CHAPTER 1

Using the Command-Line Interface 1

Information About Using the Command-Line Interface 1

Command Modes 1

Using the Help System 3

Understanding Abbreviated Commands 4

No and Default Forms of Commands 4

CLI Error Messages 4

Configuration Logging 5

How to Use the CLI to Configure Features 5

Configuring the Command History 5

Changing the Command History Buffer Size 5

Recalling Commands 5

Disabling the Command History Feature 6

Enabling and Disabling Editing Features 6

Editing Commands Through Keystrokes 7

Editing Command Lines That Wrap 8

Searching and Filtering Output of show and more Commands 9

Accessing the CLI on a Switch Stack 9

Accessing the CLI Through a Console Connection or Through Telnet 10

CHAPTER 2

Using the Web Graphical User Interface 11
Configuring Layer 2 NetFlow 41
Configuring WLAN to Apply Flow Monitor in Data Link Input/Output Direction 42
Configuring WLAN to Apply Flow Monitor in IPV4 and IPV6 Input/Output Direction 43
Monitoring Flexible NetFlow 44
Configuration Examples for Flexible NetFlow 45
  Example: Configuring a Flow 45
  Example: Configuring IPv4 Flexible NetFlow in WLAN (Ingress Direction) 46
  Example: Configuring IPv6 and Transport Flag Flexible NetFlow in WLAN (Egress Direction) 46
  Example: Configuring IPv6 Flexible NetFlow in WLAN (Both Ingress and Egress Directions) 47
Additional References 48
Feature Information for Flexible NetFlow 49

PART II

CleanAir 51

CHAPTER 4

Configuring Cisco CleanAir 53
  Finding Feature Information 53
  Prerequisites for CleanAir 53
  Restrictions for CleanAir 54
  Information About CleanAir 55
    Cisco CleanAir Components 55
    Terms Used in Cisco CleanAir 57
    Interference Types that Cisco CleanAir can Detect 57
    Interference Device Merging 58
    Persistent Devices 59
      Persistent Devices Detection 59
      Persistent Device Avoidance 59
    EDRRM and AQR Update Mode 59
    CleanAir High Availability 59
  How to Configure CleanAir 60
    Enabling CleanAir for 2.4-GHz Band 60
    Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices 60
    Configuring Interference Reporting for 2.4-GHz Devices 62
    Enabling CleanAir for 5-GHz Band 63
    Configuring a CleanAir Alarm for 5-GHz Air-Quality and Devices 64

### PART III

**Interface and Hardware Component**

### CHAPTER 5

**Configuring Interface Characteristics**

Finding Feature Information

Information About Configuring Interface Characteristics

Interface Types

Port-Based VLANs

Switch Ports

Routed Ports

Switch Virtual Interfaces

EtherChannel Port Groups

Power over Ethernet Ports

Using the Switch USB Ports

USB Mini-Type B Console Port

Interface Connections

Default Ethernet Interface Configuration

Interface Speed and Duplex Mode
CHAPTER 11

Configuring PoE 151
Finding Feature Information 151
Information about PoE 151
Power over Ethernet Ports 151
Supported Protocols and Standards 152
Powered-Device Detection and Initial Power Allocation 152
Power Management Modes 153
How to Configure PoE 156
Configuring a Power Management Mode on a PoE Port 156
Configuring Power Policing 157
Monitoring Power Status 159
Additional References 160
Feature Information for PoE 160

CHAPTER 12

Configuring EEE 161
Finding Feature Information 161
Information About EEE 161
EEE Overview 161
Default EEE Configuration 161
Restrictions for EEE 162
How to Configure EEE 162
Enabling or Disabling EEE 162
Monitoring EEE 163
Configuration Examples for Configuring EEE 163
Additional References 164
Feature History and Information for Configuring EEE 164

PART IV

IP Multicast Routing 165

CHAPTER 13

Configuring IGMP 167

CHAPTER 17

Configuring IP Multicast Routing 297
Finding Feature Information 297
Prerequisites for Configuring IP Multicast Routing 297
Restrictions for Configuring IP Multicast Routing 298
Information About IP Multicast Routing 298
Cