distribute group-to-RP mapping information to all PIM routers and multilayer devices in the network. It eliminates the need to manually configure RP information in every router and device in the network. However, instead of using IP multicast to distribute group-to-RP mapping information, BSR uses hop-by-hop flooding of special BSR messages to distribute the mapping information.

The BSR is elected from a set of candidate routers and devices in the domain that have been configured to function as BSRs. The election mechanism is similar to the root-bridge election mechanism used in bridged LANs. The BSR election is based on the BSR priority of the device contained in the BSR messages that are sent hop-by-hop through the network. Each BSR device examines the message and forwards out all interfaces only the message that has either a higher BSR priority than its BSR priority or the same BSR priority, but with a higher BSR IP address. Using this method, the BSR is elected.

The elected BSR sends BSR messages with a TTL of 1. Neighboring PIMv2 routers or multilayer devices receive the BSR message and multicast it out all other interfaces (except the one on which it was received) with a TTL of 1. In this way, BSR messages travel hop-by-hop throughout the PIM domain. Because BSR messages contain the IP address of the current BSR, the flooding mechanism enables candidate RPs to automatically learn which device is the elected BSR.

Candidate RPs send candidate RP advertisements showing the group range for which they are responsible to the BSR, which stores this information in its local candidate-RP cache. The BSR periodically advertises the contents of this cache in BSR messages to all other PIM devices in the domain. These messages travel hop-by-hop through the network to all routers and devices, which store the RP information in the BSR message in their local RP cache. The routers and devices select the same RP for a given group because they all use a common RP hashing algorithm.
PIM Domain Border

As IP multicast becomes more widespread, the chance of one PIMv2 domain bordering another PIMv2 domain increases. Because two domains probably do not share the same set of RPs, BSR, candidate RPs, and candidate BSRs, you need to constrain PIMv2 BSR messages from flowing into or out of the domain. Allowing messages to leak across the domain borders could adversely affect the normal BSR election mechanism and elect a single BSR across all bordering domains and comingle candidate RP advertisements, resulting in the election of RPs in the wrong domain.

Multicast Forwarding

Forwarding of multicast traffic is accomplished by multicast-capable routers. These routers create distribution trees that control the path that IP multicast traffic takes through the network in order to deliver traffic to all receivers.

Multicast traffic flows from the source to the multicast group over a distribution tree that connects all of the sources to all of the receivers in the group. This tree may be shared by all sources (a shared tree) or a separate distribution tree can be built for each source (a source tree). The shared tree may be one-way or bidirectional.

Before describing the structure of source and shared trees, it is helpful to explain the notations that are used in multicast routing tables. These notations include the following:

- \((S,G)\) = (unicast source for the multicast group G, multicast group G)
- \((*,G)\) = (any source for the multicast group G, multicast group G)

The notation of \((S,G)\), pronounced “S comma G,” enumerates a shortest path tree where S is the IP address of the source and G is the multicast group address.

Shared trees are \((*,G)\) and the source trees are \((S,G)\) and always routed at the sources.

Multicast Distribution Source Tree

The simplest form of a multicast distribution tree is a source tree. A source tree has its root at the source host and has branches forming a spanning tree through the network to the receivers. Because this tree uses the shortest path through the network, it is also referred to as a shortest path tree (SPT).

The figure shows an example of an SPT for group 224.1.1.1 rooted at the source, Host A, and connecting two receivers, Hosts B and C.
Using standard notation, the SPT for the example shown in the figure would be (192.168.1.1, 224.1.1.1).

The (S,G) notation implies that a separate SPT exists for each individual source sending to each group—which is correct.

**Multicast Distribution Shared Tree**

Unlike source trees that have their root at the source, shared trees use a single common root placed at some chosen point in the network. This shared root is called a rendezvous point (RP).

The following figure shows a shared tree for the group 224.2.2.2 with the root located at Router D. This shared tree is unidirectional. Source traffic is sent towards the RP on a source tree. The traffic is then forwarded down the shared tree from the RP to reach all of the receivers (unless the receiver is located between the source and the RP, in which case it will be serviced directly).
In this example, multicast traffic from the sources, Hosts A and D, travels to the root (Router D) and then down the shared tree to the two receivers, Hosts B and C. Because all sources in the multicast group use a common shared tree, a wildcard notation written as (\(\star, G\)), pronounced “star comma G,” represents the tree. In this case, \(\star\) means all sources, and \(G\) represents the multicast group. Therefore, the shared tree shown in the figure would be written as (\(\star, 224.2.2.2\)).

Both source trees and shared trees are loop-free. Messages are replicated only where the tree branches. Members of multicast groups can join or leave at any time; therefore the distribution trees must be dynamically updated. When all the active receivers on a particular branch stop requesting the traffic for a particular multicast group, the routers prune that branch from the distribution tree and stop forwarding traffic down that branch. If one receiver on that branch becomes active and requests the multicast traffic, the router will dynamically modify the distribution tree and start forwarding traffic again.

**Source Tree Advantage**

Source trees have the advantage of creating the optimal path between the source and the receivers. This advantage guarantees the minimum amount of network latency for forwarding multicast traffic. However, this optimization comes at a cost. The routers must maintain path information for each source. In a network that has thousands of sources and thousands of groups, this overhead can quickly become a resource issue on the routers. Memory consumption from the size of the multicast routing table is a factor that network designers must take into consideration.

**Shared Tree Advantage**

Shared trees have the advantage of requiring the minimum amount of state in each router. This advantage lowers the overall memory requirements for a network that only allows shared trees. The disadvantage of shared trees is that under certain circumstances the paths between the source and receivers might not be the optimal paths, which might introduce some latency in packet delivery. For example, in the figure above the shortest path between Host A (source 1) and Host B (a receiver) would be Router A and Router C. Because we are using Router D as the root for a shared tree, the traffic must traverse Routers A, B, D and then C.
Network designers must carefully consider the placement of the rendezvous point (RP) when implementing a shared tree-only environment.

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination address and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)—which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is described in the following section.

**PIM Shared Tree and Source Tree**

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

*Figure 28: Shared Tree and Source Tree (Shortest-Path Tree)*

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

![Diagram of Shared Tree and Source Tree](image)

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software devices to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.
4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.

5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.

6. By default, reception of the first data packet prompts Router C to send a join message toward the source.

7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.

8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the ip pim spt-threshold global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

**Reverse Path Forwarding**

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination network and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)--which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is an algorithm used for forwarding multicast datagrams.
Protocol Independent Multicast (PIM) uses the unicast routing information to create a distribution tree along the reverse path from the receivers towards the source. The multicast routers then forward packets along the distribution tree from the source to the receivers. RPF is a key concept in multicast forwarding. It enables routers to correctly forward multicast traffic down the distribution tree. RPF makes use of the existing unicast routing table to determine the upstream and downstream neighbors. A router will forward a multicast packet only if it is received on the upstream interface. This RPF check helps to guarantee that the distribution tree will be loop-free.

**RPF Check**

When a multicast packet arrives at a router, the router performs an RPF check on the packet. If the RPF check succeeds, the packet is forwarded. Otherwise, it is dropped.

For traffic flowing down a source tree, the RPF check procedure works as follows:

1. The router looks up the source address in the unicast routing table to determine if the packet has arrived on the interface that is on the reverse path back to the source.

2. If the packet has arrived on the interface leading back to the source, the RPF check succeeds and the packet is forwarded out the interfaces present in the outgoing interface list of a multicast routing table entry.

3. If the RPF check in Step 2 fails, the packet is dropped.

The figure shows an example of an unsuccessful RPF check.

*Figure 29: RPF Check Fails*

As the figure illustrates, a multicast packet from source 151.10.3.21 is received on serial interface 0 (S0). A check of the unicast route table shows that S1 is the interface this router would use to forward unicast data to 151.10.3.21. Because the packet has arrived on interface S0, the packet is discarded.

The figure shows an example of a successful RPF check.
In this example, the multicast packet has arrived on interface S1. The router refers to the unicast routing table and finds that S1 is the correct interface. The RPF check passes, and the packet is forwarded.

PIM uses both source trees and RP-rooted shared trees to forward datagrams. The RPF check is performed differently for each:

- If a PIM router or multilayer device has a source-tree state (that is, an (S, G) entry is present in the multicast routing table), it performs the RPF check against the IP address of the source of the multicast packet.
- If a PIM router or multilayer device has a shared-tree state (and no explicit source-tree state), it performs the RPF check on the RP address (which is known when members join the group).

**Note**

DVMRP is not supported on the device.

Sparse-mode PIM uses the RPF lookup function to decide where it needs to send joins and prunes:

- (S, G) joins (which are source-tree states) are sent toward the source.
- (*, G) joins (which are shared-tree states) are sent toward the RP.

**Default PIM Routing Configuration**

### How to Configure PIM

#### Enabling PIM Stub Routing (CLI)

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip pim passive`
5. `end`
6. `show ip pim interface`
7. `show ip igmp groups detail`
8. `show ip mroute`
9. `show running-config`
10. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: <code>Device&gt; enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 3 <code>interface interface-id</code></td>
<td>Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

The specified interface must be one of the following:

- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command.
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command.

These interfaces must have IP addresses assigned to them.

### Command or Action

| Step 4 | ip pim passive  
Example: |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>

Example: |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
### Configuring a Rendezvous Point

You must have a rendezvous point (RP), if the interface is in sparse-dense mode and if you want to handle the group as a sparse group. You can use these methods:

- By manually assigning an RP to multicast groups.
- As a standalone, Cisco-proprietary protocol separate from PIMv1, which includes:
  - Setting up Auto-RP in a new internetwork
  - Adding Auto-RP to an existing sparse-mode cloud
  - Preventing join messages to false RPs
  - Filtering incoming RP announcement messages
- By using a standards track protocol in the Internet Engineering Task Force (IETF), which includes configuring PIMv2 BSR.

**Note**

You can use Auto-RP, BSR, or a combination of both, depending on the PIM version that you are running and the types of routers in your network. For information about working with different PIM versions in your network, see PIMv1 and PIMv2 Interoperability, on page 540.

**Related Topics**

- Configuring the Candidate RPs (CLI), on page 576
- Rendezvous Points, on page 547

### Manually Assigning an RP to Multicast Groups (CLI)

If the rendezvous point (RP) for a group is learned through a dynamic mechanism (such as Auto-RP or BSR), you need not perform this task for that RP.

Senders of multicast traffic announce their existence through register messages received from the source first-hop router (designated router) and forwarded to the RP. Receivers of multicast packets use RPs to join a multicast group by using explicit join messages.
RPs are not members of the multicast group; they serve as a *meeting place* for multicast sources and group members.

You can configure a single RP for multiple groups defined by an access list. If there is no RP configured for a group, the multilayer device responds to the group as dense and uses the dense-mode PIM techniques.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip pim rp-address ip-address [access-list-number] [override]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. end
6. show running-config
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip pim rp-address ip-address [access-list-number] [override]</code></td>
<td>Configures the address of a PIM RP.</td>
</tr>
<tr>
<td>Example: Device(config)# ip pim rp-address 10.1.1.1 20 override</td>
<td>By default, no PIM RP address is configured. You must configure the IP address of RPs on all routers and multilayer devices (including the RP).</td>
</tr>
<tr>
<td><strong>Note</strong> If there is no RP configured for a group, the device treats the group as dense, using the dense-mode PIM techniques.</td>
<td></td>
</tr>
<tr>
<td>A PIM device can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain. The access list conditions specify for which groups the device is an RP.</td>
<td></td>
</tr>
<tr>
<td>• For <code>ip-address</code>, enter the unicast address of the RP in dotted-decimal notation.</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Step 4** access-list access-list-number {deny | permit} source [source-wildcard] | • (Optional) For access-list-number, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.  
• (Optional) The override keyword indicates that if there is a conflict between the RP configured with this command and one learned by Auto-RP or BSR, the RP configured with this command prevails.  
Creates a standard access list, repeating the command as many times as necessary.  
• For access-list-number, enter the access list number specified in Step 2.  
• The deny keyword denies access if the conditions are matched.  
• The permit keyword permits access if the conditions are matched.  
• For source, enter the multicast group address for which the RP should be used.  
• (Optional) For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
The access list is always terminated by an implicit deny statement for everything. |
| **Step 5** end | Returns to privileged EXEC mode. |
| **Step 6** show running-config | Verifies your entries. |
| **Step 7** copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

<td>Configures another PIM device to be the candidate RP for local groups.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| `Device(config)# ip pim send-rp-announce gigabitethernet 1/0/5 scope 20 group-list 10 interval 120` | - For *interface-id*, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs.  
- For *scope ttl*, specify the time-to-live value in hops. Enter a hop count that is high enough so that the RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255.  
- For *group-list access-list-number*, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.  
- For *interval seconds*, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383.  
| **Step 5** access-list access-list-number {deny | permit} source [source-wildcard] | Creates a standard access list, repeating the command as many times as necessary.  
- For *access-list-number*, enter the access list number specified in Step 3.  
- The *deny* keyword denies access if the conditions are matched.  
- The *permit* keyword permits access if the conditions are matched.  
- For *source*, enter the multicast group address range for which the RP should be used.  
- (Optional) For *source-wildcard*, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. |
| **Example:**      |         |
| `Device(config)# access-list 10 permit 224.0.0.0 15.255.255.255` | Recall that the access list is always terminated by an implicit deny statement for everything. |
| **Step 6** ip pim send-rp-discovery scope ttl | Finds a device whose connectivity is not likely to be interrupted, and assigns it the role of RP-mapping agent.  
- For *scope ttl*, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255. |
| **Example:**      |         |
| `Device(config)# ip pim send-rp-discovery scope 50` |

*IP Multicast Routing*

*Adding Auto-RP to an Existing Sparse-Mode Cloud (CLI)*

---

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
### Preventing Join Messages to False RPs (CLI)

Determine whether the `ip pim accept-rp` command was previously configured throughout the network by using the `show running-config` privileged EXEC command. If the `ip pim accept-rp` command is not configured on any device, this problem can be addressed later. In those routers or multilayer devices already configured with the `ip pim accept-rp` command, you must enter the command again to accept the newly advertised RP.

To accept all RPs advertised with Auto-RP and reject all other RPs by default, use the `ip pim accept-rp auto-rp` global configuration command.

This procedure is optional.
Related Topics
Example: Preventing Join Messages to False RPs, on page 598

Filtering Incoming RP Announcement Messages (CLI)

You can add configuration commands to the mapping agents to prevent a maliciously configured router from masquerading as a candidate RP and causing problems.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim rp-announce-filter rp-list access-list-number group-list access-list-number
4. access-list access-list-number {deny | permit} source [source-wildcard]
5. end
6. show running-config
7. copy running-config startup-config

Configuring PIMv2 BSR

The process for configuring PIMv2 BSR may involve the following optional tasks:

- Defining the PIM domain border
- Defining the IP multicast boundary
- Configuring candidate BSRs
- Configuring candidate RPs

Related Topics
Configuring Candidate BSRs (CLI), on page 574

Defining the PIM Domain Border (CLI)

Perform the following steps to configure the PIM domain border. This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip pim bsr-border
5. end
6. show running-config
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface interface-id</td>
<td>Specifies the interface to be configured, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td>The specified interface must be one of the following:</td>
</tr>
</tbody>
</table>
Purpose

Command or Action | Purpose
--- | ---
| • A routed port—a physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. | 
| • An SVI—a VLAN interface created by using the `interface vlan vlan-id` global configuration command. | 
| These interfaces must have IP addresses assigned to them. | 

### Step 4

**ip pim bsr-border**

**Example:**

```
Device(config-if)# ip pim bsr-border
```

Defines a PIM bootstrap message boundary for the PIM domain.

Enter this command on each interface that connects to other bordering PIM domains. This command instructs the device to neither send nor receive PIMv2 BSR messages on this interface.

**Note** To remove the PIM border, use the `no ip pim bsr-border` interface configuration command.

### Step 5

**end**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

### Step 6

**show running-config**

**Example:**

```
Device# show running-config
```

Verifies your entries.

### Step 7

**copy running-config startup-config**

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

**Defining the IP Multicast Boundary (CLI)**

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.

This procedure is optional.

### SUMMARY STEPS

1. enable
2. `configure terminal`  
3. `access-list access-list-number deny source [source-wildcard]`  
4. `interface interface-id`  
5. `ip multicast boundary access-list-number`  
6. `end`  
7. `show running-config`  
8. `copy running-config startup-config`  

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable | Enables privileged EXEC mode.  
* Enter your password if prompted.  
Example:  
Device> enable |
| Step 2 | configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal |
| Step 3 | access-list access-list-number deny source [source-wildcard] | Creates a standard access list, repeating the command as many times as necessary.  
* For `access-list-number`, the range is 1 to 99.  
* The `deny` keyword denies access if the conditions are matched.  
* For `source`, enter multicast addresses 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.  
* (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
Example:  
Device(config)# access-list 12 deny 224.0.1.39  
Device(config)# access-list 12 deny 224.0.1.40  
The access list is always terminated by an implicit deny statement for everything. |
| Step 4 | interface interface-id | Specifies the interface to be configured, and enters interface configuration mode.  
The specified interface must be one of the following:  
* A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command.  
* An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command.  
Example:  
Device(config)# interface gigabitethernet 1/0/1 |
Configuring Candidate BSRs (CLI)

You can configure one or more candidate BSRs. The devices serving as candidate BSRs should have good connectivity to other devices and be in the backbone portion of the network.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip pim bsr-candidate interface-id hash-mask-length [priority]`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

Configuring the Candidate RPs (CLI)

You can configure one or more candidate RPs. Similar to BSRs, the RPs should also have good connectivity to other devices and be in the backbone portion of the network. An RP can serve the entire IP multicast address space or a portion of it. Candidate RPs send candidate RP advertisements to the BSR.

This procedure is optional.

**Before you begin**

When deciding which devices should be RPs, consider these options:

- In a network of Cisco routers and multilayer devices where only Auto-RP is used, any device can be configured as an RP.
- In a network that includes only Cisco PIMv2 routers and multilayer devices and with routers from other vendors, any device can be used as an RP.
- In a network of Cisco PIMv1 routers, Cisco PIMv2 routers, and routers from other vendors, configure only Cisco PIMv2 routers and multilayer devices as RPs.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip pim rp-candidate interface-id [group-list access-list-number]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>

<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Step 2** | **configure terminal**  
  **Example:**  
  Device# configure terminal |
| | Enters global configuration mode. |
| **Step 3** | **ip pim rp-candidate interface-id [group-list access-list-number]**  
  **Example:**  
  Device(config)# ip pim rp-candidate gigabitethernet 1/0/5 group-list 10 |
| | Configures your device to be a candidate RP.  
  - For *interface-id*, specify the interface whose associated IP address is advertised as a candidate RP address. Valid interfaces include physical ports, port channels, and VLANs.  
  - (Optional) For *group-list access-list-number*, enter an IP standard access list number from 1 to 99. If no group-list is specified, the device is a candidate RP for all groups. |
| **Step 4** | **access-list access-list-number {deny | permit} source [source-wildcard]**  
  **Example:**  
  Device(config)# access-list 10 permit 239.0.0.0 0.255.255.255 |
| | Creates a standard access list, repeating the command as many times as necessary.  
  - For *access-list-number*, enter the access list number specified in Step 2.  
  - The *deny* keyword denies access if the conditions are matched. The *permit* keyword permits access if the conditions are matched.  
  - For *source*, enter the number of the network or host from which the packet is being sent.  
  - (Optional) For *source-wildcard*, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
  The access list is always terminated by an implicit deny statement for everything. |
| **Step 5** | **end**  
  **Example:**  
  Device(config)# end |
| | Returns to privileged EXEC mode. |
| **Step 6** | **show running-config**  
  **Example:**  
  Device# show running-config |
| | Verifies your entries. |
### Configuring Sparse Mode with Auto-RP (CLI)

**Before you begin**

- All access lists that are needed when Auto-RP is configured should be configured prior to beginning the configuration task.

**Note**

- If a group has no known RP and the interface is configured to be sparse-dense mode, the interface is treated as if it were in dense mode, and data is flooded over the interface. To avoid this data flooding, configure the Auto-RP listener and then configure the interface as sparse mode.
- When configuring Auto-RP, you must either configure the Auto-RP listener feature (Step 5) and specify sparse mode (Step 7).
- When you configure sparse-dense mode, dense mode failover may result in a network dense-mode flood. To avoid this condition, use PIM sparse mode with the Auto-RP listener feature.

Follow this procedure to configure auto-rendezvous point (Auto-RP). Auto-RP can also be optionally used with anycast RP.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast-routing [distributed]`
4. Either perform Steps 5 through 7 or perform Steps 6 and 8.
5. `interface type number`
6. `ip pim sparse-mode`
7. `exit`
8. Repeat Steps 1 through 9 on all PIM interfaces.
9. `ip pim send-rp-announce {interface-type interface-number | ip-address} scope ttl-value [group-list access-list] [interval seconds] [bidir]`
10. `ip pim send-rp-discovery [interface-type interface-number] scope ttl-value [interval seconds]`
11. `ip pim rp-announce-filter rp-list access-list group-list access-list`
12. `interface type number`
13. `ip multicast boundary access-list [filter-autorp]`
14. `end`
15. `show ip pim autorp`
16. `show ip pim rp [mapping] [rp-address]`
17. `show ip igmp groups [group-name | group-address] [interface-type interface-number] detail`
18. `show ip mroute [group-address | group-name] [source-address | source-name] [interface-type interface-number] summary [count] [active kbps]`

<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> Repeat Steps 1 through 9 on all PIM interfaces.</td>
<td>--</td>
</tr>
</tbody>
</table>
### Command or Action

#### Step 9

```
ip pim send-rp-announce {interface-type interface-number | ip-address} scope ttl-value [group-list access-list] [interval seconds] [bidir]
```

**Example:**

```
Device(config)# ip pim send-rp-announce loopback0 scope 31 group-list 5
```

**Purpose**

Sends RP announcements out all PIM-enabled interfaces.

- Perform this step on the RP device only.
- Use the `interface-type` and `interface-number` arguments to define which IP address is to be used as the RP address.
- Use the `ip-address` argument to specify a directly connected IP address as the RP address.

**Note**

If the `ip-address` argument is configured for this command, the RP-announce message will be sourced by the interface to which this IP address is connected (that is, the source address in the IP header of the RP-announce message is the IP address of that interface).

- This example shows that the interface is enabled with a maximum of 31 hops. The IP address by which the device wants to be identified as RP is the IP address associated with loopback interface 0. Access list 5 describes the groups for which this device serves as RP.

#### Step 10

```
ip pim send-rp-discovery {interface-type interface-number} scope ttl-value [interval seconds]
```

**Example:**

```
Device(config)# ip pim send-rp-discovery loopback 1 scope 31
```

**Purpose**

Configures the device to be an RP mapping agent.

- Perform this step on RP mapping agent devices or on combined RP/RP mapping agent devices.

**Note**

Auto-RP allows the RP function to run separately on one device and the RP mapping agent to run on one or multiple devices. It is possible to deploy the RP and the RP mapping agent on a combined RP/RP mapping agent device.

- Use the optional `interface-type` and `interface-number` arguments to define which IP address is to be used as the source address of the RP mapping agent.
- Use the `scope` keyword and `ttl-value` argument to specify the Time-to-Live (TTL) value in the IP header of Auto-RP discovery messages.
- Use the optional `interval` keyword and `seconds` argument to specify the interval at which Auto-RP discovery messages are sent.
Lowering the interval at which Auto-RP discovery messages are sent from the default value of 60 seconds results in more frequent floodings of the group-to-RP mappings. In some network environments, the disadvantages of lowering the interval (more control packet overhead) may outweigh the advantages (more frequent group-to-RP mapping updates).

- The example shows limiting the Auto-RP discovery messages to 31 hops on loopback interface 1.

**Step 11**  
`ip pim rp-announce-filter rp-list access-list group-list access-list`  
Filters incoming RP announcement messages sent from candidate RPs (C-RPs) to the RP mapping agent.  
- Perform this step on the RP mapping agent only.

**Example:**
```
Device(config)# ip pim rp-announce-filter rp-list 1 group-list 2
```

**Step 12**  
`interface type number`  
Selects an interface that is connected to hosts on which PIM can be enabled.

**Example:**
```
Device(config)# interface gigabitethernet 1/0/0
```

**Step 13**  
`ip multicast boundary access-list [filter-autorp]`  
Configures an administratively scoped boundary.  
- Perform this step on the interfaces that are boundaries to other devices.  
- The access list is not shown in this task.  
- An access list entry that uses the `deny` keyword creates a multicast boundary for packets that match that entry.

**Example:**
```
Device(config-if)# ip multicast boundary 10 filter-autorp
```

**Step 14**  
`end`  
Returns to global configuration mode.

**Example:**
```
Device(config-if)# end
```

**Step 15**  
`synchronized ip pim autorp`  
(Optional) Displays the Auto-RP information.

**Example:**
```
Device# show ip pim autorp
```

**Step 16**  
`synchronized ip pim rp [mapping] [rp-address]`  
(Optional) Displays RPs known in the network and shows how the device learned about each RP.

**Example:**
```
Device# show ip pim rp mapping
```
### Delaying the Use of PIM Shortest-Path Tree (CLI)

Perform these steps to configure a traffic rate threshold that must be reached before multicast routing is switched from the source tree to the shortest-path tree.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `access-list access-list-number {deny | permit} source [source-wildcard]`
4. `ip pim spt-threshold {kbps | infinity} [group-list access-list-number]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

</table>
| Step 3 | access-list access-list-number {deny | permit} source [source-wildcard] | Creates a standard access list.  
- For **access-list-number**, the range is 1 to 99.  
- The **deny** keyword denies access if the conditions are matched.  
- The **permit** keyword permits access if the conditions are matched.  
- For **source**, specify the multicast group to which the threshold will apply.  
- (Optional) For **source-wildcard**, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
The access list is always terminated by an implicit deny statement for everything. |
| **Example:** | Device(config)# access-list 16 permit 225.0.0.0 0.255.255.255 |
| Step 4 | ip pim spt-threshold {kbps | infinity} [group-list access-list-number] | Specifies the threshold that must be reached before moving to shortest-path tree (spt).  
- For **kbps**, specify the traffic rate in kilobits per second. The default is 0 kbps.  
**Note** Because of device hardware limitations, 0 kbps is the only valid entry even though the range is 0 to 4294967.  
- Specify **infinity** if you want all sources for the specified group to use the shared tree, never switching to the source tree.  
- (Optional) For **group-list access-list-number**, specify the access list created in Step 2. If the value is 0 or if the group list is not used, the threshold applies to all groups. |
| **Example:** | Device(config)# ip pim spt-threshold infinity group-list 16 |
| Step 5 | end | Returns to privileged EXEC mode. |
| **Example:** | Device(config)# end |
| Step 6 | show running-config | Verifies your entries. |
| **Example:** | Device# show running-config |
### Modifying the PIM Router-Query Message Interval (CLI)

PIM routers and multilayer devices send PIM router-query messages to find which device will be the designated router (DR) for each LAN segment (subnet). The DR is responsible for sending IGMP host-query messages to all hosts on the directly connected LAN.

With PIM DM operation, the DR has meaning only if IGMPv1 is in use. IGMPv1 does not have an IGMP querier election process, so the elected DR functions as the IGMP querier. With PIM-SM operation, the DR is the device that is directly connected to the multicast source. It sends PIM register messages to notify the RP that multicast traffic from a source needs to be forwarded down the shared tree. In this case, the DR is the device with the highest IP address.

This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip pim query-interval seconds`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3** | `interface interface-id` **Example:** Device(config)# interface gigabitethernet 1/0/1 | Specifies the interface to be configured, and enters interface configuration mode. The specified interface must be one of the following:  
- A routed port—a physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command.  
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. These interfaces must have IP addresses assigned to them. |
| **Step 4** | `ip pim query-interval seconds` **Example:** Device(config-if)# ip pim query-interval 45 | Configures the frequency at which the device sends PIM router-query messages. The default is 30 seconds. The range is 1 to 65535. |
| **Step 5** | `end` **Example:** Device(config)# end | Returns to privileged EXEC mode. |
| **Step 6** | `show ip igmp interface [interface-id]` **Example:** Device# show ip igmp interface | Verifies your entries. |
| **Step 7** | `copy running-config startup-config` **Example:** Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Verifying PIM Operations

**Verifying IP Multicast Operation in a PIM-SM or a PIM-SSM Network**

When you verify the operation of IP multicast in a PIM-SM network environment or in an PIM-SSM network environment, a useful approach is to begin the verification process on the last hop router, and then continue the verification process on the routers along the SPT until the first hop router has been reached. The goal of the verification is to ensure that IP multicast traffic is being routed properly through an IP multicast network.
Perform the following optional tasks to verify IP multicast operation in a PIM-SM or a PIM-SSM network. The steps in these tasks help to locate a faulty hop when sources and receivers are not operating as expected.

Note

If packets are not reaching their expected destinations, you might want consider disabling IP multicast fast switching, which would place the router in process switching mode. If packets begin reaching their proper destinations after IP multicast fast switching has been disabled, then the issue most likely was related to IP multicast fast switching.

Verifying IP Multicast on the First Hop Router

Enter these commands on the first hop router to verify IP multicast operations on the first hop router:

SUMMARY STEPS

1. `enable`
2. `show ip mroute [group-address]`
3. `show ip mroute active [kb/s]`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> show ip mroute [group-address]</td>
<td>Confirms that the F flag has been set for mroutes on the first hop router.</td>
</tr>
</tbody>
</table>
| Example: Device# show ip mroute 239.1.2.3 (*, 239.1.2.3), 00:18:10/00:03:22, flags: SPF
Incoming interface: GigabitEthernet0/0/0, RPF nbr 0.0.0.0
Outgoing interface list: Null |
| | (10.0.0.1, 239.1.2.3), 00:18:10/00:03:22, flags: FT
Incoming interface: GigabitEthernet0/0/0, RPF nbr 0.0.0.0
Outgoing interface list: Serial1/0, Forward/Sparse, 00:18:10/00:03:19 |
| **Step 3** show ip mroute active [kb/s] | Displays information about active multicast sources sending to groups. The output of this command provides information about the multicast packet rate for active sources. |
| Example: Device# show ip mroute active Active IP Multicast Sources - sending >= 4 kbps |
Verifying IP Multicast on Routers Along the SPT

Enter these commands on routers along the SPT to verify IP multicast operations on routers along the SPT in a PIM-SM or PIM-SSM network:

**SUMMARY STEPS**

1. enable
2. show ip mroute [group-address]
3. show ip mroute active

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>show ip mroute [group-address]</td>
<td>Confirms the RPF neighbor towards the source for a particular group or groups.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ip mroute 239.1.2.3</td>
<td></td>
</tr>
<tr>
<td>(*, 239.1.2.3), 00:17:56/00:03:02, RP 172.16.0.1, flags: S</td>
<td></td>
</tr>
<tr>
<td>Incoming interface: Null, RPF nbr 0.0.0.0</td>
<td></td>
</tr>
<tr>
<td>Outgoing interface list:</td>
<td></td>
</tr>
<tr>
<td>GigabitEthernet0/0/0, Forward/Sparse, 00:17:56/00:03:02</td>
<td></td>
</tr>
<tr>
<td>(10.0.0.1, 239.1.2.3), 00:15:34/00:03:28, flags: T</td>
<td></td>
</tr>
<tr>
<td>Incoming interface: Serial1/0, RPF nbr 172.31.200.1</td>
<td></td>
</tr>
<tr>
<td>Outgoing interface list:</td>
<td></td>
</tr>
</tbody>
</table>
Verifying IP Multicast Operation on the Last Hop Router

Enter these commands on the last hop router to verify IP multicast operations on the last hop router:

SUMMARY STEPS

1. enable
2. show ip igmp groups
3. show ip pim rp mapping
4. show ip mroute
5. show ip interface [type number]
6. show ip mfib
7. show ip pim interface count
8. show ip mroute count
9. show ip mroute active [kb/s]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>(enable)</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 1 show ip igmp groups</td>
<td>Verifies IGMP memberships on the last hop router. This information will confirm the multicast groups with receivers</td>
</tr>
<tr>
<td>Example: Device&gt; show ip igmp groups</td>
<td></td>
</tr>
</tbody>
</table>
Verifying IP Multicast Operation on the Last Hop Router

### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device# show ip igmp groups</code></td>
<td>that are directly connected to the last hop router and that are learned through IGMP.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Group Address</th>
<th>Interface</th>
<th>Uptime</th>
<th>Expires</th>
<th>Last Reporter</th>
</tr>
</thead>
<tbody>
<tr>
<td>239.1.2.3</td>
<td>GigabitEthernet1/0/0</td>
<td>00:05:14</td>
<td>00:02:14</td>
<td>10.1.0.6</td>
</tr>
<tr>
<td>224.0.1.39</td>
<td>GigabitEthernet0/0/0</td>
<td>00:09:11</td>
<td>00:02:08</td>
<td>172.31.100.1</td>
</tr>
</tbody>
</table>

### Step 3

**show ip pim rp mapping**

**Example:**

```
Device# show ip pim rp mapping
PIM Group-to-RP Mappings

Group(s) 224.0.0.0/4
  RP 172.16.0.1 (?), v2v1
    Info source: 172.16.0.1 (?), elected via Auto-RP
    Uptime: 00:09:11, expires: 00:02:47
```

**Purpose:** Confirms that the group-to-RP mappings are being populated correctly on the last hop router.

**Note:** Ignore this step if you are verifying a last hop router in a PIM-SSM network. The `show ip pim rp mapping` command does not work with routers in a PIM-SSM network because PIM-SSM does not use RPs. In addition, if configured correctly, PIM-SSM groups do not appear in the output of the `show ip pim rp mapping` command.

### Step 4

**show ip mroute**

**Example:**

```
Device# show ip mroute
(*, 239.1.2.3), 00:05:14/00:03:04, RP 172.16.0.1, flags: SJ
  Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1
  Outgoing interface list:
    GigabitEthernet1/0, Forward/Sparse, 00:05:10/00:03:04
  (10.0.0.1, 239.1.2.3), 00:02:49/00:03:29, flags: T
    Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1
    Outgoing interface list:
      GigabitEthernet1/0, Forward/Sparse, 00:02:49/00:03:04
  (*, 224.0.1.39), 00:10:05/stopped, RP 0.0.0.0, flags: DC
    Incoming interface: Null, RPF nbr 0.0.0.0
    Outgoing interface list:
      GigabitEthernet1/0, Forward/Sparse, 00:05:15/00:00:00
      GigabitEthernet0/0, Forward/Sparse, 00:10:05/00:00:00
  (172.16.0.1, 224.0.1.39), 00:02:00/00:01:33, flags: PTX
    Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1
```

**Purpose:** Verifies that the mroute table is being populated properly on the last hop router.

### Step 5

**show ip interface [type number]**

**Example:**

```
```

**Purpose:** Verifies that multicast fast switching is enabled for optimal performance on the outgoing interface on the last hop router.
### Purpose

**Command or Action**

Device# `show ip interface GigabitEthernet 0/0/0`

- GigabitEthernet0/0 is up, line protocol is up
- Internet address is 172.31.100.2/24
- Broadcast address is 255.255.255.255
- Address determined by setup command
- MTU is 1500 bytes
- Helper address is not set
- Directed broadcast forwarding is disabled
- Multicast reserved groups joined: 224.0.0.1, 224.0.0.22, 224.0.0.5, 224.0.0.6, 224.0.0.13
- Outgoing access list is not set
- Inbound access list is not set
- Proxy ARP is enabled
- Local Proxy ARP is disabled
- Security level is default
- Split horizon is enabled
- ICMP redirects are always sent
- ICMP unreaches are always sent
- ICMP mask replies are never sent
- IP fast switching is enabled
- IP fast switching on the same interface is disabled
- IP Flow switching is disabled
- IP CEF switching is disabled
- IP Fast switching turbo vector
- IP multicast fast switching is enabled
- IP multicast distributed fast switching is disabled
- IP route-cache flags are Fast
- Router Discovery is disabled
- IP output packet accounting is disabled
- IP access violation accounting is disabled
- TCP/IP header compression is disabled
- RTP/IP header compression is disabled
- Policy routing is disabled
- Network address translation is disabled
- WCCP Redirect outbound is disabled
- WCCP Redirect inbound is disabled
- WCCP Redirect exclude is disabled
- BGP Policy Mapping is disabled

**Note**

Using the `no ip mroute-cache` interface command disables IP multicast fast-switching. When IP multicast fast switching is disabled, packets are forwarded through the process-switched path.

### Step 6

**show ip mfib**

*Example:*

Device# `show ip mfib`

Displays the forwarding entries and interfaces in the IP Multicast Forwarding Information Base (MFIB).

### Step 7

**show ip pim interface count**

*Example:*

Device# `show ip pim interface count`

<table>
<thead>
<tr>
<th>Address</th>
<th>Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.31.100.2</td>
<td>GigabitEthernet0/0/0</td>
<td>*</td>
</tr>
<tr>
<td>4122/0</td>
<td>GigabitEthernet1/0/0</td>
<td>*</td>
</tr>
</tbody>
</table>

State: * - Fast Switched, D - Distributed Fast Switched, H - Hardware Switching Enabled

Confirms that multicast traffic is being forwarded on the last hop router.
### Purpose

Confirm that multicast traffic is being forwarded on the last hop router.

### Command or Action

**Step 8**  
**show ip mroute count**

**Example:**

Device# show ip mroute count
IP Multicast Statistics
6 routes using 4008 bytes of memory
3 groups, 1.00 average sources per group
Forwarding Counts: Pkt Count/Pkts per second/Avg Pkt Size/Kilobits per second
Other counts: Total/RPF failed/Other drops(GIF-null, rate-limit etc)

Group: 239.1.2.3, Source count: 1, Packets forwarded: 3165, Packets received: 3165
- RP-tree: Forwarding: 0/0/0/0, Other: 0/0/0
  - Source: 10.0.0.1/32, Forwarding: 3165/20/28/4, Other: 0/0/0

Group: 224.0.1.39, Source count: 1, Packets forwarded: 21, Packets received: 120
  - Source: 172.16.0.1/32, Forwarding: 21/1/48/0, Other: 120/0/99

Group: 224.0.1.40, Source count: 1, Packets forwarded: 10, Packets received: 10
  - Source: 172.16.0.1/32, Forwarding: 10/1/48/0, Other: 10/0/0

**Step 9**  
**show ip mroute active [kb/s]**

**Example:**

Device# show ip mroute active
Active IP Multicast Sources - sending >= 4 kbps

Group: 239.1.2.3, (?)
  - Source: 10.0.0.1 (?)
    - Rate: 20 pps/4 kbps(1sec), 4 kbps(last 50 secs), 4 kbps(life avg)

### Purpose

Displays information about active multicast sources sending traffic to groups on the last hop router. The output of this command provides information about the multicast packet rate for active sources.

**Note**  
By default, the output of the **show ip mroute** command with the **active** keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the **kb/s** argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.

## Using PIM-Enabled Routers to Test IP Multicast Reachability

If all the PIM-enabled routers and access servers that you administer are members of a multicast group, pinging that group causes all routers to respond, which can be a useful administrative and debugging tool.

To use PIM-enabled routers to test IP multicast reachability, perform the following tasks:
## Configuring Routers to Respond to Multicast Pings

Follow these steps to configure a router to respond to multicast pings. Perform the task on all the interfaces of a router and on all the routers participating in the multicast network:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip igmp join-group group-address`
5. Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network.
6. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device&gt; <code>enable</code></td>
</tr>
<tr>
<td>2</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device# <code>configure terminal</code></td>
</tr>
<tr>
<td>3</td>
<td><code>interface type number</code></td>
<td>Enters interface configuration mode. For the <code>type</code> and <code>number</code> arguments, specify an interface that is directly connected to hosts or is facing hosts.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config)# <code>interface gigabitethernet 1/0/0</code></td>
</tr>
<tr>
<td>4</td>
<td><code>ip igmp join-group group-address</code></td>
<td>(Optional) Configures an interface on the router to join the specified group. For the purpose of this task, configure the same group address for the <code>group-address</code> argument on all interfaces on the router participating in the multicast network.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config-if)# <code>ip igmp join-group 225.2.2.2</code></td>
</tr>
<tr>
<td>5</td>
<td>Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network.</td>
<td>--</td>
</tr>
<tr>
<td>6</td>
<td><code>end</code></td>
<td>Ends the current configuration session and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

Note: With this method, the router accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the router from fast switching.
### Pinging Routers Configured to Respond to Multicast Pings

Follow these steps on a router to initiate a ping test to the routers configured to respond to multicast pings. This task is used to test IP multicast reachability in a network.

**SUMMARY STEPS**

1. `enable`
2. `ping group-address`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>ping group-address</code></td>
<td>Pings an IP multicast group address. A successful response indicates that the group address is functioning.</td>
</tr>
</tbody>
</table>

### Monitoring and Troubleshooting PIM

#### Monitoring PIM Information

Use the privileged EXEC commands in the following table to monitor your PIM configurations.

*Table 43: PIM Monitoring Commands*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip pim all-vrfs tunnel [tunnel tunnel_number</td>
<td>Displays all VRFs.</td>
</tr>
<tr>
<td>[verbose]]`</td>
<td></td>
</tr>
<tr>
<td><code>show ip pim autorp</code></td>
<td>Displays global auto-RP information.</td>
</tr>
<tr>
<td><code>show ip pim boundary</code></td>
<td>Displays information about mroutes filtered by administratively scoped IPv4 multicast boundaries configured on an interface.</td>
</tr>
</tbody>
</table>
### Command Table

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip pim interface</code></td>
<td>Displays information about interfaces configured for Protocol Independent Multicast (PIM).</td>
</tr>
<tr>
<td><code>show ip pim neighbor</code></td>
<td>Displays the PIM neighbor information.</td>
</tr>
<tr>
<td>`show ip pim rp[group-name</td>
<td>group-address]`</td>
</tr>
<tr>
<td>`show ip pim tunnel [tunnel</td>
<td>verbose]`</td>
</tr>
<tr>
<td>`show ip pim vrf { word { all-vrfs</td>
<td>autop</td>
</tr>
<tr>
<td><code>show ip igmp groups detail</code></td>
<td>Displays the interested clients that have joined the specific multicast source group.</td>
</tr>
</tbody>
</table>

### Monitoring the RP Mapping and BSR Information

Use the privileged EXEC mode in the following table to verify the consistency of group-to-RP mappings:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip pim rp [ hostname or IP address</td>
<td>mapping [ hostname or IP address</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For the <code>hostname</code>, specify the IP name of the group about which to display RPs.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For the <code>IP address</code>, specify the IP address of the group about which to display RPs.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Use the <code>mapping</code> keyword to display all group-to-RP mappings of which the Cisco device is aware (either configured or learned from Auto-RP).</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Use the <code>metric</code> keyword to display the RP RPF metric.</td>
</tr>
<tr>
<td><code>show ip pim rp-hash group</code></td>
<td>Displays the RP that was selected for the specified group. That is, on a PIMv2 router or multilayer device, confirms that the same RP is the one that a PIMv1 system chooses. For <code>group</code>, enter the group address for which to display RP information.</td>
</tr>
</tbody>
</table>
Use the privileged EXEC commands in the following table to monitor BSR information:

**Table 45: BSR Monitoring Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip pim bsr</td>
<td>Displays information about the elected BSR.</td>
</tr>
<tr>
<td>show ip pim bsr-router</td>
<td>Displays information about the BSRv2.</td>
</tr>
</tbody>
</table>

**Troubleshooting PIMv1 and PIMv2 Interoperability Problems**

When debugging interoperability problems between PIMv1 and PIMv2, check these in the order shown:

1. Verify RP mapping with the `show ip pim rp-hash` privileged EXEC command, making sure that all systems agree on the same RP for the same group.
2. Verify interoperability between different versions of DRs and RPs. Make sure that the RPs are interacting with the DRs properly (by responding with register-stops and forwarding decapsulated data packets from registers).

- [PIM Versions](#), on page 545

**Configuration Examples for PIM**

**Example: Enabling PIM Stub Routing**

In this example, IP multicast routing is enabled, Switch A PIM uplink port 25 is configured as a routed uplink port with `spare-dense-mode` enabled. PIM stub routing is enabled on the VLAN 100 interfaces and on Gigabit Ethernet port 20.

```
Device(config)# ip multicast-routing distributed
Device(config)# interface GigabitEthernet3/0/25
Device(config-if)# no switchport
Device(config-if)# ip address 3.1.1.2 255.255.255.0
Device(config-if)# ip pim sparse-dense-mode
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# no switchport
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
```
Example: Verifying PIM Stub Routing

To verify that PIM stub is enabled for each interface, use the `show ip pim interface` privileged EXEC command:

```
Device# show ip pim interface
Address Interface Ver/ Nbr Query DR DR
Mode Count Intvl Prior
3.1.1.2 GigabitEthernet3/0/25 v2/SD 1 30 1 3.1.1.2
100.1.1.1 Vlan100 v2/P 0 30 1 100.1.1.1
10.1.1.1 GigabitEthernet3/0/20 v2/P 0 30 1 10.1.1.1
```

Example: Manually Assigning an RP to Multicast Groups

This example shows how to configure the address of the RP to 147.106.6.22 for multicast group 225.2.2.2 only:

```
Device(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Device(config)# ip pim rp-address 147.106.6.22 1
```

Example: Configuring Auto-RP

This example shows how to send RP announcements out all PIM-enabled interfaces for a maximum of 31 hops. The IP address of port 1 is the RP. Access list 5 describes the group for which this device serves as RP:

```
Device(config)# ip pim send-rp-announce gigabitethernet1/0/1 scope 31 group-list 5
Device(config)# access-list 5 permit 224.0.0.0 15.255.255.255
```

Example: Sparse Mode with Auto-RP

The following example configures sparse mode with Auto-RP:
Example: Defining the IP Multicast Boundary to Deny Auto-RP Information

This example shows a portion of an IP multicast boundary configuration that denies Auto-RP information:

```
Device(config)# access-list 1 deny 224.0.1.39
Device(config)# access-list 1 deny 224.0.1.40
Device(config)# access-list 1 permit all
Device(config-if)# interface gigabitethernet1/0/1
Device(config-if)# ip multicast boundary 1
```

Example: Filtering Incoming RP Announcement Messages

This example shows a sample configuration on an Auto-RP mapping agent that is used to prevent candidate RP announcements from being accepted from unauthorized candidate RPs:

```
Device(config)# ip pim rp-announce-filter rp-list 10 group-list 20
Device(config)# access-list 10 permit host 172.16.5.1
Device(config)# access-list 10 permit host 172.16.2.1
Device(config)# access-list 20 deny 239.0.0.0 0.0.0.255
Device(config)# access-list 20 permit 224.0.0.0 15.255.255.255
```

The mapping agent accepts candidate RP announcements from only two devices, 172.16.5.1 and 172.16.2.1. The mapping agent accepts candidate RP announcements from these two devices only for multicast groups that fall in the group range of 224.0.0.0 to 239.255.255.255. The mapping agent does not accept candidate RP announcements from any other devices in the network. Furthermore, the mapping agent does not accept candidate RP announcements from 172.16.5.1 or 172.16.2.1 if the announcements are for any groups in the 239.0.0.0 through 239.255.255.255 range. This range is the administratively scoped address range.

Example: Preventing Join Messages to False RPs

If all interfaces are in sparse mode, use a default-configured RP to support the two well-known groups 224.0.1.39 and 224.0.1.40. Auto-RP uses these two well-known groups to collect and distribute RP-mapping information. When this is the case and the `ip pim accept-rp auto-rp` command is configured, another `ip pim accept-rp` command accepting the RP must be configured as follows:

```
Device(config)# ip pim accept-rp 172.10.20.1 1
Device(config)# access-list 1 permit 224.0.1.39
Device(config)# access-list 1 permit 224.0.1.40
```

Information About PIM MIB Extension for IP Multicast

PIM MIB Extensions for SNMP Traps for IP Multicast

Protocol Independent Multicast (PIM) is an IP multicast routing protocol used for routing multicast data packets to multicast groups. RFC 2934 defines the PIM MIB for IPv4, which describes managed objects that enable users to remotely monitor and configure PIM using Simple Network Management Protocol (SNMP).

PIM MIB extensions introduce the following new classes of PIM notifications:

- **neighbor-change**—This notification results from the following conditions:
  - A router’s PIM interface is disabled or enabled (using the `ip pim` command in interface configuration mode)
  - A router's PIM neighbor adjacency expires (defined in RFC 2934)

- **rp-mapping-change**—This notification results from a change in the rendezvous point (RP) mapping information due to either Auto-RP messages or bootstrap router (BSR) messages.

- **invalid-pim-message**—This notification results from the following conditions:
  - An invalid (*, G) Join or Prune message is received by the device (for example, when a router receives a Join or Prune message for which the RP specified in the packet is not the RP for the multicast group)
  - An invalid PIM register message is received by the device (for example, when a router receives a register message from a multicast group for which it is not the RP)

Benefits of PIM MIB Extensions

PIM MIB extensions:
How to Configure PIM MIB Extension for IP Multicast

Enabling PIM MIB Extensions for IP Multicast

Perform this task to enable PIM MIB extensions for IP multicast.

**Note**
- The pimInterfaceVersion object was removed from RFC 2934 and, therefore, is no longer supported in software.
- The following MIB tables are not supported in Cisco software:
  - pimIpMRouteTable
  - pimIpMRouteNextHopTable

**SUMMARY STEPS**

1.  enable
2.  configure terminal
3.  snmp-server enable traps pim [neighbor-change | rp-mapping-change | invalid-pim-message]
4.  snmp-server host host-address [traps | informs] community-string pim

</table>
| **Example:** Device(config)# snmp-server enable traps pim neighbor-change | - **neighbor-change** -- This keyword enables notifications indicating when a device’s PIM interface is disabled or enabled, or when a device’s PIM neighbor adjacency expires.  
- **rp-mapping-change** -- This keyword enables notifications indicating a change in RP mapping information due to either Auto-RP messages or BSR messages.  
- **invalid-pim-message** -- This keyword enables notifications for monitoring invalid PIM protocol operations (for example, when a device receives a join or prune message for which the RP specified in the packet is not the RP for the multicast group or when a device receives a register message from a multicast group for which it is not the RP). |

**Step 4**  
**snmp-server host** *host-address* [traps | informs]  
**community-string** pim  

**Example:** Device(config)# snmp-server host 10.10.10.10 traps public pim  

Specifies the recipient of a PIM SNMP notification operation.

---

**Configuration Examples for PIM MIB Extensions**

**Example Enabling PIM MIB Extensions for IP Multicast**

The following example shows how to configure a router to generate notifications indicating that a PIM interface of the router has been enabled. The first line configures PIM traps to be sent as SNMP v2c traps to the host with IP address 10.0.0.1. The second line configures the router to send the neighbor-change class of trap notification to the host.

```
snmp-server host 10.0.0.1 traps version 2c public pim  
snmp-server enable traps pim neighbor-change  
interface ethernet0/0  
ip pim sparse-mode
```

Information About Using MSDP to Interconnect Multiple PIM-SM Domains

Benefits of Using MSDP to Interconnect Multiple PIM-SM Domains

- Allows a rendezvous point (RP) to dynamically discover active sources outside of its domain.
- Introduces a more manageable approach for building multicast distribution trees between multiple domains.

MSDP is a mechanism to connect multiple PIM-SM domains. The purpose of MSDP is to discover multicast sources in other PIM domains. The main advantage of MSDP is that it reduces the complexity of interconnecting multiple PIM-SM domains by allowing PIM-SM domains to use an interdomain source tree (rather than a common shared tree). When MSDP is configured in a network, RPs exchange source information with RPs in other domains. An RP can join the interdomain source tree for sources that are sending to groups for which it has receivers. The RP can do that because it is the root of the shared tree within its domain, which has branches to all points in the domain where there are active receivers. When a last-hop device learns of a new source outside the PIM-SM domain (through the arrival of a multicast packet from the source down the shared tree), it then can send a join toward the source and join the interdomain source tree.

---

**Note**

If the RP either has no shared tree for a particular group or a shared tree whose outgoing interface list is null, it does not send a join to the source in another domain.
When MSDP is enabled, an RP in a PIM-SM domain maintains MSDP peering relationships with MSDP-enabled devices in other domains. This peering relationship occurs over a TCP connection, where primarily a list of sources sending to multicast groups is exchanged. MSDP uses TCP (port 639) for its peering connections. As with BGP, using point-to-point TCP peering means that each peer must be explicitly configured. The TCP connections between RPs, moreover, are achieved by the underlying routing system. The receiving RP uses the source lists to establish a source path. If the multicast sources are of interest to a domain that has receivers, multicast data is delivered over the normal, source-tree building mechanism provided by PIM-SM. MSDP is also used to announce sources sending to a group. These announcements must originate at the RP of the domain.

The figure illustrates MSDP operating between two MSDP peers. PIM uses MSDP as the standard mechanism to register a source with the RP of a domain.

**Note**

Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

**Figure 31: MSDP Running Between RP Peers**

When MSDP is implemented, the following sequence of events occurs:

1. When a PIM designated device (DR) registers a source with its RP as illustrated in the figure, the RP sends a Source-Active (SA) message to all of its MSDP peers.
The DR sends the encapsulated data to the RP only once per source (when the source goes active). If the source times out, this process happens again when it goes active again. This situation is different from the periodic SA message that contains all sources that are registered to the originating RP. Those SA messages are MSDP control packets, and, thus, do not contain encapsulated data from active sources.

1. The SA message identifies the source address, the group that the source is sending to, and the address or the originator ID of the RP, if configured.

2. Each MSDP peer that receives the SA message floods the SA message to all of its peers downstream from the originator. In some cases (such as the case with the RPs in PIM-SM domains B and C in the figure), an RP may receive a copy of an SA message from more than one MSDP peer. To prevent looping, the RP consults the BGP next-hop database to determine the next hop toward the originator of the SA message. If both MBGP and unicast BGP are configured, MBGP is checked first, and then unicast BGP. That next-hop neighbor is the RPF for the originator. SA messages that are received from the originator on any interface other than the interface to the RPF peer are dropped. The SA message flooding process, therefore, is referred to as peer-RPF flooding. Because of the peer-RPF flooding mechanism, BGP or MBGP must be running in conjunction with MSDP.

1. When an RP receives an SA message, it checks to see whether there are any members of the advertised groups in its domain by checking to see whether there are interfaces on the group’s (S, G) outgoing interface list. If there are no group members, the RP does nothing. If there are group members, the RP sends an (S, G) join toward the source. As a result, a branch of the interdomain source tree is constructed across autonomous system boundaries to the RP. As multicast packets arrive at the RP, they are then forwarded down its own shared tree to the group members in the RP’s domain. The members’ DRs then have the option of joining the rendezvous point tree (RPT) to the source using standard PIM-SM procedures.

2. The originating RP continues to send periodic SA messages for the (S, G) state every 60 seconds for as long as the source is sending packets to the group. When an RP receives an SA message, it caches the SA message. Suppose, for example, that an RP receives an SA message for (172.16.5.4, 228.1.2.3) from originating RP 10.5.4.3. The RP consults its mroute table and finds that there are no active members for group 228.1.2.3, so it passes the SA message to its peers downstream of 10.5.4.3. If a host in the domain then sends a join to the RP for group 228.1.2.3, the RP adds the interface toward the host to the outgoing interface list of its (S, G) entry. Because the RP caches SA messages, the device will have an entry for (172.16.5.4, 228.1.2.3) and can join the source tree as soon as a host requests a join.

In all current and supported software releases, caching of MSDP SA messages is mandatory and cannot be manually enabled or disabled. By default, when an MSDP peer is configured, the `ip multicast cache-sa-state` command will automatically be added to the running configuration.

**MSDP Message Types**

There are four basic MSDP message types, each encoded in their own Type, Length, and Value (TLV) data format.
SA Messages

SA messages are used to advertise active sources in a domain. In addition, these SA messages may contain the initial multicast data packet that was sent by the source.

SA messages contain the IP address of the originating RP and one or more (S, G) pairs being advertised. In addition, the SA message may contain an encapsulated data packet.

Note
For more information about SA messages, see the SA Message Origination Receipt and Processing, on page 608 section.

SA Request Messages

SA request messages are used to request a list of active sources for a specific group. These messages are sent to an MSDP SA cache that maintains a list of active (S, G) pairs in its SA cache. Join latency can be reduced by using SA request messages to request the list of active sources for a group instead of having to wait up to 60 seconds for all active sources in the group to be readvertised by originating RPs.

SA Response Messages

SA response messages are sent by the MSDP peer in response to an SA request message. SA response messages contain the IP address of the originating RP and one or more (S, G) pairs of the active sources in the originating RP’s domain that are stored in the cache.

Keepalive Messages

Keepalive messages are sent every 60 seconds in order to keep the MSDP session active. If no keepalive messages or SA messages are received for 75 seconds, the MSDP session is reset.

SA Message Origination Receipt and Processing

The section describes SA message origination, receipt, and processing in detail.

SA Message Origination

SA messages are triggered by an RP (assuming MSDP is configured) when any new source goes active within a local PIM-SM domain. A local source is a source that is directly connected to the RP or is the first-hop DR that has registered with it. An RP originates SA messages only for local sources in its PIM-SM domain; that is, for local sources that register with it.

Note
A local source is denoted by the A flag being set in the (S, G) mroute entry on the RP (which can be viewed in the output of the show ip mroute command). This flag indicates that the source is a candidate for advertisement by the RP to other MSDP peers.

When a source is in the local PIM-SM domain, it causes the creation of (S, G) state in the RP. New sources are detected by the RP either by the receipt of a register message or the arrival of the first (S, G) packet from a directly connected source. The initial multicast packet sent by the source (either encapsulated in the register message or received from a directly connected source) is encapsulated in the initial SA message.
SA Message Receipt

SA messages are only accepted from the MSDP RPF peer that is in the best path back toward the originator. The same SA message arriving from other MSDP peers must be ignored or SA loops can occur. Deterministically selecting the MSDP RPF peer for an arriving SA message requires knowledge of the MSDP topology. However, MSDP does not distribute topology information in the form of routing updates. MSDP infers this information by using (M)BGP routing data as the best approximation of the MSDP topology for the SA RPF check mechanism. An MSDP topology, therefore, must follow the same general topology as the BGP peer topology. Besides a few exceptions (such as default MSDP peers and MSDP peers in MSDP mesh groups), MSDP peers, in general should also be (M)BGP peers.

How RPF Check Rules Are Applied to SA Messages

The rules that apply to RPF checks for SA messages are dependent on the BGP peerings between the MSDP peers:

- Rule 1: Applied when the sending MSDP peer is also an interior (M)BGP peer.
- Rule 2: Applied when the sending MSDP peer is also an exterior (M)BGP peer.
- Rule 3: Applied when the sending MSDP peer is not an (M)BGP peer.

RPF checks are not performed in the following cases:

- If the sending MSDP peer is the only MSDP peer, which would be the case if only a single MSDP peer or a default MSDP peer is configured.
- If the sending MSDP peer is a member of a mesh group.
- If the sending MSDP peer address is the RP address contained in the SA message.

How the Software Determines the Rule to Apply to RPF Checks

The software uses the following logic to determine which RPF rule to apply to RPF checks:

- Find the (M)BGP neighbor that has the same IP address as the sending MSDP peer.
  - If the matching (M)BGP neighbor is an internal BGP (iBGP) peer, apply Rule 1.
  - If the matching (M)BGP neighbor is an external BGP (eBGP) peer, apply Rule 2.
  - If no match is found, apply Rule 3.

The implication of the RPF check rule selection is as follows: The IP address used to configure an MSDP peer on a device must match the IP address used to configure the (M)BGP peer on the same device.

Rule 1 of RPF Checking of SA Messages in MSDP

Rule 1 of RPF checking in MSDP is applied when the sending MSDP peer is also an i(M)BGP peer. When Rule 1 is applied, the RPF check proceeds as follows:

1. The peer searches the BGP Multicast Routing Information Base (MRIB) for the best path to the RP that originated the SA message. If a path is not found in the MRIB, the peer then searches the Unicast Routing Information Base (URIB). If a path is still not found, the RPF check fails.

2. If the previous search succeeds (that is, the best path is found), the peer then determines the address of the BGP neighbor for this best path, which will be the address of the BGP neighbor that sent the peer the path in BGP update messages.
The BGP neighbor address is not the same as the next-hop address in the path. Because i(M)BGP peers do not update the next-hop attribute of a path, the next-hop address usually is not the same as the address of the BGP peer that sent us the path.

Note
The BGP neighbor address is not necessarily the same as the BGP ID of the peer that sent the peer the path.

1. If the IP address of the sending MSDP peer is the same as the BGP neighbor address (that is, the address of the BGP peer that sent the peer the path), then the RPF check succeeds; otherwise it fails.

Implications of Rule 1 of RPF Checking on MSDP

The MSDP topology must mirror the (M)BGP topology. In general, wherever there is an i(M)BGP peer connection between two devices, an MSDP peer connection should be configured. More specifically, the IP address of the far-end MSDP peer connection must be the same as the far-end i(M)BGP peer connection. The addresses must be the same because the BGP topology between i(M)BGP peers inside an autonomous system is not described by the AS path. If it were always the case that i(M)BGP peers updated the next-hop address in the path when sending an update to another i(M)BGP peer, then the peer could rely on the next-hop address to describe the i(M)BGP topology (and hence the MSDP topology). However, because the default behavior for i(M)BGP peers is to not update the next-hop address, the peer cannot rely on the next-hop address to describe the (M)BGP topology (MSDP topology). Instead, the i(M)BGP peer uses the address of the i(M)BGP peer that sent the path to describe the i(M)BGP topology (MSDP topology) inside the autonomous system.

Care should be taken when configuring the MSDP peer addresses to make sure that the same address is used for both i(M)BGP and MSDP peer addresses.

Rule 2 of RPF Checking of SA Messages in MSDP

Rule 2 of RPF checking in MSDP is applied when the sending MSDP peer is also an e(M)BGP peer. When Rule 2 is applied, the RPF check proceeds as follows:
1. The peer searches the BGP MRIB for the best path to the RP that originated the SA message. If a path is not found in the MRIB, the peer then searches the URIB. If a path is still not found, the RPF check fails.
2. If the previous search succeeds (that is, the best path is found), the peer then examines the path. If the first autonomous system in the best path to the RP is the same as the autonomous system of the e(M)BGP peer (which is also the sending MSDP peer), then the RPF check succeeds; otherwise it fails.

Implications of Rule 2 of RPF Checking on MSDP

The MSDP topology must mirror the (M)BGP topology. In general, wherever there is an e(M)BGP peer connection between two devices, an MSDP peer connection should be configured. As opposed to Rule 1, the IP address of the far-end MSDP peer connection does not have to be the same as the far-end e(M)BGP peer connection. The reason that the addresses do not have to be identical is that BGP topology between two e(M)BGP peers is not described by the AS path.
Rule 3 of RPF Checking of SA Messages in MSDP

Rule 3 of RPF checking is applied when the sending MSDP peer is not a (M)BGP peer at all. When Rule 3 is applied, the RPF check proceeds as follows:

1. The peer searches the BGP MRIB for the best path to the RP that originated the SA message. If a path is not found in the MRIB, the peer then searches the URIB. If a path is still not found, the RPF check fails.

2. If the previous search succeeds (that is, the best path to the RP that originated the SA message is found), the peer then searches the BGP MRIB for the best path to the MSDP peer that sent the SA message. If a path is not found in the MRIB, the peer then searches the URIB. If a path is still not found, the RPF check fails.

Note

The autonomous system of the MSDP peer that sent the SA is the origin autonomous system, which is the last autonomous system in the AS path to the MSDP peer.

1. If the first autonomous system in the best path to the RP is the same as the autonomous system of the sending MSDP peer, then the RPF check succeeds; otherwise it fails.

SA Message Processing

The following steps are taken by an MSDP peer whenever it processes an SA message:

1. Using the group address G of the (S, G) pair in the SA message, the peer locates the associated (*, G) entry in the mroute table. If the (*, G) entry is found and its outgoing interface list is not null, then there are active receivers in the PIM-SM domain for the source advertised in the SA message.

2. The MSDP peer then creates an (S, G) entry for the advertised source.

3. If the (S, G) entry did not already exist, the MSDP peer immediately triggers an (S, G) join toward the source in order to join the source tree.

4. The peer then floods the SA message to all other MSDP peers with the exception of:
   - The MSDP peer from which the SA message was received.
   - Any MSDP peers that are in the same MSDP mesh group as this device (if the peer is a member of a mesh group).

Note

SA messages are stored locally in the device’s SA cache.

MSDP Peers

Like BGP, MSDP establishes neighbor relationships with other MSDP peers. MSDP peers connect using TCP port 639. The lower IP address peer takes the active role of opening the TCP connection. The higher IP address peer waits in LISTEN state for the other to make the connection. MSDP peers send keepalive messages every 60 seconds. The arrival of data performs the same function as the keepalive message and keeps the session from timing out. If no keepalive messages or data is received for 75 seconds, the TCP connection is reset.
MSDP MD5 Password Authentication

The MSDP MD5 password authentication feature is an enhancement to support Message Digest 5 (MD5) signature protection on a TCP connection between two MSDP peers. This feature provides added security by protecting MSDP against the threat of spoofed TCP segments being introduced into the TCP connection stream.

How MSDP MD5 Password Authentication Works

Developed in accordance with RFC 2385, the MSDP MD5 password authentication feature is used to verify each segment sent on the TCP connection between MSDP peers. The `ip msdp password peer` command is used to enable MD5 authentication for TCP connections between two MSDP peers. When MD5 authentication is enabled between two MSDP peers, each segment sent on the TCP connection between the peers is verified. MD5 authentication must be configured with the same password on both MSDP peers; otherwise, the connection between them will not be made. Configuring MD5 authentication causes the Cisco IOS software to generate and verify the MD5 digest of every segment sent on the TCP connection.

Benefits of MSDP MD5 Password Authentication

- Protects MSDP against the threat of spoofed TCP segments being introduced into the TCP connection stream.
- Uses the industry-standard MD5 algorithm for improved reliability and security.

SA Message Limits

The `ip msdp sa-limit` command is used to limit the overall number of SA messages that a device can accept from specified MSDP peers. When the `ip msdp sa-limit` command is configured, the device maintains a per-peer count of SA messages stored in the SA cache and will ignore new messages from a peer if the configured SA message limit for that peer has been reached.

The `ip msdp sa-limit` command was introduced as a means to protect an MSDP-enabled device from denial of service (DoS) attacks. We recommended that you configure SA message limits for all MSDP peerings on the device. An appropriately low SA limit should be configured on peerings with a stub MSDP region (for example, a peer that may have some further downstream peers but that will not act as a transit for SA messages across the rest of the Internet). A high SA limit should be configured for all MSDP peerings that act as transits for SA messages across the Internet.

MSDP Keepalive and Hold-Time Intervals

The `ip msdp keepalive` command is used to adjust the interval at which an MSDP peer will send keepalive messages and the interval at which the MSDP peer will wait for keepalive messages from other peers before declaring them down.

Once an MSDP peering session is established, each side of the connection sends a keepalive message and sets a keepalive timer. If the keepalive timer expires, the local MSDP peer sends a keepalive message and restarts its keepalive timer; this interval is referred to as the keepalive interval. The `keepalive-interval` argument is used to adjust the interval for which keepalive messages will be sent. The keepalive timer is set to the value specified for the `keepalive-interval` argument when the peer comes up. The keepalive timer is reset to the value of the `keepalive-interval` argument whenever an MSDP keepalive message is sent to the peer and reset when
the timer expires. The keepalive timer is deleted when an MSDP peering session is closed. By default, the keepalive timer is set to 60 seconds.

---

**Note**

The value specified for the `keepalive-interval` argument must be less than the value specified for the `holdtime-interval` argument and must be at least one second.

The hold-time timer is initialized to the value of the `hold-time-interval` argument whenever an MSDP peering connection is established, and is reset to the value of the `hold-time-interval` argument whenever an MSDP keepalive message is received. The hold-time timer is deleted whenever an MSDP peering connection is closed. By default, the hold-time interval is set to 75 seconds.

Use the `hold-time-interval` argument to adjust the interval at which the MSDP peer will wait for keepalive messages from other peers before declaring them down.

---

**MSDP Connection-Retry Interval**

You can adjust the interval at which all MSDP peers will wait after peering sessions are reset before attempting to reestablish the peering sessions. This interval is referred to as the connection-retry interval. By default, MSDP peers will wait 30 seconds after the session is reset before attempting to reestablish sessions with other peers. The modified configured connection-retry interval applies to all MSDP peering sessions on the device.

---

**Default MSDP Peers**

A stub autonomous system also might want to have MSDP peerings with more than one RP for the sake of redundancy. For example, SA messages cannot just be accepted from multiple default peers, because there is no RPF check mechanism. Instead, SA messages are accepted from only one peer. If that peer fails, SA messages are then accepted from the other peer. The underlying assumption here, of course, is that both default peers are sending the same SA messages.

The figure illustrates a scenario where default MSDP peers might be used. In the figure, a customer that owns Device B is connected to the Internet through two Internet service providers (ISPs), one that owns Device A and the other that owns Device C. They are not running BGP or MBGP between them. In order for the customer to learn about sources in the ISP domain or in other domains, Device B identifies Device A as its default MSDP peer. Device B advertises SA messages to both Device A and Device C, but accepts SA messages either from Device A only or Device C only. If Device A is the first default peer in the configuration, it will be used if it is up and running. Only if Device A is not running will Device B accept SA messages from Device C.

The ISP will also likely use a prefix list to define which prefixes it will accept from the customer device. The customer will define multiple default peers, each having one or more prefixes associated with it.

The customer has two ISPs to use. The customer defines both ISPs as default peers. As long as the first default peer identified in the configuration is up and running, it will be the default peer and the customer will accept all SA messages it receives from that peer.

---

**Note**

Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.
Device B advertises SAs to Device A and Device C, but uses only Device A or Device C to accept SA messages. If Device A is first in the configuration, it will be used if it is up and running. Only when Device A is not running will Device B accept SAs from Device C. This is the behavior without a prefix list.

If you specify a prefix list, the peer will be a default peer only for the prefixes in the list. You can have multiple active default peers when you have a prefix list associated with each. When you do not have any prefix lists, you can configure multiple default peers, but only the first one is the active default peer as long as the device has connectivity to this peer and the peer is alive. If the first configured peer goes down or the connectivity to this peer goes down, the second configured peer becomes the active default, and so on.

**MSDP Mesh Groups**

An MSDP mesh group is a group of MSDP speakers that have fully meshed MSDP connectivity between one another. In other words, each of the MSDP peers in the group must have an MSDP peering relationship (MSDP connection) to every other MSDP peer in the group. When an MSDP mesh group is configured between a group of MSDP peers, SA message flooding is reduced. Because when an MSDP peer in the group receives an SA message from another MSDP peer in the group, it assumes that this SA message was sent to all the other MSDP peers in the group. As a result, it is not necessary for the receiving MSDP peer to flood the SA message to the other MSDP peers in the group.

**Benefits of MSDP Mesh Groups**

- Optimizes SA flooding--MSDP mesh groups are particularly useful for optimizing SA flooding when two or more peers are in a group.
- Reduces the amount of SA traffic across the Internet--When MSDP mesh groups are used, SA messages are not flooded to other mesh group peers.
- Eliminates RPF checks on arriving SA messages--When an MSDP mesh group is configured, SA messages are always accepted from mesh group peers.
SA Origination Filters

By default, an RP that is configured to run MSDP will originate SA messages for all local sources for which it is the RP. Local sources that register with an RP, therefore, will be advertised in SA messages, which in some cases is not desirable. For example, if sources inside a PIM-SM domain are using private addresses (for example, network 10.0.0.0/8), you should configure an SA origination filter to restrict those addresses from being advertised to other MSDP peers across the Internet.

To control what sources are advertised in SA messages, you can configure SA origination filters on an RP. By creating SA origination filters, you can control the sources advertised in SA messages as follows:

- You can configure an RP to prevent the device from advertising local sources in SA messages. The device will still forward SA messages from other MSDP peers in the normal fashion; it will just not originate any SA messages for local sources.
- You can configure the device to only originate SA messages for local sources sending to specific groups that match (S, G) pairs defined in the extended access list. All other local sources will not be advertised in SA messages.
- You can configure the device to only originate SA messages for local sources sending to specific groups that match AS paths defined in an AS-path access list. All other local sources will not be advertised in SA messages.
- You can configure the device to only originate SA messages for local sources that match the criteria defined in the route map. All other local sources will not be advertised in SA messages.
- You configure an SA origination filter that includes an extended access list, an AS-path access list, and route map, or a combination thereof. In this case, all conditions must be true before any local sources are advertised in SA messages.

Use of Outgoing Filter Lists in MSDP

By default, an MSDP-enabled device forwards all SA messages it receives to all of its MSDP peers. However, you can prevent SA messages from being forwarded to MSDP peers by creating outgoing filter lists. Outgoing filter lists apply to all SA messages, whether locally originated or received from another MSDP peer, whereas SA origination filters apply only to locally originated SA messages. For more information about enabling a filter for MSDP SA messages originated by the local device, see the Controlling SA Messages Originated by an RP for Local Sources section.

By creating an outgoing filter list, you can control the SA messages that a device forwards to a peer as follows:

- You can filter all outgoing SA messages forwarded to a specified MSDP peer by configuring the device to stop forwarding its SA messages to the MSDP peer.
- You can filter a subset of outgoing SA messages forwarded to a specified MSDP peer based on (S, G) pairs defined in an extended access list by configuring the device to only forward SA messages to the MSDP peer that match the (S, G) pairs permitted in an extended access list. The forwarding of all other SA messages to the MSDP peer will be stopped.
- You can filter a subset of outgoing SA messages forwarded to a specified MSDP peer based on match criteria defined in a route map by configuring the device to only forward SA messages that match the criteria defined in the route map. The forwarding of all other SA messages to the MSDP peer will be stopped.
• You can filter a subset of outgoing SA messages from a specified peer based on the announcing RP address contained in the SA message by configuring the device to filter outgoing SA messages based on their origin, even after an SA message has been transmitted across one or more MSDP peers. The forwarding of all other SA messages to the MSDP peer will be stopped.

• You can configure an outgoing filter list that includes an extended access list, a route map, and either an RP access list or an RP route map. In this case, all conditions must be true for the MSDP peer to forward the outgoing SA message.

⚠️ **Caution**

Arbitrary filtering of SA messages can result in downstream MSDP peers being starved of SA messages for legitimate active sources. Care, therefore, should be taken when using these sorts of filters. Normally, outgoing filter lists are used only to reject undesirable sources, such as sources using private addresses.

### Use of Incoming Filter Lists in MSDP

By default, an MSDP-enabled device receives all SA messages sent to it from its MSDP peers. However, you can control the source information that a device receives from its MSDP peers by creating incoming filter lists.

By creating incoming filter lists, you can control the incoming SA messages that a device receives from its peers as follows:

• You can filter all incoming SA messages from a specified MSDP peer by configuring the device to ignore all SA messages sent to it from the specified MSDP peer.

• You can filter a subset of incoming SA messages from a specified peer based on (S, G) pairs defined in an extended access list by configuring the device to only receive SA messages from the MSDP peer that match the (S, G) pairs defined in the extended access list. All other incoming SA messages from the MSDP peer will be ignored.

• You can filter a subset of incoming SA request messages from a specified peer based on match criteria defined in a route map by configuring the device to only receive SA messages that match the criteria defined in the route map. All other incoming SA messages from the MSDP peer will be ignored.

• You can filter a subset of incoming SA messages from a specified peer based on both (S, G) pairs defined in an extended access list and on match criteria defined in a route map by configuring the device to only receive incoming SA messages that both match the (S, G) pairs defined in the extended access list and match the criteria defined in the route map. All other incoming SA messages from the MSDP peer will be ignored.

• You can filter a subset of incoming SA messages from a specified peer based on the announcing RP address contained in the SA message by configuring the device to filter incoming SA messages based on their origin, even after the SA message may have already been transmitted across one or more MSDP peers.

• You can configure an incoming filter list that includes an extended access list, a route map, and either an RP access list or an RP route map. In this case, all conditions must be true for the MSDP peer to receive the incoming SA message.
Arbitrary filtering of SA messages can result in downstream MSDP peers being starved of SA messages for legitimate active sources. Care, therefore, should be taken when using these sorts of filters. Normally, incoming filter lists are used only to reject undesirable sources, such as sources using private addresses.

### TTL Thresholds in MSDP

The time-to-live (TTL) value provides a means to limit the number of hops a packet can take before being dropped. The `ip multicast ttl-threshold` command is used to specify a TTL for data-encapsulated SA messages sent to specified MSDP peers. By default, multicast data packets in SA messages are sent to an MSDP peer, provided the TTL value of the packet is greater than 0, which is standard TTL behavior.

In general, a TTL-threshold problem can be introduced by the encapsulation of a source’s initial multicast packet in an SA message. Because the multicast packet is encapsulated inside of the unicast SA message (whose TTL is 255), its TTL is not decremented as the SA message travels to the MSDP peer. Furthermore, the total number of hops that the SA message traverses can be drastically different than a normal multicast packet because multicast and unicast traffic may follow completely different paths to the MSDP peer and hence the remote PIM-SM domain. As a result, encapsulated packets can end up violating TTL thresholds. The solution to this problem is to configure a TTL threshold that is associated with any multicast packet that is encapsulated in an SA message sent to a particular MSDP peer using the `ip multicast ttl-threshold` command. The `ip msdp ttl-threshold` command prevents any multicast packet whose TTL in the IP header is less than the TTL value specified for the `ttl-value` argument from being encapsulated in SA messages sent to that peer.

### SA Request Messages

You can configure a noncaching device to send SA request messages to one or more specified MSDP peers. If an noncaching RP has an MSDP peer that is caching SAs, you can reduce the join latency for a noncaching peer by enabling the noncaching peer to send SA request messages. When a host requests a join to a particular group, the noncaching RP sends an SA request message to its caching peers. If a peer has cached source information for the group in question, it sends the information to the requesting RP with an SA response message. The requesting RP uses the information in the SA response but does not forward the message to any other peers. If a noncaching RP receives an SA request, it sends an error message back to the requestor.

In all current and supported software releases, caching of MSDP SA messages is mandatory and cannot be manually enabled or disabled. By default, when an MSDP peer is configured, the configured commands are automatically added to the running configuration.

### SA Request Filters

By default, a device honors all outgoing SA request messages from its MSDP peers; that is, it sends cached source information to requesting MSDP peers in SA response messages. You can control the outgoing SA request messages that a device will honor from specified peers by creating an SA request filter. An SA request filter controls the outgoing SA requests that the device will honor from MSDP peers as follows:

- You can filter all SA request messages from a specified peer by configuring the device to ignore all SA requests from the specified MSDP peer.
• You can filter a subset of SA request messages from a specified peer based on groups defined in a standard access list by configuring the device to honor only SA request messages from the MSDP peer that match the groups defined in a standard access list. SA request messages from the specified peer for other groups will be ignored.

How to Use MSDP to Interconnect Multiple PIM-SM Domains

The first task is required; all other tasks are optional.

Configuring an MSDP Peer

By enabling an MSDP peer, you implicitly enable MSDP.

Before you begin

• IP multicast routing must be enabled and PIM-SM must be configured.

• With the exception of a single MSDP peer, default MSDP peer, and MSDP mesh group scenarios, all MSDP peers must be configured to run BGP prior to being configured for MSDP.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip msdp peer {peer-name|peer-address} [connect-source type number] [remote-as as-number]
4. ip msdp description {peer-name|peer-address} text
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip msdp peer {peer-name</td>
<td>peer-address} [connect-source type number] [remote-as as-number]</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)# ip msdp peer 192.168.1.2 connect-source loopback0</td>
<td>The device that is selected to be configured as an MSDP peer is also usually a BGP neighbor. If it is not, see the Configuring a Default MSDP Peer, on page 625 section or the Configuring an MSDP Mesh Group, on page 626 section.</td>
</tr>
</tbody>
</table>

- If you specify the `connect-source` keyword, the primary address of the specified local interface `type` and `number` values are used as the source IP address for the TCP connection. The `connect-source` keyword is recommended, especially for MSDP peers on a border that peer with a device inside of a remote domain.

**Step 4**

**ip msdp description** `{peer-name|peer-address} text` (Optional) Configures a description for a specified peer to make it easier to identify in a configuration or in `show` command output.

Example:

Device(config)# ip msdp description 192.168.1.2 router at customer a

**Step 5**

**end** Exits global configuration mode and returns to privileged EXEC mode.

Example:

Device(config)# end

---

**Shutting Down an MSDP Peer**

Perform this optional task to shut down an MSDP peer.

If you are configuring several MSDP peers and you do not want any of the peers to go active until you have finished configuring all of them, you can shut down each peer, configure each peer, and later bring each peer up. You might also want to shut down an MSDP session without losing the configuration for that MSDP peer.

**Note**

When an MSDP peer is shut down, the TCP connection is terminated and not restarted until the peer is brought back up using the `no ip msdp shutdown` command (for the specified peer).

**Before you begin**

MSDP is running and the MSDP peers must be configured.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip msdp shutdown` `{peer-name|peer-address}`
4. Repeat Step 3 to shut down additional MSDP peers.
5. end
Configuring MSDP MD5 Password Authentication Between MSDP Peers

Perform this optional task to configure MSDP MD5 password authentication between MSDP peers.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip msdp password peer \{peer-name | peer-address\} [encryption-type] string
4. exit
5. show ip msdp peer [peer-address | peer-name]

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip msdp shutdown {peer-name</td>
<td>peer-address}</td>
</tr>
<tr>
<td>Example: Device(config)# ip msdp shutdown 192.168.1.3</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Exits global configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show ip msdp peer [peer-address</td>
<td>peer-name]</td>
</tr>
</tbody>
</table>

---

### Additional Information

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ip msdp shutdown 192.168.1.3</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# show ip msdp peer 192.168.1.3</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td>Enables MD5 password encryption for a TCP connection between two MSDP peers.</td>
</tr>
</tbody>
</table>

**Step 3**

**ip msdp password peer** 

*peer-name | peer-address*  

*encryption-type*  

**string**

**Example:**

Device(config)# ip msdp password peer 10.32.43.144 0 test

**Note**

MD5 authentication must be configured with the same password on both MSDP peers; otherwise, the connection between them will not be made.

- If you configure or change the password or key, which is used for MD5 authentication between two MSDP peers, the local device does not disconnect the existing session after you configure the password. You must manually disconnect the session to activate the new or changed password.

**Step 4**

**exit**

**Example:**

Device(config)# exit

Exits global configuration mode and returns to privileged EXEC mode.

**Step 5**

**show ip msdp peer**  

*peer-address | peer-name*

**Example:**

Device# show ip msdp peer

(Optional) Displays detailed information about MSDP peers.

**Note**

Use this command to verify whether MD5 password authentication is enabled on an MSDP peer.

---

**Troubleshooting Tips**

If a device has a password configured for an MSDP peer but the MSDP peer does not, a message such as the following will appear on the console while the devices attempt to establish an MSDP session between them:

```
%TCP-6-BADAUTH: No MD5 digest from [peer's IP address]:11003 to [local router's IP address]:179
```

Similarly, if the two devices have different passwords configured, a message such as the following will appear on the console:

```
%TCP-6-BADAUTH: Invalid MD5 digest from [peer's IP address]:11004 to [local router's IP address]:179
```

The **debug ip tcp transactions** command is used to display information on significant TCP transactions such as state changes, retransmissions, and duplicate packets. In the context of monitoring or troubleshooting MSDP MD5 password authentication, use the **debug ip tcp transactions** command to verify that the MD5 password is enabled and that the keepalive message is received by the MSDP peer.
Preventing DoS Attacks by Limiting the Number of SA Messages Allowed in the SA Cache from Specified MSDP Peers

Perform this optional (but highly recommended) task to limit the overall number of SA messages that the device can accept from specified MSDP peers. Performing this task protects an MSDP-enabled device from distributed denial-of-service (DoS) attacks.

Note
We recommend that you perform this task for all MSDP peerings on the device.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip msdp sa-limit {peer-address | peer-name} sa-limit
4. Repeat Step 3 to configure SA limits for additional MSDP peers.
5. exit
6. show ip msdp count [as-number]
7. show ip msdp peer [peer-address | peer-name]
8. show ip msdp summary

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>

<tr>
<td>Example: Device(config)# exit</td>
<td></td>
</tr>
</tbody>
</table>
Adjusting the MSDP Keepalive and Hold-Time Intervals

Perform this optional task to adjust the interval at which an MSDP peer will send keepalive messages and the interval at which the MSDP peer will wait for keepalive messages from other peers before declaring them down. By default, it may take as long as 75 seconds for an MSDP peer to detect that a peering session with another MSDP peer has gone down. In network environments with redundant MSDP peers, decreasing the hold-time interval can expedite the reconvergence time of MSDP peers in the event that an MSDP peer fails.

Note
We recommend that you do not change the command defaults for the `ip msdp keepalive` command, because the command defaults are in accordance with RFC 3618, Multicast Source Discovery Protocol. If your network environment requires that you modify the defaults, you must configure the same time values for the `keepalive-interval` and `hold-time-interval` arguments on both ends of the MSDP peering session.

SUMMARY STEPS
1. `enable`
2. `configure terminal`
3. `ip msdp keepalive {peer-address | peer-name} keepalive-interval hold-time-interval`
4. Repeat Step 3 to adjust the keepalive message interval for additional MSDP peers.
5. `exit`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>• Enter your password if prompted.</td>
<td></td>
</tr>
</tbody>
</table>
### Adjusting the MSDP Connection-Retry Interval

Perform this optional task to adjust the interval at which MSDP peers will wait after peering sessions are reset before attempting to reestablish the peering sessions. In network environments where fast recovery of SA messages is required, such as in trading floor network environments, you may want to decrease the connection-retry interval to a time value less than the default value of 30 seconds.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip msdp timer connection-retry-interval`
4. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

---

---
### Configuring a Default MSDP Peer

Perform this optional task to configure a default MSDP peer.

**Before you begin**

An MSDP default peer must be a previously configured MSDP peer. Before configuring a default MSDP peer, you must first configure an MSDP peer.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip msdp default-peer {peer-address | peer-name} [prefix-list list]`
4. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  | `enable` |
  | Example:
  | Device> enable |
| **Step 2**
  | `configure terminal` |
  | Example:
  | Device# configure terminal |
| **Step 3**
  | `ip msdp default-peer {peer-address | peer-name} [prefix-list list]` |
  | Example:
  | Device(config)# ip msdp default-peer 192.168.1.3 |

Changes the interval at which MSDP peers will wait after peering sessions are reset before attempting to reestablish the peering sessions.

### ip msdp timer connection-retry-interval

**Example:**

Device# ip msdp timer 45

Exits global configuration mode and returns to privileged EXEC mode.

**Example:**

Device(config)# exit
Configuring an MSDP Mesh Group

Perform this optional task to configure an MSDP mesh group.

### Note
You can configure multiple mesh groups per device.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip msdp mesh-group mesh-name {peer-address | peer-name}**
4. Repeat Step 3 to add MSDP peers as members of the mesh group.
5. **exit**

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
  Example:  
  Device# configure terminal |
| **Step 3** ip msdp mesh-group mesh-name {peer-address | peer-name} | Configures an MSDP mesh group and indicates that an MSDP peer belongs to that mesh group.  
  Example:  
  Device(config)# ip msdp mesh-group peermesh |

#### Note
All MSDP peers on a device that participate in a mesh group must be fully meshed with all other MSDP peers in the group. Each MSDP peer on each device must be configured as a peer using the **ip msdp peer** command and also as a member of the mesh group using the **ip msdp mesh-group** command.
Controlling SA Messages Originated by an RP for Local Sources

Perform this task to control SA messages originated by an RP by enabling a filter to restrict which registered sources are advertised in SA messages.

For best practice information related to configuring MSDP SA message filters, see the Multicast Source Discovery Protocol SA Filter Recommendations tech note.

<table>
<thead>
<tr>

### Controlling the Forwarding of SA Messages to MSDP Peers Using Outgoing Filter Lists

Perform this optional task to control the forwarding of SA messages to MSDP peers by configuring outgoing filter lists.

#### Note
For best practice information related to configuring MSDP SA message filters, see the Multicast Source Discovery Protocol SA Filter Recommendations tech note.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip msdp sa-filter out peer-address [peer-name] [list access-list] [route-map map-name] [rp-list access-list | rp-route-map map-name]`
4. Repeat Step 3 to configure outgoing filter lists for additional MSDP peers.
5. `exit`

#### DETAILED STEPS

<table>

## Controlling the Receipt of SA Messages from MSDP Peers Using Incoming Filter Lists

Perform this optional task to control the receipt of incoming SA messages from MSDP peers.

### Note

For best practice information related to configuring MSDP SA message filters, see the [Multicast Source Discovery Protocol SA Filter Recommendations](#) tech note.

### SUMMARY STEPS

1. enable
2. configure terminal
3. `ip msdp sa-filter in {peer-address | peer-name} [list access-list] [route-map map-name] [rp-list access-list | rp-route-map map-name]`
4. Repeat Step 3 to configure incoming filter lists for additional MSDP peers.
5. **exit**

### DETAILED STEPS

<table>
<thead>

</tbody>
</table>
Using TTL Thresholds to Limit the Multicast Data Sent in SA Messages

Perform this optional task to establish a time to live (TTL) threshold to limit the multicast data sent in SA messages.

### SUMMARY STEPS

1. enable
2. configure terminal
3. `ip msdp ttl-threshold {peer-address | peer-name} ttl-value`
4. exit

### DETAILED STEPS

<tr>
<td><code>Device(config)# exit</code></td>
<td></td>
</tr>
</tbody>
</table>

**Requesting Source Information from MSDP Peers**

Perform this optional task to enable a device to request source information from MSDP peers.

**Note**  
Because SA caching is enabled by default and cannot be explicitly enabled or disabled in earlier Cisco software releases, performing this task is seldom needed.

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. `ip msdp sa-request {peer-address | peer-name}`  
4. Repeat Step 3 to specify that the device send SA request messages to additional MSDP caching peers.  
5. exit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>

</tr>
</thead>
</table>
| Step 1 | **enable**  
**Example:**  
Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| Step 2 | **configure terminal**  
**Example:**  
Device# configure terminal | Enters global configuration mode. |
| Step 3 | `ip msdp sa-request {peer-address | peer-name}`  
**Example:**  
Device(config)# ip msdp sa-request 192.168.10.1 | Specifies that the device send SA request messages to the specified MSDP peer. |
| Step 4 | Repeat Step 3 to specify that the device send SA request messages to additional MSDP caching peers. | -- |
| Step 5 | **exit**  
**Example:**  
Device(config)# exit | Exits global configuration mode and returns to privileged EXEC mode. |
Controlling the Response to Outgoing SA Request Messages from MSDP Peers Using SA Request Filters

Perform this optional task to control the outgoing SA request messages that the device will honor from MSDP peers.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip msdp filter-sa-request {peer-address | peer-name} [list access-list]
4. Repeat Step 3 to configure SA request filters for additional MSDP peers.
5. exit

</table>

Including a Bordering PIM Dense Mode Region in MSDP

Perform this optional task to configure a border device to send SA messages for sources active in a PIM dense mode (PIM-DM) region.
You can have a device that borders a PIM-SM region and a PIM-DM region. By default, sources in the PIM-DM domain are not included in MSDP. You can configure this border device to send SA messages for sources active in the PIM-DM domain. If you do so, it is very important to also configure the `ip msdp redistribute` command to control what local sources from the PIM-DM domain are advertised. Not configuring this command can result in the (S, G) state remaining long after a source in the PIM-DM domain has stopped sending. For configuration information, see the Controlling SA Messages Originated by an RP for Local Sources, on page 627 section.

### SUMMARY STEPS

1. `enable`  
2. `configure terminal`  
3. `ip msdp border sa-address type number`  
4. `exit`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
<tr>
<td>Step 3</td>
<td>Configures the device on the border between a PIM-SM and PIM-DM domain to originate SA messages for active sources in the PIM-DM domain.</td>
</tr>
<tr>
<td>ip msdp border sa-address type number</td>
<td>• The IP address of the interface is used as the originator ID, which is the RP field in the SA message.</td>
</tr>
<tr>
<td>Example: Device(config)# ip msdp border sa-address gigabitethernet0/0/0</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>Exits global configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>exit</td>
<td>Example: Device(config)# exit</td>
</tr>
</tbody>
</table>

**Configuring an Originating Address Other Than the RP Address**

Perform this optional task to allow an MSDP speaker that originates an SA message to use the IP address of its interface as the RP address in the SA message.

You can also change the originator ID for any one of the following reasons:

- If you configure multiple devices in an MSDP mesh group for Anycast RP.
• If you have a device that borders a PIM-SM domain and a PIM-DM domain. If a device borders a PIM-SM domain and a PIM-DM domain and you want to advertise active sources within the PIM-DM domain, configure the RP address in SA messages to be the address of the originating device’s interface.

Before you begin
MSDP is enabled and the MSDP peers are configured. For more information about configuring MSDP peers, see the Configuring an MSDP Peer, on page 618 section.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip msdp originator-id type number
4. exit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>

Monitoring MSDP

Perform this optional task to monitor MSDP SA messages, peers, state, and peer status.

SUMMARY STEPS

1. enable
2. debug ip msdp [peer-address | peer-name] [detail] [routes]
3. debug ip msdp resets
4. `show ip msdp count [as-number]`
5. `show ip msdp peer [peer-address | peer-name]`
6. `show ip msdp sa-cache [group-address | source-address | group-name | source-name] [as-number]`
7. `show ip msdp summary`

**DETAILED STEPS**

**Step 1**

`enable`

**Example:**

```
Device# enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

**Step 2**

`debug ip msdp [peer-address | peer-name] [detail] [routes]`

Use this command to debug MSDP activity.

Use the optional `peer-address` or `peer-name` argument to specify for which peer debug events are logged.

The following is sample output from the `debug ip msdp` command:

**Example:**

```
Device# debug ip msdp
MSDP debugging is on
Device# MSDP: 224.150.44.254: Received 1388-byte message from peer
Device# MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.92, used EMBGP peer
Device# MSDP: 224.150.44.254: Forward 1388-byte SA to peer
Device# MSDP: 224.150.44.254: Received 1028-byte message from peer
Device# MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.92, used EMBGP peer
Device# MSDP: 224.150.44.254: Forward 1028-byte SA to peer
Device# MSDP: 224.150.44.254: Received 1388-byte message from peer
Device# MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.92, used EMBGP peer
```

**Step 3**

`debug ip msdp resets`

Use this command to debug MSDP peer reset reasons.
Example:

Device# debug ip msdp resets

Step 4 show ip msdp count [as-number]

Use this command to display the number of sources and groups originated in MSDP SA messages and the number of SA messages from an MSDP peer in the SA cache. The `ip msdp cache-sa-state` command must be configured for this command to produce any output.

The following is sample output from the `show ip msdp count` command:

Example:

```
Device# show ip msdp count
SA State per Peer Counters, <Peer>: <$# SA learned>
  192.168.4.4: 8
SA State per ASN Counters, <asn>: <$# sources>/<$# groups>
  Total entries: 8
? : 8/8
```

Step 5 show ip msdp peer [peer-address | peer-name]

Use this command to display detailed information about MSDP peers.

Use the optional `peer-address` or `peer-name` argument to display information about a particular peer.

The following is sample output from the `show ip msdp peer` command:

Example:

```
Device# show ip msdp peer 192.168.4.4
MSDP Peer 192.168.4.4 (?), AS 64512 (configured AS)
  Connection status:
    State: Up, Resets: 0, Connection source: Loopback0 (2.2.2.2)
    Uptime(Downtime): 00:07:55, Messages sent/received: 8/18
    Output messages discarded: 0
    Connection and counters cleared 00:08:55 ago
  SA Filtering:
    Input (S,G) filter: none, route-map: none
    Input RP filter: none, route-map: none
    Output (S,G) filter: none, route-map: none
    Output RP filter: none, route-map: none
  SA-Requests:
    Input filter: none
    Peer ttl threshold: 0
    SAs learned from this peer: 8
    Input queue size: 0, Output queue size: 0
    MD5 signature protection on MSDP TCP connection: not enabled
```

Step 6 show ip msdp sa-cache [group-address | source-address | group-name | source-name] [as-number]

Use this command to display the (S, G) state learned from MSDP peers.

The following is sample output from the `show ip msdp sa-cache` command:

Example:

```
Device# show ip msdp sa-cache
MSDP Source-Active Cache - 8 entries
  (10.44.44.5, 239.232.1.0), RP 192.168.4.4, BGP/AS 64512, 00:01:20/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.1), RP 192.168.4.4, BGP/AS 64512, 00:01:20/00:05:32, Peer 192.168.4.4
```
Step 7  
**show ip msdp summary**

Use this command to display MSDP peer status.

The following is sample output from the *show ip msdp summary* command:

**Example:**

```
Device# show ip msdp summary
MSDP Peer Status Summary
Peer Address   AS  State Uptime/ Reset SA Peer Name
               Count Count
192.168.4.4   4  Up   00:08:05 0 8 ?
```

Clearing MSDP Connections Statistics and SA Cache Entries

Perform this optional task to clear MSDP connections, statistics, and SA cache entries.

**SUMMARY STEPS**

1. **enable**
2. **clear ip msdp peer**  
   `[peer-address | peer-name]`
3. **clear ip msdp statistics**  
   `[peer-address | peer-name]`
4. **clear ip msdp sa-cache**  
   `[group-address]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>

<tr>
<td><code>[group-address]</code></td>
<td></td>
</tr>
</tbody>
</table>
Enabling SNMP Monitoring of MSDP

Perform this optional task to enable Simple Network Management Protocol (SNMP) monitoring of MSDP.

**Before you begin**
- SNMP and MSDP is configured on your devices.
- In each PIM-SM domain there should be a device that is configured as the MSDP speaker. This device must have SNMP and the MSDP MIB enabled.

**Note**
- All MSDP-MIB objects are implemented as read-only.
- The Requests table is not supported in Cisco’s implementation of the MSDP MIB.
- The msdpEstablished notification is not supported in Cisco’s implementation of the MSDP MIB.

**SUMMARY STEPS**

1. enable
2. snmp-server enable traps msdp
3. snmp-server host host [traps | informs] [version {1 | 2c | 3 [auth | priv | noauth]}] community-string [udp-port port-number] msdp
4. exit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

- enable

  **Example:**
  
  Device# enable

  Enables privileged EXEC mode.
  - Enter your password if prompted.

| **Step 2**

- snmp-server enable traps msdp

  **Example:**
  
  Device# snmp-server enable traps msdp

  Enables the sending of MSDP notifications for use with SNMP.

  **Note**
  The **snmp-server enable traps msdp** command enables both traps and informs.
### Purpose

**Command or Action**

| Step 3 | snmp-server host host [traps | informs] [version {1 | 2c | 3 [auth | priv | noauth]}] community-string [udp-port port-number] msdp |
|--------|------------------------------------------------------------------------------------------------------------------|
| **Example:** | Device# snmp-server host examplehost msdp |

**Step 4**

| exit |
| **Example:** | Device(config)# exit |

**Purpose**

Specifies the recipient (host) for MSDP traps or informs.

Exits global configuration mode and returns to privileged EXEC mode.

### Troubleshooting Tips

You can compare the results of MSDP MIB notifications to the output from the software by using the `show ip msdp summary` and `show ip msdp peer` commands on the appropriate device. You can also compare the results of these commands to the results from SNMP Get operations. You can verify SA cache table entries using the `show ip msdp sa-cache` command. Additional troubleshooting information, such as the local address of the connection, the local port, and the remote port, can be obtained using the output from the `debug ip msdp` command.

### Configuration Examples for Using MSDP to Interconnect Multiple PIM-SM Domains

#### Example: Configuring an MSDP Peer

The following example shows how to establish MSDP peering connections between three MSDP peers:

**Device A**

```
! interface Loopback 0  
ip address 10.220.8.1 255.255.255.255
! ip msdp peer 10.220.16.1 connect-source Loopback0
ip msdp peer 10.220.32.1 connect-source Loopback0
```

**Device B**

```
! interface Loopback 0  
ip address 10.220.16.1 255.255.255.255
! ip msdp peer 10.220.8.1 connect connect-source Loopback0
```
Example: Configuring MSDP MD5 Password Authentication

The following example shows how to enable MD5 password authentication for TCP connections between two MSDP peers:

Device A

```
! ip msdp peer 10.3.32.154
ip msdp password peer 10.3.32.154 0 test
```

Device B

```
! ip msdp peer 10.3.32.153
ip msdp password peer 10.3.32.153 0 test
```

Example: Configuring a Default MSDP Peer

The figure illustrates a scenario where default MSDP peers might be used. In the figure, a customer that owns Device B is connected to the internet through two ISPs, one that owns Device A and the other that owns Device C. They are not running (M)BGP between them. In order for the customer to learn about sources in the ISP domain or in other domains, Device B identifies Device A as its default MSDP peer. Device B advertises SA messages to both Device A and Device C, but accepts SA messages either from Device A only or Device C only. If Device A is the first default peer in the configuration, it will be used if it is up and running. Only if Device A is not running will Device B accept SA messages from Device C.

The ISP will also likely use a prefix list to define which prefixes it will accept from the customer device. The customer will define multiple default peers, each having one or more prefixes associated with it.

The customer has two ISPs to use. The customer defines both ISPs as default peers. As long as the first default peer identified in the configuration is up and running, it will be the default peer and the customer will accept all SA messages it receives from that peer.

Note: Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.
Device B advertises SAs to Device A and Device C, but uses only Device A or Device C to accept SA messages. If Device A is first in the configuration file, it will be used if it is up and running. Only when Device A is not running will Device B accept SAs from Device C. This is the behavior without a prefix list.

If you specify a prefix list, the peer will be a default peer only for the prefixes in the list. You can have multiple active default peers when you have a prefix list associated with each. When you do not have any prefix lists, you can configure multiple default peers, but only the first one is the active default peer as long as the device has connectivity to this peer and the peer is alive. If the first configured peer goes down or the connectivity to this peer goes down, the second configured peer becomes the active default, and so on.

The following example shows a partial configuration of Device A and Device C in the figure. Each of these ISPs may have more than one customer using default peering, like the customer in the figure. In that case, they may have similar configurations. That is, they will only accept SAs from a default peer if the SA is permitted by the corresponding prefix list.

**Device A Configuration**

```
ip msdp default-peer 10.1.1.1
ip msdp default-peer 10.1.1.1 prefix-list site-b ge 32
ip prefix-list site-b permit 10.0.0.0/8
```

**Device C Configuration**

```
ip msdp default-peer 10.1.1.1 prefix-list site-b ge 32
ip prefix-list site-b permit 10.0.0.0/8
```

**Example: Configuring MSDP Mesh Groups**

The following example shows how to configure three devices to be fully meshed members of an MSDP mesh group:
Device A Configuration

ip msdp peer 10.2.2.2
ip msdp peer 10.3.3.3
ip msdp mesh-group test-mesh-group 10.2.2.2
ip msdp mesh-group test-mesh-group 10.3.3.3

Device B Configuration

ip msdp peer 10.1.1.1
ip msdp peer 10.3.3.3
ip msdp mesh-group test-mesh-group 10.1.1.1
ip msdp mesh-group test-mesh-group 10.3.3.3

Device C Configuration

ip msdp peer 10.1.1.1
ip msdp peer 10.2.2.2
ip msdp mesh-group test-mesh-group 10.1.1.1
ip msdp mesh-group test-mesh-group 10.2.2.2

Configuring Wireless Multicast

- Prerequisites for Configuring Wireless Multicast, on page 645
- Restrictions on Configuring Wireless Multicast, on page 645
- Information About Wireless Multicast, on page 646
- How to Configure Wireless Multicast, on page 650
- Verifying Wireless Multicast, on page 658
- Where to Go Next for Wireless Multicast, on page 658

Prerequisites for Configuring Wireless Multicast

- IP multicast routing must be enabled and the PIM version and PIM mode must be configured. The default routes should be available in the device. After performing these tasks, the device can forward multicast packets and populate its multicast routing table.
- To participate in IP multicasting, the multicast hosts, routers, and multilayer switches must have IGMP operating.
- When enabling multicast mode on the device, a CAPWAP multicast group address should also be configured. Access points listen to the CAPWAP multicast group using IGMP.

Restrictions on Configuring Wireless Multicast

The following are the restrictions for configuring IP multicast routing:

- Access points in monitor mode, sniffer mode, or rogue-detector mode do not join the CAPWAP multicast group address.
- The CAPWAP multicast group configured on the should be different for different devices.
- Multicast routing should not be enabled for the management interface.

Restrictions for IPv6 Snooping

The IPv6 snooping feature is not supported on Etherchannel ports.
Restrictions for IPv6 RA Guard

• The IPv6 RA Guard feature does not offer protection in environments where IPv6 traffic is tunneled.
• This feature is supported only in hardware when the ternary content addressable memory (TCAM) is programmed.
• This feature can be configured on a switch port interface in the ingress direction.
• This feature supports host mode and router mode.
• This feature is supported only in the ingress direction; it is not supported in the egress direction.
• This feature is not supported on EtherChannel and EtherChannel port members.
• This feature is not supported on trunk ports with merge mode.
• This feature is supported on auxiliary VLANs and private VLANs (PVLANS). In the case of PVLANS, primary VLAN features are inherited and merged with port features.
• Packets dropped by the IPv6 RA Guard feature can be spanned.
• If the `platform ipv6 acl icmp optimize neighbor-discovery` command is configured, the IPv6 RA Guard feature cannot be configured and an error message will be displayed. This command adds default global Internet Control Message Protocol (ICMP) entries that will override the RA guard ICMP entries.

Information About Wireless Multicast

If the network supports packet multicasting, the multicast method that the device uses can be configured. The device performs multicasting in two modes:

• Unicast mode—The device unicasts every multicast packet to every access point associated to the device. This mode is inefficient, but is required on networks that do not support multicasting.
• Multicast mode—The device sends multicast packets to a CAPWAP multicast group. This method reduces the overhead on the device processor and shifts the work of packet replication to the network, which is much more efficient than the unicast method.

The flexconnect mode has two submodes: local switching and central switching. In local switching mode, the data traffic is switched at the AP level and the controller does not see any multicast traffic. In central switching mode, the multicast traffic reaches the controller. However, IGMP snooping takes place at the AP.

When the multicast mode is enabled and the device receives a multicast packet from the wired LAN, the device encapsulates the packet using CAPWAP and forwards the packet to the CAPWAP multicast group address. The device always uses the management VLAN for sending multicast packets. Access points in the multicast group receive the packet and forward it to all the BSSIDs mapped to the VLAN on which clients receive multicast traffic.

The device supports all the capabilities of IGMP v1, including Multicast Listener Discovery (MLD) v1 snooping, but the IGMP v2 and IGMP v3 capabilities are limited. This feature keeps track of and delivers IPv6 multicast flows to the clients that request them. To support IPv6 multicast, global multicast mode should be enabled.

Internet Group Management Protocol (IGMP) snooping is introduced to better direct multicast packets. When this feature is enabled, the device snooping gathers IGMP reports from the clients, processes them, creates
unique multicast group IDs (MGIDs) based on the Layer 3 multicast address and the VLAN number, and sends the IGMP reports to the IGMP querier. The device then updates the access-point MGID table on the corresponding access point with the client MAC address. When the device receives multicast traffic for a particular multicast group, it forwards it to all the access points, but only those access points that have active clients listening or subscribed to that multicast group send multicast traffic on that particular WLAN. IP packets are forwarded with an MGID that is unique for an ingress VLAN and the destination multicast group. Layer 2 multicast packets are forwarded with an MGID that is unique for the ingress VLAN.

MGID is a 14-bit value filled in the 16-bit reserved field of wireless information in the CAPWAP header. The remaining two bits should be set to zero.

**Multicast Optimization**

Multicast used to be based on the group of the multicast addresses and the VLAN as one entity, MGID. With the VLAN group feature, every client listens to the multicast stream on a different VLAN. As a result, the device creates different MGIDs for each multicast address and the VLAN. Therefore, the upstream router sends a copy for each VLAN, which results in as many copies as the number of VLANs in the group. Because the VLAN remains the same for all the clients, multiple copies of the multicast packet are sent over the wireless network. To suppress the duplication of a multicast stream on the wireless medium between the device and the access points, the multicast optimization feature can be used.

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the device can be configured as a multicast VLAN where multicast groups are registered. The clients are allowed to listen to a multicast stream on the multicast VLAN. The MGID is generated using the multicast VLAN and multicast IP addresses. If multiple clients on different VLANs of the same WLAN are listening to a single multicast IP address, a single MGID is generated. The device makes sure that all the multicast streams from the clients on this VLAN group always go out on the multicast VLAN to ensure that the upstream router has one entry for all the VLANs of the VLAN group. Only one multicast stream hits the VLAN group even if the clients are on different VLANs. Therefore, the multicast packets that are sent out over the network is just one stream.

**IPv6 Global Policies**

IPv6 global policies provide storage and access policy database services. IPv6 ND inspection and IPv6 RA guard are IPv6 global policies features. Every time an ND inspection or RA guard is configured globally, the policy attributes are stored in the software policy database. The policy is then applied to an interface, and the software policy database entry is updated to include this interface to which the policy is applied.

**IPv6 RA Guard**

The IPv6 RA Guard feature provides support for allowing the network administrator to block or reject unwanted or rogue RA guard messages that arrive at the network device platform. RAs are used by devices to announce themselves on the link. The IPv6 RA Guard feature analyzes these RAs and filters out RAs that are sent by unauthorized devices. In host mode, all RA and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 (L2) device with the information found in the received RA frame. Once the L2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.
In the wireless deployment RAs coming on wireless ports are dropped as routers cannot reside on these interfaces.

**Information About IPv6 Snooping**

**IPv6 Neighbor Discovery Inspection**

The IPv6 Neighbor Discovery Inspection, or IPv6 "snooping," feature bundles several Layer 2 IPv6 first-hop security features, including IPv6 Address Glean and IPv6 Device Tracking. IPv6 neighbor discovery (ND) inspection operates at Layer 2, or between Layer 2 and Layer 3, and provides IPv6 features with security and scalability. This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables and analyzes ND messages in order to build a trusted binding table. IPv6 ND messages that do not have valid bindings are dropped. An ND message is considered trustworthy if its IPv6-to-MAC mapping is verifiable. This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

When IPv6 ND inspection is configured on a target (which varies depending on platform target support and may include device ports, switch ports, Layer 2 interfaces, Layer 3 interfaces, and VLANs), capture instructions are downloaded to the hardware to redirect the ND protocol and Dynamic Host Configuration Protocol (DHCP) for IPv6 traffic up to the switch integrated security features (SISF) infrastructure in the routing device. For ND traffic, messages such as NS, NA, RS, RA, and REDIRECT are directed to SISF. For DHCP, UDP messages sourced from port 546 or 547 are redirected.

IPv6 ND inspection registers its "capture rules" to the classifier, which aggregates all rules from all features on a given target and installs the corresponding ACL down into the platform-dependent modules. Upon receiving redirected traffic, the classifier calls all entry points from any registered feature (for the target on which the traffic is being received), including the IPv6 ND inspection entry point. This entry point is the last to be called, so any decision (such as drop) made by another feature supersedes the IPv6 ND inspection decision.

**IPv6 ND Inspection**

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables. IPv6 ND inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery messages that do not have valid bindings are dropped. A neighbor discovery message is considered trustworthy if its IPv6-to-MAC mapping is verifiable.

This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

**IPv6 Device Tracking**

IPv6 device tracking provides IPv6 host liveness tracking so that a neighbor table can be immediately updated when an IPv6 host disappears.

**IPv6 First-Hop Security Binding Table**

The IPv6 First-Hop Security Binding Table recovery mechanism feature enables the binding table to recover in the event of a device reboot. A database table of IPv6 neighbors connected to the device is created from information sources such as ND snooping. This database, or binding, table is used by various IPv6 guard
features to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors
to prevent spoofing and redirect attacks.

This mechanism enables the binding table to recover in the event of a device reboot. The recovery mechanism
will block any data traffic sourced from an unknown source; that is, a source not already specified in the
binding table and previously learned through ND or DHCP gleaning. This feature recovers the missing binding
table entries when the resolution for a destination address fails in the destination guard. When a failure occurs,
a binding table entry is recovered by querying the DHCP server or the destination host, depending on the
configuration.

Recovery Protocols and Prefix Lists

The IPv6 First-Hop Security Binding Table Recovery Mechanism feature introduces the capability to provide
a prefix list that is matched before the recovery is attempted for both DHCP and NDP.

If an address does not match the prefix list associated with the protocol, then the recovery of the binding table
entry will not be attempted with that protocol. The prefix list should correspond to the prefixes that are valid
for address assignment in the Layer 2 domain using the protocol. The default is that there is no prefix list, in
which case the recovery is attempted for all addresses. The command to associate a prefix list to a protocol
is `protocol {dhcp | ndp} [prefix-list prefix-list-name].`

**IPv6 Device Tracking**

IPv6 device tracking provides IPv6 host liveness tracking so that a neighbor table can be immediately updated
when an IPv6 host disappears.

**IPv6 Address Glean**

IPv6 address glean is the foundation for many other IPv6 features that depend on an accurate binding table.
It inspects ND and DHCP messages on a link to glean addresses, and then populates the binding table with
these addresses. This feature also enforces address ownership and limits the number of addresses any given
node is allowed to claim.

The following figure shows how IPv6 address glean works.
How to Configure Wireless Multicast

Configuring Wireless Multicast-MCMC Mode (CLI)

SUMMARY STEPS

1. enable
2. configure terminal
3. wireless multicast
4. end

## Configuring Wireless Broadcast (CLI)

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `wireless broadcast`
4. `wireless broadcast vlan vlanid`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
*enable*  
*Example:*  
Device> `enable` | Enables privileged EXEC mode. Enter your password, if prompted. |
| **Step 2**  
*configure terminal*  
*Example:*  
Device# `configure terminal` | Enters global configuration mode. |
| **Step 3**  
*wireless broadcast*  
*Example:*  
Device(config)# `wireless broadcast`  
Device(config)# `no wireless broadcast` | Enables broadcast packets for wireless clients. By default, the broadcast packets for wireless clients is in Disabled state. Enabling `wireless broadcast` enables broadcast traffic for each VLAN. Use the `no` form of this command to disable broadcasting packets. |
| **Step 4**  
*wireless broadcast vlan vlanid*  
*Example:*  
Device(config)# `wireless broadcast vlan 3`  
Device(config)# `no wireless broadcast vlan 3` | Enables broadcast packets for single VLAN. By default, the Broadcast Packets for a Single VLAN feature is in Disabled state. Wireless broadcast must be enabled for broadcasting. Use the `no` form of this command to disable broadcast traffic for each VLAN. |
| **Step 5**  
*end*  
*Example:*  
Device(config)# `end` | Exits configuration mode. Alternatively, press `Ctrl-Z` to exit configuration mode. |

## Configuring IP Multicast VLAN for WLAN (CLI)

### SUMMARY STEPS

1. `enable`

</table>

Where to Go Next for Wireless Multicast

You can configure the following:

- IGMP
- PIM
- SSM
- IP Multicast Routing
- Service Discovery Gateway
Configuring SSM

- Prerequisites for Configuring SSM, on page 659
- Restrictions for Configuring SSM, on page 659
- Information About SSM, on page 661
- How to Configure SSM, on page 664
- Monitoring SSM, on page 671
- Where to Go Next for SSM, on page 671
- Additional References, on page 672
- Feature History and Information for SSM, on page 672

Prerequisites for Configuring SSM

The following are the prerequisites for configuring source-specific multicast (SSM) and SSM mapping:

- Before you configure SSM mapping, you must perform the following tasks:
  - Enable IP multicast routing.
  - Enable PIM sparse mode.
  - Configure SSM.

- Before you configure static SSM mapping, you must configure access control lists (ACLs) that define the group ranges to be mapped to source addresses.

- Before you can configure and use SSM mapping with DNS lookups, you need to add records to a running DNS server. If you do not already have a DNS server running, you need to install one.

  You can use a product such as Cisco Network Registrar to add records to a running DNS server.

Restrictions for Configuring SSM

The following are the restrictions for configuring SSM:
• To run SSM with IGMPv3, SSM must be supported in the Cisco IOS router, the host where the application is running, and the application itself.

• Existing applications in a network predating SSM will not work within the SSM range unless they are modified to support (S, G) channel subscriptions. Therefore, enabling SSM in a network may cause problems for existing applications if they use addresses within the designated SSM range.

• IGMP Snooping—IGMPv3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.

• Address management is still necessary to some degree when SSM is used with Layer 2 switching mechanisms. Cisco Group Management Protocol (CGMP), IGMP snooping, or Router-Port Group Management Protocol (RGMP) support only group-specific filtering, not (S, G) channel-specific filtering. If different receivers in a switched network request different (S, G) channels sharing the same group, they do not benefit from these existing mechanisms. Instead, both receivers receive all (S, G) channel traffic and filter out the unwanted traffic on input. Because SSM can re-use the group addresses in the SSM range for many independent applications, this situation can lead to decreased traffic filtering in a switched network. For this reason, it is important to use random IP addresses from the SSM range for an application to minimize the chance for re-use of a single address within the SSM range between different applications. For example, an application service providing a set of television channels should, even with SSM, use a different group for each television (S, G) channel. This setup guarantees that multiple receivers to different channels within the same application service never experience traffic aliasing in networks that include Layer 2 devices.

• In PIM-SSM, the last hop router will continue to periodically send (S, G) join messages if appropriate (S, G) subscriptions are on the interfaces. Therefore, as long as receivers send (S, G) subscriptions, the shortest path tree (SPT) state from the receivers to the source will be maintained, even if the source is not sending traffic for longer periods of time (or even never).

  The opposite situation occurs with PIM-SM, where (S, G) state is maintained only if the source is sending traffic and receivers are joining the group. If a source stops sending traffic for more than 3 minutes in PIM-SM, the (S, G) state is deleted and only reestablished after packets from the source arrive again through the RPT (rendezvous point tree). Because no mechanism in PIM-SSM notifies a receiver that a source is active, the network must maintain the (S, G) state in PIM-SSM as long as receivers are requesting receipt of that channel.

The following are the restrictions for configuring SSM mapping:

• The SSM Mapping feature does not share the benefit of full SSM. SSM mapping takes a group G join from a host and identifies this group with an application associated with one or more sources, therefore, it can only support one such application per group G. Nevertheless, full SSM applications may still share the same group also used in SSM mapping.

• Enable IGMPv3 with care on the last hop router when you rely solely on SSM mapping as a transition solution for full SSM. When you enable both SSM mapping and IGMPv3 and the hosts already support IGMPv3 (but not SSM), the hosts send IGMPv3 group reports. SSM mapping does not support these IGMPv3 group reports, and the router does not correctly associate sources with these reports.
Information About SSM

The source-specific multicast (SSM) feature is an extension of IP multicast in which datagram traffic is forwarded to receivers from only those multicast sources that the receivers have explicitly joined. For multicast groups configured for SSM, only SSM distribution trees (no shared trees) are created.

This section describes how to configure source-specific multicast (SSM). For a complete description of the SSM commands in this section, refer to the IP Multicast Command Reference. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

SSM Components Overview

SSM is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core networking technology for the Cisco implementation of IP multicast solutions targeted for audio and video broadcast application environments. The device supports the following components that support SSM implementation:

- Protocol independent multicast source-specific mode (PIM-SSM)
  PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM sparse mode (PIM-SM).

- Internet Group Management Protocol version 3 (IGMPv3)

SSM and Internet Standard Multicast (ISM)

The current IP multicast infrastructure in the Internet and many enterprise intranets is based on the PIM-SM protocol and Multicast Source Discovery Protocol (MSDP). These protocols have the limitations of the Internet Standard Multicast (ISM) service model. For example, with ISM, the network must maintain knowledge about which hosts in the network are actively sending multicast traffic.

The ISM service consists of the delivery of IP datagrams from any source to a group of receivers called the multicast host group. The datagram traffic for the multicast host group consists of datagrams with an arbitrary IP unicast source address (S) and the multicast group address (G) as the IP destination address. Systems receive this traffic by becoming members of the host group. Membership in a host group simply requires signaling the host group through IGMP version 1, 2, or 3.

In SSM, delivery of datagrams is based on (S, G) channels. In both SSM and ISM, no signaling is required to become a source. However, in SSM, receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources. In other words, receivers can receive traffic only from (S, G) channels to which they are subscribed, whereas in ISM, receivers need not know the IP addresses of sources from which they receive their traffic. The proposed standard approach for channel subscription signaling uses IGMP and includes modes membership reports, which are supported only in IGMP version 3.

SSM IP Address Range

SSM can coexist with the ISM service by applying the SSM delivery model to a configured subset of the IP multicast group address range. Cisco IOS software allows SSM configuration for the IP multicast address range of 224.0.0.0 through 239.255.255.255. When an SSM range is defined, existing IP multicast receiver
applications do not receive any traffic when they try to use an address in the SSM range (unless the application is modified to use an explicit (S, G) channel subscription).

SSM Operations

An established network, in which IP multicast service is based on PIM-SM, can support SSM services. SSM can also be deployed alone in a network without the full range of protocols required for interdomain PIM-SM (for example, MSDP, Auto-RP, or bootstrap router [BSR]) if only SSM service is needed.

If SSM is deployed in a network already configured for PIM-SM, only the last-hop routers support SSM. Routers that are not directly connected to receivers do not require support for SSM. In general, these not-last-hop routers must only run PIM-SM in the SSM range and might need additional access control configuration to suppress MSDP signalling, registering, or PIM-SM shared tree operations from occurring within the SSM range.

Use the `ip pim ssm` global configuration command to configure the SSM range and to enable SSM. This configuration has the following effects:

- For groups within the SSM range, (S, G) channel subscriptions are accepted through IGMPv3 include-mode membership reports.

- PIM operations within the SSM range of addresses change to PIM-SSM, a mode derived from PIM-SM. In this mode, only PIM (S, G) join and prune messages are generated by the router, and no (S, G) rendezvous point tree (RPT) or (*, G) RPT messages are generated. Incoming messages related to RPT operations are ignored or rejected, and incoming PIM register messages are immediately answered with register-stop messages. PIM-SSM is backward-compatible with PIM-SM unless a router is a last-hop router. Therefore, routers that are not last-hop routers can run PIM-SM for SSM groups (for example, if they do not yet support SSM).

- No MSDP source-active (SA) messages within the SSM range are accepted, generated, or forwarded.

SSM Mapping

In a typical set-top box (STB) deployment, each TV channel uses one separate IP multicast group and has one active server host sending the TV channel. A single server can send multiple TV channels, but each to a different group. In this network environment, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the report addresses the well-known TV server for the TV channel associated with the multicast group.

When SSM mapping is configured, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the router translates this report into one or more channel memberships for the well-known sources associated with this group.

When the router receives an IGMPv1 or IGMPv2 membership report for a group, the router uses SSM mapping to determine one or more source IP addresses for the group. SSM mapping then translates the membership report as an IGMPv3 report and continues as if it had received an IGMPv3 report. The router then sends PIM joins and continues to be joined to these groups as long as it continues to receive the IGMPv1 or IGMPv2 membership reports, and the SSM mapping for the group remains the same.

SSM mapping enables the last hop router to determine the source addresses either by a statically configured table on the router or through a DNS server. When the statically configured table or the DNS mapping changes, the router leaves the current sources associated with the joined groups.
**Static SSM Mapping**

With static SSM mapping, you can configure the last hop router to use a static map to determine the sources that are sending to groups. Static SSM mapping requires that you configure ACLs to define group ranges. After configuring the ACLs to define group ranges, you can then map the groups permitted by those ACLs to sources by using the `ip igmp ssm-map static` global configuration command.

You can configure static SSM mapping in smaller networks when a DNS is not needed or to locally override DNS mappings. When configured, static SSM mappings take precedence over DNS mappings.

**DNS-Based SSM Mapping**

You can use DNS-based SSM mapping to configure the last hop router to perform a reverse DNS lookup to determine sources sending to groups. When DNS-based SSM mapping is configured, the router constructs a domain name that includes the group address and performs a reverse lookup into the DNS. The router looks up IP address resource records and uses them as the source addresses associated with this group. SSM mapping supports up to 20 sources for each group. The router joins all sources configured for a group.

*Figure 35: DNS-Based SSM Mapping*

The following figure displays DNS-based SSM mapping.

The SSM mapping mechanism that enables the last hop router to join multiple sources for a group can provide source redundancy for a TV broadcast. In this context, the last hop router provides redundancy using SSM mapping to simultaneously join two video sources for the same TV channel. However, to prevent the last hop router from duplicating the video traffic, the video sources must use a server-side switchover mechanism. One video source is active, and the other backup video source is passive. The passive source waits until an active source failure is detected before sending the video traffic for the TV channel. Thus, the server-side switchover mechanism ensures that only one of the servers is actively sending video traffic for the TV channel.

To look up one or more source addresses for a group that includes G1, G2, G3, and G4, you must configure these DNS records on the DNS server:

```
```
IN A source-address-2
IN A source-address-n

See your DNS server documentation for more information about configuring DNS resource records.

# How to Configure SSM

For a complete description of the source-specific multicast (SSM) commands in this section, see the *IP Multicast Command Reference, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

## Configuring SSM (CLI)

Follow these steps to configure SSM:

This procedure is optional.

**Before you begin**

If you want to use an access list to define the Source Specific Multicast (SSM) range, configure the access list before you reference the access list in the `ip pim ssm` command.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip pim ssm [default | range access-list]`
4. `interface type number`
5. `ip pim {sparse-mode | }`
6. `ip igmp version 3`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Command</strong></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Command</strong></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ip pim ssm [default</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ip pim ssm range 20</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>interface type number</td>
</tr>
</tbody>
</table>
| Example: | Device(config)# interface gigabitethernet 1/0/1 | The specified interface must be one of the following:  
  • A routed port—A physical port that has been configured as a Layer 3 port by entering the no switchport interface configuration command.  
  • An SVI—A VLAN interface created by using the interface vlan vlan-id global configuration command.  
These interfaces must have IP addresses assigned to them. |
| **Step 5** | ip pim {sparse-mode | } | Enables PIM on an interface. |
| Example: | Device(config-if)# ip pim sparse-mode | |
| **Step 6** | ip igmp version 3 | Enables IGMPv3 on this interface. The default version of IGMP is set to Version 2. |
| Example: | Device(config-if)# ip igmp version 3 | |
| **Step 7** | end | Returns to privileged EXEC mode. |
| Example: | Device(config)# end | |
| **Step 8** | show running-config | Verifies your entries. |
| Example: | Device# show running-config | |
| **Step 9** | copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| Example: | Device# copy running-config startup-config | |
Configuring Source Specific Multicast Mapping

The Source Specific Multicast (SSM) mapping feature supports SSM transition when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. You can use SSM mapping to leverage SSM for video delivery to legacy STBs that do not support IGMPv3 or for applications that do not use the IGMPv3 host stack.

Configuring Static SSM Mapping (CLI)

Follow these steps to configure static SSM Mapping:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp ssm-map enable`
4. `no ip igmp ssm-map query dns`
5. `ip igmp ssm-map static access-list source-address`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong> ip igmp ssm-map enable</td>
<td>Enables SSM mapping for groups in the configured SSM range.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ip igmp ssm-map enable</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> By default, this command enables DNS-based SSM mapping.</td>
</tr>
<tr>
<td><strong>Step 4</strong> no ip igmp ssm-map query dns</td>
<td>(Optional) Disables DNS-based SSM mapping.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# no ip igmp ssm-map query dns</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Disable DNS-based SSM mapping if you only want to rely on static SSM mapping. By default, the <code>ip igmp ssm-map</code> command enables DNS-based SSM mapping.</td>
</tr>
</tbody>
</table>
Purpose

Command or Action | Purpose
---|---
**Step 5**
ip igmp ssm-map static access-list source-address 172.16.8.11

Example:
Device(config)# ip igmp ssm-map static 11

Configures static SSM mapping.

- The ACL supplied for the `access-list` argument defines the groups to be mapped to the source IP address entered for the `source-address` argument.

**Note**
You can configure additional static SSM mappings. If additional SSM mappings are configured and the router receives an IGMPv1 or IGMPv2 membership report for a group in the SSM range, the device determines the source addresses associated with the group by walking each configured `ip igmp ssm-map static` command. The device associates up to 20 sources per group.

Repeat Step to configure additional static SSM mappings, if required.

**Step 6**
end

Example:
Device(config)# end

Returns to privileged EXEC mode.

**Step 7**
show running-config

Example:
Device# show running-config

Verifies your entries.

**Step 8**
copy running-config startup-config

Example:
Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

Configuring DNS-Based SSM Mapping (CLI)

To configure DNS-based SSM mapping, you need to create a DNS server zone or add records to an existing zone. If the routers that are using DNS-based SSM mapping are also using DNS for other purposes, you should use a normally configured DNS server. If DNS-based SSM mapping is the only DNS implementation being used on the router, you can configure a false DNS setup with an empty root zone or a root zone that points back to itself.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip igmp ssm-map enable`
4. `ip igmp ssm-map query dns`
5. `ip domain multicast domain-prefix`
6. `ip name-server server-address1 [server-address2...server-address6]`
7. Repeat Step 6 to configure additional DNS servers for redundancy, if required.
8. `end`
9. `show running-config`
10. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Enable</strong></td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>enters global configuration mode.</td>
</tr>
<tr>
<td><strong>configure terminal</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>enables SSM mapping for groups in a configured SSM range.</td>
</tr>
<tr>
<td><strong>ip igmp ssm-map enable</strong></td>
<td>Enables SSM mapping for groups in a configured SSM range.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ip igmp ssm-map enable</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>(Optional) enables DNS-based SSM mapping.</td>
</tr>
<tr>

</tbody>
</table>
### Configuring Static Traffic Forwarding with SSM Mapping (CLI)

Follow these steps to configure static traffic forwarding with SSM mapping on the last hop router:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp static-group group-address source ssm-map`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config)# ip name-server 10.48.81.21</code></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Repeat Step 6 to configure additional DNS servers for redundancy, if required.</td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# show running-config</code></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

</tbody>
</table>
| 3    | interface interface-id | Selects an interface on which to statically forward traffic for a multicast group using SSM mapping, and enters interface configuration mode. The specified interface must be one of the following:  
  - A routed port—A physical port that has been configured as a Layer 3 port by entering the **no switchport** interface configuration command.  
  - An SVI—A VLAN interface created by using the **interface vlan vlan-id** global configuration command. These interfaces must have IP addresses assigned to them. |
|      | Example: Device(config)# interface gigabitethernet 1/0/1 | |
| 4    | ip igmp static-group group-address source ssm-map | Configures SSM mapping to statically forward a (S, G) channel from the interface. Use this command if you want to statically forward SSM traffic for certain groups. Use DNS-based SSM mapping to determine the source addresses of the channels. |
|      | Example: Device(config-if)# ip igmp static-group 239.1.2.1 source ssm-map | |
| 5    | end | Returns to privileged EXEC mode. |
|      | Example: Device(config)# end | |
| 6    | show running-config | Verifies your entries. |
|      | Example: Device# show running-config | |
| 7    | copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
|      | Example: Device# copy running-config startup-config | |
Monitoring SSM

Use the privileged EXEC commands in the following table to monitor SSM.

**Table 47: Commands for Monitoring SSM**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip igmp groups detail</code></td>
<td>Displays the (S, G) channel subscription through IGMPv3.</td>
</tr>
<tr>
<td><code>show ip mroute</code></td>
<td>Displays whether a multicast group supports SSM service or whether a source-specific host report was received.</td>
</tr>
</tbody>
</table>

Monitoring SSM Mapping

Use the privileged EXEC commands in the following table to monitor SSM mapping.

**Table 48: SSM Mapping Monitoring Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device# show ip igmp ssm-mapping</code></td>
<td>Displays information about SSM mapping.</td>
</tr>
<tr>
<td><code>Device#show ip igmp ssm-mapping group-address</code></td>
<td>Displays the sources that SSM mapping uses for a particular group.</td>
</tr>
<tr>
<td>`Device#show ip igmp groups [group-name</td>
<td>Displays the multicast groups with receivers that are directly connected to the router and that were learned through IGMP.</td>
</tr>
<tr>
<td>group-address</td>
<td>interface-type interface-number]</td>
</tr>
<tr>
<td>[detail]</td>
<td></td>
</tr>
<tr>
<td><code>Device#show host</code></td>
<td>Displays the default domain name, the style of name lookup service, a list of name server hosts, and the cached list of hostnames and addresses.</td>
</tr>
<tr>
<td><code>Device#debug ip igmp group-address</code></td>
<td>Displays the IGMP packets received and sent and IGMP host-related events.</td>
</tr>
</tbody>
</table>

Where to Go Next for SSM

You can configure the following:

- IGMP
- PIM
- IP Multicast Routing
- Service Discovery Gateway

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Basic IP Multicast Routing

The following are the prerequisites for configuring basic IP multicast routing:

• To use this feature, the device or active device must be running the IP services feature set. The IP Services image contains complete multicast routing.

• You must configure the PIM version and the PIM mode in order to perform IP multicast routing. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting. You can configure an interface to be in the PIM dense mode, sparse mode, or sparse-dense mode.

• Enabling PIM on an interface also enables IGMP operation on that interface. (To participate in IP multicasting, the multicast hosts, routers, and multilayer device must have IGMP operating.)
If you enable PIM on multiple interfaces, when most of these interfaces are not on the outgoing interface list, and IGMP snooping is disabled, the outgoing interface might not be able to sustain line rate for multicast traffic because of the extra replication.

Restrictions for Basic IP Multicast Routing

The following are the restrictions for IP multicast routing:

- IP multicast routing is not supported on switches running the LAN base feature set.
- You cannot have a device stack containing a mix of Catalyst 3850 and Catalyst 3650 devices.

Information About Basic IP Multicast Routing

IP multicasting is an efficient way to use network resources, especially for bandwidth-intensive services such as audio and video. IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address.

The sending host inserts the multicast group address into the IP destination address field of the packet, and IP multicast routers and multilayer devices forward incoming IP multicast packets out all interfaces that lead to members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

Multicast Forwarding Information Base Overview

The device uses the Multicast Forwarding Information Base (MFIB) architecture and the Multicast Routing Information Base (MRIB) for IP multicast.

The MFIB architecture provides both modularity and separation between the multicast control plane (Protocol Independent Multicast [PIM] and Internet Group Management Protocol [IGMP]) and the multicast forwarding plane (MFIB). This architecture is used in Cisco IOS IPv6 multicast implementations.

MFIB itself is a multicast routing protocol independent forwarding engine; that is, it does not depend on PIM or any other multicast routing protocol. It is responsible for:

- Forwarding multicast packets
- Registering with the MRIB to learn the entry and interface flags set by the control plane
- Handling data-driven events that must be sent to the control plane
- Maintaining counts, rates, and bytes of received, dropped, and forwarded multicast packets
The MRIB is the communication channel between MRIB clients. Examples of MRIB clients are PIM, IGMP, the multicast routing (mroute) table, and the MFIB.

## Multicast Routing and Device Stacks

For all multicast routing protocols, the entire stack appears as a single router to the network and operates as a single multicast router.

In a device stack, the active device performs these functions:

- It is responsible for completing the IP multicast routing functions of the stack. It fully initializes and runs the IP multicast routing protocols.
- It builds and maintains the multicast routing table for the entire stack.
- It is responsible for distributing the multicast routing table to all stack members.

The stack members perform these functions:

- They act as multicast routing standby devices and are ready to take over if there is a active device failure.
  
  If the active device fails, all stack members delete their multicast routing tables. The newly elected active device starts building the routing tables and distributes them to the stack members.

- They do not build multicast routing tables. Instead, they use the multicast routing table that is distributed by the active device.

## Default IP Multicast Routing Configuration

This table displays the default IP multicast routing configuration.

How to Configure Basic IP Multicast Routing

Configuring Basic IP Multicast Routing

By default, multicast routing is disabled, and there is no default mode setting. This procedure is required.

Before you begin

You must configure the PIM version and the PIM mode. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting. In populating the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream devices or when there is a directly connected member on the interface. When forwarding from a LAN, sparse-mode operation occurs if there is an RP known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver’s first-hop router might send join messages toward the source to build a source-based distribution tree.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast-routing
4. interface interface-id
5. ip pim {dense-mode | sparse-mode | sparse-dense-mode}
6. end
7. show running-config
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>

<tr>
<td>Example:</td>
<td>Enter your password, if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
</tbody>
</table>
| 2    | `configure terminal`  
**Example:**  
Device# `configure terminal` | Enters global configuration mode. |
| 3    | `ip multicast-routing`  
**Example:**  
Device(config)# `ip multicast-routing` | Enables IP multicast routing. IP multicast routing is supported with Multicast Forwarding Information Base (MFIB) and Multicast Routing Information Base (MRIB). |
| 4    | `interface interface-id`  
**Example:**  
Device(config)# `interface gigabitethernet 1/0/1` | Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode. The specified interface must be one of the following:  
- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group.  
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface.  
These interfaces must have IP addresses assigned to them. |
| 5    | `ip pim {dense-mode | sparse-mode | sparse-dense-mode}`  
**Example:**  
Device(config-if)# `ip pim sparse-dense-mode` | Enables a PIM mode on the interface.  
By default, no mode is configured.  
The keywords have these meanings:  
- `dense-mode`—Enables dense mode of operation.  
- `sparse-mode`—Enables sparse mode of operation. If you configure sparse mode, you must also configure an RP.  
- `sparse-dense-mode`—Causes the interface to be treated in the mode in which the group belongs. Sparse-dense mode is the recommended setting.  
**Note** To disable PIM on an interface, use the `no ip pim` interface configuration command. |
You can use the following procedure to configure IPv4 Multicast Forwarding Information Base (MFIB) interrupt-level IP multicast forwarding of incoming packets or outgoing packets on the device.

**Note**
After you have enabled IP multicast routing by using the `ip multicast-routing` command, IPv4 multicast forwarding is enabled. Because IPv4 multicast forwarding is enabled by default, you can use the `no` form of the `ip mfib` command to disable IPv4 multicast forwarding.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip mfib
4. exit
5. show running-config
6. copy running-config startup-config

### Configuring a Static Multicast Route (mroute) (CLI)

You can use the following procedure to configure static mroutes. Static mroutes are similar to unicast static routes but differ in the following ways:

- Static mroutes are used to calculate RPF information, not to forward traffic.
- Static mroutes cannot be redistributed.
Static mroutes are strictly local to the device on which they are defined. Because Protocol Independent Multicast (PIM) does not have its own routing protocol, there is no mechanism to distribute static mroutes throughout the network. Consequently, the administration of static mroutes tends to be more complicated than the administration of unicast static routes.

When static mroutes are configured, they are stored on the device in a separate table referred to as the static mroute table. When configured, the `ip mroute` command enters a static mroute into the static mroute table for the source address or source address range specified for the source-address and mask arguments. Sources that match the source address or that fall in the source address range specified for the source-address argument will RPF to either the interface associated with the IP address specified for the `rpf-address` argument or the local interface on the device specified for the `interface-type` and `interface-number` arguments. If an IP address is specified for the `rpf-address` argument, a recursive lookup is done from the unicast routing table on this address to find the directly connected neighbor.

If there are multiple static mroutes configured, the device performs a longest-match lookup of the mroute table. When the mroute with the longest match (of the source-address) is found, the search terminates and the information in the matching static mroute is used. The order in which the static mroutes are configured is not important.

The administrative distance of an mroute may be specified for the optional distance argument. If a value is not specified for the distance argument, the distance of the mroute defaults to zero. If the static mroute has the same distance as another RPF source, the static mroute will take precedence. There are only two exceptions to this rule: directly connected routes and the default unicast route.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip mroute [vrf vrf-name] source-address mask { fallback-lookup {global | vrf vrf-name }[ protocol ] {rpf-address | interface-type interface-number} } [distance]
4. **exit**
5. **show running-config**
6. **copy running-config startup-config**

Configuring Optional IP Multicast Routing Features

Defining the IP Multicast Boundary (CLI)

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. access-list access-list-number deny source [source-wildcard]
4. interface interface-id
5. ip multicast boundary access-list-number
6. end
7. show running-config
8. copy running-config startup-config
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
   Example:  
   Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
   Example:  
   Device# configure terminal |
| **Step 3** access-list access-list-number deny source [source-wildcard] | Creates a standard access list, repeating the command as many times as necessary.  
   Example:  
   Device(config)# access-list 12 deny 224.0.1.39  
   access-list 12 deny 224.0.1.40  
   • For `access-list-number`, the range is 1 to 99.  
   • The `deny` keyword denies access if the conditions are matched.  
   • For `source`, enter multicast addresses 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.  
   • (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
   The access list is always terminated by an implicit deny statement for everything. |
| **Step 4** interface interface-id | Specifies the interface to be configured, and enters interface configuration mode.  
   Example:  
   Device(config)# interface gigabitethernet 1/0/1  
   The specified interface must be one of the following:  
   • A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command.  
   • An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command.  
   These interfaces must have IP addresses assigned to them. |
| **Step 5** ip multicast boundary access-list-number | Configures the boundary, specifying the access list you created in Step 2.  
   Example:  
   Device(config-if)# ip multicast boundary 12 |
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>

#### Step 6

**Example:**

Device(config)# end

#### Step 7

### Configuring sdr Listener Support

#### Enabling sdr Listener Support (CLI)

By default, the device does not listen to session directory advertisements.

This procedure is optional.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip sap listen
5. end
6. show running-config
7. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
## Enabling sdr Listener Support (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Example:**  
Device> `enable` | Enter your password, if prompted. |
| **Step 2**  
**Example:**  
Device# `configure terminal` | Enters global configuration mode. |
| **Step 3**  
**Example:**  
Device(config)# `interface interface-id`  
Device(config-if)# `interface gigabitethernet 1/0/1` | Specifies the interface to be enabled for sdr, and enters interface configuration mode.  

The specified interface must be one of the following:
- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 516
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 516

These interfaces must have IP addresses assigned to them. |
| **Step 4**  
**Example:**  
Device(config-if)# `ip sap listen` | Enables the device software to listen to session directory announcements. |
| **Step 5**  
**Example:**  
Device(config-if)# `end` | Returns to privileged EXEC mode. |
| **Step 6**  
**Example:** | Verifies your entries. |
### Purpose

Command or Action   | Purpose
--- | ---
**Device# show running-config** |  

### Step 7

**copy running-config startup-config**  
**Example:**  

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

### Limiting How Long an sdr Cache Entry Exists (CLI)

By default, entries are never deleted from the sdr cache. You can limit how long the entry remains active so that if a source stops advertising SAP information, old advertisements are not unnecessarily kept.

This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ip sap cache-timeout minutes
4. end
5. show running-config
6. show ip sap
7. copy running-config startup-config

### DETAILED STEPS

## Monitoring and Maintaining Basic IP Multicast Routing

### Clearing Caches, Tables, and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure are or suspected to be invalid.

You can use any of the privileged EXEC commands in the following table to clear IP multicast caches, tables, and databases.

**Table 50: Commands for Clearing Caches, Tables, and Databases**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ip igmp group [group [hostname</td>
<td>IP address]</td>
</tr>
<tr>
<td></td>
<td>vrf name group [hostname</td>
</tr>
<tr>
<td>clear ip mfib { counters [group</td>
<td>source]</td>
</tr>
<tr>
<td></td>
<td>counters [group</td>
</tr>
<tr>
<td>clear ip mrm {status-report [source ] }</td>
<td>IP multicast routing clear commands.</td>
</tr>
</tbody>
</table>
### Displaying System and Network Statistics

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

**Note**

This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 51: Commands for Displaying System and Network Statistics**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ping [group-name</td>
<td>group-address]</td>
</tr>
<tr>
<td>show ip igmp filter</td>
<td>Displays IGMP filter information.</td>
</tr>
<tr>
<td>show ip igmp groups [group-name</td>
<td>group-address</td>
</tr>
<tr>
<td>show ip igmp interface [type number]</td>
<td>Displays multicast-related information about an interface.</td>
</tr>
<tr>
<td>show ip igmp profile [ profile_number]</td>

<tr>
<td>`show ip pim rp-hash [group-name</td>
<td>group-address]`</td>
</tr>
<tr>
<td>`show ip pim tunnel [ tunnel</td>
<td>verbose ]`</td>
</tr>
<tr>
<td><code>show ip pim vrf name</code></td>
<td>Displays VPN routing and forwarding instances.</td>
</tr>
</tbody>
</table>
Command | Purpose
--- | ---
**show ip rpf** `{source-address | name}` | Displays how the device is doing Reverse-Path Forwarding (that is, from the unicast routing table, DVMRP routing table, or static mroutes).
Command parameters include:
- **Host name or IP address**—IP name or group address.
- **Select**—Group-based VRF select information.
- **vrf**—Selects VPN Routing/Forwarding instance.

**show ip sap** `[group | “session-name” | detail]` | Displays the Session Announcement Protocol (SAP) Version 2 cache.
Command parameters include:
- **A.B.C.D**—IP group address.
- **WORD**—Session name (in double quotes).
- **detail**—Session details.

**Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing**

You can use the privileged EXEC commands in the following table to monitor IP multicast routers, packets, and paths.

*Table 52: Commands for Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>mrinfo `{ [hostname</td>
<td>address]</td>
</tr>
<tr>
<td>mstat `{ [hostname</td>
<td>address]</td>
</tr>
<tr>
<td>mtrace `{ [hostname</td>
<td>address]</td>
</tr>
</tbody>
</table>

**Configuration Examples for IP Multicast Routing**

**Example: Configuring an IP Multicast Boundary**

This example shows how to set up a boundary for all administratively-scoped addresses:
Example: Responding to mrinfo Requests

The software answers mrinfo requests sent by mrouted systems and Cisco routers and multilayer devices. The software returns information about neighbors through DVMRP tunnels and all the routed interfaces. This information includes the metric (always set to 1), the configured TTL threshold, the status of the interface, and various flags. You can also use the mrinfo privileged EXEC command to query the router or device itself, as in this example:

Device# mrinfo
171.69.214.27 (mm1-7kd.cisco.com) [version cisco 11.1] [flags: PMS]:
171.69.214.27 -> 171.69.214.26 (mm1-r7kb.cisco.com) [1/0/pim/querier]
171.69.214.27 -> 171.69.214.25 (mm1-45a.cisco.com) [1/0/pim/querier]
171.69.214.33 -> 171.69.214.34 (mm1-45c.cisco.com) [1/0/pim]
171.69.214.137 -> 0.0.0.0 [1/0/pim/querier/down/leaf]
171.69.214.203 -> 0.0.0.0 [1/0/pim/querier/down/leaf]
171.69.214.18 -> 171.69.214.20 (mm1-45e.cisco.com) [1/0/pim]

Configuring Multicast Routing over GRE Tunnel

- Prerequisites for Configuring Multicast Routing over GRE Tunnel, on page 693
- Restrictions for Configuring Multicast Routing over GRE Tunnel, on page 693
- Information About Multicast Routing over GRE Tunnel, on page 693
- How to Configure Multicast Routing over GRE Tunnel, on page 694

Prerequisites for Configuring Multicast Routing over GRE Tunnel

Before configuring multicast routing over GRE, you should be familiar with the concepts of IP Multicast Routing Technology and GRE Tunneling.

Restrictions for Configuring Multicast Routing over GRE Tunnel

The following are the restrictions for configuring multicast routing over GRE tunnel:

- IPv6 multicast over GRE tunnel is not supported.
- The total number of supported multicast routes (mroutes) is 32000, across all tunnels.
  Use the formula 8000/(((Number of tunnels)/4) + 1) to derive the number of mroutes.
- Bidirectional PIM is not supported.
- Multicast routing should be configured on the first hop router (FHR), the rendezvous point (RP) and the last hop router (LHR) to support multicast over the GRE tunnel.
- On Catalyst 3650 series switches, the tunnel source can be a loopback, physical, or L3 EtherChannel interface.
- No feature interactions such as IPSec, ACL, Tunnel counters, Crypto support, Fragmentation, Cisco Discovery Protocol (CDP), QoS, GRE keepalive, Multipoint GRE, etc. are supported on the GRE Tunnel.

Information About Multicast Routing over GRE Tunnel

This chapter describes how to configure a Generic Route Encapsulation (GRE) tunnel to tunnel IP multicast packets between non-IP multicast areas. The benefit is that IP multicast traffic can be sent from a source to a
multicast group, over an area where IP multicast is not supported. Multicast Routing over GRE Tunnel supports
sparse mode and pim-smm mode; and supports static RP and auto-RP. See Rendezvous Point and Auto-RP for
information on configuring static RP and auto-RP.

Beginning in Cisco IOS XE Denali 16.3.1, multicast routing and NHRP are supported with GRE Tunneling.
NHRP can optionally be configured along with the multicast configuration on the tunnel interface to facilitate
dynamic discovery of tunnel end points. Please see NHRP for configuring NHRP on a tunnel interface.

Benefits of Tunneling to Connect Non-IP Multicast Areas

• If the path between a source and a group member (destination) does not support IP multicast, a tunnel
between them can transport IP multicast packets.

How to Configure Multicast Routing over GRE Tunnel

Configuring a GRE Tunnel to Connect Non-IP Multicast Areas

You can configure a GRE tunnel to transport IP multicast packets between a source and destination that are
connected by a medium that does not support multicast routing.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast-routing
4. interface tunnel number
5. ip address ip_address subnet_mask
6. ip pim sparse-mode
7. tunnel source { ip-address | interface-name }
8. tunnel destination { hostname | ip-address }
9. end
10. show interface type number

## Tunneling to Connect Non-IP Multicast Areas Example

The following example shows multicast-routing between a Catalyst 3650/3850 switch through a GRE tunnel.
Figure 36: Tunnel Connecting Non-IP Multicast Areas

In the figure above, the multicast source (10.1.1.1) is connected to Catalyst 3650/3850 Switch-1 and is configured for multicast group 239.1.1.20. The multicast receiver (10.2.2.3) is connected to Catalyst 3650/3850 Switch-2 and is configured to receive multicast packets for group 239.1.1.20. Separating Switch-1 and Switch-2 is an IP cloud, which is not configured for multicast routing.

A GRE tunnel is configured between Switch-1 to Switch-2 sourced with their loopback interfaces. Multicast-routing is enabled on Switch-1 and Switch-2. The **ip pim sparse-mode** command is configured on tunnel interfaces to support PIM in the sparse mode. Sparse mode configuration on the tunnel interfaces allows sparse-mode packets to be forwarded over the tunnel depending on rendezvous point (RP) configuration for the group.

**Switch-1 Configuration:**

```
Device(config)# ip multicast-routing
Device(config)# interface Loopback0  //Tunnel source interface
Device(config-if)# ip address 2.2.2.2 255.255.255.255
Device(config)# interface Tunnel 10  //Tunnel interface configured for PIM traffic
Device(config-if)# ip address 192.168.24.1 255.255.255.252
Device(config-if)# ip pim sparse-mode
Device(config-if)# ip nhrp map 192.168.24.3 4.4.4.4  //NHRP may optionally be configured to dynamically discover tunnel end points.
Device(config-if)# ip nhrp map multicast 4.4.4.4
Device(config-if)# ip nhrp network-id 1
Device(config-if)# tunnel source Loopback0
Device(config-if)# tunnel destination 4.4.4.4
Device(config)# interface GigabitEthernet 0/0/0  //Source interface
Device(config-if)# ip address 10.1.1.2 255.255.255.0
Device(config-if)# ip pim sparse-mode
```

**Switch-2 Configuration:**

```
Device(config)# ip multicast-routing
Device(config)# interface Loopback0  //Tunnel source interface
Device(config-if)# ip address 4.4.4.4 255.255.255.255
Device(config)# interface Tunnel 10  //Tunnel interface configured for PIM traffic
Device(config-if)# ip address 192.168.24.2 255.255.255.252
Device(config-if)# ip nhrp map 192.168.24.3 2.2.2.2  //NHRP may optionally be configured to dynamically discover tunnel end points.
Device(config-if)# ip nhrp map multicast 2.2.2.2
Device(config-if)# ip nhrp network-id 1
```
Device(config-if)# ip nhrp nhs 192.168.24.4
Device(config-if)# ip pim sparse-mode
Device(config-if)# tunnel source Loopback0
Device(config-if)# tunnel destination 2.2.2.2

Device(config)# interface GigabitEthernet 0/0/0  //Receiver interface
Device(config-if)# ip address 10.2.2.2 255.255.255.0
Device(config-if)# ip pim sparse-mode
Tunneling to Connect Non-IP Multicast Areas Example
Restrictions for Configuring the Service Discovery Gateway

The following are restrictions for configuring the Service Discovery Gateway:

- The Service Discovery Gateway does not support topologies with multiple hops. All network segments must be connected directly to it. The Service Discovery Gateway can learn services from all connected segments to build its cache and respond to requests acting as a proxy.

- The use of third-party mDNS servers or applications are not supported with this feature.

- On a Cat4500sup8e MC (3.7 ) running mDNS, iphone and ipads running iOS7.0 might have problems in accessing print services through mDNS.

Information about the Service Discovery Gateway and mDNS

mDNS

mDNS was defined to achieve zero configuration, with zero configuration being defined as providing the following features:

- Addressing—Allocating IP addresses to hosts
- Naming—Using names to refer to hosts instead of IP addresses
- Service discovery—Finding services automatically on the network
With mDNS, network users no longer have to assign IP addresses, assign host names, or type in names to access services on the network. Users only need to ask to see what network services are available, and choose from a list.

With mDNS, addressing is accomplished through the use of DHCP/DHCPv6 or IPv4 and IPv6 Link Local scoped addresses. The benefit of zero-configuration occurs when no infrastructure services such as DHCP or DNS are present and self-assigned link-local addressing can be used. The client can then select a random IPv4 address in the link-local range (169.254.0.0/24) or use its IPv6 link-local address (FE80::/10) for communication.

With mDNS, naming (name-to-address translation on a local network using mDNS) queries are sent over the local network using link-local scoped IP multicast. Because these DNS queries are sent to a multicast address (IPv4 address 224.0.0.251 or IPv6 address FF02::FB), no single DNS server with global knowledge is required to answer the queries. When a service or device sees a query for any service it is aware of, it provides a DNS response with the information from its cache.

With mDNS, service discovery is accomplished by browsing. An mDNS query is sent out for a given service type and domain, and any device that is aware of matching services replies with service information. The result is a list of available services for the user to choose from.

The mDNS protocol (mDNS-RFC), together with DNS Service Discovery (DNS-SD-RFC) achieves the zero-configuration addressing, naming, and service discovery.

mDNS-SD

Multicast DNS Service Discovery (mDNS-SD) uses DNS protocol semantics and multicast over well-known multicast addresses to achieve zero configuration service discovery. DNS packets are sent to and received on port 5353 using a multicast address of 224.0.0.251 and its IPv6 equivalent FF02::FB.

Because mDNS uses a link-local multicast address, its scope is limited to a single physical or logical LAN. If the networking reach needs to be extended to a distributed campus or to a wide-area environment consisting of many different networking technologies, mDNS gateway is implemented. An mDNS gateway provides a transport for mDNS packets across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain to another.

mDNS-SD Considerations for Wireless Clients

- mDNS packets can be sent out of Layer 3 interfaces that might not have an IP address.
- Packets with mDNS multicast IP and multicast MAC are sent on a multicast CAPWAP tunnel, if multicast-multicast mode is enabled. A multicast CAPWAP tunnel is a special CAPWAP tunnel used for reducing the number of copies of multicast packet that are required to be generated for each AP CAPWAP tunnel. Sending packets on the multicast CAPWAP tunnel requires the outer IP header to be destined to the multicast CAPWAP tunnel's address, which all APs are subscribed to.
- All mDNS packet handling is done at a foreign switch for roamed clients. A foreign switch is the new switch that a roamed wireless client is actually attached to, which is called the point of attachment.

Service Discovery Gateway

The Service Discovery Gateway feature enables multicast Domain Name System (mDNS) to operate across Layer 3 boundaries (different subnets). An mDNS gateway provides transport for service discovery across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain (subnet) to another. Prior to implementation of this feature, mDNS was limited in scope to within a subnet because of the use of link-local scoped multicast addresses. This feature enhances Bring Your Own Device (BYOD).
mDNS Gateway and Subnets

You need to enable an mDNS gateway for service discovery to operate across subnets. You can enable mDNS gateway for a device or for an interface.

**Note**
You need to configure service routing globally before configuring at the interface level.

After the device or interface is enabled, you can redistribute service discovery information across subnets. You can create service policies and apply filters on either incoming service discovery information (called IN-bound filtering) or outgoing service discovery information (called OUT-bound filtering).

**Note**
If redistribution is enabled globally, global configuration is given higher priority than interface configuration.

*Figure 37: Sample Networking Scenario*

For example, if the mDNS gateway functionality is enabled on the router in this figure, then service information can be sent from one subnet to another and vice-versa. For example, the printer and fax service information being advertised in the network with IP address 192.0.2.6 are redistributed to the network with IP address 198.51.100.4. The printer and fax service information in the network with IP address 192.0.2.6 is learned by mDNS-enabled hosts and devices in the other network.

**Filtering**

After configuring the mDNS gateway and subnets, you can filter services that you want to redistribute. While creating a service list, the **permit** or **deny** command options are used:

- The **permit** command option allows you to permit or transport specific service list information.
• The **deny** option allows you to deny service list information that is available to be transported to other subnets.

You need to include a sequence number when using the **permit** or **deny** command option. The same service list name can be associated with multiple sequence numbers and each sequence number will be mapped to a rule.

---

**Note**

If no filters are configured, then the default action is to deny service list information to be transported through the device or interface.

---

Query is another option provided when creating service lists. You can create queries using a service list. If you want to browse for a service, then active queries can be used. This function is helpful to keep the records refreshed in the cache.

---

**Note**

Active queries can only be used globally and cannot be used at the interface level.

---

A service end-point (such as a printer or fax) sends unsolicited announcements when a service starts up. After that, it sends unsolicited announcements whenever a network change event occurs (such as an interface coming up or going down). The device always respond to queries.

After creating a service list and using the **permit** or **deny** command options, you can filter using match statements (commands) based on **service-instance**, **service-type**, or **message-type** (announcement or query).

---

### How to Configure the Service Discovery Gateway

#### Configuring the Service List (CLI)

This procedure describes how to create a service list, apply a filter for the service list, and configure parameters for the service list name.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **service-list mdns-sd service-list-name {deny sequence-number | permit sequence-number | query}**
4. **match message-type {announcement | any | query}**
5. **match service-instance { LINE }**
6. **match service-type { LINE }**
7. **end**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action** | **Purpose**
--- | ---
Example: Device> enable | Enter your password, if prompted.

**Step 2**

- **configure terminal**
  **Example:**
  Device# configure terminal

  Enters global configuration mode.

**Step 3**

- **service-list mdns-sd service-list-name {deny sequence-number | permit sequence-number | query}**
  **Example:**
  Device(config)# service-list mdns-sd sl1 permit 3
  Device(config)# service-list mdns-sd sl4 query

  Enters mDNS service discovery service list mode. In this mode, you can:
  - Create a service list and apply a filter on the service list according to the **permit** or **deny** option applied to the sequence number.
  - Create a service list and associate a query for the service list name if the **query** option is used.

  **Note** The sequence number sets the priority of the rule. A rule with a lower sequence number is selected first and the service announcement or query is allowed or denied accordingly. You define the sequence number as per your network requirements.

**Step 4**

- **match message-type {announcement | any | query}**
  **Example:**
  Device(config-mdns-sd-sl)# match message-type announcement

  (Optional) Sets the message type to match. You can match the following message types:
  - announcement
  - any
  - query

  These commands configure the parameters for the service list name that is created in step 2.

If the **match message-type** is an announcement, then the service list rule only allows service advertisements or announcements for the device. If the **match message-type** is a query, then only a query from the client for a certain service in the network is allowed.

Multiple service maps of the same name with different sequence numbers can be created and the evaluation of the filters will be ordered on the sequence number. Service lists are an ordered sequence of individual statements, each one has a permit or deny result. Evaluation of service list consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches.
### Command or Action

<table>
<thead>
<tr>
<th>Step 5</th>
<th><code>match service-instance \{ LINE \}</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Device(config-mdns-sd-sl)# match service-instance servInst 1</code></td>
</tr>
</tbody>
</table>

(Optional) Sets the service instance to match.

This command configures the parameters for the service list name that is created in step 2.

**Note**: You cannot use the `match` command if you have used the `query` option in the previous step. The `match` command can be used only for the `permit` or `deny` option.

<table>
<thead>
<tr>
<th>Step 6</th>
<th><code>match service-type \{LINE \}</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Device(config-mdns-sd-sl)# match service-type _ipp._tcp</code></td>
</tr>
</tbody>
</table>

(Optional) Sets the value of the mDNS service type string to match.

This command configures the parameters for the service list name that is created in step 2.

**Note**: You cannot use the `match` command if you have used the `query` option in the previous step. The `match` command can be used only for the `permit` or `deny` option.

<table>
<thead>
<tr>
<th>Step 7</th>
<th><code>end</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Device(config-mdns-sd-sl)# end</code></td>
</tr>
</tbody>
</table>

Returns to privileged EXEC mode.

### Purpose

List scan is stopped once the first statement match is found and an action permit/deny associated with the statement match is performed. The default action after scanning through the entire list is to deny.

**Note**: You cannot use the `match` command if you have used the `query` option in the previous step. The `match` command can be used only for the `permit` or `deny` option.

### What to do next

Proceed to enable the mDNS gateway and redistribution of services.

### Enabling mDNS Gateway and Redistributing Services (CLI)

After enabling mDNS gateway for a device, you can apply filters (apply IN-bound filtering or OUT-bound filtering) and active queries by using `service-policy` and `service-policy-query` commands, respectively. You can redistribute services and service announcements using the `redistribute mdns-sd` command, and set some part of the system memory for cache using the `cache-memory-max` command.
By default, mDNS gateway is disabled on all interfaces.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. service-routing mdns-sd
4. service-policy service-policy-name {IN | OUT}
5. redistribute mdns-sd
6. cache-memory-max cache-config-percentage
7. service-policy-query service-list-query-name service-list-query-periodicity
8. exit
9. wireless multicast
10. no wireless mdns-bridging
11. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password, if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td>service-routing mdns-sd</td>
<td>Enables mDNS gateway functionality for a device and enters multicast DNS configuration (config-mdns) mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device (config)# service-routing mdns-sd</td>
</tr>
</tbody>
</table>

**Note**

This command enables the mDNS function globally.

**Note**

Enter the `service-routing mdns-sd source-interface if-name` command in either global-config or interface-config mode, to specify an alternate source interface for outgoing mDNS packets, so its IP address can be used when there is none configured on the outgoing interface.

### Configuration Examples

#### Example: Specify Alternative Source Interface for Outgoing mDNS Packets

The following example displays how to specify an alternate source interface for outgoing mDNS packets, so its IP address can be used when there is none configured on the outgoing interface.

```
Device(config)# service-routing mdns-sd
Device(config-mdns)# source-interface if-name
```

#### Example: Redistribute Service Announcements

The following example displays how to redistribute service announcements received on one interface over all the interfaces or over a specific interface.

```
Device(config)# service-routing mdns-sd
Device(config-mdns)# redistribute mdns-sd if-name
```
Example: Disable Bridging of mDNS Packets to Wireless Clients

The following example displays how to disable bridging of mDNS packets to wireless clients.

Device(config)# wireless multicast
Device(config)# no wireless mdns-bridging

Example: Creating a Service-List, Applying a Filter and Configuring Parameters

The following example shows the creation of a service-list sl1. The `permit` command option is being applied on sequence number 3 and all services with message-type announcement are filtered and available for transport across various subnets associated with the device.

Device# configure terminal
Device(config)# service-list mdns-sd sl1 permit 3
Device(config-mdns-sl)# match message-type announcement
Device(config-mdns)# exit

Example: Enabling mDNS Gateway and Redistributing Services

The following example shows how to enable an mDNS gateway for a device and enable redistribution of services across subnets. IN-bound filtering is applied on the service-list serv-pol1. Twenty percent of system memory is made available for cache and service-list-query periodicity is configured at 100 seconds.

Device# configure terminal
Device(config-mdns)# service-routing mdns-sd
Device(config-mdns)# service-policy serv-pol1 IN
Device(config-mdns)# redistribute mdns-sd
Device(config-mdns)# cache-memory-max 20
Device(config-mdns)# service-policy-query sl-query1 100
Device(config-mdns)# exit

Example: Global mDNS Configuration

The following example displays how to globally configure mDNS.

Device# configure terminal
Device(config)# service-list mdns-sd mypermit-all permit 10
Device(config-mdns-sl)# exit
Device(config)# service-list mdns-sd querier query
Device(config-mdns-sl)# service-type _dns._udp
Device(config-mdns-sl)# end
Device(config)# configure terminal
Device(config)# service-routing mdns-sd
Device(config-mdns)# service-policy mypermit-all IN
Device(config-mdns)# service-policy mypermit-all OUT
Example: Interface mDNS Configuration

The following example displays how to configure mDNS for an interface.

```
Device(config)#interface Vlan136
Device(config-if)#  description *** Mgmt VLAN ***
Device(config-if)#  ip address 9.7.136.10 255.255.255.0
Device(config-if)#  ip helper-address 9.1.0.100
Device(config-if)#  service-routing mdns-sd
Device(config-if-mdns-sd)#  service-policy mypermit-all IN
Device(config-if-mdns-sd)#  service-policy mypermit-all OUT
Device(config-if-mdns-sd)#  service-policy-query querier 60
```

Where to Go Next for Configuring Services Discovery Gateway

You can configure the following:

- IGMP
- Wireless Multicast
- PIM
- SSM
- IP Multicast Routing

IP Multicast Optimization: Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

Prerequisites for Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

- You must have PIM sparse mode running in your network.
- If you plan to use a group list to control to which groups the shortest-path tree (SPT) threshold applies, you must have configured your access list before performing the task.

Information About Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

PIM Registering Process

IP multicast sources do not use a signaling mechanism to announce their presence. Sources just send their data into the attached network, as opposed to receivers that use Internet Group Management Protocol (IGMP) to announce their presence. If a source sends traffic to a multicast group configured in PIM sparse mode (PIM-SM), the Designated Router (DR) leading toward the source must inform the rendezvous point (RP) about the presence of this source. If the RP has downstream receivers that want to receive the multicast traffic (natively) from this source and has not joined the shortest path leading toward the source, then the DR must
send the traffic from the source to the RP. The PIM registering process, which is individually run for each (S, G) entry, accomplishes these tasks between the DR and RP.

The registering process begins when a DR creates a new (S, G) state. The DR encapsulates all the data packets that match the (S, G) state into PIM register messages and unicasts those register messages to the RP.

If an RP has downstream receivers that want to receive register messages from a new source, the RP can either continue to receive the register messages through the DR or join the shortest path leading toward the source. By default, the RP will join the shortest path, because delivery of native multicast traffic provides the highest throughput. Upon receipt of the first packet that arrives natively through the shortest path, the RP will send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

If an RP has no downstream receivers that want to receive register messages from a new source, the RP will not join the shortest path. Instead, the RP will immediately send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

Once a routing entry is established for a source, a periodic rerегистering takes place between the DR and RP. One minute before the multicast routing table state times out, the DR will send one dataless register message to the RP each second that the source is active until the DR receives a register-stop message from the RP. This action restarts the timeout time of the multicast routing table entry, typically resulting in one rerегистering exchange every 2 minutes. Reregistering is necessary to maintain state, to recover from lost state, and to keep track of sources on the RP. It will take place independently of the RP joining the shortest path.

**PIM Version 1 Compatibility**

If an RP is running PIM Version 1, it will not understand dataless register messages. In this case, the DR will not send dataless register messages to the RP. Instead, approximately every 3 minutes after receipt of a register-stop message from the RP, the DR encapsulates the incoming data packets from the source into register messages and sends them to the RP. The DR continues to send register messages until it receives another register-stop message from the RP. The same behavior occurs if the DR is running PIM Version 1.

When a DR running PIM Version 1 encapsulates data packets into register messages for a specific (S, G) entry, the entry is process-switched, not fast-switched or hardware-switched. On platforms that support these faster paths, the PIM registering process for an RP or DR running PIM Version 1 may lead to periodic out-of-order packet delivery. For this reason, we recommend upgrading your network from PIM Version 1 to PIM Version 2.

**PIM Designated Router**

Devices configured for IP multicast send PIM hello messages to determine which device will be the designated router (DR) for each LAN segment (subnet). The hello messages contain the device’s IP address, and the device with the highest IP address becomes the DR.

The DR sends Internet Group Management Protocol (IGMP) host query messages to all hosts on the directly connected LAN. When operating in sparse mode, the DR sends source registration messages to the rendezvous point (RP).

By default, multicast devices send PIM router query messages every 30 seconds. By enabling a device to send PIM hello messages more often, the device can discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently. It is appropriate to make this change only on redundant devices on the edge of the network.
PIM Sparse-Mode Register Messages

Dataless register messages are sent at a rate of one message per second. Continuous high rates of register messages might occur if a DR is registering bursty sources (sources with high data rates) and if the RP is not running PIM Version 2.

By default, PIM sparse-mode register messages are sent without limiting their rate. Limiting the rate of register messages will limit the load on the DR and RP, at the expense of dropping those register messages that exceed the set limit. Receivers may experience data packet loss within the first second in which packets are sent from bursty sources.

Preventing Use of Shortest-Path Tree to Reduce Memory Requirement

Understanding PIM shared tree and source tree will help you understand how preventing the use of the shortest-path tree can reduce memory requirements.

PIM Shared Tree and Source Tree

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

Figure 38: Shared Tree and Source Tree (Shortest-Path Tree)

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

![Shared Tree and Source Tree](image)

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software devices to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.

4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.

5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.

6. By default, reception of the first data packet prompts Router C to send a join message toward the source.

7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.

8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the ip pim spt-threshold global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

**Related Topics**

Delaying the Use of PIM Shortest-Path Tree (CLI), on page 582

**Benefit of Preventing or Delaying the Use of the Shortest-Path Tree**

The switch from shared to source tree happens upon the arrival of the first data packet at the last hop device (Router C in PIM Shared Tree and Source Tree, on page 554). This switch occurs because the ip pim spt-threshold command controls that timing, and its default setting is 0 kbps.

The shortest-path tree requires more memory than the shared tree, but reduces delay. You might want to prevent or delay its use to reduce memory requirements. Instead of allowing the leaf device to move to the shortest-path tree immediately, you can prevent use of the SPT or specify that the traffic must first reach a threshold.

You can configure when a PIM leaf device should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the device triggers a PIM Join message toward the source to construct a source tree (shortest-path tree). If the infinity keyword is specified, all sources for the specified group use the shared tree, never switching to the source tree.
How to Optimize PIM Sparse Mode in a Large IP Multicast Deployment

Optimizing PIM Sparse Mode in a Large Deployment

Consider performing this task if your deployment of IP multicast is large.

Steps 3, 5, and 6 in this task are independent of each other and are therefore considered optional. Any one of these steps will help optimize PIM sparse mode. If you are going to perform Step 5 or 6, you must perform Step 4. Step 6 applies only to a designated router; changing the PIM query interval is only appropriate on redundant routers on the edge of the PIM domain.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim register-rate-limit rate
4. ip pim spt-threshold {kbps|infinity}[group-list access-list]
5. interface type number
6. ip pim query-interval period [msec]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>
<td>Example: Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example: Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>(Optional) Sets a limit on the maximum number of PIM sparse mode register messages sent per second for each (S, G) routing entry.</td>
</tr>
<tr>
<td>ip pim register-rate-limit rate</td>
<td></td>
</tr>
<tr>
<td>Example: Router(config)# ip pim register-rate-limit 10</td>
<td>• Use this command to limit the number of register messages that the designated router (DR) will allow for each (S, G) entry.</td>
</tr>
<tr>
<td></td>
<td>• By default, there is no maximum rate set.</td>
</tr>
<tr>
<td></td>
<td>• Configuring this command will limit the load on the DR and RP at the expense of dropping those register messages that exceed the set limit.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 4</strong> ip pim spt-threshold {kbps} {infinity} [group-list access-list]</td>
<td>Receivers may experience data packet loss within the first second in which register messages are sent from bursty sources.</td>
</tr>
</tbody>
</table>

**Example:**

Router(config)# ip pim spt-threshold infinity group-list 5

(Optional) Specifies the threshold that must be reached before moving to the shortest-path tree.

- The default value is 0, which causes the router to join the SPT immediately upon the first data packet it receives.
- Specifying the infinity keyword causes the router never to move to the shortest-path tree; it remains on the shared tree. This keyword applies to a multicast environment of “many-to-many” communication.
- The group list is a standard access list that controls which groups the SPT threshold applies to. If a value of 0 is specified or the group list is not used, the threshold applies to all groups.
- In the example, group-list 5 is already configured to permit the multicast groups 239.254.2.0 and 239.254.3.0; access-list 5 permit 239.254.2.0 0.0.0.255 access-list 5 permit 239.254.3.0 0.0.0.255

**Step 5** interface type number

**Example:**

Router(config)# interface ethernet 0

Configures an interface.

- If you do not want to change the default values of the PIM SPT threshold or the PIM query interval, do not perform this step; you are done with this task.

**Step 6** ip pim query-interval period [msec]

**Example:**

Router(config-if)# ip pim query-interval 1

(Optional) Configures the frequency at which multicast routers send PIM router query messages.

- Perform this step only on redundant routers on the edge of a PIM domain.
- The default query interval is 30 seconds.
- The period argument is in seconds unless the msec keyword is specified.
- Set the query interval to a smaller number of seconds for faster convergence, but keep in mind the trade-off between faster convergence and higher CPU and bandwidth usage.
Configuration Examples for Optimizing PIM Sparse Mode in a Large Multicast Deployment

Optimizing PIM Sparse Mode in a Large IP Multicast Deployment Example

The following example shows how to:

- Set the query interval to 1 second for faster convergence.
- Configure the router to never move to the SPT but to remain on the shared tree.
- Set a limit of 10 PIM sparse mode register messages sent per second for each (S, G) routing entry.

```
interface ethernet 0
  ip pim query-interval 1

ip pim spt-threshold infinity
ip pim register-rate-limit 10
```

IP Multicast Optimization: Multicast Subsecond Convergence

- Prerequisites for Multicast Subsecond Convergence, on page 719
- Restrictions for Multicast Subsecond Convergence, on page 719
- Information About Multicast Subsecond Convergence, on page 719
- How to Configure Multicast Subsecond Convergence, on page 721
- Configuration Examples for Multicast Subsecond Convergence, on page 725
- Additional References, on page 726
- Feature History and Information for Multicast Subsecond Convergence, on page 726

Prerequisites for Multicast Subsecond Convergence

Service providers must have a multicast-enabled core in order to use the Cisco Multicast Subsecond Convergence feature.

Restrictions for Multicast Subsecond Convergence

Devices that use the subsecond designated router (DR) failover enhancement must be able to process hello interval information arriving in milliseconds. Devices that are congested or do not have enough CPU cycles to process the hello interval can assume that the Protocol Independent Multicast (PIM) neighbor is disconnected, although this may not be the case.

Information About Multicast Subsecond Convergence

Benefits of Multicast Subsecond Convergence

- The scalability components improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content).
- New algorithms and processes (such as aggregated join messages, which deliver up to 1000 individual messages in a single packet) reduce the time to reach convergence by a factor of 10.
• Multicast subsecond convergence improves service availability for large multicast networks.
• Multicast users such as financial services firms and brokerages receive better quality of service (QoS), because multicast functionality is restored in a fraction of the time previously required.

**Multicast Subsecond Convergence Scalability Enhancements**

The Multicast Subsecond Convergence feature provides scalability enhancements that improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content). Scalability enhancements in this release include the following:

• Improved Internet Group Management Protocol (IGMP) and PIM state maintenance through new timer management techniques
• Improved scaling of the Multicast Source Discovery Protocol (MSDP) Source-Active (SA) cache

The scalability enhancements provide the following benefits:

• Increased potential PIM multicast route (mroute), IGMP, and MSDP SA cache state capacity
• Decreased CPU usage

**PIM Router Query Messages**

Multicast subsecond convergence allows you to send PIM router query messages (PIM hellos) every few milliseconds. The PIM hello message is used to locate neighboring PIM devices. Before the introduction of this feature, the device could send the PIM hellos only every few seconds. By enabling a device to send PIM hello messages more often, this feature allows the device to discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently.

**Reverse Path Forwarding**

Unicast Reverse Path Forwarding (RPF) helps to mitigate problems caused by the introduction of malformed or forged IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. Malformed or forged source addresses can indicate denial-of-service (DoS) attacks based on source IP address spoofing.

RPF uses access control lists (ACLs) in determining whether to drop or forward data packets that have malformed or forged IP source addresses. An option in the ACL commands allows system administrators to log information about dropped or forwarded packets. Logging information about forged packets can help in uncovering information about possible network attacks.

Per-interface statistics can help system administrators quickly discover the interface serving as the entry point for an attack on the network.

**RPF Checks**

PIM is designed to forward IP multicast traffic using the standard unicast routing table. PIM uses the unicast routing table to decide if the source of the IP multicast packet has arrived on the optimal path from the source. This process, the RPF check, is protocol-independent because it is based on the contents of the unicast routing table and not on any particular routing protocol.
Triggered RPF Checks

Multicast subsecond convergence provides the ability to trigger a check of RPF changes for mroute states. This check is triggered by unicast routing changes. By performing a triggered RPF check, users can set the periodic RPF check to a relatively high value (for example, 10 seconds) and still fail over quickly.

The triggered RPF check enhancement reduces the time needed for service to be restored after disruption, such as for single service events (for example, in a situation with one source and one receiver) or as the service scales along any parameter (for example, many sources, many receivers, and many interfaces). This enhancement decreases in time-to-converge PIM (mroute), IGMP, and MSDP (SA cache) states.

RPF Failover

In an unstable unicast routing environment that uses triggered RPF checks, the environment could be constantly triggering RPF checks, which places a burden on the resources of the device. To avoid this problem, use the `ip multicast rpf backoff` command to prevent a second triggered RPF check from occurring for the length of time configured. That is, the PIM “backs off” from another triggered RPF check for a minimum amount of milliseconds as configured by the user.

If the backoff period expires without further routing table changes, PIM then scans for routing changes and accordingly establishes multicast RPF changes. However, if more routing changes occur during the backoff period, PIM doubles the backoff period to avoid overloading the device with PIM RPF changes while the routing table is still converging.

Topology Changes and Multicast Routing Recovery

The Multicast Subsecond Convergence feature set enhances both enterprise and service provider network backbones by providing almost instantaneous recovery of multicast paths after unicast routing recovery.

Because PIM relies on the unicast routing table to calculate its RPF when a change in the network topology occurs, unicast protocols first need to calculate options for the best paths for traffic, and then multicast can determine the best path.

Multicast subsecond convergence allows multicast protocol calculations to finish almost immediately after the unicast calculations are completed. As a result, multicast traffic forwarding is restored substantially faster after a topology change.

How to Configure Multicast Subsecond Convergence

Modifying the Periodic RPF Check Interval

Perform this optional task to modify the intervals at which periodic RPF checks occur.

Note

Cisco recommends that you do not change the default values for the `ip rpf interval` command. The default values allow subsecond RPF failover. The default interval at which periodic RPF checks occur is 10 seconds.
SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast rpf interval seconds [list access-list | route-map route-map]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td>Step 3 ip multicast rpf interval seconds [list access-list</td>
<td>route-map route-map]</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ip multicast rpf interval 10</td>
</tr>
</tbody>
</table>

Configuring PIM RPF Failover Intervals

Perform this optional task to configure the intervals at which PIM RPF failover will be triggered by changes in the routing tables.

Note
Cisco recommends that you do not modify the default values for the ip multicast rpf backoff command. The default values allow subsecond RPF failover.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast rpf backoff minimum maximum [disable]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

Verifying Multicast Subsecond Convergence Configurations

Perform this task to display detailed information about and to verify information regarding the Multicast Subsecond Convergence feature.

SUMMARY STEPS

1. enable
2. show ip pim interface type number
3. show ip pim neighbor

DETAILED STEPS

Step 1  enable
Example:

Device> enable
Enables privileged EXEC mode.
   • Enter your password if prompted.

Step 2  show ip pim interface type number
Use this command to display information about interfaces configured for PIM.
The following is sample output from the show ip pim interface command:

Example:

Device# show ip pim interface GigabitEthernet 1/0/0
Address Interface Ver/ Nbr Query DR DR
Mode Count Intvl Prior
172.16.1.4 GigabitEthernet1/0/0 v2/S 1 100 ms 1 172.16.1.4

Step 3  show ip pim neighbor
Use this command to display the PIM neighbors discovered by the Cisco IOS XE software.
The following is sample output from the show ip pim neighbor command:

Example:

Device# show ip pim neighbor
PIM Neighbor Table
Neighbor Interface Uptime/Expires Ver DR Prio/Mode
Address Address
172.16.1.3 GigabitEthernet1/0/0 00:03:41/250 msec v2 1 / S
Configuration Examples for Multicast Subsecond Convergence

Example Modifying the Periodic RPF Check Interval

In the following example, the `ip multicast rpf interval` command has been set to 10 seconds. This command does not show up in `show running-config` output unless the interval value has been configured to be the nondefault value.

```plaintext
! ip multicast-routing
ip multicast rpf interval 10
! interface Ethernet0/0
  ip address 172.16.2.1 255.255.255.0
! ip pim sparse-mode
!
```

Example Configuring PIM RPF Failover Intervals

In the following example, the `ip multicast rpf backoff` command has been configured with a minimum backoff interval value of 100 and a maximum backoff interval value of 2500. This command does not show up in `show running-config` command output unless the interval value has been configured to be the nondefault value.

```plaintext
! ip multicast-routing
! ip multicast rpf backoff 100 2500
!
interface Ethernet0/0
  ip address 172.16.2.1 255.255.255.0
! ip pim sparse-mode
!
```

Modifying the PIM Router Query Message Interval Example

In the following example, the `ip pim query-interval` command has been set to 100 milliseconds. This command does not show up in `show running-config` command output unless the interval value has been configured to be the nondefault value.

```plaintext
!
```
interface gigabitethernet0/0/1
  ip address 172.16.2.1 255.255.255.0
  ip pim query-interval 100 msec
  ip pim sparse-mode

Prerequisites for IP Multicast Load Splitting across Equal-Cost Paths

IP multicast is enabled on the device using the tasks described in the “Configuring Basic IP Multicast” module of the IP Multicast: PIM Configuration Guide.

Information about IP Multicast Load Splitting across Equal-cost Paths

Load Splitting Versus Load Balancing

Load splitting and load balancing are not the same. Load splitting provides a means to randomly distribute (*, G) and (S, G) traffic streams across multiple equal-cost reverse path forwarding (RPF) paths, which does not necessarily result in a balanced IP multicast traffic load on those equal-cost RPF paths. By randomly distributing (*, G) and (S, G) traffic streams, the methods used for load splitting IP multicast traffic attempt to distribute an equal amount of traffic flows on each of the available RPF paths not by counting the flows, but, rather, by making a pseudorandom decision. These methods are collectively referred to as equal-cost multipath (ECMP) multicast load splitting methods and result in better load-sharing in networks where there are many traffic streams that utilize approximately the same amount of bandwidth.
If there are just a few (S, G) or (*, G) states flowing across a set of equal-cost links, the chance that they are well balanced is quite low. To overcome this limitation, precalculated source addresses—for (S, G) states or rendezvous point (RP) addresses for (*, G) states, can be used to achieve a reasonable form of load balancing. This limitation applies equally to the per-flow load splitting in Cisco Express Forwarding (CEF) or with EtherChannels: As long as there are only a few flows, those methods of load splitting will not result in good load distribution without some form of manual engineering.

**Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist**

By default, for Protocol Independent Multicast sparse mode (PIM-SM), Source Specific Multicast (PIM-SSM), bidirectional PIM (bidir-PIM), groups, if multiple equal-cost paths are available, Reverse Path Forwarding (RPF) for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address. This method is referred to as the highest PIM neighbor behavior. This behavior is in accordance with RFC 2362 for PIM-SM, but also applies to PIM-SSM, and bidir-PIM.

The figure illustrates a sample topology that is used in this section to explain the default behavior for IP multicast when multiple equal-cost paths exist.

---

**Note**

Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

---

**Figure 39: Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist**

In the figure, two sources, S1 and S2, are sending traffic to IPv4 multicast groups, G1 and G2. Either PIM-SM, PIM-SSM can be used in this topology. If PIM-SM is used, assume that the default of 0 for the `ip pim spt-threshold` command is being used on Device 2, that an Interior Gateway Protocol (IGP) is being run, and that the output of the `show ip route` command for S1 and for S2 (when entered on Device 2) displays serial interface 0 and serial interface 1 on Device 1 as equal-cost next-hop PIM neighbors of Device 2.

Without further configuration, IPv4 multicast traffic in the topology illustrated in the figure would always flow across one serial interface (either serial interface 0 or serial interface 1), depending on which interface has the higher IP address. For example, suppose that the IP addresses configured on serial interface 0 and serial interface 1 on Device 1 are 10.1.1.1 and 10.1.2.1, respectively. Given that scenario, in the case of PIM-SM and PIM-SSM, Device 2 would always send PIM join messages towards 10.1.2.1 and would always receive IPv4 multicast traffic on serial interface 1 for all sources and groups shown in the figure.

IPv4 RPF lookups are performed by intermediate multicast device to determine the RPF interface and RPF neighbor for IPv4 (*,G) and (S, G) multicast routes (trees). An RPF lookup consists of RPF route-selection and route-path-selection. RPF route-selection operates solely on the IP unicast address to identify the root of...
the multicast tree. For (*, G) routes (PIM-SM and Bidir-PIM), the root of the multicast tree is the RP address for the group G; for (S, G) trees (PIM-SM, PIM-SSM, the root of the multicast tree is the source S. RPF route-selection finds the best route towards the RP or source in the routing information base (RIB), and, if configured (or available), the Distance Vector Multicast Routing Protocol (DVMRP) routing table, the Multiprotocol Border Gateway Protocol (MBGP) routing table or configured static mroutes. If the resulting route has only one available path, then the RPF lookup is complete, and the next-hop device and interface of the route become the RPF neighbor and RPF interface of this multicast tree. If the route has more than one path available, then route-path-selection is used to determine which path to choose.

For IP multicast, the following route-path-selection methods are available:

---

**Note**

All methods but the default method of route-path-selection available in IP multicast enable some form of ECMP multicast load splitting.

- Highest PIM neighbor--This is the default method; thus, no configuration is required. If multiple equal-cost paths are available, RPF for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address; as a result, without configuration, ECMP multicast load splitting is disabled by default.

- ECMP multicast load splitting method based on source address--You can configure ECMP multicast load splitting using the `ip multicast multipath` command. Entering this form of the `ip multicast multipath` command enables ECMP multicast load splitting based on source address using the S-hash algorithm. For more information, see the ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm, on page 730 section.

- ECMP multicast load splitting method based on source and group address--You can configure ECMP multicast load splitting using the `ip multicast multipath` command with the `s-g-hash` and `basic` keywords. Entering this form of the `ip multicast multipath` command enables ECMP multicast load splitting based on source and group address using the basic S-G-hash algorithm. For more information, see the ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm, on page 730 section.

- ECMP multicast load splitting method based on source, group, and next-hop address--You can configure ECMP multicast load splitting using the `ip multicast multipath` command with the `s-g-hash` and `next-hop-based` keywords. Entering this form of the command enables ECMP multicast load splitting based on source, group, and next-hop address using the next-hop-based S-G-hash algorithm. For more information, see the ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address, on page 732 section.

The default behavior (the highest PIM neighbor behavior) does not result in any form of ECMP load-splitting in IP multicast, but instead selects the PIM neighbor that has the highest IP address among the next-hop PIM neighbors for the available paths. A next hop is considered to be a PIM neighbor when it displays in the output of the `show ip pim neighbor` command, which is the case when PIM hello messages have been received from it and have not timed out. If none of the available next hops are PIM neighbors, then simply the next hop with the highest IP address is chosen.

### Methods to Load Split IP Multicast Traffic

In general, the following methods are available to load split IP multicast traffic:

- You can enable ECMP multicast load splitting based on source address, based on source and group address, or based on source, group, and next-hop address. After the equal-cost paths are recognized,
ECMP multicast load splitting operates on a per (S, G) basis, rather than a per packet basis as in unicast traffic.

- Alternative methods to load split IP multicast are to consolidate two or more equal-cost paths into a generic routing encapsulation (GRE) tunnel and allow the unicast routing protocol to perform the load splitting, or to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, Multilink PPP (MLPPP) link bundles, or Multilink Frame Relay (FR.16) link bundles.

### Overview of ECMP Multicast Load Splitting

By default, ECMP multicast load splitting of IPv4 multicast traffic is disabled. ECMP multicast load splitting can be enabled using the `ip multicast multipath` command.

#### ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm

ECMP multicast load splitting traffic based on source address uses the S-hash algorithm, enabling the RPF interface for each (*, G) or (S, G) state to be selected among the available equal-cost paths, depending on the RPF address to which the state resolves. For an (S, G) state, the RPF address is the source address of the state; for a (*, G) state, the RPF address is the address of the RP associated with the group address of the state.

When ECMP multicast load splitting based on source address is configured, multicast traffic for different states can be received across more than just one of the equal-cost interfaces. The method applied by IPv4 multicast is quite similar in principle to the default per-flow load splitting in IPv4 CEF or the load splitting used with Fast and Gigabit EtherChannels. This method of ECMP multicast load splitting, however, is subject to polarization.

#### ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm

ECMP multicast load splitting based on source and group address uses a simple hash, referred to as the basic S-G-hash algorithm, which is based on source and group address. The basic S-G-hash algorithm is predictable because no randomization is used in coming up with the hash value. The S-G-hash mechanism, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device this hash is being calculated on.

---

**Note**

The basic S-G-hash algorithm ignores bidir-PIM groups.

### Predictability As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The method used by ECMP multicast load splitting in IPv4 multicast allows for consistent load splitting in a network where the same number of equal-cost paths are present in multiple places in a topology. If an RP address or source addresses are calculated once to have flows split across N paths, then they will be split...
across those N paths in the same way in all places in the topology. Consistent load splitting allows for predictability, which, in turn, enables load splitting of IPv4 multicast traffic to be manually engineered.

**Polarization As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms**

The hash mechanism used in IPv4 multicast to load split multicast traffic by source address or by source and group address is subject to a problem usually referred to as polarization. A by-product of ECMP multicast load splitting based on source address or on source and group address, polarization is a problem that prevents routers in some topologies from effectively utilizing all available paths for load splitting.

The figure illustrates a sample topology that is used in this section to explain the problem of polarization when configuring ECMP multicast load splitting based on source address or on source and group address.

**Note**

Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

![Figure 40: Polarization Topology](image)

In the topology illustrated in the figure, notice that Router 7 has two equal-cost paths towards the sources, S1 to S10, through Router 5 and Router 6. For this topology, suppose that ECMP multicast load splitting is enabled with the `ip multicast multipath` command on all routers in the topology. In that scenario, Router 7 would apply equal-cost load splitting to the 10 (S, G) states. The problem of polarization in this scenario would affect Router 7 because that router would end up choosing serial interface 0 on Router 5 for sources S1 to S5 and serial interface 1 on Router 6 for sources S6 to S10. The problem of polarization, furthermore, would also affect Router 5 and Router 6 in this topology. Router 5 has two equal-cost paths for S1 to S5 through serial interface 0 on Router 1 and serial interface 1 on Router 2. Because Router 5 would apply the same hash algorithm to select which of the two paths to use, it would end up using just one of these two upstream paths for sources S1 to S5; that is, either all the traffic would flow across Router 1 and Router 5 or across Router 2 and Router 5. It would be impossible in this topology to utilize Router 1 and Router 5 and Router 2 and Router 5 for load splitting. Likewise, the polarization problem would apply to Router 3 and Router 6 and Router 4 and Router 6; that is, it would be impossible in this topology to utilize both Router 3 and Router 6 and Router 4 and Router 6 for load splitting.
ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address

Configuring ECMP multicast load splitting based on source, group, and next-hop address enables a more complex hash, the next-hop-based S-G-hash algorithm, which is based on source, group, and next-hop address. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

Note
The next-hop-based S-G-hash algorithm in IPv4 multicast is the same algorithm used in IPv6 ECMP multicast load splitting, which, in turn, utilizes the same hash function used for PIM-SM bootstrap device (BSR).

The next-hop-based hash mechanism does not produce polarization and also maintains better RPF stability when paths fail. These benefits come at the cost that the source or RP IP addresses cannot be used to reliably predict and engineer the outcome of load splitting when the next-hop-based S-G-hash algorithm is used. Because many customer networks have implemented equal-cost multipath topologies, the manual engineering of load splitting, thus, is not a requirement in many cases. Rather, it is more of a requirement that the default behavior of IP multicast be similar to IP unicast; that is, it is expected that IP multicast use multiple equal-cost paths on a best-effort basis. Load splitting for IPv4 multicast, therefore, could not be enabled by default because of the anomaly of polarization.

Note
Load splitting for CEF unicast also uses a method that does not exhibit polarization and likewise cannot be used to predict the results of load splitting or engineer the outcome of load splitting.

The next-hop-based hash function avoids polarization because it introduces the actual next-hop IP address of PIM neighbors into the calculation, so the hash results are different for each device, and in effect, there is no problem of polarization. In addition to avoiding polarization, this hash mechanism also increases stability of the RPF paths chosen in the face of path failures. Consider a device with four equal-cost paths and a large number of states that are load split across these paths. Suppose that one of these paths fails, leaving only three available paths. With the hash mechanism used by the polarizing hash mechanisms (the hash mechanism used by the S-hash and basic S-G-hash algorithms), the RPF paths of all states would likely reconverge and thus change between those three paths, especially those paths that were already using one of those three paths. These states, therefore, may unnecessarily change their RPF interface and next-hop neighbor. This problem exists simply because the chosen path is determined by taking the total number of paths available into consideration by the algorithm, so once a path changes, the RPF selection for all states is subject to change too. For the next-hop-based hash mechanism, only the states that were using the changed path for RPF would need to reconverge onto one of the three remaining paths. The states that were already using one of those paths would not change. If the fourth path came back up, the states that initially used it would immediately reconverge back to that path without affecting the other states.

Note
The next-hop-based S-G-hash algorithm ignores bidir-PIM groups.
Effect of ECMP Multicast Load Splitting on PIM Neighbor Query and Hello Messages for RPF Path Selection

If load splitting of IP multicast traffic over ECMP is not enabled and there are multiple equal-cost paths towards an RP or a source, IPv4 multicast will first elect the highest IP address PIM neighbor. A PIM neighbor is a device from which PIM hello (or PIMv1 query) messages are received. For example, consider a device that has two equal-cost paths learned by an IGP or configured through two static routes. The next hops of these two paths are 10.1.1.1 and 10.1.2.1. If both of these next-hop devices send PIM hello messages, then 10.1.2.1 would be selected as the highest IP address PIM neighbor. If only 10.1.1.1 sends PIM hello messages, then 10.1.1.1 would be selected. If neither of these devices sends PIM hello messages, then 10.1.2.1 would be selected. This deference to PIM hello messages allows the construction of certain types of dynamic failover scenarios with only static multicast routes (mroutes); it is otherwise not very useful.

Note
For more information about configuring static mroutes, see the Configuring Multiple Static Mroutes in Cisco IOS configuration note on the Cisco IOS IP multicast FTP site, which is available at: ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt.

When load splitting of IP multicast traffic over ECMP is enabled, the presence of PIM hello message from neighbors is not considered; that is, the chosen RPF neighbor does not depend on whether or not PIM hello messages are received from that neighbor--it only depends on the presence or absence of an equal-cost route entry.

Effect of ECMP Multicast Loading Splitting on Assert Processing in PIM-DM and DF Election in Bidir-PIM

The ip multicast multipath command only changes the RPF selection on the downstream device; it does not have an effect on designated forwarder (DF) election in bidir-PIM or the assert processing on upstream devices in PIM-DM.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on assert processing in PIM-DM and DF election in bidir-PIM.

Note
Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.
In the figure, Device 2 has two equal-cost paths to S1 and S2 and the RP addresses on Device 1. Both paths are across Gigabit Ethernet interface 1/0/0: one path towards Device 3 and one path towards Device 4. For PIM-SM and PIM-SSM (*, G) and (S, G) RPF selection, there is no difference in the behavior of Device 2 in this topology versus Device 2 in the topology illustrated in the figure. There is, however, a difference when using PIM-DM or bidir-PIM.

If PIM-DM is used in the topology illustrated in the figure, Device 3 and Device 4 would start flooding traffic for the states onto Gigabit Ethernet interface 1/0/0 and would use the PIM assert process to elect one device among them to forward the traffic and to avoid traffic duplication. As both Device 3 and Device 4 would have the same route cost, the device with the higher IP address on Gigabit Ethernet interface 1/0/0 would always win the assert process. As a result, if PIM-DM is used in this topology, traffic would not be load split across Device 3 and Device 4.

If bidir-PIM is used in the topology illustrated in the figure, a process called DF election would take place between Device 2, Device 3, and Device 4 on Gigabit Ethernet interface 1/0/0. The process of DF election would elect one device for each RP to forward traffic across Gigabit Ethernet interface 1/0/0 for any groups using that particular RP, based on the device with the highest IP address configured for that interface. Even if multiple RPs are used (for example one for G1 and another one for G2), the DF election for those RPs would always be won by the device that has the higher IP address configured on Gigabit Ethernet interface 1/0/0 (either Device 3 or Device 4 in this topology). The election rules used for DF election are virtually the same as the election rules used for the PIM assert process, only the protocol mechanisms to negotiate them are more refined for DF election (in order to return the results more expediently). As a result, when bidir-PIM is used in this topology, load splitting would always occur across Gigabit Ethernet interface 1/0/0.

The reason that ECMP multicast load splitting does influence the RPF selection but not the assert process in PIM-DM or DF election in bidir-PIM is because both the assert process and DF election are cooperative processes that need to be implemented consistently between participating devices. Changing them would require some form of protocol change that would also need to be agreed upon by the participating devices. RPF selection is a purely device local policy and, thus, can be enabled or disabled without protocol changes individually on each device.

For PIM-DM and bidir-PIM, configuring ECMP multicast load splitting with the `ip multicast multipath` command is only effective in topologies where the equal-cost paths are not upstream PIM neighbors on the same LAN, but rather neighbors on different LANs or point-to-point links.
Effect of ECMP Multicast Load Splitting on the PIM Assert Process in PIM-SM and PIM-SSM

There are also cases where ECMP multicast load splitting with the `ip multicast multipath` command can become ineffective due to the PIM assert process taking over, even when using PIM-SM with (*, G) or (S, G) forwarding or PIM-SSM with (S, G) forwarding.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on the PIM assert process in PIM-SM and PIM-SSM.

Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

**Figure 42: ECMP Multicast Load Splitting and the PIM Assert Process in PIM-SM and PIM-SSM**

In the topology illustrated in the figure, if both Device 2 and Device 5 are Cisco devices and are consistently configured for ECMP multicast load splitting with the `ip multicast multipath` command, then load splitting would continue to work as expected; that is, both devices would have Device 3 and Device 4 as equal-cost next hops and would sort the list of equal-cost paths in the same way (by IP address). When applying the multipath hash function, for each (S, G) or (*, G) state, they would choose the same RPF neighbor (either Device 3 or Device 4) and send their PIM joins to this neighbor.

If Device 5 and Device 2 are inconsistently configured with the `ip multicast multipath` command, or if Device 5 is a third-party device, then Device 2 and Device 5 may choose different RPF neighbors for some (*, G) or (S, G) states. For example, Device 2 could choose Device 3 for a particular (S, G) state or Device 5 could choose Device 4 for a particular (S, G) state. In this scenario, Device 3 and Device 4 would both start to forward traffic for that state onto Gigabit Ethernet interface 1/0/0, see each other’s forwarded traffic, and--to avoid traffic duplication--start the assert process. As a result, for that (S, G) state, the device with the higher IP address for Gigabit Ethernet interface 1/0/0 would forward the traffic. However, both Device 2 and Device 5 would be tracking the winner of the assert election and would send their PIM joins for that state to this assert winner, even if this assert winner is not the same device as the one that they calculated in their RPF selection. For PIM-SM and PIM-SSM, therefore, the operation of ECMP multicast load splitting can only be guaranteed when all downstream devices on a LAN are consistently configured Cisco devices.
ECMP Multicast Load Splitting and Reconvergence When Unicast Routing Changes

When unicast routing changes, all IP multicast routing states reconverge immediately based on the available unicast routing information. Specifically, if one path goes down, the remaining paths reconverge immediately, and if the path comes up again, multicast forwarding will subsequently reconverge to the same RPF paths that were used before the path failed. Reconvergence occurs whether load splitting of IP multicast traffic over ECMP is configured or not.

Use of BGP with ECMP Multicast Load Splitting

ECMP multicast load splitting works with RPF information learned through BGP in the same way as with RPF information learned from other protocols: It chooses one path out of the multiple paths installed by the protocol. The main difference with BGP is that it only installs a single path, by default. For example, when a BGP speaker learns two identical external BGP (eBGP) paths for a prefix, it will choose the path with the lowest device ID as the best path. The best path is then installed in the IP routing table. If BGP multipath support is enabled and the eBGP paths are learned from the same neighboring AS, instead of picking the single best path, BGP installs multiple paths in the IP routing table. By default, BGP will install only one path to the IP routing table.

To leverage ECMP multicast load splitting for BGP learned prefixes, you must enable BGP multipath. Once configured, when BGP installs the remote next-hop information, RPF lookups will execute recursively to find the best next hop towards that BGP next hop (as in unicast). If for example there is only a single BGP path for a given prefix, but there are two IGP paths to reach that BGP next hop, then multicast RPF will correctly load split between the two different IGP paths.

Use of ECMP Multicast Load Splitting with Static Mroutes

If it is not possible to use an IGP to install equal cost routes for certain sources or RPs, static routes can be configured to specify the equal-cost paths for load splitting. You cannot use static mroutes to configure equal-cost paths because the software does not support the configuration of one static mroute per prefix. There are some workarounds for this limitation using recursive route lookups but the workarounds cannot be applied to equal-cost multipath routing.

Note

For more information about configuring static mroutes, see the Configuring Multiple Static Mroutes in Cisco IOS configuration note on the Cisco IOS IP multicast FTP site at ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt.

You can specify only static mroutes for equal-cost multipaths in IPv4 multicast; however, those static mroutes would only apply to multicast, or you can specify that the equal-cost multipaths apply to both unicast and multicast routing. In IPv6 multicast, there is no such restriction. Equal-cost multipath mroutes can be configured for static IPv6 mroutes that apply to only unicast routing, only multicast routing, or both unicast and multicast routing.
Alternative Methods of Load Splitting IP Multicast Traffic

Load splitting of IP multicast traffic can also be achieved by consolidating multiple parallel links into a single tunnel over which the multicast traffic is then routed. This method of load splitting is more complex to configure than ECMP multicast load splitting. One such case where configuring load splitting across equal-cost paths using GRE links can be beneficial is the case where the total number of (S, G) or (*, G) states is so small and the bandwidth carried by each state so variable that even the manual engineering of the source or RP addresses cannot guarantee the appropriate load splitting of the traffic.

Note
With the availability of ECMP multicast load splitting, tunnels typically only need to be used if per-packet load sharing is required.

IP multicast traffic can also be used to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, MLPPP link bundles or Multilink Frame Relay (FRF.16) bundles. GRE or other type of tunnels can also constitute such forms of Layer 2 link bundles. Before using such an Layer 2 mechanism, it is necessary to understand how unicast and multicast traffic is load split.

Before load splitting IP multicast traffic across equal-cost paths over a tunnel, you must configure CEF per-packet load balancing or else the GRE packets will not be load balanced per packet.

How to Load Split IP Multicast Traffic over ECMP

Enabling ECMP Multicast Load Splitting

Perform the following tasks to load split IP multicast traffic across multiple equal-cost paths, based on source address.

If two or more equal-cost paths from a source are available, unicast traffic will be load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the RPF neighbor. According to PIM specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.

Configuring load splitting with the `ip multicast multipath` command causes the system to load split multicast traffic across multiple equal-cost paths based on source address using the S-hash algorithm. When the `ip multicast multipath` command is configured and multiple equal-cost paths exist, the path in which multicast traffic will travel is selected based on the source IP address. Multicast traffic from different sources will be load split across the different equal-cost paths. Load splitting will not occur across equal-cost paths for multicast traffic from the same source sent to different multicast groups.

Note
The `ip multicast multipath` command load splits the traffic and does not load balance the traffic. Traffic from a source will use only one path, even if the traffic far outweighs traffic from other sources.

Prerequisites for IP Multicast Load Splitting - ECMP

- You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.
You must have multiple paths available to the RP to configure ECMP multicast load splitting.

Note
Use the `show ip route` command with either the IP address of the source for the `ip-address` argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

- When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.
- Before configuring ECMP multicast load splitting, it is best practice to use the `show ip rpf` command to validate whether sources can take advantage of IP multicast multipath capabilities.
- BGP does not install multiple equal-cost paths by default. Use the `maximum-paths` command to configure multipath (for example in BGP). For more information, see the Use of BGP with ECMP Multicast Load Splitting, on page 736 section.

Restrictions for IP Multicast Load Splitting - ECMP

- If two or more equal-cost paths from a source are available, unicast traffic will be load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the RPF neighbor. According to PIM specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.
- The `ip multicast multipath` command does not support configurations in which the same PIM neighbor IP address is reachable through multiple equal-cost paths. This situation typically occurs if unnumbered interfaces are used. Use different IP addresses for all interfaces when configuring the `ip multicast multipath` command.
- The `ip multicast multipath` command load splits the traffic and does not load balance the traffic. Traffic from a source will use only one path, even if the traffic far outweighs traffic from other sources.

Enabling ECMP Multicast Load Splitting Based on Source Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source address (using the S-hash algorithm) to take advantage of multiple paths through the network. The S-hash algorithm is predictable because no randomization is used in calculating the hash value. The S-hash algorithm, however, is subject to polarization because for a given source, the same hash is always picked irrespective of the device on which the hash is being calculated.

Note
Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.
Before you begin

- You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.

- You must have multiple paths available to the RP to configure ECMP multicast load splitting.

Note
Use the `show ip route` command with either the IP address of the source for the `ip-address` argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

- When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.

- Before configuring ECMP multicast load splitting, it is best practice to use the `show ip rpf` command to validate whether sources can take advantage of IP multicast multipath capabilities.

- BGP does not install multiple equal-cost paths by default. Use the `maximum-paths` command to configure multipath (for example in BGP). For more information, see the Use of BGP with ECMP Multicast Load Splitting, on page 736 section.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast multipath`
4. Repeat step 3 on all the devices in a redundant topology.
5. `exit`
6. `show ip rpf source-address [group-address]`
7. `show ip route ip-address`

Enabling ECMP Multicast Load Splitting Based on Source and Group Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source and group address (using the basic S-G-hash algorithm) to take advantage of multiple paths through the network. The basic S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. The basic S-G-hash algorithm, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device on which the hash is being calculated.
The basic S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than the the S-hash algorithm. Using the basic S-G-hash algorithm for load splitting, in particular, enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

**Note**
Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip multicast multipath s-g-hash basic**
4. Repeat Step 3 on all the devices in a redundant topology.
5. **exit**
6. **show ip rpf source-address [group-address]**
7. **show ip route ip-address**

## Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source, group, and next-hop address (using the next-hop-based S-G-hash algorithm) to take advantage of multiple paths through the network. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

The next-hop-based S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than S-hash algorithm and eliminates the polarization problem. Using the next-hop-based S-G-hash algorithm for ECMP multicast load splitting enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast multipath s-g-hash next-hop-based`
4. Repeat Steps 1 through 3 on all the routers in a redundant topology.
5. `end`
6. `show ip rpf source-address [group-address]`
7. `show ip route ip-address`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 6** `show ip rpf source-address [group-address]` | (Optional) Displays the information that IP multicast routing uses to perform the RPF check.  
- Use this command to verify RPF selection so as to ensure that IP multicast traffic is being properly load split. |

**Example:**
```
Device# show ip rpf 10.1.1.2
```

| **Step 7** `show ip route ip-address` | (Optional) Displays the current state of the IP routing table.  
- Use this command to verify that there multiple paths available to a source or RP for ECMP multicast load splitting.  
- For the `ip-address` argument, enter the IP address of a source to validate that there are multiple paths available to the source (for shortest path trees) or the IP address of an RP to validate that there are multiple paths available to the RP (for shared trees). |

**Example:**
```
Device# show ip route 10.1.1.2
```

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router&gt; enable</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**

configure terminal  
Example:  
Router# configure terminal

Enables ECMP multicast load splitting based on source, group, and next-hop-address using the next-hop-based S-G-hash algorithm.

**Note**  
Because this command changes the way an RPF neighbor is selected, it must be configured consistently on all routers in a redundant topology to avoid looping.

**Step 3**

ip multicast multipath s-g-hash next-hop-based  
Example:  
Router(config)# ip multicast multipath s-g-hash next-hop-based

**Step 4**
Repeat Steps 1 through 3 on all the routers in a redundant topology.

**Step 5**
end  
Example:  
Router(config)# end

Exits global configuration mode and returns to privileged EXEC mode.

**Step 6**

show ip rpf source-address [group-address]  
Example:  
Router# show ip rpf 10.1.1.2

(Optional) Displays the information that IP multicast routing uses to perform the RPF check.

**Note**  
Use this command to verify RPF selection so as to ensure that IP multicast traffic is being properly load split.

**Step 7**

show ip route ip-address  
Example:  
Router# show ip route 10.1.1.2

(Optional) Displays the current state of the IP routing table.

**Note**  
Use this command to verify that there multiple paths available to a source or RP for ECMP multicast load splitting.

For the ip-address argument, enter the IP address of a source to validate that there are multiple paths available to the source (for shortest path trees) or the IP address of an RP to validate that there are multiple paths available to the RP (for shared trees).
Configuration Examples for Load Splitting IP Multicast Traffic over ECMP

Example Enabling ECMP Multicast Load Splitting Based on Source Address

The following example shows how to enable ECMP multicast load splitting on a router based on source address using the S-hash algorithm:

ip multicast multipath

Example Enabling ECMP Multicast Load Splitting Based on Source and Group Address

The following example shows how to enable ECMP multicast load splitting on a router based on source and group address using the basic S-G-hash algorithm:

ip multicast multipath s-g-hash basic

Example Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address

The following example shows how to enable ECMP multicast load splitting on a router based on source, group, and next-hop address using the next-hop-based S-G-hash algorithm:

ip multicast multipath s-g-hash next-hop-based

Prerequisites for SSM Channel Based Filtering for Multicast Boundaries

IP multicast is enabled on the device using the tasks described in the "Configuring Basic IP Multicast" module of the IP Multicast: PIM Configuration Guide.

Information About the SSM Channel Based Filtering for Multicast Boundaries Feature

Rules for Multicast Boundaries

The SSM Channel Based Filtering for Multicast Boundaries feature expands the ip multicast boundary command for control plane filtering support. More than one ip multicast boundary command can be applied to an interface.

The following rules govern the ip multicast boundary command:

- One instance of the in and out keywords can be configured on an interface.
- The in and out keywords can be used for standard or extended access lists.
- Only standard access lists are permitted with the use of the filter-autorp keyword or no keyword.
• A maximum of three instances of a command will be allowed on an interface: one instance of in, one instance of out, and one instance of filter-autorp or no keyword.

• When multiple instances of the command are used, the filtering will be cumulative. If a boundary statement with no keyword exists with a boundary statement with the in keyword, both access lists will be applied on the in direction and a match on either one will be sufficient.

• All instances of the command apply to both control and data plane traffic.

• Protocol information on the extended access list is parsed to allow reuse and filtering for consistency. An (S,G) operation will be filtered by an extended access list under all conditions stated above for keywords if the access list filters (S,G) traffic for all protocols.

Benefits of SSM Channel Based Filtering for Multicast Boundaries

• This feature allows input on the source interface.

• The access control capabilities are the same for SSM and Any Source Multicast (ASM).

How to Configure SSM Channel Based Filtering for Multicast Boundaries

Configuring Multicast Boundaries

SUMMARY STEPS

1. enable
2. configure terminal
3. ip access-list {standard extended} access-list-name
4. permit protocol host address host address
5. deny protocol host address host address
6. Repeat Step 4 or Step 5 as needed.
7. interface type interface-number port-number
8. ip multicast boundary access-list-name [in out filter-autorp]

**Configuration Examples for SSM Channel Based Filtering for Multicast Boundaries**

### Configuring the Multicast Boundaries Permitting and Denying Traffic Example

The following example permits outgoing traffic for (181.1.2.201, 232.1.1.1) and (181.1.2.202, 232.1.1.1) and denies all other (S,G)s.

```
configure terminal
ip access-list extended acc_grpl
permit ip host 0.0.0.0 232.1.1.1 0.0.0.255
permit ip host 181.1.2.201 host 232.1.1.1
```
Configuring the Multicast Boundaries Permitting Traffic Example

The following example permits outgoing traffic for (192.168.2.201, 232.1.1.5) and 192.168.2.202, 232.1.1.5).

```bash
configure terminal
ip access-list extended acc_grp6
permit ip host 0.0.0.0 232.1.1.1 5.0.0.255
deny udp host 192.168.2.201 host 232.1.1.5
permit ip host 192.168.2.201 host 232.1.1.5
deny pim host 192.168.2.201 host 232.1.1.5
permit ip host 192.168.2.202 host 232.1.1.5
deny igmp host 192.2.3.303 host 232.1.1.1
interface gigabitethernet 2/3/0
ip multicast boundary acc_grp6 out
```

Configuring the Multicast Boundaries Denying Traffic Example

The following example denies a group-range that is announced by the candidate RP. Because the group range is denied, no pim auto-rp mappings are created.

```bash
configure terminal
ip access-list standard acc_grp10
deny 225.0.0.0 0.255.255.255
permit any
access-list extended acc_grp12
permit pim host 181.1.2.201 host 232.1.1.8
deny udp host 181.1.2.201 host 232.1.1.8
permit pim host 181.1.2.203 0.0.0.255 host 227.7.7.7
permit ip host 0.0.0.0 host 227.7.7.7
permit ip 181.1.2.203 0.0.0.255 host 227.7.7.7
permit ip host 181.1.2.201 host 232.1.1.7
ip access-list extended acc_grp13
deny ip host 181.1.2.201 host 232.1.1.8
permit ip any any
interface gigabitethernet 2/3/0
ip multicast boundary acc grp10 filter-autorp
ip multicast boundary acc grp12 out
ip multicast boundary acc grp13 in
```

CHAPTER 43

IP Multicast Optimization: PIM Dense Mode State Refresh

Prerequisite for PIM Dense Mode State Refresh

• You must have PIM dense mode enabled on an interface before configuring the PIM Dense Mode State Refresh feature.

Restrictions on PIM Dense Mode State Refresh

• All routers in a PIM dense mode network must run a software release that supports the PIM Dense Mode State Refresh feature to process and forward state refresh control messages.

• The origination interval for the state refresh control message must be the same for all PIM routers on the same LAN. Specifically, the same origination interval must be configured on each router interface that is directly connected to the LAN.

Information About PIM Dense Mode State Refresh

PIM Dense Mode State Refresh Overview

The PIM Dense Mode State Refresh feature is an extension of the PIM Version 2 multicast routing architecture.
PIM dense mode builds source-based multicast distribution trees that operate on a flood and prune principle. Multicast packets from a source are flooded to all areas of a PIM dense mode network. PIM routers that receive multicast packets and have no directly connected multicast group members or PIM neighbors send a prune message back up the source-based distribution tree toward the source of the packets. As a result, subsequent multicast packets are not flooded to pruned branches of the distribution tree. However, the pruned state in PIM dense mode times out approximately every 3 minutes and the entire PIM dense mode network is reflooded with multicast packets and prune messages. This reflooding of unwanted traffic throughout the PIM dense mode network consumes network bandwidth.

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out by periodically forwarding a control message down the source-based distribution tree. The control message refreshes the prune state on the outgoing interfaces of each router in the distribution tree.

**Benefits of PIM Dense Mode State Refresh**

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out, which saves network bandwidth by greatly reducing the reflooding of unwanted multicast traffic to pruned branches of the PIM dense mode network. This feature also enables PIM routers in a PIM dense mode multicast network to recognize topology changes (sources joining or leaving a multicast group) before the default 3-minute state refresh timeout period.

**How to Configure PIM Dense Mode State Refresh**

**Configuring PIM Dense Mode State Refresh**

There are no configuration tasks for enabling the PIM Dense Mode State Refresh feature. By default, all PIM routers that are running a Cisco IOS XE software release that supports the PIM Dense Mode State Refresh feature automatically process and forward state refresh control messages.

To disable the processing and forwarding of state refresh control messages on a PIM router, use the `ip pim state-refresh disable` global configuration command. To enable state refresh again if it has been disabled, use the `no ip pim state-refresh disable` global configuration command.

The origination of state refresh control messages is disabled by default. To configure the origination of the control messages on a PIM router, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# interface type number</code></td>
<td>Specifies an interface and places the router in interface configuration mode.</td>
</tr>
<tr>
<td><code>Router(config-if)# ip pim state-refresh origination-interval [interval]</code></td>
<td>Configures the origination of the PIM Dense Mode State Refresh control message. Optionally, you can configure the number of seconds between control messages by using the <code>interval</code> argument. The default interval is 60 seconds. The interval range is 1 second to 100 seconds.</td>
</tr>
</tbody>
</table>
Verifying PIM Dense Mode State Refresh Configuration

Use the `show ip pim interface [type number] detail` and the `show ip pim neighbor [interface]` commands to verify that the PIM Dense Mode State Refresh feature is configured correctly. The following output of the `show ip pim interface [type number] detail` command indicates that processing, forwarding, and origination of state refresh control messages is enabled.

```
Router# show ip pim interface fastethernet 0/1/0 detail
FastEthernet0/1/0 is up, line protocol is up
  Internet address is 172.16.8.1/24
  Multicast switching:process
  Multicast packets in/out:0/0
  Multicast boundary:not set
  Multicast TTL threshold:0
  PIM:enabled
    PIM version:2, mode:dense
    PIM DR:172.16.8.1 (this system)
    PIM neighbor count:0
    PIM Hello/Query interval:30 seconds
  PIM State-Refresh processing:enabled
  PIM State-Refresh origination:enabled, interval:60 seconds
  PIM NBMA mode:disabled
  PIM ATM multipoint signalling:disabled
  PIM domain border:disabled
  Multicast Tagswitching:disabled
```

The S in the Mode field of the following `show ip pim neighbor [interface]` command output indicates that the neighbor has the PIM Dense Mode State Refresh feature configured.

```
Router# show ip pim neighbor
PIM Neighbor Table
Neighbor Address  Interface    Uptime/Expires Ver DR Priority/Mode
172.16.5.1       Ethernet1/1  00:09:03/00:01:41 v2 1 /  B S
```

Monitoring and Maintaining PIM DM State Refresh

Following are the PIM Dense Mode State Refresh control messages that are sent and received by a PIM router after the `debug ip pim` privileged EXEC command is configured for multicast group 239.0.0.1:

```
Router# debug ip pim 239.0.0.1
*Mar 1 00:25:10.416:PIM:Originating refresh message for (172.16.8.3,239.0.0.1)
*Mar 1 00:25:10.416:PIM:Send SR on GigabitEthernet1/1/0 for (172.16.8.3,239.0.0.1) TTL=9
```

The following output from the `show ip mroute` command displays the resulting prune timer changes for GigabitEthernet interface1/0/0 and multicast group 239.0.0.1. (The following output assumes that the `debug ip pim` privileged EXEC command has already been configured on the router.) In the first output from the `show ip mroute` command, the prune timer reads 00:02:06. The debug messages indicate that a PIM Dense Mode State Refresh control message is received and sent on Ethernet interface 1/0, and that other PIM Dense Mode State Refresh routers were discovered. In the second output from the `show ip mroute` command, the prune timer has been reset to 00:02:55.

```
Router# show ip mroute 239.0.0.1
(172.16.8.3, 239.0.0.1), 00:09:50/00:02:06, flags:PT
```
Configuration Examples for PIM Dense Mode State Refresh

Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is originating, processing, and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 0/1/0 every 60 seconds:

```plaintext
ip multicast-routing distributed
interface FastEthernet0/1/0
ip address 172.16.8.1 255.255.255.0
ip pim state-refresh origination-interval 60
ip pim dense-mode
```

Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is just processing and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 1/1/0:

```plaintext
ip multicast-routing
interface FastEthernet1/1/0
ip address 172.16.7.3 255.255.255.0
ip pim dense-mode
```

IP Multicast Optimization: IGMP State Limit

Prerequisites for IGMP State Limit

- IP multicast is enabled and the Protocol Independent Multicast (PIM) interfaces are configured using the tasks described in the "Configuring Basic IP Multicast" module of the IP Multicast: PIM Configuration Guide.
- ALL ACLs must be configured. For information, see the "Creating an IP Access List and Applying It to an Interface" module of the Security Configuration Guide: Access Control Lists guide.

Restrictions for IGMP State Limit

You can configure only one global limit per device and one limit per interface.

Information About IGMP State Limit

IGMP State Limit

The IGMP State Limit feature allows for the configuration of IGMP state limiters, which impose limits on mroutestates resulting from IGMP membership reports (IGMP joins) on a global or per interface basis. Membership reports exceeding the configured limits are not entered into the IGMP cache. This feature can be used to prevent DoS attacks or to provide a multicast CAC mechanism in network environments where all the multicast flows roughly utilize the same amount of bandwidth.
IGMP Statelimiter impose limits on the number of mroute states resulting from IGMP, IGMP v3 lite, and URL Rendezvous Directory (URD) membership reports on a global or per interface basis.

**IGMP State Limit Feature Design**

- Configuring IGMP state limiters in global configuration mode specifies a global limit on the number of IGMP membership reports that can be cached.
- Configuring IGMP state limiters in interface configuration mode specifies a limit on the number of IGMP membership reports on a per interface basis.
- Use ACLs to prevent groups or channels from being counted against the interface limit. A standard or an extended ACL can be specified. A standard ACL can be used to define the (*, G) state to be excluded from the limit on an interface. An extended ACLs can be used to define the (S, G) state to be excluded from the limit on an interface. An extended ACL also can be used to define the (*, G) state to be excluded from the limit on an interface, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.
- You can only configure one global limit per device and one limit per interface.

**Mechanics of IGMP State Limiters**

The mechanics of IGMP state limiters are as follows:

- Each time a router receives an IGMP membership report for a particular group or channel, the Cisco IOS software checks to see if either the limit for the global IGMP state limiter or the limit for the per interface IGMP state limiter has been reached.
- If only a global IGMP state limiter has been configured and the limit has not been reached, IGMP membership reports are honored. When the configured limit has been reached, subsequent IGMP membership reports are then ignored (dropped) and a warning message in one of the following formats is generated:
  
  - %IGMP-6-IGMP_GROUP_LIMIT: IGMP limit exceeded for <group (*, group address)> on <interface type number> by host <ip address>
  
  - %IGMP-6-IGMP_CHANNEL_LIMIT: IGMP limit exceeded for <channel (source address, group address)> on <interface type number> by host <ip address>

- If only per interface IGMP state limiters are configured, then each limit is only counted against the interface on which it was configured.
- If both a global IGMP state limiter and per interface IGMP state limiters are configured, the limits configured for the per interface IGMP state limiters are still enforced but are constrained by the global limit.
How to Configure IGMP State Limit

Configuring IGMP State Limiters

IGMP state limiters impose limits on the number of mroute states resulting from IGMP, IGMP v3 lite, and URD membership reports on a global or per interface basis.

Configuring Global IGMP State Limiters

Perform this optional task to configure one global IGMP state limiter per device.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp limit number
4. end
5. show ip igmp groups

DETAILED STEPS

### Configuring Per Interface IGMP State Limiters

Perform this optional task to configure a per interface IGMP state limiter.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip igmp limit number [except access-list]`
5. Do one of the following:
   - `exit`
   - `end`
6. `show ip igmp interface [type number]`
7. `show ip igmp groups`

**DETAILED STEPS**

<table>

</table>
### Purpose

**Command or Action**

**Step 5**

Do one of the following:

- `exit`
- `end`

**Example:**

Device(config-if)# `exit`

Device(config-if)# `end`

- (Optional) Ends the current configuration session and returns to global configuration mode. Repeat steps 3 and 4 to configure a per interface limiter on another interface.
- Ends the current configuration session and returns to privileged EXEC mode.

**Step 6**

`show ip igmp interface` `[type number]`

**Example:**

Device# `show ip igmp interface`

(Optional) Displays information about the status and configuration of IGMP and multicast routing on interfaces.

**Step 7**

`show ip igmp groups`

**Example:**

Device# `show ip igmp groups`

(Optional) Displays the multicast groups with receivers that are directly connected to the device and that were learned through IGMP.

---

### Configuration examples for IGMP State Limit

#### Configuring IGMP State Limiters Example

The following example shows how to configure IGMP state limiters to provide multicast CAC in a network environment where all the multicast flows roughly utilize the same amount of bandwidth.

This example uses the topology illustrated in the figure.

—

**Note**

Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.
In this example, a service provider is offering 300 Standard Definition (SD) TV channels. Each SD channel utilizes approximately 4 Mbps.

The service provider must provision the Gigabit Ethernet interfaces on the PE router connected to the Digital Subscriber Line Access Multiplexers (DSLAMs) as follows: 50% of the link’s bandwidth (500 Mbps) must be available to subscribers of the Internet, voice, and video on demand (VoD) service offerings while the remaining 50% (500 Mbps) of the link’s bandwidth must be available to subscribers of the SD channel offerings.

Because each SD channel utilizes the same amount of bandwidth (4 Mbps), per interface IGMP state limiters can be used to provide the necessary CAC to provision the services being offered by the service provider. To determine the required CAC needed per interface, the total number of channels is divided by 4 (because each channel utilizes 4 Mbps of bandwidth). The required CAC needed per interface, therefore, is as follows:

\[
\frac{500 \text{ Mbps}}{4 \text{ Mbps}} = 125 \text{ mroutes}
\]

Once the required CAC is determined, the service provider uses the results to configure the per IGMP state limiters required to provision the Gigabit Ethernet interfaces on the PE router. Based on the network’s CAC requirements, the service provider must limit the SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 125. Configuring a per interface IGMP state limit of 125 for the SD channels provisions the interface for 500 Mbps of bandwidth, the 50% of the link’s bandwidth that must always be available (but never exceeded) for the SD channel offerings.

The following configuration shows how the service provider uses a per interface mroute state limiter to provision interface Gigabit Ethernet 0/0/0 for the SD channels and Internet, Voice, and VoD services being offered to subscribers:

```
interface GigabitEthernet0/0/0
description --- Interface towards the DSLAM ---

ip igmp limit 125
```

Configuring Spanning Tree Protocol

This chapter describes how to configure the Spanning Tree Protocol (STP) on port-based VLANs on the Catalyst devices. The device can use either the per-VLAN spanning-tree plus (PVST+) protocol based on the IEEE 802.1D standard and Cisco proprietary extensions, or the rapid per-VLAN spanning-tree plus (rapid-PVST+) protocol based on the IEEE 802.1w standard. A switch stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID.

- Restrictions for STP, on page 769
- Information About Spanning Tree Protocol, on page 769
- How to Configure Spanning-Tree Features, on page 780
- Monitoring Spanning-Tree Status, on page 792
- Additional References for Spanning-Tree Protocol, on page 793
- Feature Information for STP, on page 794

Restrictions for STP

- An attempt to configure a device as the root device fails if the value necessary to be the root device is less than 1.

- If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected devices running older software.

- The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About Spanning Tree Protocol

Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path
can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Devices might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

The STP uses a spanning-tree algorithm to select one device of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

- **Root**—A forwarding port elected for the spanning-tree topology
- **Designated**—A forwarding port elected for every switched LAN segment
- **Alternate**—A blocked port providing an alternate path to the root bridge in the spanning tree
- **Backup**—A blocked port in a loopback configuration

The device that has all of its ports as the designated role or as the backup role is the root device. The device that has at least one of its ports in the designated role is called the designated device.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Devices send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The devices do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending device and its ports, including device and MAC addresses, device priority, port priority, and path cost. Spanning tree uses this information to elect the root device and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a device are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

---

**Note**

By default, the device sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the [no] keepalive interface configuration command with no keywords.

---

**Spanning-Tree Topology and BPDUs**

The stable, active spanning-tree topology of a switched network is controlled by these elements:

- The unique bridge ID (device priority and MAC address) associated with each VLAN on each device. In a device stack, all devices use the same bridge ID for a given spanning-tree instance.

- The spanning-tree path cost to the root device.

- The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the devices in a network are powered up, each functions as the root device. Each device sends a configuration BPDU through all of its ports. The BPDUs communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the device that the sending device identifies as the root device
• The spanning-tree path cost to the root
• The bridge ID of the sending device
• Message age
• The identifier of the sending interface
• Values for the hello, forward delay, and max-age protocol timers

When a device receives a configuration BPDU that contains superior information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the device, the device also forwards it with an updated message to all attached LANs for which it is the designated device.

If a device receives a configuration BPDU that contains inferior information to that currently stored for that port, it discards the BPDU. If the device is a designated device for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:
• One device in the network is elected as the root device (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.
  
  For each VLAN, the device with the highest device priority (the lowest numerical priority value) is elected as the root device. If all devices are configured with the default priority (32768), the device with the lowest MAC address in the VLAN becomes the root device. The device priority value occupies the most significant bits of the bridge ID, as shown in the following figure.

• A root port is selected for each device (except the root device). This port provides the best path (lowest cost) when the device forwards packets to the root device.

When selecting the root port on a device stack, spanning tree follows this sequence:
• Selects the lowest root bridge ID
• Selects the lowest path cost to the root device
• Selects the lowest designated bridge ID
• Selects the lowest designated path cost
• Selects the lowest port ID

• Only one outgoing port on the stack root device is selected as the root port. The remaining devices in the stack become its designated devices (Device 2 and Device 3) as shown in the following figure.

• The shortest distance to the root device is calculated for each device based on the path cost.

• A designated device for each LAN segment is selected. The designated device incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
One stack member is elected as the stack root device. The stack root device contains the outgoing root port (Device 1).

![Figure 44: Spanning-Tree Port States in a Device Stack](image)

**Figure 44: Spanning-Tree Port States in a Device Stack**

All paths that are not needed to reach the root device from anywhere in the switched network are placed in the spanning-tree blocking mode.

### Bridge ID, Device Priority, and Extended System ID

The IEEE 802.1D standard requires that each device has an unique bridge identifier (bridge ID), which controls the selection of the root device. Because each VLAN is considered as a different logical bridge with PVST+ and Rapid PVST+, the same device must have a different bridge ID for each configured VLAN. Each VLAN on the device has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the device priority, and the remaining 6 bytes are derived from the device MAC address.

The device supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the device priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for the device, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.
The 2 bytes previously used for the device priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

Spanning tree uses the extended system ID, the device priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the device stack appears as a single device to the rest of the network, all devices in the stack use the same bridge ID for a given spanning tree. If the stack master fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack master.

Support for the extended system ID affects how you manually configure the root device, the secondary root device, and the device priority of a VLAN. For example, when you change the device priority value, you change the probability that the device will be elected as the root device. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root device for the specified VLAN has a device priority lower than 24576, the device sets its own priority for the specified VLAN to 4096 less than the lowest device priority. 4096 is the value of the least-significant bit of a 4-bit device priority value as shown in the table.

**Port Priority Versus Path Cost**

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your device is a member of a device stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see Related Topics.

**Spanning-Tree Interface States**

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

Each Layer 2 interface on a device using spanning tree exists in one of these states:
• Blocking—The interface does not participate in frame forwarding.

• Listening—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.

• Learning—The interface prepares to participate in frame forwarding.

• Forwarding—The interface forwards frames.

• Disabled—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:

• From initialization to blocking

• From blocking to listening or to disabled

• From listening to learning or to disabled

• From learning to forwarding or to disabled

• From forwarding to disabled

Figure 45: Spanning-Tree Interface States

An interface moves through the states.

When you power up the device, spanning tree is enabled by default, and every interface in the device, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:

1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.

2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.

3. In the learning state, the interface continues to block frame forwarding as the device learns end-station location information for the forwarding database.
4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

**Blocking State**

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each device interface. A device initially functions as the root until it exchanges BPDU's with other devices. This exchange establishes which device in the network is the root or root device. If there is only one device in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after device initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

**Listening State**

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

**Learning State**

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs

**Forwarding State**

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface
Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:

• Discards frames received on the interface
• Discards frames switched from another interface for forwarding
• Does not learn addresses
• Does not receive BPDUs

How a Device or Port Becomes the Root Device or Root Port

If all devices in a network are enabled with default spanning-tree settings, the device with the lowest MAC address becomes the root device.

Figure 46: Spanning-Tree Topology

Device A is elected as the root device because the device priority of all the devices is set to the default (32768) and Device A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Device A might not be the ideal root device. By increasing the priority (lowering the numerical value) of the ideal device so that it becomes the root device, you force a spanning-tree recalculation to form a new topology with the ideal device as the root.

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.

For example, assume that one port on Device B is a Gigabit Ethernet link and that another port on Device B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.
Spanning Tree and Redundant Connectivity

You can create a redundant backbone with spanning tree by connecting two device interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds are the same, the port priority and port ID are added together, and spanning tree disables the link with the highest value.

You can also create redundant links between devices by using EtherChannel groups.

Spanning-Tree Address Management

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C200000 to 0x0180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each device in the stack receives but does not forward packets destined for addresses between 0x0180C200000 and 0x0180C20000F.

If spanning tree is enabled, the CPU on the device or on each device in the stack receives packets destined for 0x0180C200000 and 0x0180C2000010. If spanning tree is disabled, the device or each device in the stack forwards those packets as unknown multicast addresses.

Accelerated Aging to Retain Connectivity

The default for aging dynamic addresses is 5 minutes, the default setting of the mac address-table aging-time global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (spanning-tree vlan vlan-id forward-time seconds global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the device accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the device.

Spanning-Tree Modes and Protocols

The device supports these spanning-tree modes and protocols:
• PVST+—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. The PVST+ runs on each VLAN on the device up to the maximum supported, ensuring that each has a loop-free path through the network. The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root device. This root device propagates the spanning-tree information associated with that VLAN to all other devices in the network. Because each device has the same information about the network, this process ensures that the network topology is maintained.

• Rapid PVST+—Rapid PVST+ is the default STP mode on your device. This spanning-tree mode is the same as PVST+ except that it uses a rapid convergence based on the IEEE 802.1w standard. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to repurpose your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

• MSTP—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a device stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

**Supported Spanning-Tree Instances**

In PVST+ or Rapid PVST+ mode, the device or device stack supports up to 128 spanning-tree instances.

In MSTP mode, the device or device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

**Spanning-Tree Interoperability and Backward Compatibility**

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ device cannot connect to multiple MST regions.

When a network contains devices running Rapid PVST+ and devices running PVST+, we recommend that the Rapid PVST+ devices and PVST+ devices be configured for different spanning-tree instances. In the Rapid PVST+ spanning-tree instances, the root device must be a Rapid PVST+ device. In the PVST+ instances, the root device must be a PVST+ device. The PVST+ devices should be at the edge of the network.

All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

### STP and IEEE 802.1Q Trunks

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for all VLANs allowed on the trunks. However, in a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for each VLAN allowed on the trunks.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the device uses it instead of PVST+. The device combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.

Rapid PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

### Spanning Tree and Device Stacks

When the device stack is operating in PVST+ or Rapid PVST+ mode:

- A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

- When a new device joins the stack, it sets its bridge ID to the active switch bridge ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root.

- When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

- If a neighboring device external to the device stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a device in the active topology.

- If a new device external to the device stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a device in the network.

Note
Beginning in Cisco IOS Release 15.2(4)E, the default STP mode is Rapid PVST+.

How to Configure Spanning-Tree Features

Changing the Spanning-Tree Mode (CLI)

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the device runs the Rapid PVST+ protocol.

If you want to enable a mode that is different from the default mode, this procedure is required.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mode {pvst | mst | rapid-pvst}`
4. `interface interface-id`
5. `spanning-tree link-type point-to-point`
6. `end`
7. `clear spanning-tree detected-protocols`

</table>
Disabling Spanning Tree (CLI)

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

⚠️ Caution

When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. no spanning-tree vlan vlan-id
4. end

### Configuring the Root Device (CLI)

To configure a device as the root for the specified VLAN, use the `spanning-tree vlan vlan-id root` global configuration command to modify the device priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the device priority of the root devices for each VLAN. Because of the extended system ID support, the device sets its own priority for the specified VLAN to 24576 if this value will cause this device to become the root for the specified VLAN.

Use the `diameter` keyword to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the `hello` keyword to override the automatically calculated hello time.

This procedure is optional.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree vlan vlan-id root primary [diameter net-diameter]`
4. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  `enable`
  **Example:**
  `Device> enable`
| Enables privileged EXEC mode.
  - Enter your password if prompted. |
| **Step 2**
  `configure terminal`
  **Example:**
  `Device# configure terminal`
| Enters global configuration mode. |
| **Step 3**
  `spanning-tree vlan vlan-id root primary [diameter net-diameter]`
  **Example:**
  `Device(config)# spanning-tree vlan 20-24 root primary diameter 4`
| Configures a device to become the root for the specified VLAN.
  - For `vlan-id`, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) For <code>diameter net-diameter</code>, specify the maximum number of devices between any two end stations. The range is 2 to 7.</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# <code>end</code></td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**What to do next**

After configuring the device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the `spanning-tree vlan vlan-id hello-time`, `spanning-tree vlan vlan-id forward-time`, and the `spanning-tree vlan vlan-id max-age` global configuration commands.

### Configuring a Secondary Root Device (CLI)

When you configure a device as the secondary root, the device priority is modified from the default value (32768) to 28672. With this priority, the device is likely to become the root device for the specified VLAN if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768, and therefore, are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the `spanning-tree vlan vlan-id root primary` global configuration command.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree vlan vlan-id root secondary [diameter net-diameter`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device&gt; enable</code></td>
</tr>
<tr>
<td></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Step 3**

spanning-tree vlan *vlan-id* root secondary [diameter net-diameter]

**Example:**

Device(config)# spanning-tree vlan 20-24 root secondary diameter 4

Configures a device to become the secondary root for the specified VLAN.

- For *vlan-id*, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.

- (Optional) For **diameter net-diameter**, specify the maximum number of devices between any two end stations. The range is 2 to 7.

Use the same network diameter value that you used when configuring the primary root device.

**Step 4**

end

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

---

**Configuring Port Priority (CLI)**

**Note**

If your device is a member of a device stack, you must use the spanning-tree [vlan *vlan-id*] cost cost interface configuration command instead of the spanning-tree [vlan *vlan-id*] port-priority priority interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface *interface-id*
4. spanning-tree port-priority *priority*
5. spanning-tree vlan *vlan-id* port-priority *priority*
6. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
### Configuring Path Cost (CLI)

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Example:**
Device> enable | • Enter your password if prompted. |

**Step 2**

configure terminal
Example:
Device# configure terminal

Enters global configuration mode.

**Step 3**

interface interface-id
Example:
Device(config) # interface gigabitethernet 1/0/2

Specifies an interface to configure, and enters interface configuration mode.

Valid interfaces include physical ports and port-channel logical interfaces (`port-channel port-channel-number`).

**Step 4**

spanning-tree port-priority priority
Example:
Device(config-if) # spanning-tree port-priority 0

Configures the port priority for an interface.

For `priority`, the range is 0 to 240, in increments of 16; the default is 128. Valid values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. The lower the number, the higher the priority.

**Step 5**

spanning-tree vlan vlan-id port-priority priority
Example:
Device(config-if) # spanning-tree vlan 20-25 port-priority 0

Configures the port priority for a VLAN.

- For `vlan-id`, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.

- For `priority`, the range is 0 to 240, in increments of 16; the default is 128. Valid values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. The lower the number, the higher the priority.

**Step 6**

end
Example:
Device(config-if) # end

Returns to privileged EXEC mode.

Configuring Multiple Spanning-Tree Protocol

Prerequisites for MSTP

• For two or more devices to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

• For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

• For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a device stack by manually configuring the path cost.

• For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the internal spanning tree (IST) master of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST regions must contain the CST root, and all of the other MST regions must have a better path to the root contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the devices in the clouds.

Restrictions for MSTP

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

• The device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

• PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)
• VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each device within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.

• Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.

• A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

• After configuring a device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the spanning-tree mst hello-time, spanning-tree mst forward-time, and the spanning-tree mst max-age global configuration commands.

Information About MSTP

MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing, and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

Note

The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment.

When the device is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.
Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same device ID.

**MSTP Configuration Guidelines**

- When you enable MST by using the `spanning-tree mode mst` global configuration command, RSTP is automatically enabled.
- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.
- When the device is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

<table>
<thead>
<tr>
<th>Speed</th>
<th>Path Cost Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 Mb/s</td>
<td>2,000,000</td>
</tr>
<tr>
<td>100 Mb/s</td>
<td>200,000</td>
</tr>
<tr>
<td>1 Gb/s</td>
<td>20,000</td>
</tr>
<tr>
<td>10 Gb/s</td>
<td>2,000</td>
</tr>
<tr>
<td>100 Gb/s</td>
<td>200</td>
</tr>
</tbody>
</table>

**Root Switch**

The device maintains a spanning-tree instance for the group of VLANs mapped to it. A device ID, consisting of the device priority and the device MAC address, is associated with each instance. For a group of VLANs, the device with the lowest device ID becomes the root device.

When you configure a device as the root, you modify the device priority from the default value (32768) to a significantly lower value so that the device becomes the root device for the specified spanning-tree instance. When you enter this command, the device checks the device priorities of the root devices. Because of the extended system ID support, the device sets its own priority for the specified instance to 24576 if this value will cause this devices to become the root for the specified spanning-tree instance.

If any root device for the specified instance has a device priority lower than 24576, the device sets its own priority to 4096 less than the lowest device priority. (4096 is the value of the least-significant bit of a 4-bit device priority value. For more information, select "Bridge ID, Device Priority, and Extended System ID" link in Related Topics.

If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected switches running older software.
The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Use the `diameter` keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the `hello` keyword to override the automatically calculated hello time.

**Multiple Spanning-Tree Regions**

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each device belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the device for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the "Specifying the MST Region Configuration and Enabling MSTP" link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

**IST, CIST, and CST**

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- **An internal spanning tree (IST),** which is the spanning tree that runs in an MST region.
  
  Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

  The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because the MSTP BPDU carries information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

  All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root device ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

  An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- **A common and internal spanning tree (CIST),** which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.

  The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that
support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

**Operations Within an MST Region**

The IST connects all the MSTP switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the IST master before the implementation of the IEEE 802.1s standard). It is the device within the region with the lowest device ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MSTP switches at the boundary of the region is selected as the CIST regional root.

When an MSTP device initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The device also initializes all of its MST instances and claims to be the root for all of them. If the device receives superior MST root information (lower device ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

**Operations Between MST Regions**

If there are multiple regions or legacy IEEE 802.1D devices within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP devices in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP devices in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual device to adjacent STP devices and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring devices and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPDU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, device priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.

MSTP devices use Version 3 RSTP BPDUs or IEEE 802.1D STP BPDUs to communicate with legacy IEEE 802.1D devices. MSTP devices use MSTP BPDUs to communicate with MSTP devices.

**IEEE 802.1s Terminology**

Some MST naming conventions used in Cisco’s prestandard implementation have been changed to identify some internal or regional parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root device for the unique instance that spans the whole network, the CIST.
• The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single device for the CIST. The CIST external root path cost is the root path cost calculated between these virtual devices and devices that do not belong to any region.

• The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest device to the CIST root in the region. The CIST regional root acts as a root device for the IST.

• The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

**Illustration of MST Regions**

This figure displays three MST regions and a legacy IEEE 802.1D device (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.
Figure 48: MST Regions, CIST Masters, and CST Root

**Hop Count**

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the `spanning-tree mst max-hops` global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root device of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a device receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDUs it generates. When the count reaches zero, the device discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.

**Boundary Ports**

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.
There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both devices and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

---

**Note**

If there is a legacy STP device on the segment, messages are always considered external.

The other change from the Cisco prestandard implementation is that the CIST regional root device ID field is now inserted where an RSTP or legacy IEEE 802.1Q device has the sender device ID. The whole region performs like a single virtual device by sending a consistent sender device ID to neighboring devices. In this example, device C would receive a BPDU with the same consistent sender device ID of root, whether or not A or B is designated for the segment.

---

**IEEE 802.1s Implementation**

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

**Port Role Naming Change**

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco’s implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special master role.

- The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the show commands identify a port as boundary in the type column of the output.
Interoperation Between Legacy and Standard Devices

Because automatic detection of prestandard devices can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard device, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a device receives a prestandard BPU on a port that has not been configured for prestandard BPU transmission.

Figure 49: Standard and Prestandard Device Interoperation

Assume that A is a standard device and B a prestandard device, both configured to be in the same region. A is the root device for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPU, AY cannot detect that a prestandard device is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology changes.

Note
We recommend that you minimize the interaction between standard and prestandard MST implementations.

Detecting Unidirectional Link Failure

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

Figure 50: Detecting Unidirectional Link Failure

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Device A is the root device, and its BPDUs are lost on the link leading to device B. RSTP and MST BPDUs include the role and state of the sending port. With this information, device A can detect that device B does not react to the superior
MSTP and Device Stacks

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

If a device that does not support MSTP is added to a device stack that does support MSTP or the reverse, the device is put into a version mismatch state. If possible, the device is automatically upgraded or downgraded to the same version of software that is running on the device stack.

Interoperability with IEEE 802.1D STP

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDPUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDPUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device might also continue to assign a boundary role to a port when the device to which this device is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring devices), use the clear spanning-tree detected-protocols privileged EXEC command.

If all the legacy devices on the link are RSTP devices, they can process MSTP BPDPUs as if they are RSTP BPDPUs. Therefore, MSTP devices send either a Version 0 configuration and TCN BPDPUs or Version 3 MSTP BPDPUs on a boundary port. A boundary port connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).

Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the device with the highest device priority (lowest numerical priority value) as the root device. The RSTP then assigns one of these port roles to individual ports:
• Root port—Provides the best path (lowest cost) when the device forwards packets to the root device.
• Designated port—Connects to the designated device, which incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
• Alternate port—Offers an alternate path toward the root device to that provided by the current root port.
• Backup port—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a device has two or more connections to a shared LAN segment.
• Disabled port—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

### Table 60: Port State Comparison

<table>
<thead>
<tr>
<th>Operational Status</th>
<th>STP Port State (IEEE 802.1D)</th>
<th>RSTP Port State</th>
<th>Is Port Included in the Active Topology?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Blocking</td>
<td>Discarding</td>
<td>No</td>
</tr>
<tr>
<td>Enabled</td>
<td>Listening</td>
<td>Discarding</td>
<td>No</td>
</tr>
<tr>
<td>Enabled</td>
<td>Learning</td>
<td>Learning</td>
<td>Yes</td>
</tr>
<tr>
<td>Enabled</td>
<td>Forwarding</td>
<td>Forwarding</td>
<td>Yes</td>
</tr>
<tr>
<td>Disabled</td>
<td>Disabled</td>
<td>Discarding</td>
<td>No</td>
</tr>
</tbody>
</table>

To be consistent with Cisco STP implementations, this guide defines the port state as *blocking* instead of *discarding*. Designated ports start in the listening state.

### Rapid Convergence

The RSTP provides for rapid recovery of connectivity following the failure of a device, a device port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

• Edge ports—If you configure a port as an edge port on an RSTP device by using the `spanning-tree portfast` interface configuration command, the edge port immediately transitions to the forwarding state. An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.

• Root ports—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.
Point-to-point links—if you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

**Figure 51: Proposal and Agreement Handshaking for Rapid Convergence**

Device A is connected to Device B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Device A is a smaller numerical value than the priority of Device B. Device A sends a proposal message (a configuration BPDU with the proposal flag set) to Device B, proposing itself as the designated device.

After receiving the proposal message, Device B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Device B’s agreement message, Device A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Device B blocked all of its nonedge ports and because there is a point-to-point link between Devices A and B.

When Device C is connected to Device B, a similar set of handshaking messages are exchanged. Device C selects the port connected to Device B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more device joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a device stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the device is in MST mode.

The device learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the `spanning-tree link-type` interface configuration command.
Synchronization of Port Roles

When the device receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The device is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the device is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

Figure 52: Sequence of Events During Rapid Convergence

After ensuring that all of the ports are synchronized, the device sends an agreement message to the designated device corresponding to its root port. When the devices connected by a point-to-point link are in agreement about their port roles, the RSTP immediately transitions the port states to forwarding.

Bridge Protocol Data Unit Format and Processing

The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

Table 61: RSTP BPDU Flags

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Topology change (TC)</td>
</tr>
</tbody>
</table>
### Processing Superior BPDU Information

If a port receives superior root information (lower device ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDU received is an RSTP BPDU with the proposal flag set, the device sends an agreement message after all of the other ports are synchronized. If the BPDU is an IEEE 802.1D BPDU, the device does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

### Processing Inferior BPDU Information

If a designated port receives an inferior BPDU (such as a higher device ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.
Topology Changes

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- Detection—Unlike IEEE 802.1D in which any transition between the blocking and the forwarding state causes a topology change, only transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP device detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.

- Notification—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP device processes and generates TCN BPDUs.

- Acknowledgement—When an RSTP device receives a TCN message on a designated port from an IEEE 802.1D device, it replies with an IEEE 802.1D configuration BPDU with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D device and a configuration BPDU with the TCA bit set is received, the TC-while timer is reset.

This behavior is only required to support IEEE 802.1D devices. The RSTP BPDUs never have the TCA bit set.

- Propagation—When an RSTP device receives a TC message from another device through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding the port on which it is received). The device starts the TC-while timer for all such ports and flushes the information learned on them.

- Protocol migration—For backward compatibility with IEEE 802.1D devices, RSTP selectively sends IEEE 802.1D configuration BPDUs and TCN BPDUs on a per-port basis.

When a port is initialized, the migrate-delay timer is started (specifies the minimum time during which RSTP BPDUs are sent), and RSTP BPDUs are sent. While this timer is active, the device processes all BPDUs received on that port and ignores the protocol type.

If the device receives an IEEE 802.1D BPDU after the port migration-delay timer has expired, it assumes that it is connected to an IEEE 802.1D device and starts using only IEEE 802.1D BPDUs. However, if the RSTP device is using IEEE 802.1D BPDUs on a port and receives an RSTP BPDU after the timer has expired, it restarts the timer and starts using RSTP BPDUs on that port.

Protocol Migration Process

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device also might continue to assign a boundary role to a port when the device to which it is connected has joined the region.

How to Configure MSTP Features

Specifying the MST Region Configuration and Enabling MSTP (CLI)

For two or more switches to be in the same MST region, they must have the same VLAN-to-instance mapping, the same configuration revision number, and the same name.

A region can have one member or multiple members with the same MST configuration; each member must be capable of processing RSTP BPDUs. There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mst configuration
4. instance instance-id vlan vlan-range
5. `name name`
6. `revision version`
7. `show pending`
8. `exit`
9. `spanning-tree mode mst`
10. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst configuration</td>
<td>Enters MST configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>spanning-tree mst configuration</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>instance instance-id vlan vlan-range</code></td>
<td>Maps VLANs to an MST instance.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-mst)# <code>instance 1 vlan 10-20</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For <code>instance-id</code>, the range is 0 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• For <code>vlan vlan-range</code>, the range is 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>When you map VLANs to an MST instance, the mapping is incremental, and the VLANs specified in the command are added to or removed from the VLANs that were previously mapped.</td>
</tr>
<tr>
<td></td>
<td>To specify a VLAN range, use a hyphen; for example, <code>instance 1 vlan 1-63</code> maps VLANs 1 through 63 to MST instance 1.</td>
</tr>
<tr>
<td></td>
<td>To specify a VLAN series, use a comma; for example, <code>instance 1 vlan 10, 20, 30</code> maps VLANs 10, 20, and 30 to MST instance 1.</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>name name</code></td>
<td>Specifies the configuration name. The <code>name</code> string has a maximum length of 32 characters and is case sensitive.</td>

</tbody>
</table>

**Configuring the Root Device (CLI)**

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. Step 2 in the example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree mst instance-id root primary
4. end
### DETAILED STEPS

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

| **Step 2** | Enters global configuration mode. |
| `configure terminal` | |
| **Example:** | |
| `Device# configure terminal` | |

| **Step 3** | Configures a device as the root device. |
| `spanning-tree mst instance-id root primary` | |
| **Example:** | - For `instance-id`, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. |
| `Device(config)# spanning-tree mst 0 root primary` | |

| **Step 4** | Returns to privileged EXEC mode. |
| `end` | |
| **Example:** | |
| `Device(config)# end` | |

### Configuring a Secondary Root Device (CLI)

When you configure a device with the extended system ID support as the secondary root, the device priority is modified from the default value (32768) to 28672. The device is then likely to become the root device for the specified instance if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768 and therefore are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the `spanning-tree mst instance-id root primary` global configuration command.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. `enable`
2. configure terminal
3. spanning-tree mst instance-id root secondary
4. end

DETAILED STEPS

<table>

<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Port Priority (CLI)

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

**Note**

If the device is a member of a device stack, you must use the spanning-tree mst [instance-id] cost cost interface configuration command instead of the spanning-tree mst [instance-id] port-priority priority interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.
Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface interface-id**
4. **spanning-tree mst instance-id port-priority priority**
5. **end**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>

</tr>
<tr>
<td><strong>Step 4</strong> spanning-tree mst instance-id port-priority priority</td>
<td>Configures port priority.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# spanning-tree mst 0 port-priority 64</td>
<td>• For instance-id, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• For priority, the range is 0 to 240 in increments of 16. The default is 128. The lower the number, the higher the priority.</td>
</tr>
<tr>
<td></td>
<td>The priority values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected.</td>
</tr>
</tbody>
</table>
### Configuring Path Cost (CLI)

The MSTP path cost default value is derived from the media speed of an interface. If a loop occurs, the MSTP uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree mst instance-id cost cost`
5. `end`

| `configure terminal` | Enters global configuration mode. |
| `Example:`        |         |
### Configuring the Device Priority (CLI)

Changing the priority of a device makes it more likely to be chosen as the root device whether it is a standalone device or a device in the stack.

**Note**

Exercise care when using this command. For normal network configurations, we recommend that you use the `spanning-tree mst instance-id root primary` and the `spanning-tree mst instance-id root secondary` global configuration commands to specify a device as the root or secondary root device. You should modify the device priority only in circumstances where these commands do not work.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

The `show spanning-tree mst interface interface-id` privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the `show running-config` privileged EXEC command to confirm the configuration.
You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree mst instance-id priority priority`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| `enable` | Enables privileged EXEC mode.
| **Example:**
| Device> `enable` | • Enter your password if prompted. |
| **Step 2**
| `configure terminal` | Enters global configuration mode. |
| **Example:**
| Device# `configure terminal` | |
| **Step 3**
| `spanning-tree mst instance-id priority priority` | Configures the device priority. |
| **Example:**
| Device(config)# `spanning-tree mst 0 priority 40960` | • For `instance-id`, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.
| | • For `priority`, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device. |
| | Priority values are 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. These are the only acceptable values. |
| **Step 4**
| `end` | Returns to privileged EXEC mode. |
| **Example:**
| Device(config-if)# `end` | |

**Configuring the Hello Time (CLI)**

The hello time is the time interval between configuration messages generated and sent by the root device.
This procedure is optional.

Before you begin
A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree mst hello-time seconds
4. end

### Specifying the Link Type to Ensure Rapid Transitions (CLI)

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote device running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree link-type point-to-point`
5. `end`

</table>

### Designating the Neighbor Type (CLI)

A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.

You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the `show` commands, even if the port is in STP compatibility mode.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree mst pre-standard
5. end

**Restarting the Protocol Migration Process (CLI)**

This procedure restarts the protocol migration process and forces renegotiation with neighboring devices. It reverts the device to MST mode. It is needed when the device no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Follow these steps to restart the protocol migration process (force the renegotiation with neighboring devices) on the device.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.
If you want to use the interface version of the command, you must also know the MST interface used. This example uses GigabitEthernet1/0/1 as the interface because that was the interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. **enable**
2. Enter one of the following commands:
   - clear spanning-tree detected-protocols
   - clear spanning-tree detected-protocols interface interface-id

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> Enter one of the following commands:</td>
<td>The device reverts to the MSTP mode, and the protocol migration process restarts.</td>
</tr>
<tr>
<td>• clear spanning-tree detected-protocols</td>
<td></td>
</tr>
<tr>
<td>• clear spanning-tree detected-protocols interface</td>
<td></td>
</tr>
<tr>
<td>interface-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# clear spanning-tree detected-protocols</td>
<td></td>
</tr>
<tr>
<td>or</td>
<td></td>
</tr>
<tr>
<td>Device# clear spanning-tree detected-protocols interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

This procedure may need to be repeated if the device receives more legacy IEEE 802.1D configuration BPDUs (BPDUs with the protocol version set to 0).

PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

Figure 53: PortFast-Enabled Interfaces

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to converge. Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.
BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast edge-enabled ports, spanning tree shuts down ports that are in a PortFast edge-operational state if any BPDU is received on them. In a valid configuration, PortFast edge-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast edge-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast edge feature, and the port receives a BPDU, it is put in the error-disabled state.

The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.

BPDU Filtering

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast edge-enabled interfaces at the global level keeps those interfaces that are in a PortFast edge-operational state from sending or receiving BPDUs. The interfaces still send a few BPDUs at link-up before the switch begins to filter outbound BPDUs. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDUs. If a BPDU is received on a PortFast edge-enabled interface, the interface loses its PortFast edge-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast edge feature keeps the interface from sending or receiving BPDUs.

⚠️ Caution

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature for the entire switch or for an interface.

UplinkFast

Figure 54: Switches in a Hierarchical Network

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one
redundant link that spanning tree blocks to prevent loops.

If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.

When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

**Note**

UplinkFast is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.
Cross-Stack UplinkFast

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see Related Topics.

How Cross-Stack UplinkFast Works

Cross-Stack UplinkFast (CSUF) ensures that one link in the stack is elected as the path to the root.
The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.

When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.

Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments...
from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate ($2 \times$ forward-delay time + max-age time).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur. Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.
  
  If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.

- The failed link, which connects the stack root to the spanning-tree root, recovers.

- A network reconfiguration causes a new stack-root switch to be selected.

- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

---

**Note**

The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.

- The stack-root switch, which was powered off or failed, is powered on.

- A new switch, which might become the stack root, is added to the stack.

BackboneFast

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches. BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDUs from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDUs for the maximum aging time (default is 20 seconds).
The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.

Figure 58: BackboneFast Example Before Indirect Link Failure

This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B is in the blocking state.

Figure 59: BackboneFast Example After Indirect Link Failure

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDU's to Switch C, identifying itself as the root. When Switch C receives the inferior BPDU's from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes
approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is set. BackboneFast reconfigures the topology to account for the failure of link L1.

![Figure 60: Adding a Switch in a Shared-Medium Topology](image)

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDU did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDU that indicate it is the root switch. However, the other switches ignore these inferior BPDU, and the new switch learns that Switch B is the designated switch to Switch A, the root switch.

**EtherChannel Guard**

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel, but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.
Root Guard

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer’s network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer’s switch from becoming the root switch or being in the path to the root.

If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer’s switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

Caution
Misuse of the root guard feature can cause a loss of connectivity.

Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched...
network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDU's on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDU's on root or alternate ports.

When the switch is operating in MST mode, BPDU's are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.

How to Configure Optional Spanning-Tree Features

Enabling PortFast (CLI)

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution

Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree portfast [trunk]
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Specifies an interface to configure, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Step 3 interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 4 spanning-tree portfast [trunk]</td>
<td>Enables PortFast on an access port connected to a single workstation or server.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 5 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### What to do next

You can use the `spanning-tree portfast default` global configuration command to globally enable the PortFast feature on all nontrunking ports.

### Enabling BPDU Guard (CLI)

You can enable the BPDU guard feature if your switch is running PVST+, Rapid PVST+, or MSTP.

---

**Caution**

Configure PortFast edge only on ports that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

### SUMMARY STEPS

1. `enable`
### Enabling BPDU Filtering (CLI)

Enabling BPDU Filtering (CLI)

You can also use the `spanning-tree bpduguard enable` interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put it in the error-disabled state.

---

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface interface-id</td>
<td>Specifies the interface connected to an end station, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>spanning-tree portfast edge</td>
<td>Enables the PortFast edge feature.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# spanning-tree portfast edge</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

To prevent the port from shutting down, you can use the `errdisable detect cause bpduguard shutdown vlan` global configuration command to shut down just the offending VLAN on the port where the violation occurred.

You also can use the `spanning-tree bpduguard enable` interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put it in the error-disabled state.
Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Configure PortFast edge only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree portfast edge bpdufilter default
4. interface interface-id
5. spanning-tree portfast edge
6. end

**DETAILED STEPS**

<table>

</table>
### Enabling UplinkFast for Use with Redundant Links (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong> spanning-tree portfast edge</td>
<td>Enables the PortFast edge feature on the specified interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# spanning-tree portfast edge</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

---

**Note**

When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable UplinkFast and CSUF.

**Before you begin**

UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the `no spanning-tree vlan vlan-id priority` global configuration command.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree uplinkfast [max-update-rate pkts-per-second]`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal | Enters global configuration mode. |
| Example:                     |                                 |
Disabling UplinkFast (CLI)

This procedure is optional.

Follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

**Before you begin**
UplinkFast must be enabled.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no spanning-tree uplinkfast
4. end
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>enable</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
<td>Enables privileged EXEC mode.&lt;br&gt;• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td><strong>configure terminal</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td><strong>no spanning-tree uplinkfast</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# no spanning-tree uplinkfast</td>
<td>Disables UplinkFast and CSUF on the switch and all of its VLANs.</td>
</tr>
<tr>
<td>Step 4</td>
<td><strong>end</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you disable the UplinkFast feature using these instructions, CSUF is automatically globally disabled on nonstack port interfaces.

### Enabling BackboneFast (CLI)

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable BackboneFast on the switch.

**Before you begin**

If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree backbonefast**
Enabling EtherChannel Guard (CLI)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable EtherChannel Guard on the device.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree etherchannel guard misconfig`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree backbonefast</td>
<td>Enables BackboneFast.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# spanning-tree backbonefast</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Enabling Root Guard (CLI)

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.

---

**Note**

You cannot enable both root guard and loop guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable root guard on the switch.

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
</tr>
</tbody>
</table>

**Step 2**

**configure terminal**  
**Example:**  
Device# configure terminal

**Step 3**

**spanning-tree etherchannel guard misconfig**  
**Example:**  
Device(config)# spanning-tree etherchannel guard misconfig

**Step 4**

**end**  
**Example:**  
Device(config)# end

### What to do next

You can use the `show interfaces status err-disabled` privileged EXEC command to show which device ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the `show etherchannel summary` privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the `shutdown` and `no shutdown` interface configuration commands on the port-channel interfaces that were misconfigured.
SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree guard root
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode.</td>
</tr>

<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> spanning-tree guard root</td>
<td>Enables root guard on the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>By default, root guard is disabled on all interfaces.</td>
</tr>
<tr>
<td>Device(config-if)# spanning-tree guard root</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

Enabling Loop Guard (CLI)

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

Note

You cannot enable both loop guard and root guard at the same time.
You can enable this feature if your device is running PVST+, Rapid PVST+, or MSTP. This procedure is optional. Follow these steps to enable loop guard on the device.

**SUMMARY STEPS**

1. Enter one of the following commands:
   - `show spanning-tree active`
   - `show spanning-tree mst`

2. `configure terminal`

3. `spanning-tree loopguard default`

4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>

CHAPTER 48

Configuring EtherChannels

• Restrictions for EtherChannels, on page 849
• Information About EtherChannels, on page 849
• How to Configure EtherChannels, on page 862
• Monitoring EtherChannel, PAgP, and LACP Status, on page 879
• Configuration Examples for Configuring EtherChannels, on page 880
• Additional References for EtherChannels, on page 883
• Feature Information for EtherChannels, on page 883

Restrictions for EtherChannels

The following are restrictions for EtherChannels:

• All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.

• Layer 3 EtherChannels are not supported if running the LAN Base license feature set.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About EtherChannels

EtherChannel Overview

EtherChannel provides fault-tolerant high-speed links between switches, routers, and servers. You can use the EtherChannel to increase the bandwidth between the wiring closets and the data center, and you can deploy it anywhere in the network where bottlenecks are likely to occur. EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention.

An EtherChannel consists of individual Ethernet links bundled into a single logical link.
Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The number of EtherChannels is limited to 128.

The LAN Base feature set supports up to 24 EtherChannels.

All ports in each EtherChannel must be configured as either Layer 2 or Layer 3 ports. The EtherChannel Layer 3 ports are made up of routed ports. Routed ports are physical ports configured to be in Layer 3 mode by using the `no switchport` interface configuration command. For more information, see the Configuring Interface Characteristics chapter.

### EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as would any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.

- When you configure an EtherChannel in the `on` mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the `on` mode; otherwise, packet loss can occur.

### EtherChannel on Devices

You can create an EtherChannel on a device, on a single device in the stack, or on multiple devices in the stack (known as cross-stack EtherChannel).
EtherChannel Link Failover

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

Channel Groups and Port-Channel Interfaces

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.
The **channel-group** command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 128. This port-channel interface number corresponds to the one specified with the **channel-group** interface configuration command.

- With Layer 2 ports, use the **channel-group** interface configuration command to dynamically create the port-channel interface.

  You also can use the **interface port-channel** port-channel-number global configuration command to manually create the port-channel interface, but then you must use the **channel-group** channel-group-number command to bind the logical interface to a physical port. The channel-group-number can be the same as the port-channel-number, or you can use a new number. If you use a new number, the **channel-group** command dynamically creates a new port channel.

- With Layer 3 ports, you should manually create the logical interface by using the **interface port-channel** global configuration command followed by the **no switchport** interface configuration command. You then manually assign an interface to the EtherChannel by using the **channel-group** interface configuration command.

- With Layer 3 ports, use the **no switchport** interface command to configure the interface as a Layer 3 interface, and then use the **channel-group** interface configuration command to dynamically create the port-channel interface.

### Port Aggregation Protocol

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco devices and on those devices licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports.

By using PAgP, the device or device stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single device in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single device port.
PAgP Modes

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

Table 64: EtherChannel PAgP Modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets.</td>
</tr>
<tr>
<td>desirable</td>
<td>Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel).</td>
</tr>
</tbody>
</table>

Switch ports exchange PAgP packets only with partner ports configured in the auto or desirable modes. Ports configured in the on mode do not exchange PAgP packets.

Both the auto and desirable modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the desirable mode can form an EtherChannel with another port that is in the desirable or auto mode.
- A port in the auto mode can form an EtherChannel with another port in the desirable mode.

A port in the auto mode cannot form an EtherChannel with another port that is also in the auto mode because neither port starts PAgP negotiation.

Silent Mode

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the non-silent keyword. If you do not specify non-silent with the auto or desirable mode, silent mode is assumed.

Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

PAgP Learn Method and Priority

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.

When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.
PAgP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the `pagp port-priority` interface configuration command. The higher the priority, the more likely that the port will be selected.

The device supports address learning only on aggregate ports even though the `physical-port` keyword is provided in the CLI. The `pagp learn-method` command and the `pagp port-priority` command have no effect on the device hardware, but they are required for PAgP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the device is a physical learner, we recommend that you configure the device as a physical-port learner by using the `pagp learn-method physical-port` interface configuration command. Set the load-distribution method based on the source MAC address by using the `port-channel load-balance src-mac` global configuration command. The device then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the `pagp learn-method` command in this situation.

**PAgP Interaction with Other Features**

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAgP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created (through the `interface port-channel` global configuration command). PAgP sends and receives PAgP PDUs only from ports that are up and have PAgP enabled for the auto or desirable mode.

**Link Aggregation Control Protocol**

The LACP is defined in IEEE 802.3ad and enables Cisco devices to manage Ethernet channels between devices that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the device or device stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single device port.
The independent mode behavior of ports in a port channel is changed. With CSCtn96950, by default, standalone mode is enabled. When no response is received from an LACP peer, ports in the port channel are moved to suspended state.

**LACP Modes**

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

*Table 65: EtherChannel LACP Modes*

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.</td>
</tr>
<tr>
<td>passive</td>
<td>Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets.</td>
</tr>
</tbody>
</table>

Both the *active* and *passive* LACP modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the *active* mode can form an EtherChannel with another port that is in the *active* or *passive* mode.
- A port in the *passive* mode cannot form an EtherChannel with another port that is also in the *passive* mode because neither port starts LACP negotiation.

**LACP and Link Redundancy**

LACP port-channel operation, bandwidth availability, and link redundancy can be further refined with the LACP port-channel min-links and the LACP max-bundle features.

The LACP port-channel min-links feature:

- Configures the minimum number of ports that must be linked up and bundled in the LACP port channel.
- Prevents a low-bandwidth LACP port channel from becoming active.
- Causes an LACP port channel to become inactive if there are too few active members ports to supply the required minimum bandwidth.

The LACP max-bundle feature:

- Defines an upper limit on the number of bundled ports in an LACP port channel.
- Allows hot-standby ports with fewer bundled ports. For example, in an LACP port channel with five ports, you can specify a max-bundle of three, and the two remaining ports are designated as hot-standby ports.
**LACP Interaction with Other Features**

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created through the `interface port-channel` global configuration command.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

**EtherChannel On Mode**

EtherChannel on mode can be used to manually configure an EtherChannel. The on mode forces a port to join an EtherChannel without negotiations. The on mode can be useful if the remote device does not support PAgP or LACP. In the on mode, a usable EtherChannel exists only when the devices at both ends of the link are configured in the on mode.

Ports that are configured in the on mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the on mode.

---

**Caution**

You should use care when using the on mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

**Load-Balancing and Forwarding Methods**

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the device.

---

**Note**

Layer 3 Equal-cost multi path (ECMP) load balancing is based on source IP address, destination IP address, source port, destination port, and layer 4 protocol. Fragmented packets will be treated on two different links based on the algorithm calculated using these parameters. Any changes in one of these parameters will result in load balancing.

You configure the load-balancing and forwarding method by using the `port-channel load-balance` and the `port-channel load-balance extended` global configuration commands.

**MAC Address Forwarding**

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide
load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host’s MAC address of the incoming packet. Therefore, packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular device. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

**IP Address Forwarding**

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel.

Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular device. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

**Load-Balancing Advantages**

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the device in the network and the kind of traffic that needs to be load-distributed.

**Figure 66: Load Distribution and Forwarding Methods**

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the device EtherChannel ensures that the device uses all available bandwidth to the router. The router is configured for destination-based forwarding because
the large number of workstations ensure that the traffic is evenly distributed from the router EtherChannel.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

**EtherChannel and Device Stacks**

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active device removes the failed stack member device ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a device is added to an existing stack, the new device receives the running configuration from the active device and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAgP or LACP configuration on a winning device stack is not affected, but the PAgP or LACP configuration on the losing device stack is lost after the stack reboots.

**Device Stack and PAgP**

With PAgP, if the active device fails or leaves the stack, the standby device becomes the new active device. A spanning-tree reconvergence is not triggered unless there is a change in the EtherChannel bandwidth. The new active device synchronizes the configuration of the stack members to that of the active device. The PAgP configuration is not affected after an active device change unless the EtherChannel has ports residing on the old active device.
Device Stacks and LACP

With LACP, the system ID uses the stack MAC address from the active device. When an active device fails or leaves the stack and the standby device becomes the new active device change, the LACP system ID is unchanged. By default, the LACP configuration is not affected after the active device changes.

Default EtherChannel Configuration

The default EtherChannel configuration is described in this table.

Table 66: Default EtherChannel Configuration

<table>
<thead>
<tr>
<th>Feature</th>

</tbody>
</table>

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

• Do not try to configure more than 128 EtherChannels on the device or device stack.
• Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
• Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
• Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
• Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the `shutdown` interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.

• When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:
  • Allowed-VLAN list
  • Spanning-tree path cost for each VLAN
  • Spanning-tree port priority for each VLAN
  • Spanning-tree Port Fast setting

• Do not configure a port to be a member of more than one EtherChannel group.

• Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same device or on different devices in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.

• Do not configure a secure port as part of an EtherChannel or the reverse.

• Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.

• If EtherChannels are configured on device interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a device by using the `dot1x system-auth-control` global configuration command.

• If cross-stack EtherChannel is configured and the device stack partitions, loops and forwarding issues can occur.

### Layer 2 EtherChannel Configuration Guidelines

When configuring Layer 2 EtherChannels, follow these guidelines:

• Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.

• An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAgP is set to the `auto` or `desirable` mode.

• Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

### Layer 3 EtherChannel Configuration Guidelines

• For Layer 3 EtherChannels, assign the Layer 3 address to the port-channel logical interface, not to the physical ports in the channel.
Auto-LAG

The auto-LAG feature provides the ability to auto create EtherChannels on ports connected to a switch. By default, auto-LAG is disabled globally and is enabled on all port interfaces. The auto-LAG applies to a switch only when it is enabled globally.

On enabling auto-LAG globally, the following scenarios are possible:

• All port interfaces participate in creation of auto EtherChannels provided the partner port interfaces have EtherChannel configured on them. For more information, see the “The supported auto-LAG configurations between the actor and partner devices” table below.

• Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.

• When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:

<table>
<thead>
<tr>
<th>Actor/Partner</th>
<th>Active</th>
<th>Passive</th>
<th>Auto</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Passive</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Auto</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels.

You cannot add any configurations in an existing auto created EtherChannel. To add, you should first convert it into a manual EtherChannel by executing the `port-channel<channel-number> persistent` command.

Note

Auto-LAG uses the LACP protocol to create auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

Auto-LAG Configuration Guidelines

Follow these guidelines when configuring the auto-LAG feature.

• When auto-LAG is enabled globally and on the port interface, and if you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.

• A port interface will not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.

• When auto-LAG is enabled and auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.

• The auto-LAG is supported only on Layer 2 EtherChannel. It is not supported on Layer 3 interface and Layer 3 EtherChannel.
• The auto-LAG is supported on cross-stack EtherChannel.

How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

Configuring Layer 2 EtherChannels (CLI)

You configure Layer 2 EtherChannels by assigning ports to a channel group with the `channel-group` interface configuration command. This command automatically creates the port-channel logical interface.

SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `switchport mode {access | trunk}`
4. `switchport access vlan vlan-id`
5. `channel-group channel-group-number mode {auto [non-silent] | desirable [non-silent] | on } | { active | passive}`
6. `end`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>interface interface-id</code></td>
<td>Specifies a physical port, and enters interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device(config)# interface gigabitethernet</code></td>
<td>Valid interfaces are physical ports.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>`switchport mode {access</td>
<td>trunk}`</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device(config-if)# switchport mode access</code></td>
<td>If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action** | **Purpose**
---|---
**Step 4** | (Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.

**Example:**

Device(config-if)# `switchport access vlan 22`

**Step 5** | Assigns the port to a channel group, and specifies the PAgP or the LACP mode.

**Example:**

Device(config-if)# `channel-group 5 mode auto`

For **mode**, select one of these keywords:

- **auto** – Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **desirable** – Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **on** – Forces the port to channel without PAgP or LACP. In the **on** mode, an EtherChannel exists only when a port group in the **on** mode is connected to another port group in the **on** mode.

- **non-silent** – (Optional) If your device is connected to a partner that is PAgP-capable, configures the device port for nonsilent operation when the port is in the **auto** or **desirable** mode. If you do not specify **non-silent**, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

- **active** – Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.

- **passive** – Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.

**Step 6** | Returns to privileged EXEC mode.

**Example:**
### Configuring Layer 3 EtherChannels (CLI)

Follow these steps to assign an Ethernet port to a Layer 3 EtherChannel. This procedure is required.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `no ip address`
5. `no switchport`
6. `channel-group channel-group-number mode { auto [ non-silent ] | desirable [ non-silent ] | on } | { active | passive }`
7. `end`

</tbody>
</table>

**Step 5**

**Example:**

Device(config-if)# no switchport

**Purpose**

Assigns the port to a channel group, and specifies the PAgP or the LACP mode.

**For mode, select one of these keywords:**

- **auto**—Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **desirable**—Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **on**—Forces the port to channel without PAgP or LACP. In the on mode, an EtherChannel exists only when a port group in the on mode is connected to another port group in the on mode.

- **non-silent**—(Optional) If your device is connected to a partner that is PAgP capable, configures the device port for nonsilent operation when the port is in the auto or desirable mode. If you do not specify non-silent, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

- **active**—Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.

- **passive**—Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.
Configuring EtherChannel Load-Balancing (CLI)

You can configure EtherChannel load-balancing to use one of several different forwarding methods. This task is optional.

**SUMMARY STEPS**

1. `configure terminal`
3. `end`

**DETAILED STEPS**

<table>

**Configuring EtherChannel Extended Load-Balancing (CLI)**

Configure EtherChannel extended load-balancing when you want to use a combination of load-balancing methods.

This task is optional.

**SUMMARY STEPS**

1. configure terminal
2. port-channel load-balance extended [ dst-ip | dst-mac dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port ]
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
Configuring the PAgP Learn Method and Priority (CLI)

This task is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. pagp learn-method physical-port
4. pagp port-priority priority
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**

Port-channel load-balance extended [ dst-ip | dst-mac dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port ]

**Example:**

Device(config)# port-channel load-balance extended dst-ip dst-mac src-ip

**Purpose**

Configures an EtherChannel extended load-balancing method.

The default is src-mac.

Select one of these load-distribution methods:

- **dst-ip**—Specifies destination-host IP address.
- **dst-mac**—Specifies the destination-host MAC address of the incoming packet.
- **dst-port**—Specifies the destination TCP/UDP port.
- **ipv6-label**—Specifies the IPv6 flow label.
- **l3-proto**—Specifies the Layer 3 protocol.
- **src-ip**—Specifies the source host IP address.
- **src-mac**—Specifies the source MAC address of the incoming packet.
- **src-port**—Specifies the source TCP/UDP port.

**Step 3**

end

**Example:**

Device(config)# end

**Purpose**

Returns to privileged EXEC mode.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Device# configure terminal</strong></td>
<td>Specifies the port for transmission, and enters interface configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**

**interface interface-id**

*Example:*

Device(config)# interface gigabitethernet

**Step 3**

**pagp learn-method physical-port**

*Example:*

Device(config-if)# pagp learn-method physical port

**Step 4**

**pagp port-priority priority**

*Example:*

Device(config-if)# pagp port-priority 200

**Step 5**

**end**

*Example:*

Device(config-if)# end

---

**Configuring LACP Hot-Standby Ports**

When LACP is enabled, the software, by default, tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time; the remaining eight links are placed in hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.

You can override the default behavior by specifying the maximum number of active ports in a channel, in which case, the remaining ports become hot-standby ports. For example, if you specify a maximum of five ports in a channel, up to 11 ports become hot-standby ports.
If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the device MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

**Configuring the LACP Max Bundle Feature (CLI)**

When you specify the maximum number of bundled LACP ports allowed in a port channel, the remaining ports in the port channel are designated as hot-standby ports.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of LACP ports in a port channel. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface port-channel channel-number
3. lacp max-bundle max-bundle-number
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>

<td>Device(config)# interface port-channel 2</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring LACP Port-Channel Standalone Disable

To disable the standalone EtherChannel member port state on a port channel, perform this task on the port channel interface:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface port-channel channel-group`
3. `port-channel standalone-disable`
4. `end`
5. `show etherchannel`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
configure terminal  |
Example: DEVICE # configure terminal |
| **Step 2**
interface port-channel channel-group |
Example: DEVICE(config)# interface port-channel channel-group |
| **Step 3**
port-channel standalone-disable |
Example: DEVICE(config-if)# port-channel standalone-disable |
| **Step 4**
end |
Example: |

**Command or Action**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3**
lACP max-bundle max-bundle-number |
Example: DEVICE(config-if)# lacp max-bundle 3 |
| **Step 4**
end |
Example: DEVICE(config)# end |

**Purpose**

Specifies the maximum number of LACP ports in the port-channel bundle.
The range is 1 to 8.

Returns to privileged EXEC mode.
Configuring the LACP Port Channel Min-Links Feature (CLI)

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

To configure the minimum number of links that are required for a port channel. Perform the following tasks.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface port-channel channel-number
4. port-channel min-links min-links-number
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>interface port-channel channel-number</td>
<td>Enters interface configuration mode for a port-channel.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface port-channel 2</td>
<td>For channel-number, the range is 1 to 63.</td>
</tr>
</tbody>
</table>
### Configuring the LACP System Priority (CLI)

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the `lacp system-priority` global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Follow these steps to configure the LACP system priority. This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `lacp system-priority priority`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>* Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>lacp system-priority priority</code></td>
<td>Configures the LACP system priority.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>The range is 1 to 65535. The default is 32768.</td>
</tr>
</tbody>
</table>
Configuring the LACP Port Priority (CLI)

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Note

If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Follow these steps to configure the LACP port priority. This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `lacp port-priority priority`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>

### Configuring LACP Fast Rate Timer

You can change the LACP timer rate to modify the duration of the LACP timeout. Use the `lacp rate` command to set the rate at which LACP control packets are received by an LACP-supported interface. You can change the timeout rate from the default rate (30 seconds) to the fast rate (1 second). This command is supported only on LACP-enabled interfaces.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface {fastethernet | gigabitethernet | tengigabitethernet} slot/port`
4. `lacp rate {normal | fast}`
5. `end`
6. `show lacp internal`

### DETAILED STEPS

### Configuring Auto-LAG on a Port Interface

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. [no] channel-group auto
5. end
6. show etherchannel auto

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>

- Enter your password if prompted.

---

### Purpose Command or Action

| Device> enable |

**Step 2** configure terminal

**Example:**

```
Device# configure terminal
```

**Enters global configuration mode.**

**Step 3** [no] port-channel auto

**Example:**

```
Device(config)# port-channel auto
```

Enables the auto-LAG feature on a switch globally. Use the no form of this command to disable the auto-LAG feature on the switch globally.

**Note** By default, the auto-LAG feature is enabled on the port.

**Step 4** end

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 5** show etherchannel auto

**Example:**

```
Device# show etherchannel auto
```

Displays that EtherChannel is created automatically.
### Purpose

- **Command or Action**: `configure terminal`  
  **Example:**  
  Device# configure terminal

- **Command or Action**: `interface interface-id`  
  **Example:**  
  Device(config)# interface gigabitethernet

- **Command or Action**: `[no] channel-group auto`  
  **Example:**  
  Device(config-if)# channel-group auto

What to do next

### Configuring Persistence with Auto-LAG

You use the persistence command to convert the auto-created EtherChannel into a manual one and allow you to add configuration on the existing EtherChannel.

#### SUMMARY STEPS

1. `enable`
2. `port-channel channel-number persistent`
3. `show etherchannel summary`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

(Optional) Enables auto-LAG feature on individual port interface. Use the no form of this command to disable the auto-LAG feature on individual port interface.

**Note**: By default, the auto-LAG feature is enabled on the port.

### Returns to privileged EXEC mode.

**Example:**  
Device(config-if)# end

Displays that EtherChannel is created automatically.

**Example:**  
Device# show etherchannel auto
Purpose

Command or Action | Purpose
--- | ---
Step 2 | Converts the auto created EtherChannel into a manual one and allows you to add configuration on the EtherChannel.

**Example:**

Device# port-channel 1 persistent

Step 3 | Displays the EtherChannel information.

**Example:**

Device# show etherchannel summary

---

**Monitoring EtherChannel, PAgP, and LACP Status**

You can display EtherChannel, PAgP, and LACP status using the commands listed in this table.

**Table 68: Commands for Monitoring EtherChannel, PAgP, and LACP Status**

<table>
<thead>
<tr>

**Configuration Examples for Configuring EtherChannels**

**Configuring Layer 2 EtherChannels: Examples**

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAgP mode **desirable**:

```bash
Device# configure terminal
Device(config)# interface range gigabitethernet -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode desirable non-silent
Device(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode **active**:

```bash
Device# configure terminal
Device(config)# interface range gigabitethernet -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
```

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

```bash
Device# configure terminal
Device(config)# interface range gigabitethernet -5
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode passive
Device(config-if-range)# exit
Device(config)# interface gigabitethernet
Device(config-if)# switchport mode access
Device(config-if)# switchport access vlan 10
Device(config-if)# channel-group 5 mode passive
Device(config-if)# exit
```

PoE or LACP negotiation errors may occur if you configure two ports from switch to the access point (AP). This scenario can be avoided if the port channel configuration is on the switch side. For more details, see the following example:

```bash
interface Port-channel1
  switchport access vlan 20
  switchport mode access
  switchport nonegotiate
  no port-channel standalone-disable <--this one
  spanning-tree portfast
```
If the port reports LACP errors on port flap, you should include the following command as well: `no errdisable detect cause pagp-flap`

---

## Configuring Layer 3 EtherChannels: Examples

This example shows how to configure a Layer 3 EtherChannel. It assigns two ports to channel 5 with the LACP mode `active`:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
```

This example shows how to configure a cross-stack Layer 3 EtherChannel. It assigns two ports on stack member 2 and one port on stack member 3 to channel 7 using LACP active mode:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 7 mode active
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# no ip address
Device(config-if)# no switchport
Device(config-if)# channel-group 7 mode active
Device(config-if)# exit
```

---

## Configuring LACP Hot-Standby Ports: Example

This example shows how to configure an Etherchannel (port channel 2) that will be active when there are at least three active ports, will comprise up to seven active ports and the remaining ports (up to nine) as hot-standby ports:

```
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# port-channel min-links 3
Device(config-if)# lACP max-bundle 7
```

This example shows how to disable the standalone EtherChannel member port state on port channel 42:

```
Device(config)# interface port-channel channel-group
Device(config-if)# port-channel standalone-disable
```

This example shows how to verify the configuration:
Configuring Auto LAG: Examples

This example shows how to configure Auto-LAG on a switch:

```
device> enable
device# configure terminal
device (config)# port-channel auto
device (config-if)# end
device# show etherchannel auto
```

The following example shows the summary of EtherChannel that was created automatically.

```
device# show etherchannel auto
Flags:  D - down  P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby (LACP only)
        R - Layer3  S - Layer2
        U - in use  f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port
        A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators: 1

Group Port-channel Protocol Ports
-------------------------------
1 Po1(SUA) LACP Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)
```

The following example shows the summary of auto EtherChannel after executing the `port-channel 1 persistent` command.

```
device# port-channel 1 persistent
device# show etherchannel summary
```

```
Switch# show etherchannel summary
Flags:  D - down  P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby (LACP only)
        R - Layer3  S - Layer2
        U - in use  f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port
        A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators: 1

Group Port-channel Protocol Ports
-------------------------------
1 Po1(SU) LACP Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)
```

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
Overview of Resilient Ethernet Protocol

Resilient Ethernet Protocol (REP) is a Cisco-proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

A REP segment is a chain of ports connected to each other and configured with a segment ID. Each segment consists of standard (non-edge) segment ports and two user-configured edge ports. A device can have no more than two ports that belong to the same segment, and each segment port can have only one external neighbor. A segment can go through a shared medium, but on any link, only two ports can belong to the same segment. REP is supported only on Trunk Ethernet Flow Point (EFP) interfaces.

The following figure shows an example of a segment consisting of six ports spread across four switches. Ports E1 and E2 are configured as edge ports. When all the ports are operational (as in the segment on the left), a single port is blocked, as shown by the diagonal line. When there is a failure in the network, the blocked port returns to the forwarding state to minimize network disruption.

*Figure 67: REP Open Segment*
The segment shown in the figure above is an open segment; there is no connectivity between the two edge ports. The REP segment cannot cause a bridging loop, and you can safely connect the segment edges to any network. All the hosts connected to devices inside the segment have two possible connections to the rest of the network through the edge ports, but only one connection is accessible at any time. If a failure occurs on any segment or on any port on a REP segment, REP unblocks all the ports to ensure that connectivity is available through the other gateway.

The segment shown in the following figure is a ring segment, with both the edge ports located on the same device. With this configuration, you can create a redundant connection between any two devices in the segment.

**Figure 68: REP Ring Segment**

REP segments have the following characteristics:

- If all the ports in a segment are operational, one port (referred to as the *alternate* port) is in the blocked state for each VLAN. If VLAN load balancing is configured, two ports in the segment control the blocked state of VLANs.

- If one or more ports in a segment is not operational, and cause a link failure, all the ports forward traffic on all the VLANs to ensure connectivity.

- In case of a link failure, alternate ports are unblocked as quickly as possible. When the failed link is up, a logically blocked port per VLAN is selected with minimal disruption to the network.

You can construct almost any type of network based on REP segments. REP also supports VLAN load balancing, which is controlled by the primary edge port (any port in the segment).

In access ring-topologies, the neighboring switch might not support REP as shown in the following figure. In this scenario, you can configure the non-REP-facing ports (E1 and E2) as edge no-neighbor ports. These ports inherit all the properties of edge ports, and you can configure them the same as any edge port, including configuring them to send STP or REP topology change notices to the aggregation switch. In this scenario, the STP topology change notice (TCN) that is sent is a multiple spanning-tree (MST) STP message.
REP has these limitations:

- You must configure each segment port; an incorrect configuration might cause forwarding loops in the networks.
- REP can manage only a single failed port within the segment; multiple port failures within the REP segment cause loss of network connectivity.
- You should configure REP only in networks with redundancy. Configuring REP in a network without redundancy causes loss of connectivity.

**Link Integrity**

REP does not use an end-to-end polling function between edge ports to verify link integrity. It implements local link failure detection. The REP Link Status Layer (LSL) detects its REP-aware neighbor and establishes connectivity within the segment. All the VLANs are blocked on an interface until the neighbor is detected. After the neighbor is identified, REP determines which neighbor port should become the alternate port and which ports should forward traffic.

Each port in a segment has a unique port ID. The port ID format is similar to that used by the spanning tree algorithm: a port number (unique on the bridge) associated to a MAC address (unique in the network). When a segment port is coming up, its LSL starts sending packets that include the segment ID and the port ID. The port is declared as operational after it performs a three-way handshake with a neighbor in the same segment.

A segment port does not become operational if:

- No neighbor has the same segment ID.
- More than one neighbor has the same segment ID.
- A neighbor does not acknowledge a local port as a peer.

Each port creates an adjacency with its immediate neighbor. After the neighbor adjacencies are created, the ports negotiate with each other to determine the blocked port for the segment, which will function as the alternate port. All the other ports become unblocked. By default, REP packets are sent to a bridge protocol data unit-class MAC address. The packets can also be sent to a Cisco multicast address, which is used only to send blocked port advertisement (BPA) messages when there is a failure in the segment. The packets are dropped by the devices not running REP.
Fast Convergence

REP runs on a physical link basis and not on a per-VLAN basis. Only one hello message is required for all the VLANs, and this reduces the load on the protocol. We recommend that you create VLANs consistently on all the switches in a given segment and configure the same allowed VLANs on the REP trunk ports. To avoid the delay introduced by relaying messages in software, REP also allows some packets to be flooded to a regular multicast address. These messages operate at the hardware flood layer (HFL) and are flooded to the entire network, not just the REP segment. Switches that do not belong to the segment treat them as data traffic. You can control flooding of these messages by configuring an administrative VLAN for the entire domain or for a particular segment.

The estimated convergence recovery time is between 150-500ms up to 1000 MACs, 5 VLANs. The estimated convergence recovery time for multicast traffic is between 300-500ms up to 100 Groups and 5 VLANs.

VLAN Load Balancing

One edge port in the REP segment acts as the primary edge port; and another as the secondary edge port. It is the primary edge port that always participates in VLAN load balancing in the segment. REP VLAN balancing is achieved by blocking some VLANs at a configured alternate port and all the other VLANs at the primary edge port. When you configure VLAN load balancing, you can specify the alternate port in one of three ways:

- By entering the port ID of the interface. To identify the port ID of a port in the segment, enter the `show interface rep detail` interface configuration command for the port.
- By entering the `preferred` keyword to select the port that you previously configured as the preferred alternate port with the `rep segment segment-id preferred` interface configuration command.
- By entering the neighbor offset number of a port in the segment, which identifies the downstream neighbor port of an edge port. The neighbor offset number range is –256 to +256; a value of 0 is invalid. The primary edge port has an offset number of 1; positive numbers above 1 identify downstream neighbors of the primary edge port. Negative numbers indicate the secondary edge port (offset number -1) and its downstream neighbors.

Note: Configure offset numbers on the primary edge port by identifying a port’s downstream position from the primary (or secondary) edge port. Never enter an offset value of 1 because that is the offset number of the primary edge port.

The following figure shows neighbor offset numbers for a segment, where E1 is the primary edge port and E2 is the secondary edge port. The red numbers inside the ring are numbers offset from the primary edge port; the black numbers outside of the ring show the offset numbers from the secondary edge port. Note that you can identify all the ports (except the primary edge port) by either a positive offset number (downstream position from the primary edge port) or a negative offset number (downstream position from the secondary edge port). If E2 became the primary edge port, its offset number would then be 1 and E1 would be -1.
When the REP segment is complete, all the VLANs are blocked. When you configure VLAN load balancing, you must also configure triggers in one of two ways:

- **Manually trigger VLAN load balancing at any time by entering the** `rep preempt segment segment-id` **privileged EXEC command on the switch that has the primary edge port.**

- **Configure a preempt delay time by entering the** `rep preempt delay seconds` **interface configuration command.** After a link failure and recovery, VLAN load balancing begins after the configured preemption time period elapses. Note that the delay timer restarts if another port fails before the time has elapsed.

---

**Note**

When VLAN load balancing is configured, it does not start working until triggered by either manual intervention or a link failure and recovery.

When VLAN load balancing is triggered, the primary edge port sends out a message to alert all the interfaces in the segment about the preemption. When the secondary port receives the message, the message is sent to the network to notify the alternate port to block the set of VLANs specified in the message and to notify the primary edge port to block the remaining VLANs.

You can also configure a particular port in the segment to block all the VLANs. Only the primary edge port initiates VLAN load balancing, which is not possible if the segment is not terminated by an edge port on each end. The primary edge port determines the local VLAN load-balancing configuration.

Reconfigure the primary edge port to reconfigure load balancing. When you change the load-balancing configuration, the primary edge port waits for the `rep preempt segment` command or for the configured preempt delay period after a port failure and recovery, before executing the new configuration. If you change an edge port to a regular segment port, the existing VLAN load-balancing status does not change. Configuring a new edge port might cause a new topology configuration.

---

**Spanning Tree Interaction**

REP does not interact with the STP or the Flex Link feature, but can coexist with both. A port that belongs to a segment is removed from spanning tree control, and STP BPDU's are not accepted or sent from segment ports. Therefore, STP cannot run on a segment.

To migrate from an STP ring configuration to an REP segment configuration, begin by configuring a single port in the ring as part of the segment and continue by configuring contiguous ports to minimize the number of segments. Since each segment always contains a blocked port, multiple segments means multiple blocked
ports and a potential loss of connectivity. After the segment is configured in both directions up to the location of the edge ports, configure the edge ports.

**REP Ports**

REP segments consist of Failed, Open, or Alternate ports:

- A port configured as a regular segment port starts as a failed port.
- After the neighbor adjacencies are determined, the port transitions to alternate port state, blocking all the VLANs on the interface. Blocked-port negotiations occur, and when the segment settles, one blocked port remains in the alternate role and all the other ports become open ports.
- When a failure occurs in a link, all the ports move to the Failed state. When the Alternate port receives the failure notification, it changes to the Open state, forwarding all the VLANs.

A regular segment port converted to an edge port, or an edge port converted to a regular segment port, does not always result in a topology change. If you convert an edge port into a regular segment port, VLAN load balancing is not implemented unless it has been configured. For VLAN load balancing, you must configure two edge ports in the segment.

A segment port that is reconfigured as a spanning tree port restarts according to the spanning tree configuration. By default, this is a designated blocking port. If PortFast is configured or if STP is disabled, the port goes into the forwarding state.

**How to Configure Resilient Ethernet Protocol**

A segment is a collection of ports connected to one another in a chain and configured with a segment ID. To configure REP segments, configure the REP administrative VLAN (or use the default VLAN 1) and then add the ports to the segment, using interface configuration mode. You should configure two edge ports in a segment, with one of them being the primary edge port and the other the secondary edge port by default. A segment should have only one primary edge port. If you configure two ports in a segment as primary edge ports, for example, ports on different switches, the REP selects one of them to serve as the segment's primary edge port. If required, you can configure the location to which segment topology change notices (STCNs) and VLAN load balancing are to be sent.

**Default REP Configuration**

REP is disabled on all the interfaces. When enabled, the interface is a regular segment port unless it is configured as an edge port.

When REP is enabled, the task of sending segment topology change notices (STCNs) is disabled, all the VLANs are blocked, and the administrative VLAN is VLAN 1.

When VLAN load balancing is enabled, the default is manual preemption with the delay timer disabled. If VLAN load balancing is not configured, the default after manual preemption is to block all the VLANs in the primary edge port.

**REP Configuration Guidelines**

Follow these guidelines when configuring REP:
• We recommend that you begin by configuring one port and then configure contiguous ports to minimize the number of segments and the number of blocked ports.

• If more than two ports in a segment fail when no external neighbors are configured, one port goes into a forwarding state for the data path to help maintain connectivity during configuration. In the `show rep interface` command output, the Port Role for this port is displayed as **Fail Logical Open**; the Port Role for the other failed port is displayed as **Fail No Ext Neighbor**. When the external neighbors for the failed ports are configured, the ports go through the alternate port transitions and eventually go to an open state, or remain as the alternate port, based on the alternate port selection mechanism.

• REP ports must be Layer 2 IEEE 802.1Q or Trunk ports.

• We recommend that you configure all the trunk ports in a segment with the same set of allowed VLANs.

• Be careful when configuring REP through a Telnet connection because REP blocks all the VLANs until another REP interface sends a message to unblock it. You might lose connectivity to the router if you enable REP in a Telnet session that accesses the router through the same interface.

• You cannot run REP and STP or REP and Flex Links on the same segment or interface.

• If you connect an STP network to an REP segment, be sure that the connection is at the segment edge. An STP connection that is not at the edge might cause a bridging loop because STP does not run on REP segments. All the STP BPDUs are dropped at REP interfaces.

• You must configure all the trunk ports in a segment with the same set of allowed VLANs. If this is not done, misconfiguration occurs.

• If REP is enabled on two ports on a switch, both the ports must be either regular segment ports or edge ports. REP ports follow these rules:
  - There is no limit to the number of REP ports on a switch. However, only two ports on a switch can belong to the same REP segment.
  - If only one port on a switch is configured in a segment, the port should be an edge port.
  - If two ports on a switch belong to the same segment, they must both be edge ports, regular segment ports, or one regular port and one edge no-neighbor port. An edge port and regular segment port on a switch cannot belong to the same segment.
  - If two ports on a switch belong to the same segment, and one is configured as an edge port and one as a regular segment port (a misconfiguration), the edge port is treated as a regular segment port.

• REP interfaces come up in a blocked state and remain in a blocked state until they are safe to be unblocked. You must, therefore, be aware of the status of REP interfaces to avoid sudden connection losses.

• REP sends all the LSL PDUs in the untagged frames to the native VLAN. The BPA message sent to a Cisco multicast address is sent to the administration VLAN, which is VLAN 1 by default.

• You can configure the duration for which a REP interface remains up without receiving a hello from a neighbor. Use the `rep lsl-age-timer` value interface configuration command to set the time from 120 ms to 10000 ms. The LSL hello timer is then set to the age-timer value divided by 3. In normal operation, three LSL hellos are sent before the age timer on the peer switch expires and checks for hello messages.
  - EtherChannel port channel interfaces do not support LSL age-timer values less than 1000 ms. If you try to configure a value less than 1000 ms on a port channel, you receive an error message and the command is rejected.
REP ports cannot be configured as one of the following port types:
  • Switched Port Analyzer (SPAN) destination port
  • Tunnel port
  • Access port

REP is supported on EtherChannels, but not on an individual port that belongs to an EtherChannel.

There can be a maximum of 26 REP segments per switch.

Configuring REP Administrative VLAN

To avoid the delay created by link-failure messages, and VLAN-blocking notifications during load balancing, REP floods packets to a regular multicast address at the hardware flood layer (HFL). These messages are flooded to the whole network, and not just the REP segment. You can control the flooding of these messages by configuring an administrative VLAN.

Follow these guidelines when configuring the REP administrative VLAN:

• If you do not configure an administrative VLAN, the default is VLAN 1.
• You can configure one admin VLAN on the switch for all segments.
• The administrative VLAN cannot be the RSPAN VLAN.

To configure the REP administrative VLAN, follow these steps, beginning in privileged EXEC mode:

**SUMMARY STEPS**

1. configure terminal
2. rep admin vlan vlan-id
3. end
4. show interface [interface-id] rep detail
5. copy running-config startup config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

---

### Configuring a REP Interface

To configure REP, enable REP on each segment interface and identify the segment ID. This task is mandatory, and must be done before other REP configurations. You must also configure a primary and secondary edge port on each segment. All the other steps are optional.

Follow these steps to enable and configure REP on an interface:

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. switchport mode trunk
5. rep segment segment-id [edge [no-neighbor] [primary]] [preferred]
6. rep stcn {interface interface-id | segment id-list | stp}
7. rep block port {id port-id | neighbor-offset | preferred} vlan {vlan-list | all}
8. rep preempt delay seconds
9. rep isl-age-timer value
10. end
11. show interface [interface-id] rep [detail]
12. copy running-config startup-config

### DETAILED STEPS

</tr>
</tbody>
</table>

**Note** You must configure two edge ports, including one primary edge port, for each segment.

These optional keywords are available:

- (Optional) **edge**—Configures the port as an edge port. Each segment has only two edge ports. Entering the keyword `edge` without the keyword `primary` configures the port as the secondary edge port.

- (Optional) **primary**—Configures the port as the primary edge port, the port on which you can configure VLAN load balancing.

- (Optional) **no-neighbor**—Configures a port with no external REP neighbors as an edge port. The port inherits all the properties of an edge port, and you can configure the properties the same way you would for an edge port.

**Note** Although each segment can have only one primary edge port, if you configure edge ports on two different switches and enter the keyword `primary` on both the switches, the configuration is valid. However, REP selects only one of these ports as the segment primary edge port. You can identify the primary edge port for a segment by entering the `show rep topology` privileged EXEC command.

- (Optional) **preferred**—Indicates that the port is the preferred alternate port or the preferred port for VLAN load balancing.
### Configuring a REP Interface

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong></td>
<td>Configuring a port as preferred does not guarantee that it becomes the alternate port; it merely gives the port a slight edge over equal contenders. The alternate port is usually a previously failed port.</td>
</tr>
</tbody>
</table>

#### Step 6

```
rep stcn {interface interface-id | segment id-list | stp}...
```

**Example:**
```
Device# rep stcn segment 25-50
```

(Optional) Configures the edge port to send segment topology change notices (STCNs).
- **interface interface-id**—Designates a physical interface or port channel to receive STCNs.
- **segment id-list**—Identifies one or more segments to receive STCNs. The range is from 1 to 1024.
- **stp**—Sends STCNs to STP networks.

**Note**

Spanning Tree (MST) mode is required on edge no-neighbor nodes when `rep stcn stp` command is configured for sending STCNs to STP networks.

#### Step 7

```
rep block port {id port-id | neighbor-offset | preferred} vlan {vlan-list | all}...
```

**Example:**
```
Device# rep block port id 0009001818D68700 vlan 1-100
```

(Optional) Configures VLAN load balancing on the primary edge port, identifies the REP alternate port in one of three ways (`id port-id`, `neighbor_offset`, `preferred`), and configures the VLANs to be blocked on the alternate port.
- **id port-id**—Identifies the alternate port by port ID. The port ID is automatically generated for each port in the segment. You can view interface port IDs by entering the `show interface type number rep [detail]` privileged EXEC command.
- **neighbor_offset**—Number to identify the alternate port as a downstream neighbor from an edge port. The range is from -256 to 256, with negative numbers indicating the downstream neighbor from the secondary edge port. A value of 0 is invalid. Enter -1 to identify the secondary edge port as the alternate port.

**Note**

Because you enter the `rep block port` command at the primary edge port (offset number 1), you cannot enter an offset value of 1 to identify an alternate port.
- **preferred**—Selects the regular segment port previously identified as the preferred alternate port for VLAN load balancing.
- **vlan vlan-list**—Blocks one VLAN or a range of VLANs.
### Configuring a REP Interface

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 8</strong></td>
<td><strong>rep preempt delay seconds</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# rep preempt delay 100</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>(Optional) Configures a preempt time delay.&lt;br&gt;- Use this command if you want VLAN load balancing to be automatically triggered after a link failure and recovery.&lt;br&gt;- The time delay range is between 15 to 300 seconds. The default is manual preemption with no time delay.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td><strong>rep lsl-age-timer value</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# rep lsl-age-timer 2000</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>(Optional) Configures a time (in milliseconds) for which the REP interface remains up without receiving a hello from a neighbor.&lt;br&gt;The range is from 120 to 10000 ms in 40-ms increments. The default is 5000 ms (5 seconds).&lt;br&gt;- EtherChannel port channel interfaces do not support LSL age-timer values that are less than 1000 ms.&lt;br&gt;- Both the ports on the link should have the same LSL age configured in order to avoid link flaps.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td><strong>end</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# end</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td><strong>show interface [interface-id] rep [detail]</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# show interface gigabitethernet1/1 rep detail</td>
</tr>
<tr>
<td><strong>Step 12</strong></td>
<td><strong>copy running-config startup-config</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# copy running-config startup-config</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>(Optional) Displays the REP interface configuration.&lt;br&gt;(Optional) Saves your entries in the router startup configuration file.</td>
</tr>
</tbody>
</table>
Setting Manual Preemption for VLAN Load Balancing

If you do not enter the `rep preempt delay seconds` interface configuration command on the primary edge port to configure a preemption time delay, the default is to manually trigger VLAN load balancing on the segment. Be sure that all the other segment configurations have been completed before manually preemption VLAN load balancing. When you enter the `rep preempt delay segment segment-id` command, a confirmation message is displayed before the command is executed because preemption might cause network disruption.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `rep preempt segment segment-id`
4. `show rep topology segment segment-id`
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device&gt; enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>rep preempt segment segment-id</code></td>
<td>Manually triggers VLAN load balancing on the segment. You need to confirm the command before it is executed.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# rep preempt segment 100</code></td>
<td>The command will cause a momentary traffic disruption. Do you still want to continue? [confirm]</td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>show rep topology segment segment-id</code></td>
<td>(Optional) Displays REP topology information.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# show rep topology segment 100</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Exits privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# end</code></td>
<td></td>
</tr>

</table>
## Configuring SNMP Traps for REP

You can configure a router to send REP-specific traps to notify the Simple Network Management Protocol (SNMP) server of link-operational status changes and port role changes.

### SUMMARY STEPS

1. `configure terminal`
2. `snmp mib rep trap-rate value`
3. `end`
4. `show running-config`
5. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> snmp mib rep trap-rate value</td>
<td>Enables the switch to send REP traps, and sets the number of traps sent per second.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# snmp mib rep trap-rate 500</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>

## Monitoring Resilient Ethernet Protocol Configurations

You can display the rep interface and rep topology details using the commands in this topic.
SUMMARY STEPS

1. `show interface [interface-id] rep [detail]`
2. `show rep topology [segment segment-id] [archive] [detail]`

DETAILED STEPS

Step 1

`show interface [interface-id] rep [detail]`

Displays REP configuration and status for an interface or for all the interfaces.

- (Optional) `detail`—Displays interface-specific REP information.

Example:

```
Device# show interfaces TenGigabitEthernet4/1 rep detail
TenGigabitEthernet4/1 REP enabled
Segment-id: 3 (Primary Edge)
PortID: 03010015FA66FF80
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 02040015FA66FF804050
Port Role: Open
Blocked VLAN: <empty>
Admin-vlan: 1
Preempt Delay Timer: disabled
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 999, tx: 652
HFL PDU rx: 0, tx: 0
BPA TLV rx: 500, tx: 4
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 6, tx: 5
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 135, tx: 136
```

Step 2

`show rep topology [segment segment-id] [archive] [detail]`

Displays REP topology information for a segment or for all the segments, including the primary and secondary edge ports in the segment.

- (Optional) `archive`—Displays the last stable topology.

  **Note**  An archive topology is not retained when the switch reloads.

- (Optional) `detail`—Displays detailed archived information.

Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another device.
- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

Caution

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.

Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

Modes of Operation

UDLD two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can
also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

### Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

### Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
- One of the fiber strands in the cable is disconnected.

In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heart beat whose presence guarantees the health of the link. Conversely, the loss of the heart beat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

### Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing
**Neighbor Database Maintenance**

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the device receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the device receives a new hello message before an older cache entry ages, the device replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the device is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

**Event-Driven Detection and Echoing**

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

**UDLD Reset Options**

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The `udld reset` interface configuration command.
- The `shutdown` interface configuration command followed by the `no shutdown` interface configuration command restarts the disabled port.
- The `no udld {aggressive | enable}` global configuration command followed by the `udld {aggressive | enable}` global configuration command reenables the disabled ports.
- The `no udld port` interface configuration command followed by the `udld port [aggressive]` interface configuration command reenables the disabled fiber-optic port.
- The `errdisable recovery cause udld` global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the `errdisable recovery interval interval` global configuration command specifies the time to recover from the UDLD error-disabled state.

**Default UDLD Configuration**

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Device for Access Point Discovery

Caution

You should connect APs directly to the Cisco Catalyst 3850 switch ports to use its wireless functionality.

- Ensure that the Control and Provisioning of Wireless Access Points (CAPWAP) UDP ports 5246 and 5247 (similar to the Lightweight Access Point Protocol (LWAPP) UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the device.

- If access control lists (ACLs) are in the control path between the device and its access points, you must open new protocol ports to prevent access points from being stranded.
• If an access point is in the UP state and its IP address changes, the access point tears down the existing CAPWAP tunnel and rejoins the device.

• Access points must be discovered by a device before they can become an active part of the network. The lightweight access points support the following device discovery processes:
  • Layer 3 CAPWAP discovery—You can enable this feature on different subnets from the access point. This feature uses IP addresses and UDP packets rather than the MAC addresses used by Layer 2 discovery.
  • Locally stored device IP address discovery—If the access point was previously associated to a device, the IP addresses of the primary, secondary, and tertiary devices are stored in the access point’s nonvolatile memory. This process of storing device IP addresses on an access point for later deployment is called priming the access point.
  • DHCP server discovery—This feature uses DHCP option 43 to provide device IP addresses to the access points. Cisco switches support a DHCP server option that is typically used for this capability.
  • DNS discovery—The access point can discover devices through your domain name server (DNS). You must configure your DNS to return device IP addresses in response to CISCO-CAPWAP-CONTROLLER.localdomain, where localdomain is the access point domain name. When an access point receives an IP address and DNS information from a DHCP server, it contacts the DNS to resolve CISCO-CAPWAP-CONTROLLER.localdomain. When the DNS sends a list of device IP addresses, the access point sends discovery requests to the devices.

Restrictions for Configuring the Device for Access Point Discovery

• Ensure that the devices are configured with the correct date and time. If the date and time configured on the device precedes the creation and installation date of certificates on the access points, the access point fails to join the device.

• During the discovery process, access points that are supported by the Cisco device, such as the 1140, 1260, 3500, 1040, 1600, 2600, or 3600 query only for Cisco devices.

• Do not configure same VLAN for both wireless management and wireless clients.

Information About Configuring the Device for Access Point Discovery

In a CAPWAP environment, a lightweight access point discovers a device by using CAPWAP discovery mechanisms and then sends a CAPWAP join request to the device. The device sends a CAPWAP join response to the access point that allows the access point to join the device. When the access point joins the device, the device manages its configuration, firmware, control transactions, and data transactions.
Access Point Communication Protocols

Cisco lightweight access points use the IETF standard CAPWAP to communicate with the device and other lightweight access points on the network.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a device to manage a collection of wireless access points. CAPWAP is implemented in device for these reasons:

- To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP
- To manage RFID readers and similar devices
- To enable devices to interoperate with third-party access points in the future

Viewing Access Point Join Information

Join statistics for an access point that sends a CAPWAP discovery request to the device at least once are maintained on the device even if the access point is rebooted or disconnected. These statistics are removed only when the device is rebooted or when you choose to clear the statistics.

Troubleshooting the Access Point Join Process

Access points can fail to join a device for many reasons such as a RADIUS authorization is pending, self-signed certificates are not enabled on the device, the access point and device’s regulatory domains do not match, and so on.

You can configure the access points to send all CAPWAP-related errors to a syslog server. You do not need to enable any debug commands on the device because all of the CAPWAP error messages can be viewed from the syslog server itself.

The state of the access point is not maintained on the device until it receives a CAPWAP join request from the access point, so it can be difficult to determine why the CAPWAP discovery request from a certain access point was rejected. In order to troubleshoot such joining issues without enabling CAPWAP debug commands on the device, the device collects information for all access points that send a discovery message to this device and maintains information for any access points that have successfully joined this device.

The device collects all join-related information for each access point that sends a CAPWAP discovery request to the device. Collection begins when the first discovery message is received from the access point and ends when the last configuration payload is sent from the device to the access point.

When the device is maintaining join-related information for the maximum number of access points, it does not collect information for any more access points.

You can also configure a DHCP server to return a syslog server IP address to the access point using option 7 on the server. The access point then starts sending all syslog messages to this IP address.

You can configure the syslog server IP address through the access point CLI, if the access point is not connected to the device by entering the `capwap ap log-server syslog_server_IP_address` command.

When the access point joins a device for the first time, the device pushes the global syslog server IP address (the default is 255.255.255.255) to the access point. After that, the access point sends all syslog messages to this IP address, until it is overridden by one of the following scenarios:
• The access point is still connected to the same device, and you changed the global syslog server IP address configuration on the device by using the `ap syslog host Syslog_Server_IP_Address` command. In this case, the device pushes the new global syslog server IP address to the access point.

• The access point is still connected to the same device, and you configured a specific syslog server IP address for the access point on the device by using the `ap name Cisco_AP syslog host Syslog_Host_IP_Address` command. In this case, the device pushes the new specific syslog server IP address to the access point.

• The access point gets disconnected from the device, and you configured the syslog server IP address from the access point CLI by using the `capwap ap log-server syslog_server_IP_address` command. This command works only if the access point is not connected to any device.

• The access point gets disconnected from the device and joins another device. In this case, the new device pushes its global syslog server IP address to the access point.

Whenever a new syslog server IP address overrides the existing syslog server IP address, the old address is erased from persistent storage, and the new address is stored in its place. The access point also starts sending all syslog messages to the new IP address, if the access point can reach the syslog server IP address.

### How to Configure Access Point Discovery

### Configuring the Syslog Server for Access Points (CLI)

**SUMMARY STEPS**

1. `show ap config global`
2. `show ap name Cisco_AP config general`

Displaying the MAC Addresses of all Access Points: Example

This example shows how to display MAC addresses of all the access points that are joined to the device:

```
Device# show ap join stats summary
Number of APs.......................................... 4
Base Mac EthernetMac AP Name IP Address Status
----------------- ----------------- ------- ------------- ----------
00:0b:85:57:bc:c0 00:0b:85:57:bc:c0 AP1130 10.10.163.217 Joined
00:1c:0f:81:db:80 00:1c:63:23:ac:a0 AP1140 10.10.163.216 Not joined
00:1c:0f:81:fc:20 00:1b:d5:9f:7d:b2 AP1 10.10.163.215 Joined
00:21:1b:ea:36:60 00:0c:d4:8a:6b:c1 AP2 10.10.163.214 Not joined
```

This example shows how to display the last join error details for a specific access point:

```
Device# show ap mac-address 000.2000.0400 join stats summary
Is the AP currently connected to controller............ Yes
Time at which the AP joined this controller last time. Aug 21 12:50:36.061
Type of error that occurred last.................. AP got or has been disconnected
Reason for error that occurred last........... The AP has been reset by the controller
Time at which the last join error occurred....... Aug 21 12:50:34.374
```

This example shows how to display all join-related statistics collected for a specific access point:

```
Device# show ap mac-address 000.2000.0400 join stats detailed
Discovery phase statistics
- Discovery requests received........................ 2

- Reason for error that occurred last................. The AP has been reset by the controller
- Time at which the last join error occurred.......... Aug 21 12:50:34.374

DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example

For more information about the AP join process, see DHCP OPTION 43 for Lightweight Cisco Aironet Access Points Configuration Example.

Configuring AP Pass Through

Information About AP Pass Through

AP pass through allows all the access points connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join another controller on the network.

Prior to this release, all access points connected Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches would be terminated on the device when the wireless management vlan is turned on. Unsupported access points connected to the device were unable to join a controller on a different vlan. AP pass through allows the connected AP to join another wireless controller on the network by assigning different vlan.

The advantages of AP pass through are:

- Allows partial deployment of Cisco New Generation Wireless Controllers where some APs are connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches but other APs continue to join other controllers on the network.

- The APs that are not supported on the Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches are allowed to join other controllers on the network.

- The wireless LAN controller is used to provide access to both wired and wireless guests. AP Pass through allows the AP to pass through Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join any other controller when wired guest accessing is turned on.

Configuring AP Pass Through

All access points on VLANs other than the one with supported access points will be put into the AP pass-through mode and will not terminate on the Device.

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Data Encryption

- Cisco 1260, 3500, 3600, 801, 1140, 1310, and 1520 series access points support Datagram Transport Layer Security (DTLS) data encryption.
- You can use the device to enable or disable DTLS data encryption for a specific access point or for all access points.
- Non-Russian customers who use the Cisco device do not need a data DTLS license.

Restrictions for Configuring Data Encryption

- Encryption limits throughput at both the device and the access point, and maximum throughput is desired for most enterprise networks.
- If your device does not have a data DTLS license and if the access point associated with the device has DTLS enabled, the data path will be unencrypted.
Information About Data Encryption

The device enables you to encrypt Control and Provisioning of Wireless Access Points (CAPWAP) control packets (and optionally, CAPWAP data packets) that are sent between the access point and the device using DTLS. DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS. CAPWAP control packets are management packets exchanged between a device and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data). If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

How to Configure Data Encryption

Configuring Data Encryption (CLI)

SUMMARY STEPS

1. configure terminal
2. ap link-encryption
3. end
4. show ap link-encryption
5. show wireless dtls connections

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enables data encryption for all access points or a specific access point by entering this command. The default value is disabled. Changing the data encryption mode requires the access points to rejoin the device.</td>
</tr>
<tr>
<td>ap link-encryption</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ap link-encryption</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>

<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuration Examples for Configuring Data Encryption

#### Displaying Data Encryption States for all Access Points: Examples

This example shows how to display the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet:

```
Device# show ap link-encryption

<table>
<thead>
<tr>
<th>AP Name</th>
<th>Encryption State</th>
<th>Dnstream Count</th>
<th>Upstream Count</th>
<th>Last Update</th>
</tr>
</thead>
<tbody>
<tr>
<td>3602a</td>
<td>Enabled</td>
<td>0</td>
<td>0</td>
<td>Never</td>
</tr>
</tbody>
</table>
```

This example shows how to display a summary of all active DTLS connections:

```
Device# show wireless dtls connections

<table>
<thead>
<tr>
<th>AP Name</th>
<th>Local Port</th>
<th>Peer IP</th>
<th>Peer Port</th>
<th>Ciphersuite</th>
</tr>
</thead>
<tbody>
<tr>
<td>3602a</td>
<td>Capwap_Ctrl</td>
<td>10.10.21.213</td>
<td>46075</td>
<td>TLS_RSA_WITH_AES_128_CBC_SHA</td>
</tr>
<tr>
<td>3602a</td>
<td>Capwap_Data</td>
<td>10.10.21.213</td>
<td>46075</td>
<td>TLS_RSA_WITH_AES_128_CBC_SHA</td>
</tr>
</tbody>
</table>

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count

- You can configure the retransmission intervals and retry count both at a global and a specific access point level. A global configuration applies these configuration parameters to all the access points. Alternatively, when you configure the retransmission level and retry count at a specific access point level, the values are applied to that particular access point. The access point specific configuration has a higher precedence than the global configuration.
Information About Retransmission Interval and Retry Count

The device and the access points exchange packets using the Control and Provisioning of Wireless Access Points (CAPWAP) reliable transport protocol. For each request, a response is defined. This response is used to acknowledge the receipt of the request message. Response messages are not explicitly acknowledged; therefore, if a response message is not received, the original request message is retransmitted after the retransmit interval. If the request is not acknowledged after a maximum number of retransmissions, the session is closed and the access points reassociate with another device.

• How to Configure wIPS on Access Points, on page 927
• Monitoring wIPS Information, on page 929
• Configuration Examples for Configuring wIPS on Access Points, on page 930

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring wIPS

• The regular local mode access point has been extended with a subset of Wireless Intrusion Prevention System (wIPS) capabilities. This feature enables you to deploy your access points to provide protection without needing a separate overlay network.

How to Configure wIPS on Access Points

Configuring wIPS on an Access Point (CLI)

SUMMARY STEPS

1. ap name Cisco_AP mode local
2. ap name Cisco_AP dot11 5ghz shutdown
3. `ap name Cisco_AP dot11 24ghz shutdown`
4. `ap name Cisco_AP mode monitor submode wips`
5. `ap name Cisco_AP monitor-mode wips-optimized`
6. `show ap dot11 24ghz monitor`
7. `ap name Cisco_AP no dot11 5ghz shutdown`
8. `ap name Cisco_AP no dot11 24ghz shutdown`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>ap name Cisco_AP mode local</code></td>
<td>Configures an access point for monitor mode. A message appears that indicates that changing the AP’s mode causes the access point to reboot. This message also displays a prompt that enables you to specify whether or not you want to continue with changing the AP mode. Enter <code>y</code> at the prompt to continue.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# ap name AP01 mode local</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>ap name Cisco_AP dot11 5ghz shutdown</code></td>
<td>Disables the 802.11a radio on the access point.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# ap name AP01 dot11 5ghz shutdown</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ap name Cisco_AP dot11 24ghz shutdown</code></td>
<td>Disables the 802.11b radio on the access point.</td>
</tr>
<tr>
<td><strong>Example:</strong> <code>Device# ap name AP02 dot11 24ghz shutdown</code></td>

Configuring Authentication for Access Points

• Finding Feature Information, on page 933
• Prerequisites for Configuring Authentication for Access Points, on page 933
• Restrictions for Configuring Authentication for Access Points, on page 934
• Information about Configuring Authentication for Access Points, on page 934
• How to Configure Authentication for Access Points, on page 934
• Configuration Examples for Configuring Authentication for Access Points, on page 940

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Authentication for Access Points

• You can set a global username, password, and enable password for all access points that are currently joined to the device and any that join in the future inherit as they join the device. If desired, you can override the global credentials and assign a unique username, password, and enable password for a specific access point.

• After an access point joins the device, the access point enables console port security, and you are prompted for your username and password whenever you log into the access point’s console port. When you log in, you are in nonprivileged mode, and you must enter the enable password in order to use the privileged mode.

• The global credentials that you configure on the device are retained across device and access point reboots. They are overwritten only if the access point joins a new device that is configured with a global username and password. If the new device is not configured with global credentials, the access point retains the global username and password configured for the first device.

• You must track the credentials used by the access points. Otherwise, you might not be able to log into an access point’s console port. If you need to return the access points to the default Cisco/Cisco username...
and password, you must clear the device’s configuration and the access point’s configuration to return them to factory-default settings. To reset the default access point configuration, enter the `ap name Cisco_AP mgmtuser username Cisco password Cisco` command. Entering the command does not clear the static IP address of the access point. Once the access point rejoins a device, it adopts the default Cisco/Cisco username and password.

- You can configure global authentication settings for all access points that are currently joined to the device and any that join in the future. If desired, you can override the global authentication settings and assign unique authentication settings for a specific access point.

- This feature is supported on the following hardware:
  - All Cisco switches that support authentication.
  - Cisco Aironet 1140, 1260, 1310, 1520, 1600, 2600, 3500, and 3600 access points

### Restrictions for Configuring Authentication for Access Points

- The device name in the AP configuration is case sensitive. Therefore, make sure to configure the exact system name on the AP configuration. Failure to do this results in the AP fallback not working.

### Information about Configuring Authentication for Access Points

Cisco IOS access points are shipped from the factory with `Cisco` as the default enable password. This password allows users to log into the nonprivileged mode and enter the `show` and `debug` commands that pose a security threat to your network. You must change the default enable password to prevent unauthorized access and to enable users to enter configuration commands from the access point’s console port.

You can configure 802.1X authentication between a lightweight access point and a Cisco switch. The access point acts as an 802.1X supplicant and is authenticated by the switch where it uses EAP-FAST with anonymous PAC provisioning.

### How to Configure Authentication for Access Points

**Configuring Global Credentials for Access Points (CLI)**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ap mgmtuser username user_name password 0 password secret 0 secret_value`
4. `end`
5. `ap name Cisco_AP mgmtuser username user_name password password secret secret`
6. `show ap summary`
7. `show ap name Cisco_AP config general`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

<tr>
<td>Example:</td>
<td>Device(config)# ap dot1x username AP3 password 0 password</td>
</tr>
<tr>
<td><strong>username</strong>—Specifies an 802.1X username for all access points.</td>
<td></td>
</tr>
<tr>
<td><strong>user-id</strong>—Username.</td>
<td></td>
</tr>
<tr>
<td><strong>password</strong>—Specifies an 802.1X password for all access points.</td>
<td></td>
</tr>
<tr>
<td><strong>0</strong>—Specifies an unencrypted password.</td>
<td></td>
</tr>
<tr>
<td><strong>8</strong>—Specifies an AES encrypted password.</td>
<td></td>
</tr>
<tr>
<td><strong>passwd</strong>—Password.</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Purpose</strong></td>
<td>You must enter a strong password for the password parameter. Strong passwords are at least eight characters long, contain a combination of uppercase and lowercase letters, numbers, and symbols, and are not a word in any language.</td>
</tr>
</tbody>
</table>

**Step 4**

End

Example:

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

**Step 5**

```
ap name Cisco_AP dot1x-user username username_value password password_value
```

Example:

```
Device# ap name AP03 dot1x-user username apuser1 password appass
```

Overrides the global authentication settings and assigns a unique username and password to a specific access point. This command contains the following keywords and arguments:

- **username**—Specifies to add a username.
- **user-id**—Username.
- **password**—Specifies to add a password.
- **0**—Specifies an unencrypted password.
- **8**—Specifies an AES encrypted password.
- **passwd**—Password.

**Note** You must enter a strong password for the password parameter. See the note in Step 2 for the characteristics of strong passwords.

The authentication settings that you enter in this command are retained across device and access point reboots and whenever the access point joins a new device.

**Step 6**

```
configure terminal
```

Example:

```
Device# configure terminal
```

Enters global configuration mode.

**Step 7**

```
o ap dot1x username user_name_value password 0 password_value
```

Example:

```
Device(config)# no ap dot1x username dot1xusr password 0 dot1xpass
```

Disables 802.1X authentication for all access points or for a specific access point.

The following message appears after you execute this command: “AP reverted to global username configuration.”

**Note** You can disable 802.1X authentication for a specific access point only if global 802.1X authentication is not enabled. If global 802.1X authentication is enabled, you can disable 802.1X for all access points only.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 8**  
end  
Example:  
Device(config)# end | Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode. |
| **Step 9**  
show ap summary  
Example:  
Device# show ap summary | Displays the authentication settings for all access points that join the device.  
**Note** If global authentication settings are not configured, the Global AP Dot1x User Name text box shows “Not Configured.” |
| **Step 10**  
show ap name *Cisco_AP* config general  
Example:  
Device# show ap name AP02 config general | Displays the authentication settings for a specific access point.  
**Note** If this access point is configured for global authentication, the AP Dot1x User Mode text boxes shows “Automatic.” If the global authentication settings have been overwritten for this access point, the AP Dot1x User Mode text box shows “Customized.” |

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Guidelines for Converting Autonomous Access Points to Lightweight Mode

- Access points that are converted to lightweight mode do not support Wireless Domain Services (WDS). Converted access points communicate only with Cisco wireless LAN devices and cannot communicate with WDS devices. However, the device provides functionality that is equivalent to WDS when an access point is associated to it.
• All Cisco lightweight access points support 16 Basic Service Set Identifiers (BSSIDs) per radio and a total of 16 wireless LANs per access point. When a converted access point is associated to a device, only wireless LANs with IDs 1 through 16 are pushed to the access point, unless the access point is a member of an access point group.

• Access points that are converted to lightweight mode must get an IP address and discover the device using DHCP, DNS, or IP subnet broadcast.

**Information About Autonomous Access Points Converted to Lightweight Mode**

You can convert autonomous Cisco Aironet access points to lightweight mode. When you upgrade the access points to lightweight mode, the access point communicates with the device and receives a configuration and software image from the device.

**Reverting from Lightweight Mode to Autonomous Mode**

After you convert an autonomous access point to lightweight mode, you can convert the access point from a lightweight unit back to an autonomous unit by loading a Cisco IOS release that supports autonomous mode (Cisco IOS Release 12.3(7)JA or earlier releases). If the access point is associated with a device, you can use the device to load the Cisco IOS release. If the access point is not associated to a device, you can load the Cisco IOS release using TFTP. In either method, the access point must be able to access a TFTP server that contains the Cisco IOS release to be loaded.

**Using DHCP Option 43 and DHCP Option 60**

Cisco Aironet Access Points use the type-length-value (TLV) format for DHCP option 43. You must program the DHCP servers to return the option based on the access point’s DHCP Vendor Class Identifier (VCI) string (DHCP option 60).

See the product documentation for your DHCP server for instructions on configuring DHCP option 43. The Converting Autonomous Access Points to Lightweight Mode document contains example steps for configuring option 43 on a DHCP server.

If the access point is ordered with the Service Provider Option - AIR-OPT60-DHCP selected, the VCI string for that access point will be different than those strings listed in the previous table. The VCI string has the following suffix: ServiceProvider, for example, a 1260 with this option returns the VCI string Cisco AP c1260-ServiceProvider.

---

**Note**

Ensure that the device IP address that you obtain from the DHCP server is a unicast IP address. Do not configure the device IP address as a multicast address when configuring DHCP option 43.

**Restrictions for DHCP Option 60**

• Cisco Wave2 APs support strings with length up to 256 characters only.
How Converted Access Points Send Crash Information to the Device

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the device. If the unit rebooted because of a crash, the device pulls up the crash file using existing CAPWAP messages and stores it in the device flash memory. The crash information copy is removed from the access point flash memory when the device pulls it from the access point.

Uploading Memory Core Dumps from Converted Access Points

By default, access points converted to lightweight mode do not send memory core dumps to the device. This section provides instructions to upload access point core dumps using the device GUI or CLI.

Displaying MAC Addresses for Converted Access Points

There are some differences in the way that controllers display the MAC addresses of converted access points on information pages in the controller GUI:

- On the AP Summary window, the controller lists the Ethernet MAC addresses of the converted access points.
- On the AP Detail window, the controller lists the BSS MAC addresses and Ethernet MAC addresses of the converted access points.
- On the Radio Summary page, the device lists converted access points by the radio MAC address.

Configuring a Static IP Address for a Lightweight Access Point

If you want to specify an IP address for an access point rather than having one assigned automatically by a DHCP server, you can use the controller GUI or CLI to configure a static IP address for the access point. Static IP addresses are generally used only for deployments with a limited number of APs.

An access point cannot discover the device using domain name system (DNS) resolution if a static IP address is configured for the access point, unless you specify a DNS server and the domain to which the access point belongs. You can configure these parameters using either the device CLI or the GUI.

If you configure an access point to use a static IP address that is not on the same subnet on which the access point’s previous DHCP address was, the access point falls back to a DHCP address after the access point reboots. If the access point falls back to a DHCP address, enter the `show ap config general Cisco AP CLI` command to show that the access point is using a fallback IP address. However, the GUI shows both the static IP address and the DHCP address, but it does not identify the DHCP address as a fallback address.
How to Convert a Lightweight Access Point Back to an Autonomous Access Point

Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)

**SUMMARY STEPS**

1. `enable`
2. `ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>

<tr>
<td><strong>Example:</strong> <code>Device# ap name AP02 tftp-downgrade 10.0.0.1 tsrvname</code></td>
<td>After entering this command, you must wait until the access point reboots and then reconfigure the access point using the CLI or GUI.</td>
</tr>
</tbody>
</table>

Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)

**Step 1** Configure the PC on which your TFTP server software runs with a static IP address in the range of 10.0.0.2 to 10.0.0.30.

**Step 2** Make sure that the PC contains the access point image file (such as `c1140-k9w7-tar.123-7.JA.tar` for a 1140 series access point) in the TFTP server folder and that the TFTP server is activated.

**Step 3** Rename the access point image file in the TFTP server folder to `c1140-k9w7-tar.default` for a 1140 series access point.

**Step 4** Connect the PC to the access point using a Category 5 (CAT5) Ethernet cable.

**Step 5** Disconnect power from the access point.

**Step 6** Press and hold the **MODE** button while you reconnect power to the access point.

**Note** The **MODE** button on the access point must be enabled.

**Step 7** Hold the **MODE** button until the status LED turns red (approximately 20 to 30 seconds), and release the **MODE** button.

**Step 8** Wait until the access point reboots as indicated by all the LEDs turning green followed by the Status LED blinking green.
Step 9  
After the access point reboots, reconfigure the access point using the GUI or the CLI.

Disabling the Reset Button on Converted Access Points (CLI)

You can enable or disable the Reset button on access points that are converted to lightweight mode. The Reset button is labeled MODE on the outside of the access point.

Note  
The procedure to perform this task using the controller GUI is not currently available.

SUMMARY STEPS

1. enable
2. configure terminal
3. no ap reset-button
4. end
5. ap name cisco_ap reset-button

<td><strong>ap static-ip name-server nameserver_ip_address</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ap static-ip name-server 10.10.10.205</td>
<td>Configures a DNS server so that a specific access point or all access points can discover the device using DNS resolution.&lt;br&gt;<strong>Note</strong> To undo the DNS server configuration, enter the <strong>no ap static-ip name-server nameserver_ip_address</strong> command.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>ap static-ip domain static_ip_domain</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong></td>
<td>Configures the domain to which a specific access point or all access points belong.</td>
</tr>
</tbody>
</table>
### Command or Action

| Device(config)# ap static-ip domain domain1 |

#### Purpose

*Note* To undo the domain name configuration, enter the `no ap static-ip domain static_ip_domain` command.

#### Step 7

**end**

**Example:**

Device(config)# end

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

#### Step 8

**show ap name Cisco_AP config general**

**Example:**

Device# show ap name AP03 config general

Displays the IP address configuration for the access point.

---

### Configuring a Static IP Address on an Access Point (GUI)

**Step 1** Choose **Configuration > Wireless > Access Points**.

**Step 2** On the **All Access Points** section, click on an **AP Name**.

**Step 3** In the **Edit AP** window that is displayed, go to the **IP Config** section.

**Step 4** Select the **Static IP (IPv4/IPv6)** check box. This activates the static IP details pane.

**Step 5** Enter the **Static IP**, **Netmask**, **Gateway**, and **DNS IP Address**.

**Step 6** Click **Update & Apply to Device**.

---

### Recovering the Access Point Using the TFTP Recovery Procedure

**Step 1** Download the required recovery image from Cisco.com (ap3g2-k9w8-tar.152-2.JA.tar) and install it in the root directory of your TFTP server.

**Step 2** Connect the TFTP server to the same subnet as the target access point and power-cycle the access point. The access point boots from the TFTP image and then joins the device to download the oversized access point image and complete the upgrade procedure.

**Step 3** After the access point has been recovered, you can remove the TFTP server.
Configuration Examples for Converting Autonomous Access Points to Lightweight Mode

Example: Displaying the IP Address Configuration for Access Points

This example shows how to display the IP address configuration for an access point:

```
Device# show ap name AP03 dot11 24ghz config general
Cisco AP Identifier.............. 4
Cisco AP Name............................. AP6
IP Address Configuration.................. Static IP assigned
IP Address................................. 10.10.10.118
IP NetMask................................ 255.255.255.0
Gateway IP Addr.......................... 10.10.10.1
Domain...................................... Domain1
Name Server............................... 10.10.10.205
```

Example: Displaying Access Point Crash File Information

This example shows how to display access point crash file information. Using this command, you can verify whether the file is downloaded to the device.

```
Device# show ap crash-file
Local Core Files:
lrad_AP1130.rdump0 (156)
```

The number in parentheses indicates the size of the file. The size should be greater than zero if a core dump file is available.

Ethernet VLAN Tagging on Access Points

Information About Ethernet VLAN Tagging on Access Points

You can configure VLAN tagging on the Ethernet interface either directly on the AP console or through the controller. The configuration is saved in the flash memory and all CAPWAP frames use the VLAN tag as configured, along with all the locally switched traffic, which is not mapped to a VLAN.

Configuring Ethernet VLAN Tagging on Access Points (GUI)

```
Step 1  Choose Configuration > Tags & Profiles > AP Join.
Step 2  Click the name of the AP Join Profile or click Add to create a new one.
Step 3  In the Add/Edit AP Join Profile window that is displayed, click the CAPWAP tab and then click the Advanced tab.
Step 4  Check the Enable VLAN Tagging check box to enable VLAN tagging for the AP Join Profile.
```
Step 5  Click Update & Apply to Device.

Configuring Ethernet VLAN Tagging on Access Points (CLI)

Follow the procedure given below to configure Ethernet VLAN tagging on APs.

Before you begin

- VLAN tagging is not supported on MAPs that are in bridge mode. The feature is automatically disabled when the APs are set to bridge mode.
- If VLAN tagging is enabled, flex native VLAN ID cannot be configured for an AP.
- APs in flexconnect standalone mode (with VLAN tag enabled) may reload at every 10 minutes, if the APs fail to discover the wireless controller during failover.

SUMMARY STEPS

1. ap name ap-name vlan-tag vlan-id
2. ap vlan-tag vlan-id
3. show ap config general

DETAILED STEPS

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges

A WGB is a mode that can be configured on an autonomous Cisco IOS access point to provide wireless connectivity to a lightweight access point on behalf of clients that are connected by Ethernet to the WGB access point. A WGB connects a wired network over a single wireless segment by learning the MAC addresses of its wired clients on the Ethernet interface and reporting them to the lightweight access point using Internet Access Point Protocol (IAPP) messaging. The WGB provides wireless access connectivity to wired clients by establishing a single wireless connection to the lightweight access point.

When a Cisco WGB is used, the WGB informs the access points of all the clients that it is associated with. The device is aware of the clients that are associated with the access point. When non-Cisco WGBs are used, the device has no information about the IP address of the clients on the wired segment behind the WGB. Without this information, the device drops the following types of messages:

- ARP REQ from the distribution system for the WGB client.
- ARP RPLY from the WGB client.
- DHCP REQ from the WGB client.
• DHCP RPLY for the WGB client.

Monitoring the Status of Workgroup Bridges

The procedure to perform this task using the device GUI is not currently available.

**SUMMARY STEPS**

1. **enable**
2. **show wireless wgb summary**
3. **show wireless wgb mac-address** *wgb_mac_address* **detail**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enters privileged EXEC mode.</td>

Configuration Examples for Configuring Workgroup Bridges

WGB Configuration: Example

This example shows how to configure a WGB access point using static WEP with a 40-bit WEP key:

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# dot11 ssid WGB_with_static_WEP
Device(config-ssid)# authentication open
Device(config-ssid)# guest-mode
Device(config-ssid)# exit
Device(config)# interface dot11Radio 0
Device(config)# station-role workgroup-bridge
Device(config-if)# encry mode wep 40
Device(config-if)# encry key 1 size 40 0 1234567890
Device(config-if)# ssid WGB_with_static_WEP
Device(config-if)# end

Verify that the WGB is associated to an access point by entering this command on the WGB:

show dot11 association

Information similar to the following appears:

Device# show dot11 associations
802.11 Client Stations on Dot11Radio0:SSID [FCVTESTING]:
MAC Address IP address Device Name Parent State
000b.8581.6aee 10.11.12.1 WGB-client map1 - Assoc
Configuring Probe Request Forwarding

- Finding Feature Information, on page 955
- Information About Configuring Probe Request Forwarding, on page 955
- How to Configure Probe Request Forwarding (CLI), on page 955

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Probe Request Forwarding

Probe requests are 802.11 management frames that are sent by clients to request information about the capabilities of Service Set Identifiers (SSIDs). By default, access points forward acknowledged probe requests to the device for processing. Acknowledged probe requests are probe requests for SSIDs that are supported by the access point. If desired, you can configure access points to forward both acknowledged and unacknowledged probe requests to the device. The device can use the information from unacknowledged probe requests to improve the location accuracy.

How to Configure Probe Request Forwarding (CLI)

The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. configure terminal
2. wireless probe filter
3. wireless probe limit num_probes interval
4. `end`
5. `show wireless probe`

**DETAILED STEPS**

<table>

Optimizing RFID Tracking on Access Points

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

How to Optimize RFID Tracking on Access Points

Optimizing RFID Tracking on Access Points (CLI)

**SUMMARY STEPS**

1. `ap name Cisco_AP mode monitor submode none`
2. `ap name Cisco_AP dot11 24ghz shutdown`
3. `ap name Cisco_AP monitor-mode tracking-opt`
4. `ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]}`
### DETAILED STEPS

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio’s broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- JP—Allows only -J radios to join the controller
- J2—Allows only -P radios to join the controller
- J3—Uses the -U frequencies, but allows -U, -P, and -Q (other than 1550/1600/2600/3600) radios to join the WLC
- J4—Allows 2.4G JPQU and 5G PQU to join the controller.
Prerequisites for Configuring Country Codes

- Generally, you should configure one country code per device; you configure one code that matches the physical location of the device and its access points. You can configure up to 20 country codes per device. This multiple-country support enables you to manage access points in various countries from a single device.

- When the multiple-country feature is used, all the devices that are going to join the same RF group must be configured with the same set of countries, configured in the same order.

- Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.

- The country list configured on the RF group leader determines which channels the members will operate on. This list is independent of which countries have been configured on the RF group members.

- For devices in the Japan regulatory domain, you should have one or more Japan country codes (JP, J2, or J3) configured on your device at the time you last booted your device.

- For devices in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your device.

Configuring Country Codes (GUI)

**Step 1** Choose **Configuration > Wireless > Access Points > Country**.

**Step 2** On the **Country** page, select the check box for each country where your access points are installed. If you selected more than one check box, a message is displayed indicating that RRM channels and power levels are limited to common channels and power levels.

**Step 3** Click **Apply**.

How to Configure Country Codes

**SUMMARY STEPS**

1. enable
2. show wireless country supported
3. configure terminal
4. ap dot11 24ghz shutdown
5. ap dot11 5ghz shutdown
6. ap country country_code
7. end
8. show wireless country channels
9. configure terminal

• Information About Configuring Link Latency, on page 968
• How to Configure Link Latency, on page 969
• How to Configure TCP MSS, on page 971
• Performing a Link Test (CLI), on page 972
• Configuration Examples for Configuring Link Latency, on page 973

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Link Latency

• The device displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the device is up or can be cleared and allowed to restart.

• You can configure link latency for a specific access point using the device GUI or CLI or for all access points joined to the device using the CLI.

Restrictions for Configuring Link Latency

• Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the device. It does not measure network latency or ping responses.
Information About Configuring Link Latency

You can configure link latency on the device to measure the link between an access point and the device. You can use this feature with all access points that are joined to the device where the link can be a slow or unreliable WAN connection.

TCP MSS

If the client’s maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the device or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the ping link test, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the CCX link test, the device can also test the link quality in the access point-to-client direction. The device issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and device. Not only can the access point or device initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or device.

The device shows the link-quality metrics for CCX link tests in both directions (out—the access point to the client; in—the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)
- Total number of packets that are retried
- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet
The controller shows this metric regardless of direction:

- Link test request/reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCX v4 or v5, the controller performs a ping link test on the client. If a client supports CCX v4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

# How to Configure Link Latency

## Configuring Link Latency (CLI)

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ap link-latency`
4. `ap tcp-adjust-mss size size`
5. `show ap name Cisco_AP config general`
6. `ap name Cisco_AP link-latency [reset]`
7. `show ap name Cisco_AP config general`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables link latency for all access points that are currently associated with the device.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

**Note** To disable link latency for all the access points that are associated with the device, use the `no ap link-latency` command.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong></td>
<td>These commands enable or disable link latency only for access points that are currently joined to the device. You have to enable or disable link latency for the access points that join in the future.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To enable or disable link latency for specific access points that are associated with the device, enter the following commands in Privileged EXEC mode:</td>
</tr>
<tr>
<td></td>
<td>• <code>ap name Cisco_AP link-latency</code>—Enables link latency.</td>
</tr>
<tr>
<td></td>
<td>• <code>ap name Cisco_AP no link-latency</code>—Disables link latency.</td>
</tr>
</tbody>
</table>

**Step 4**

```
Step 4  ap tcp-adjust-mss size size
```

**Example:**
```
Device(config)# ap tcp-adjust-mss size 537
```

Configures TCP MSS adjust size for all access points. The range is from 536 to 1363.

**Step 5**

```
Step 5  show ap name Cisco_AP config general
```

**Example:**
```
Device(config)# show ap name AP02 config general
```

Displays the general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

The output of this command contains the following link latency results:

- **Current Delay**—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.
- **Maximum Delay**—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.
- **Minimum Delay**—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.

**Step 6**

```
Step 6  ap name Cisco_AP link-latency [reset]
```

**Example:**
```
Device(config)# ap name AP02 link-latency reset
```

Clears the current, minimum, and maximum link latency statistics on the device for a specific access point.
### How to Configure TCP MSS

#### Configuring TCP MSS (CLI)

**SUMMARY STEPS**

1. `configure terminal`
2. `ap tcp-adjust-mss size size_value`
3. `reload`
4. `show ap tcp-adjust-mss`

Configuration Examples for Configuring Link Latency

Running a Link Test: Example

This example shows how to run a link test:

```
Device# test wireless linktest 6470.0227.ca55
Device# show wireless linktest statistic
```

Link Test to 64700227CA55 with 500 frame-size.
Client MAC Address : 6470.0227.ca55
AP Mac Address : 44e4.d901.19c0
Link Test Packets Sent : 20
Link Test Packets Received : 20
Link Test Pkts Lost(Total/AP->Clnt/Clnt->AP) : 0/0/0
Link Test Pkts round trip time (min/max/avg) : 9ms/31ms/14ms
RSSI at AP (min/max/average) : -53dBm/-51dBm/-52dBm
RSSI at Client (min/max/average) : -48dBm/-40dBm/-44dBm

Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

```
Device# show ap name AP01 config general
```

Cisco AP Name : AP01
Cisco AP Identifier : 55
Country Code : US - United States
Regulatory Domain Allowed by Country : 802.11bg:-A 802.11a:-A
AP Country Code : US - United States
AP Regulatory Domain : Unconfigured
Switch Port Number : Te1/0/1
MAC Address : 0000.2000.03f0
IP Address Configuration : Static IP assigned
IP Address : 9.9.9.16
IP Netmask : 255.255.0.0
Gateway IP Address : 9.9.9.2
Fallback IP Address Being Used : 9.9.9.16
Domain : Cisco
Name Server : 0.0.0.0
CAPWAP Path MTU : 1485
Telnet State : Enabled
SSH State : Disabled

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Power over Ethernet

When an access point that has been converted to lightweight mode (such as an AP1262) access point is powered by a power injector that is connected to a Cisco pre-Intelligent Power Management (pre-IPM) switch, you must configure Power over Ethernet (PoE), which is also known as inline power.

How to Configure Power over Ethernet

Configuring Power over Ethernet (CLI)

SUMMARY STEPS

1. ap name Cisco_AP power injector installed
2. ap name Cisco_AP power injector override
3. ap name Cisco_AP power injector switch-mac-address switch_mac_address
4. show ap name Cisco_AP config general
### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified.</td>
</tr>
<tr>
<td><code>ap name Cisco_AP power injector installed</code></td>
<td>Example: <code>Device# ap name AP02 power injector installed</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Removes the safety checks and allows the access point to be connected to any switch port. You can use this command if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The access point assumes that a power injector is always connected. If you relocate the access point, it continues to assume that a power injector is present.</td>
</tr>
<tr>
<td><code>ap name Cisco_AP power injector override</code></td>
<td>Example: <code>Device# ap name AP02 power injector override</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Sets the MAC address of the switch port that has a power injector.</td>
</tr>
<tr>
<td><code>ap name Cisco_AP power injector switch-mac-address switch_mac_address</code></td>
<td>Example: <code>Device# ap name AP02 power injector switch-mac-address 10a.2d.5c.3d</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Displays common information that includes the PoE settings for a specific access point.</td>
</tr>
<tr>
<td><code>show ap name Cisco_AP config general</code></td>
<td>Example: <code>Device# show ap name AP02 config general</code></td>
</tr>
</tbody>
</table>

### Configuration Examples for Configuring Power over Ethernet

#### Displaying Power over Ethernet Information: Example

This example shows how to display common information that includes the PoE settings for a specific access point:

`Device# show ap name AP01 config general`  
Cisco AP Identifier................. 1
Cisco AP Name..................... AP1
...
PoE Pre-Standard Switch......... Enabled
PoE Power Injector MAC Addr..... Disabled
Power Type/Mode.................. PoE/Low Power (degraded mode)
...

Lightweight Access Points
PART X

Multiprotocol Label Switching

• Multiprotocol Label Switching, on page 981
• Configuring Multicast Virtual Private Network, on page 989
Multiprotocol Label Switching

This module describes Multiprotocol Label Switching and how to configure it on Cisco switches.

- Restrictions for Multiprotocol Label Switching, on page 981
- Information about Multiprotocol Label Switching, on page 981
- How to Configure Multiprotocol Label Switching, on page 983
- Verifying Multiprotocol Label Switching Configuration, on page 985

Restrictions for Multiprotocol Label Switching

- Multiprotocol Label Switching (MPLS) fragmentation is not supported.
- MPLS maximum transmission unit (MTU) is not supported.
- `ip unnumbered` command is not supported in MPLS configuration.

Information about Multiprotocol Label Switching

Multiprotocol label switching (MPLS) combines the performance and capabilities of Layer 2 (data link layer) switching with the proven scalability of Layer 3 (network layer) routing. MPLS enables you to meet the challenges of explosive growth in network utilization while providing the opportunity to differentiate services without sacrificing the existing network infrastructure. The MPLS architecture is flexible and can be employed in any combination of Layer 2 technologies. MPLS support is offered for all Layer 3 protocols, and scaling is possible well beyond that typically offered in today’s networks.

Functional Description of Multiprotocol Label Switching

Label switching is a high-performance packet forwarding technology that integrates the performance and traffic management capabilities of data link layer (Layer 2) switching with the scalability, flexibility, and performance of network layer (Layer 3) routing.
Label Switching Functions

In conventional Layer 3 forwarding mechanisms, as a packet traverses the network, each switch extracts all the information relevant to forwarding the packet from the Layer 3 header. This information is then used as an index for a routing table lookup to determine the next hop for the packet.

In the most common case, the only relevant field in the header is the destination address field, but in some cases, other header fields might also be relevant. As a result, the header analysis must be done independently at each switch through which the packet passes. In addition, a complicated table lookup must also be done at each switch.

In label switching, the analysis of the Layer 3 header is done only once. The Layer 3 header is then mapped into a fixed length, unstructured value called a label.

Many different headers can map to the same label, as long as those headers always result in the same choice of next hop. In effect, a label represents a forwarding equivalence class -- that is, a set of packets which, however different they may be, are indistinguishable by the forwarding function.

The initial choice of a label need not be based exclusively on the contents of the Layer 3 packet header; for example, forwarding decisions at subsequent hops can also be based on routing policy.

Once a label is assigned, a short label header is added at the front of the Layer 3 packet. This header is carried across the network as part of the packet. At subsequent hops through each MPLS switch in the network, labels are swapped and forwarding decisions are made by means of MPLS forwarding table lookup for the label carried in the packet header. Hence, the packet header does not need to be reevaluated during packet transit through the network. Because the label is of fixed length and unstructured, the MPLS forwarding table lookup process is both straightforward and fast.

Distribution of Label Bindings

Each label switching router (LSR) in the network makes an independent, local decision as to which label value to use to represent a forwarding equivalence class. This association is known as a label binding. Each LSR informs its neighbors of the label bindings it has made. This awareness of label bindings by neighboring switches is facilitated by the following protocols:

- Label Distribution Protocol (LDP) -- enables peer LSRs in an MPLS network to exchange label binding information for supporting hop-by-hop forwarding in an MPLS network
- Border Gateway Protocol (BGP) -- Used to support MPLS virtual private networks (VPNs)

When a labeled packet is being sent from LSR A to the neighboring LSR B, the label value carried by the IP packet is the label value that LSR B assigned to represent the forwarding equivalence class of the packet. Thus, the label value changes as the IP packet traverses the network.

For more information about LDP configuration, see the see MPLS: LDP Configuration Guide at http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/mpls/config_library/xe-3s/mp-xe-3s-library.html

As the scale of label entries is limited in, especially with ECMP, it is recommended to enable LDP label filtering. LDP labels shall be allocated only for well known prefixes like loopback interfaces of routers and any prefix that needs to be reachable in the global routing table.
**MPLS Layer 3 VPN**

A Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) consists of a set of sites that are interconnected by means of an MPLS provider core network. At each customer site, one or more customer edge (CE) routers attach to one or more provider edge (PE) routers.

Before configuring MPLS Layer 3 VPNs, you should have MPLS, Label Distribution Protocol (LDP), and Cisco Express Forwarding (CEF) installed in your network. All routers in the core, including the PE routers, must be able to support CEF and MPLS forwarding.

**Classifying and Marking MPLS QoS EXP**

The QoS EXP Matching feature allows you to classify and mark network traffic by modifying the Multiprotocol Label Switching (MPLS) experimental bits (EXP) field in IP packets.

The QoS EXP Matching feature allows you to organize network traffic by setting values for the MPLS EXP field in MPLS packets. By choosing different values for the MPLS EXP field, you can mark packets so that packets have the priority that they require during periods of congestion. Setting the MPLS EXP value allows you to:

- **Classify traffic**: The classification process selects the traffic to be marked. Classification accomplishes this by partitioning traffic into multiple priority levels, or classes of service. Traffic classification is the primary component of class-based QoS provisioning.

- **Police and mark traffic**: Policing causes traffic that exceeds the configured rate to be discarded or marked to a different drop level. Marking traffic is a way to identify packet flows to differentiate them. Packet marking allows you to partition your network into multiple priority levels or classes of service.

**Restrictions**

Following is the list of restrictions for classifying and marking MPLS QoS EXP:

- Only Uniform mode and Pipe mode are supported; Short-pipe mode is not supported.
- Support range of QoS-group values range between 0 and 30. (Total 31 QoS-groups).
- EXP marking using QoS policy is supported only on the outer label; inner EXP marking is not supported.

**How to Configure Multiprotocol Label Switching**

This section explains how to perform the basic configuration required to prepare a switch for MPLS switching and forwarding.

**Configuring a Switch for MPLS Switching (CLI)**

MPLS switching on Cisco switches requires that Cisco Express Forwarding be enabled.

**Note**

The `ip unnumbered` command is not supported in MPLS configuration.
SUMMARY STEPS

1. enable
2. configure terminal
3. ip cef distributed
4. mpls label range minimum-value maximum-value
5. mpls label protocol ldp

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

### Verifying Multiprotocol Label Switching Configuration

This section explains how to verify successful configuration of MPLS switching and forwarding.
Verifying Configuration of MPLS Switching

To verify that Cisco Express Forwarding has been configured properly, issue the `show ip cef summary` command, which generates output similar to that shown below:

**SUMMARY STEPS**

1. `show ip cef summary`

**DETAILED STEPS**

```
show ip cef summary

Example:

Switch# show ip cef summary
IPv4 CEF is enabled for distributed and running
VRF Default
  150 prefixes (149/1 fwd/non-fwd)
Table id 0x0
  Database epoch: 4 (150 entries at this epoch)
Switch#
```

Verifying Configuration of MPLS Forwarding

To verify that MPLS forwarding has been configured properly, issue the `show mpls interfaces detail` command, which generates output similar to that shown below:

**Note**

The MPLS MTU value is equivalent to the IP MTU value of the port or switch by default. MTU configuration for MPLS is not supported.

**SUMMARY STEPS**

1. `show mpls interfaces detail`
2. `show running-config interface`
3. `show mpls forwarding`

**DETAILED STEPS**

**Step 1** `show mpls interfaces detail`

**Example:**

For physical (Gigabit Ethernet) interface:

Switch# `show mpls interfaces detail interface GigabitEthernet 1/0/0`
Type Unknown
IP labeling enabled
LSP Tunnel labeling not enabled
IP FRR labeling not enabled
BGP labeling not enabled
MPLS not operational
MTU = 1500

For Switch Virtual Interface (SVI):
Switch# `show mpls interfaces detail interface Vlan1000`

Type Unknown
IP labeling enabled (ldp):
Interface config
LSP Tunnel labeling not enabled
IP FRR labeling not enabled
BGP labeling not enabled
MPLS operational
MTU = 1500

**Step 2**  
`show running-config interface`

**Example:**

For physical (Gigabit Ethernet) interface:
Switch# `show running-config interface interface GigabitEthernet 1/0/0`

Building configuration...

Current configuration : 307 bytes
!
interface TenGigabitEthernet1/0/0
no switchport
ip address xx.xx.x.x xxx.xxx.xxx.x
mpls ip
mpls label protocol ldp
end

For Switch Virtual Interface (SVI):
Switch# `show running-config interface interface Vlan1000`

Building configuration...

Current configuration : 187 bytes
!
interface Vlan1000
ip address xx.xx.x.x xxx.xxx.xxx.x
mpls ip
mpls label protocol ldp
end

**Step 3**  
`show mpls forwarding`

**Example:**

For physical (Gigabit Ethernet) interface:
Switch#show mpls forwarding-table

<table>

Configuring Multicast Virtual Private Network

• Configuring Multicast VPN, on page 989

Configuring Multicast VPN

The Multicast VPN (MVPN) feature provides the ability to support multicast over a Layer 3 VPN. As enterprises extend the reach of their multicast applications, service providers can accommodate them over their Multiprotocol Label Switching (MPLS) core network. IP multicast is used to stream video, voice, and data over an MPLS VPN network core.

Historically, point-to-point tunnels were the only way to connect through a service provider network. Although such tunneled networks tend to have scalability issues, they represented the only means of passing IP multicast traffic through a VPN.

Because Layer 3 VPNs support only unicast traffic connectivity, deploying MPLS in conjunction with a Layer 3 VPN allows service providers to offer both unicast and multicast connectivity to Layer 3 VPN customers.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Multicast VPN

Enable IP multicast and configure the PIM interfaces using the tasks described in the “Configuring Basic IP Multicast” module.

Restrictions for Configuring Multicast VPN

• The update source interface for the Border Gateway Protocol (BGP) peerings must be the same for all BGP peerings configured on the device in order for the default multicast distribution tree (MDT) to be
configured properly. If you use a loopback address for BGP peering, PIM sparse mode must be enabled on the loopback address.

• MVPN does not support multiple BGP peering update sources.

• Multiple BGP update sources are not supported, and configuring them can break MVPN reverse path forwarding (RPF) checking. The source IP address of the MVPN tunnels is determined by the highest IP address used for the BGP peering update source. If this IP address is not the IP address used as the BGP peering address with the remote provider edge (PE) device, MVPN will not function properly.

• ip unnumbered command is not supported in MPLS configuration.

Information About Configuring Multicast VPN

Multicast VPN Operation

MVPN IP allows a service provider to configure and support multicast traffic in an MPLS VPN environment. This feature supports routing and forwarding of multicast packets for each individual VRF instance, and it also provides a mechanism to transport VPN multicast packets across the service provider backbone.

A VPN is network connectivity across a shared infrastructure, such as an ISP. Its function is to provide the same policies and performance as a private network, at a reduced cost of ownership, thus creating many opportunities for cost savings through operations and infrastructure.

An MVPN allows an enterprise to transparently interconnect its private network across the network backbone of a service provider. The use of an MVPN to interconnect an enterprise network in this way does not change the way that enterprise network is administered, nor does it change general enterprise connectivity.

Benefits of Multicast VPN

• Provides a scalable method to dynamically send information to multiple locations.

• Provides high-speed information delivery.

• Provides connectivity through a shared infrastructure.

Multicast VPN Routing and Forwarding and Multicast Domains

MVPN introduces multicast routing information to the VPN routing and forwarding table. When a provider edge (PE) device receives multicast data or control packets from a customer edge (CE) router, forwarding is performed according to the information in the Multicast VPN routing and forwarding instance (MVRF). MVPN does not use label switching.

A set of MVRFs that can send multicast traffic to each other constitutes a multicast domain. For example, the multicast domain for a customer that wanted to send certain types of multicast traffic to all global employees would consist of all CE routers associated with that enterprise.

Multicast Distribution Trees

MVPN establishes a static default multicast distribution tree (MDT) for each multicast domain. The default MDT defines the path used by PE routers to send multicast data and control messages to every other PE router in the multicast domain.
If Source Specific Multicast (SSM) is used as the core multicast routing protocol, the multicast IP addresses used for the default and data MDT must be configured within the SSM range on all PE routers.

MVPN also supports the dynamic creation of MDTs for high-bandwidth transmission. Data MDTs are a feature unique to Cisco IOS software. Data MDTs are intended for high-bandwidth sources such as full-motion video inside the VPN to ensure optimal traffic forwarding in the MPLS VPN core. The threshold at which the data MDT is created can be configured on a per-router or a per-VRF basis. When the multicast transmission exceeds the defined threshold, the sending PE router creates the data MDT and sends a UDP message, which contains information about the data MDT, to all routers on the default MDT. The statistics to determine whether a multicast stream has exceeded the data MDT threshold are examined once every second. After a PE router sends the UDP message, it waits 3 more seconds before switching over; 13 seconds is the worst case switchover time, and 3 seconds is the best case.

Data MDTs are created only for (S, G) multicast route entries within the VRF multicast routing table. They are not created for (*) entries regardless of the value of the individual source data rate.

In the following example, a service provider has a multicast customer with offices in San Jose, New York, and Dallas. A one-way multicast presentation is occurring in San Jose. The service provider network supports all three sites associated with this customer, in addition to the Houston site of a different enterprise customer.

The default MDT for the enterprise customer consists of provider routers P1, P2, and P3 and their associated PE routers. PE4 is not part of the default MDT, because it is associated with a different customer. The figure shows that no data flows along the default MDT, because no one outside of San Jose has joined the multicast.

**Figure 71: Default Multicast Distribution Tree Overview**

An employee in New York joins the multicast session. The PE router associated with the New York site sends a join request that flows across the default MDT for the multicast domain of the customer. PE1, the PE router...
associated with the multicast session source, receives the request. The figure depicts that the PE router forwards the request to the CE router associated with the multicast source (CE1a).

*Figure 72: Initializing the Data MDT*

The CE router (CE1a) begins to send the multicast data to the associated PE router (PE1), which sends the multicast data along the default MDT. Immediately sending the multicast data, PE1 recognizes that the multicast data exceeds the bandwidth threshold for which a data MDT should be created. Therefore, PE1 creates a data MDT, sends a message to all routers using the default MDT, which contains information about the data MDT, and, three seconds later, begins sending the multicast data for that particular stream using the data MDT. Only PE2 has interested receivers for this source, so only PE2 will join the data MDT and receive traffic on it.

PE routers maintain a PIM relationship with other PE routers over the default MDT and a PIM relationship with directly attached PE routers.

**Multicast Tunnel Interface**

An MVRF, which is created per multicast domain, requires the device to create a tunnel interface from which all MVRF traffic is sourced. A multicast tunnel interface is an interface that the MVRF uses to access the multicast domain. It can be thought of as a conduit that connects an MVRF and the global MVRF. One tunnel interface is created per MVRF.

**MDT Address Family in BGP for Multicast VPN**

The `mdt` keyword has been added to the `address-family ipv4` command to configure an MDT address-family session. MDT address-family sessions are used to pass the source PE address and MDT group address to PIM using Border Gateway Protocol (BGP) MDT Subaddress Family Identifier (SAFI) updates.
**BGP Advertisement Methods for Multicast VPN Support**

In a single autonomous system, if the default MDT for an MVPN is using PIM sparse mode (PIM-SM) with a rendezvous point (RP), then PIM is able to establish adjacencies over the Multicast Tunnel Interface (MTI) because the source PE and receiver PE discover each other through the RP. In this scenario, the local PE (the source PE) sends register messages to the RP, which then builds a shortest-path tree (SPT) toward the source PE. The remote PE, which acts as a receiver for the MDT multicast group, then sends (*, G) joins toward the RP and joins the distribution tree for that group.

However, if the default MDT group is configured in a PIM Source Specific Multicast (PIM-SSM) environment rather than a PIM-SM environment, the receiver PE needs information about the source PE and the default MDT group. This information is used to send (S, G) joins toward the source PE to build a distribution tree from the source PE (without the need for an RP). The source PE address and default MDT group address are sent using BGP.

**BGP Extended Community**

When BGP extended communities are used, the PE loopback (source address) information is sent as a VPNv4 prefix using Route Distinguisher (RD) Type 2 (to distinguish it from unicast VPNv4 prefixes). The MDT group address is carried in a BGP extended community. Using a combination of the embedded source in the VPNv4 address and the group in the extended community, PE routers in the same MVRF instance can establish SSM trees to each other.

**Note**

Prior to the introduction of MDT SAFI support, the BGP extended community attribute was used as an interim solution to advertise the IP address of the source PE and default MDT group before IETF standardization. A BGP extended community attribute in an MVPN environment, however, has certain limitations: it cannot be used in inter-AS scenarios (because the attribute is nontransitive), and it uses RD Type 2 (which is not a supported standard).

**How to Configure Multicast VPN**

**Configuring the Data Multicast Group**

A data MDT group can include a maximum of 256 multicast groups per VPN per VRF per PE device. Multicast groups used to create the data MDT group are dynamically chosen from a pool of configured IP addresses. Use the following procedure to configure data multicast group on the device.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **vrf definition vrf-name**
4. **rd route-distinguisher**
5. **route-target both ASN:nn or IP-address:nn**
6. **address family ipv4 unicast value**
7. **mdt default group-address**
8. **mdt data group number**
9. **mdt data threshold kbps**

### Configuring the MDT Address Family in BGP for Multicast VPN

Perform this task to configure an MDT address family session on PE devices to establish MDT peering sessions for MVPN.

#### Before you begin
Before MVPN peering can be established through an MDT address family, MPLS and Cisco Express Forwarding (CEF) must be configured in the BGP network and multiprotocol BGP on PE devices that provide VPN services to CE devices.

#### Note
The following policy configuration parameters are not supported:
- Route-originator attribute
- Network Layer Reachability Information (NLRI) prefix filtering (prefix lists, distribute lists)
- Extended community attributes (route target and site of origin)

#### SUMMARY STEPS

1. enable
2. configure terminal
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>

**Step 1**
- **Command or Action**: `enable`
- **Example:** Device> enable

- Enables privileged EXEC mode.
  - Enter your password if prompted.

**Step 2**
- **Command or Action**: `configure terminal`
- **Example:** Device# configure terminal

- Enters global configuration mode.

**Step 3**
- **Command or Action**: `router bgp as-number`
- **Example:** Device(config)# router bgp 65535

- Enters router configuration mode and creates a BGP routing process.

**Step 4**
- **Command or Action**: `address-family ipv4 mdt`
- **Example:** Device(config-router)# address-family ipv4 mdt

- Enters address family configuration mode to create an IP MDT address family session.

**Step 5**
- **Command or Action**: `neighbor neighbor-address activate`
- **Example:** Device(config-router-af)# neighbor 192.168.1.1 activate

- Enables the MDT address family for this neighbor.

**Step 6**
- **Command or Action**: `neighbor neighbor-address send-community [both | extended | standard]`
- **Example:** Device(config-router-af)# neighbor 192.168.1.1 send-community extended

- Enables community and (or) extended community exchange with the specified neighbor.

**Step 7**
- **Command or Action**: `exit`
- **Example:**

- Exits address family configuration mode and returns to router configuration mode.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-router-af)# exit</td>
<td>Enters address family configuration mode to create a VPNv4 address family session.</td>
</tr>
<tr>
<td>Step 8 address-family vpnv4</td>
<td>Enables the VPNv4 address family for this neighbor.</td>
</tr>
<tr>
<td>Example: Device(config-router)# address-family vpnv4</td>
<td></td>
</tr>
<tr>
<td>Step 9 neighbor neighbor-address activate</td>
<td>Enables community and (or) extended community exchange with the specified neighbor.</td>
</tr>
<tr>
<td>Example: Device(config-router-af)# neighbor 192.168.1.1 activate</td>
<td></td>
</tr>
<tr>
<td>Step 10 neighbor neighbor-address send-community [both</td>
<td>extended</td>
</tr>
<tr>
<td>Example: Device(config-router-af)# neighbor 192.168.1.1 send-community extended</td>
<td></td>
</tr>
<tr>
<td>Step 11 end</td>
<td>Exits address family configuration mode and enters privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config-router-af)# end</td>
<td></td>
</tr>
</tbody>
</table>

Verifying Information for the MDT Default Group

SUMMARY STEPS

1. enable
2. show ip pim [vrf vrf-name] mdt bgp
3. show ip pim [vrf vrf-name] mdt send
4. show ip pim vrf vrf-name mdt history interval minutes

DETAILED STEPS

Step 1 enable

Example:

Device> enable

Enables privileged EXEC mode.

• Enter your password if prompted.
Device# show ip pim mdt bgp

MDT-default group 232.2.1.4
rid:1.1.1.1 next_hop:1.1.1.1

Displays information about the BGP advertisement of the RD for the MDT default group.

**Step 3**

show ip pim [vrf vrf-name] mdt send

**Example:**

Device# show ip pim mdt send

<table>
<thead>
<tr>
<th>MDT-data group</th>
<th>ref_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>232.2.8.0</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.1</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.2</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.3</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.4</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.5</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.6</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.7</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.8</td>
<td>1</td>
</tr>
<tr>
<td>232.2.8.9</td>
<td>1</td>
</tr>
</tbody>
</table>

Displays detailed information about the MDT data group including MDT advertisements that the specified device has made.

**Step 4**

show ip pim vrf vrf-name mdt history interval minutes

**Example:**

Device# show ip pim vrf vrf1 mdt history interval 20

<table>
<thead>
<tr>
<th>MDT-data group</th>
<th>Number of reuse</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.9.9.8</td>
<td>3</td>
</tr>
<tr>
<td>10.9.9.9</td>
<td>2</td>
</tr>
</tbody>
</table>

Displays the data MDTs that have been reused during the past configured interval.

### Configuration Examples for Multicast VPN

**Example: Configuring MVPN and SSM**

In the following example, PIM-SSM is configured in the backbone. Therefore, the default and data MDT groups are configured within the SSM range of IP addresses. Inside the VPN, PIM-SM is configured and only Auto-RP announcements are accepted.

```
  ip vrf vrf1
  rd 1:1
  route-target export 1:1
  route-target import 1:1
  mdt default 232.0.0.1
  mdt data 232.0.1.0 0.0.0.255 threshold 500 list 101
!
  ip pim ssm default
  ip pim vrf vrf1 accept-rp auto-rp
```
Example: Enabling a VPN for Multicast Routing

In the following example, multicast routing is enabled with a VPN routing instance named vrf1:

```plaintext
ip multicast-routing vrf1
```

Example: Configuring the Multicast Group Address Range for Data MDT Groups

In the following example, the VPN routing instance is assigned a VRF named blue. The MDT default group for a VPN VRF is 239.1.1.1, and the multicast group address range for MDT groups is 239.1.2.0 with wildcard bits of 0.0.0.3:

```plaintext
ip vrf blue
dev 55:1111
route-target both 55:1111
mdt default 239.1.1.1
mdt data 239.1.2.0 0.0.0.3
end
```

Example: Limiting the Number of Multicast Routes

In the following example, the number of multicast routes that can be added to a multicast routing table is set to 200,000 and the threshold value of the number of mroutes that will cause a warning message to occur is set to 20,000:

```plaintext
!
ip multicast-routing
ip multicast-routing vrf cisco
ip multicast cache-headers
ip multicast route-limit 200000 20000
ip multicast vrf cisco route-limit 200000 20000
no mpls traffic-eng auto-bw timers frequency 0
!
```

Configuring Autoconf

Autoconf is a solution that can be used to manage port configurations for data or voice VLAN, quality of service (QoS) parameters, storm control, and MAC-based port security on end devices that are deployed in the access layer of a network.

- Prerequisites for Autoconf, on page 1005
- Restrictions for Autoconf, on page 1005
- Information About Autoconf, on page 1006
- How to Configure Autoconf, on page 1011
- Configuration Examples for Autoconf, on page 1018
- Additional References for Autoconf, on page 1019
- Feature Information for Autoconf, on page 1020

Prerequisites for Autoconf

- Before enabling Autoconf, disable the Auto SmartPort (ASP) macro, device classifier, and then access the session monitor.

Restrictions for Autoconf

- ASP macro and Autoconf are not supported on the same interface at the same time. Either Autoconf or ASP must be disabled on a per-interface level.

- Interface templates are not applicable for wireless sessions.

- When the Autoconf feature is enabled using the `autoconf enable` command, the default Autoconf service policy is applied to all interfaces. No other service policy can be applied globally using the `service-policy` command. To apply a different service policy, you must disable Autoconf on that interface. When a service policy is applied globally, you must disable it before enabling the Autoconf feature.

- When both local (interface-level) and global service policies exist, the local policy take precedence. Events in the local service policy are handled and the global service policy is not applied. The global service policy comes into effect only when the local policy is removed.

- Service templates cannot be applied to interfaces, and interface templates cannot be applied to service instances.
Only one service template can be nested inside an interface template.

Information About Autoconf

Benefits of Autoconf

The Autoconf feature permits hardbinding between the end device and the interface. Autoconf falls under the umbrella of the Smart Operations solution. Smart Operations is a comprehensive set of capabilities that can simplify and improve LAN switch deployment. Smart Operations help organizations deliver operational excellence and scale services on the network.

The Autoconf feature automatically applies the needed configurations on the device ports to enable the efficient performance of each directly connected end device using a set of interface configurations that are configured inside an interface template.

- Autoconf efficiently applies commands to an interface because the parser does not need to parse each command each time.
- Configurations that are applied through the Autoconf feature can be reliably removed from a port without impacting previous or subsequent configurations on the port.
- The Autoconf feature provides built-in and user-defined configurations using interface and service templates. Configurations applied through templates can be centrally updated with a single operation.
- Using the Autoconf feature, a configuration can be applied to ports and access sessions.
- The Autoconf feature reduces ongoing maintenance for devices and attached end devices by making them intuitive and autoconfigurable. This reduces operation expenses (OPEX) and lowers the total cost of ownership (TCO).

Identity Session Management and Templates

A key advantage of the Autoconf feature is that the core session management capability is decoupled from the application-specific logic; thus, allowing the same framework to be used regardless of the criteria for policy determination or the nature of the policies applied.

The identity session management infrastructure allows configurations and/or policies to be applied as templates.

Both service and interface templates are named containers of configuration and policy. Service templates may be applied only to access sessions, while interface templates may be applied only to ports. When a service template is applied to an access session, the contained configuration/policy is applied only to the target session and has no impact on other sessions that may be hosted on the same access port. Similarly, when an interface template is applied to an access port, it impacts all traffic exchanged on the port.

The Autoconf feature uses a set of built-in maps and built-in templates. The built-in templates are designed based on best practices for interface configurations. Built-in templates can be modified by the user to include customized configurations, limiting the need to create a new template.

The templates created by users are referred to as user-defined templates. User-defined templates can be defined on the device and can be mapped to any built-in or user-defined trigger.

Use the `show derived-config` command, to view the overall applied configurations applied by Autoconf template and manual configuration. The interface commands shown in the output of `show running-config interface type number` command are not necessarily the operational configuration. The Autoconf feature
dynamically applies a template to the interface, and overrides any conflicting static configuration that is already applied.

Autoconf Operation

Autoconf uses the Device Classifier to identify the end devices that are connected to a port.

The Autoconf feature uses the device classification information gleaned from Cisco Discovery Protocol, LLDP, DHCP, MAC addresses, and the Organizationally Unique Identifier (OUI) that is identified by the Device Classifier.

The Device Classifier provides improved device classification capabilities and accuracy, and increased device visibility for enhanced configuration management.

Device classification is enabled when you enable the Autoconf feature using `autoconf enable` command in global configuration mode.

The device detection acts as an event trigger, which in turn applies the appropriate automatic template to the interface.

The Autoconf feature is based on a three-tier hierarchy.

- A policy map identifies the trigger type for applying the Autoconf feature.
- A parameter map identifies the appropriate template that must be applied, based on the end device.
- The templates contain the configurations to be applied.

The Autoconf built-in templates and triggers perform these three steps automatically.

The Autoconf feature provides the following built-in templates:

- AP_INTERFACE_TEMPLATE
- DMP_INTERFACE_TEMPLATE
- IP_CAMERA_INTERFACE_TEMPLATE
- IP_PHONE_INTERFACE_TEMPLATE
- LAP_INTERFACE_TEMPLATE
- MSP_CAMERA_INTERFACE_TEMPLATE
- MSP_VC_INTERFACE_TEMPLATE
- PRINTER_INTERFACE_TEMPLATE
- ROUTER_INTERFACE_TEMPLATE
- SWITCH_INTERFACE_TEMPLATE
- TP_INTERFACE_TEMPLATE

By default built-in templates are not displayed under running configuration. The built-in templates show in the running configuration only if you edit them.
The template that is selected is based on parameter map information applied to an interface. This information can be based on the following criteria:

- End Device type
- MAC address
- OUI
- User role
- Username

The Autoconf feature provides one built-in parameter map BUILTIN_DEVICE_TO_TEMPLATE with the following configuration:

```
Parameter-map name: BUILTIN_DEVICE_TO_TEMPLATE
Map: 10 map device-type regex "Cisco-IP-Phone"
    Action(s):
        20 interface-template IP_PHONE_INTERFACE_TEMPLATE
Map: 20 map device-type regex "Cisco-IP-Camera"
    Action(s):
        20 interface-template IP_CAMERA_INTERFACE_TEMPLATE
Map: 30 map device-type regex "Cisco-DMP"
    Action(s):
        20 interface-template DMP_INTERFACE_TEMPLATE
Map: 40 map oui eq "00.0f.44"
    Action(s):
        20 interface-template DMP_INTERFACE_TEMPLATE
Map: 50 map oui eq "00.23.ac"
    Action(s):
        20 interface-template DMP_INTERFACE_TEMPLATE
Map: 60 map device-type regex "Cisco-AIR-AP"
    Action(s):
        20 interface-template AP_INTERFACE_TEMPLATE
Map: 70 map device-type regex "Cisco-AIR-LAP"
    Action(s):
        20 interface-template LAP_INTERFACE_TEMPLATE
Map: 80 map device-type regex "Cisco-TelePresence"
    Action(s):
        20 interface-template TP_INTERFACE_TEMPLATE
Map: 90 map device-type regex "Surveillance-Camera"
    Action(s):
        10 interface-template MSP_CAMERA_INTERFACE_TEMPLATE
Map: 100 map device-type regex "Video-Conference"
    Action(s):
        10 interface-template MSP_VC_INTERFACE_TEMPLATE
```

Use the `show parameter-map type subscriber attribute-to-service All` command to view the configuration for the built-in parameter map.

The Autoconf feature provides one built-in policy map BUILTIN_AUTOCONF_POLICY with the following configuration:

```
BUILTIN_AUTOCONF_POLICY
event identity-update match-all
    10 class always do-until-failure
        10 map attribute-to-service table BUILTIN_DEVICE_TO_TEMPLATE
```
You can also manually create policy maps, parameter maps, and templates.

When a trigger is created that is based on specific user information, a local 802.1X Cisco Identity Services Engine (ISE) server authenticates it ensuring the security of the operation.

An interface template can be dynamically activated (on an interface) using any of the following methods:

- RADIUS CoA—While Change of Authorization (CoA) commands are targeted to one or more access sessions, any referenced template must be applied to the interface hosting the referenced session.
- RADIUS Access-Accept for client authentication or authorization—Any referenced interface template returned in an Access-Accept must be applied to the port that is hosting the authorized access session.
- Service template—If an interface template is referenced in a service template that is either locally defined or sourced from the AAA server, the interface template must be applied to the interface hosting any access-session on which the service template is applied (add a new command for interface template reference from within a locally defined service template).
- Subscriber control-policy action—A mapping action under the subscriber control policy activates service and/or interface template (as referenced in a parameter map) based on the type of filter, and removes any templates associated with a previous policy.
- Device-to-template parameter map—A subscriber parameter map that allows the filter type to service and/or interface template mappings to be specified in an efficient and readable manner.

### Advantages of Using Templates

Using templates for autoconfiguration has the following benefits:

- Templates are parsed once when they are being defined. This makes dynamic application of the templates very efficient.
- Templates can be applied to an Ethernet interface that is connected to an end device, based on the type of the end device.
- Service templates allow the activation of session-oriented features, whereas interface templates apply configurations to the interface that is hosting a session.
- Service templates are applied to access sessions and hence only impact the traffic exchanged with a single endpoint on a port.
- Startup and running configurations of the device are not modified by the dynamic application of the template.
- Policy application is synchronized with the access-session life cycle, which is tracked by the framework by using all available techniques, including just link-up/link-down.
- Templates can be updated with a single operation. All applied instances of the templates are updated.
- Constituent commands of the templates do not appear in the running configuration.
- Templates can be removed with no impact on previous or subsequent configurations.
• Template application is acknowledged, allowing for synchronization and performing remedial actions where failures occur.

• Data VLAN, quality of service (QoS) parameters, storm control, and MAC-based port security are configured automatically based on the end device that is connected to the switch.

• The switch port is cleaned up completely by removing configurations when the device is disconnected from a port.

• Human error is reduced in the installation and configuration process.

Autoconf Functionality

The Autoconf feature is disabled by default in global configuration mode. When you enable the Autoconf feature in global configuration mode, it is enabled by default at the interface level. The built-in template configurations are applied based on the end devices detected on all interfaces.

Use the `access-session inherit disable autoconf` command to manually disable Autoconf at the interface level, even when Autoconf is enabled at the global level.

If you disable Autoconf at the global level, all interface-level configurations are disabled.

<table>
<thead>
<tr>
<th>Global</th>
<th>Interface Level</th>
<th>AutoConf Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable</td>
<td>Disable</td>
<td>No automatic configurations are applied when an end device is connected.</td>
</tr>
<tr>
<td>Enable</td>
<td>Enabled by default</td>
<td>If Autoconf is enabled at the global level, it is enabled at the interface level by default. Built-in template configurations are applied based on the end devices that are detected on all interfaces.</td>
</tr>
<tr>
<td>Enable</td>
<td>Disable</td>
<td>Enabled at global level. Disabled at interface level. No automatic configurations are applied when an end device is connected to the interface on which Autoconf is disabled.</td>
</tr>
</tbody>
</table>

Autoconf allows you to retain the template even when the link to the end device is down or the end device is disconnected, by configuring the Autoconf sticky feature. Use the `access-session interface-template sticky` command to configure the Autoconf sticky feature in global configuration mode. The Autoconf sticky feature avoids the need for detecting the end device and applying the template every time the link flaps or device is removed and connected back.

The `access-session interface-template sticky` command is mandatory to apply an inbuilt template that contains `access-session` commands on an interface. Configure the `access-session interface-template sticky` command to apply interface template on a port using a service policy.

If you want to disable the Autoconf feature on a specific interface, use the `access-session inherit disable interface-template-sticky` command in interface configuration mode.
How to Configure Autoconf

Applying a Built-in Template to an End Device

The following task shows how to apply a built-in template on an interface that is connected to an end device, for example, a Cisco IP phone.

Before you begin

Make sure that the end device, for example, a Cisco IP phone, is connected to the switch port.

SUMMARY STEPS

1. enable
2. configure terminal
3. autoconf enable
4. end
5. (Optional) show device classifier attached interface interface-type interface-number
6. show template binding target interface-type interface-number

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>autoconf enable</td>
<td>Enables the Autoconf feature.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# autoconf enable</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>end</td>
<td>Exits global configuration mode and enters privileged EXEC mode.</td>

</table>
### Applying a Built-in Template to an End Device

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 6** show template binding target *interface-type*  
  *interface-number*                                    | Displays the configuration applied through the template on the interface. |

#### Example:
```
Device# show template binding target gi3/0/26
```

#### Verifying the device classification of an End Device

#### Verifying the Interface Template on an Interface

#### Verifying the Interface Configuration

#### Verifying Global Configuration after Applying Autoconf

The following example shows that an IP phone is classified by the Device Classifier with correct attributes:
```
Device# show device classifier attached interface GigabitEthernet 3/0/26
```

**Summary:**
```
<table>
<thead>
<tr>
<th>MAC_Address</th>
<th>Port_Id</th>
<th>Profile Name</th>
<th>Device Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0026.0bd9.7bbb</td>
<td>Gi3/0/26</td>
<td>Cisco-IP-Phone-7962</td>
<td>Cisco IP Phone 7962</td>
</tr>
</tbody>
</table>
```

The following example shows that a built-in interface template is applied on the interface:
```
Device# show template binding target GigabitEthernet 3/0/26
```

**Interface Templates**
```
--------------- --------- ---------------
Interface: Gi4/0/11  
Method | Source | Template-Name      
------- | ------ | -------------------
Dynamic | Built-in | IP_PHONE_INTERFACE_TEMPLATE |
```

The following example shows how to verify the interface configuration after the interface template is applied to the IP phone connected to the GigabitEthernet interface 3/0/26:
```
Device# show running-config interface GigabitEthernet 3/0/26
```

Current configuration : 624 bytes 
```
interface GigabitEthernet3/0/26  
switchport mode access  
switchport block unicast
```

End
```
Device# show derived-config interface GigabitEthernet 3/0/26
```

Building configuration... 
Derived configuration : 649 bytes 
```
interface GigabitEthernet3/0/26  
switchport mode access  
switchport block unicast
```

End

### Verifying the Device classification of an End Device

**Verifying the Interface Template on an Interface**

The following example shows that the IP camera and access points are classified by the Device Classifier with correct attributes:

```
Device# show device classifier attached detail
DC default profile file version supported = 1

Detail:
MAC_Address  Port_Id  Cert  Parent  Proto  ProfileType  Profile_Name
Device_Name
```

Software Configuration Guide, Cisco IOS XE Denali 16.3.x (Catalyst 3650 Switches)
The following example shows that a built-in interface template is applied on the interface:

```
Device# show template interface binding all
```

<table>
<thead>
<tr>
<th>Template-Name</th>
<th>Source</th>
<th>Method</th>
<th>Interface</th>
</tr>
</thead>
<tbody>
<tr>

<td>Built-in</td>
<td>dynamic</td>
<td>Gi1/0/30</td>
</tr>
<tr>
<td>AP_INTERFACE_TEMPLATE</td>
<td>Modified-Built-in</td>
<td>dynamic</td>
<td>Gi1/0/7</td>
</tr>
</tbody>
</table>

## Migrating from ASP to Autoconf

### Before you begin

Verify that the AutoSmart Port (ASP) macro is running using the `show running-config | include macro auto global` command.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no macro auto global processing**
4. **exit**
5. **clear macro auto configuration all**
6. **configure terminal**
7. **autoconf enable**
8. **end**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>no macro auto global processing</td>
<td>Disables ASP on a global level.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# no macro auto global processing</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
**Step 4** exit  | Exits global configuration mode and returns to privileged EXEC mode.  
Example:  
Device(config)# exit

**Step 5** clear macro auto configuration all  | Clears macro configurations for all interfaces.  
Example:  
Device# clear macro auto configuration all

**Step 6** configure terminal  | Enters global configuration mode.  
Example:  
Device# configure terminal

**Step 7** autoconf enable  | Enables the Autoconf feature.  
Example:  
Device(config)# autoconf enable

**Step 8** end  | Exits global configuration mode and returns to privileged EXEC mode.  
Example:  
Device(config)# end

### Configuration Examples for Autoconf

**Example: Applying a Built-in Template to an End Device**

The following example shows how to apply a built-in template to an end device connected to an interface.

```
Device> enable
Device(config)# configure terminal
Device(config)# autoconf enable
Device(config)# end
Device# show device classifier attached interface Gi3/0/26
Device# show template binding target GigabitEthernet 3/0/26
```

**Example: Applying a Modified Built-in Template to an End Device**

The following example shows how to modified built-in template and verify the configuration:

```
Device> enable
Device(config)# configure terminal
Device(config)# template AP_INTERFACE_TEMPLATE
Device(config-template)# switchport access vlan 20
Device(config-template)# description modifiedAP
Device(config-template)# exit
Device(config)# autoconf enable
```
Example: Migrating from ASP Macros to Autoconf

The following example shows how to migrate from ASP to Autoconf:

Device> enable
Device# configure terminal
Device(config)# no macro auto global processing
Device(config)# exit
Device# clear macro auto configuration all
Device# configure terminal
Device(config)# autoconf enable
Device(config)# end

Feature Information for Autoconf

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.

- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured device.

- All devices configured with the `cns config partial` global configuration command must access the event bus. The DeviceID, as originated on the device, must match the DeviceID of the corresponding device definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured devices can share the same value for ConfigID.

- Within the scope of a single instance of the event bus, no two configured devices can share the same value for DeviceID.
Information About Configuring the Configuration Engine

Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (devices and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
  - Web server
  - File manager
  - Namespace mapping server

- Event service (event gateway)
- Data service directory (data models and schema)

Note
Support for Cisco Configuration Engine will be deprecated in future releases. Use the configuration described in Cisco Plug and Play Feature Guide.

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.
Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the device. The Configuration Service delivers device and service configurations to the device for initial configuration and mass reconfiguration by logical groups. Devices receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the device and facilitates the communication between the device and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.
NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, cisco.cns.config.load. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured device. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term ConfigID is the unique identifier for a device. Within the scope of the event bus namespace, the term DeviceID is the CNS unique identifier for a device.

ConfigID

Each configured device has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of device CLI attributes. The ConfigID defined on the device must match the ConfigID for the corresponding device definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the device hostname is reconfigured.

DeviceID

Each configured device participating on the event bus has a unique DeviceID, which is analogous to the device source address so that the device can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the device. However, the DeviceID variable and its usage reside within the event gateway adjacent to the device.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the device. The event gateway represents the device and its corresponding DeviceID to the event bus.

The device declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the device.
Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the device hostname is reconfigured.

When changing the device hostname on the device, the only way to refresh the DeviceID is to break the connection between the device and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the device sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

---

Caution

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the device acquires after, not before, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a device, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the cn=<value> of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the device.

These and other associated attributes (tag value pairs) are set when you run Setup on the Cisco Configuration Engine.

Cisco IOS CNS Agents

The CNS event agent feature allows the device to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the device Cisco IOS software, allow the device to be connected and automatically configured.

Initial Configuration

When the device first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution device acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new device and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the device.

The device automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the device loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the device.
The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

**Figure 74: Initial Configuration**

![Initial Configuration Diagram]

### Incremental (Partial) Configuration

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the device. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the device to initiate a pull operation.

The device can check the syntax of the configuration before applying it. If the syntax is correct, the device applies the incremental configuration and publishes an event that signals success to the configuration server. If the device does not apply the incremental configuration, it publishes an event showing an error status. When the device has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

### Synchronized Configuration

When the device receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the device not to save the updated configuration into its NVRAM. The device uses the updated configuration as its running configuration. This ensures that the device configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

### Automated CNS Configuration

To enable automated CNS configuration of the device, you must first complete the prerequisites listed in this topic. When you complete them, power on the device. At the `setup` prompt, do nothing; the device begins the initial configuration. When the full configuration file is loaded on your device, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

### How to Configure the Configuration Engine

#### Enabling the CNS Event Agent

**Note**

You must enable the CNS event agent on the device before you enable the CNS configuration agent.

Follow these steps to enable the CNS event agent on the device.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `cns event {hostname | ip-address} [port-number] [keepalive seconds retry-count] [failover-time seconds] [reconnect-time time] | backup]`
4. `end`
5. `show running-config`

---

**Device** | **Required Configuration**
--- | ---
Distribution device | • IP helper address
|  | • Enable DHCP relay agent
|  | • IP routing (if used as default gateway)

DHCP server | • IP address assignment
|  | • TFTP server IP address
|  | • Path to bootstrap configuration file on the TFTP server
|  | • Default gateway IP address

TFTP server | • A bootstrap configuration file that includes the CNS configuration commands that enable the device to communicate with the Configuration Engine
|  | • The device configured to use either the device MAC address or the serial number (instead of the default hostname) to generate the ConfigID and EventID
|  | • The CNS event agent configured to push the configuration file to the device

CNS Configuration Engine | One or more templates for each type of device, with the ConfigID of the device mapped to the template.

---

2 A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.
### 6. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>cnsevent {hostname</td>
<td>ip-address} [port-number] [keepalive seconds retry-count] [failover-time seconds] [reconnect-time time]</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# cnsevent 10.180.1.27 keepalive 120 10</td>
<td>• For {hostname</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) For port number, enter the port number for the event gateway. The default port number is 11011.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) For keepalive seconds, enter how often the device sends keepalive messages. For retry-count, enter the number of unanswered keepalive messages that the device sends before the connection is terminated. The default for each is 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) For failover-time seconds, enter how long the device waits for the primary gateway route after the route to the backup gateway is established.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) For reconnect-time time, enter the maximum time interval that the device waits before trying to reconnect to the event gateway.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) Enter backup to show that this is the backup gateway. (If omitted, this is the primary gateway.)</td>
</tr>
<tr>
<td></td>
<td>Note</td>
<td>Though visible in the command-line help string, the encrypt and the clock-timeout time keywords are not supported.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
---|---
**Step 5** show running-config | Verifies your entries.  
**Example:**  
Device# show running-config

**Step 6** copy running-config startup-config | (Optional) Saves your entries in the configuration file.  
**Example:**  
Device# copy running-config startup-config

---

**What to do next**

To verify information about the event agent, use the `show cnsevent connections` command in privileged EXEC mode.

To disable the CNS event agent, use the `no cnsevent { ip-address | hostname }` global configuration command.

---

## Enabling the Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent on the device.

**Before you begin**

You must enable the CNS event agent on the device before you enable this agent.

### SUMMARY STEPS

1. enable
2. configure terminal
3. `cns config initial {hostname | ip-address} [port-number]`
4. `cns config partial {hostname | ip-address} [port-number]`
5. end
6. show running-config
7. copy running-config startup-config
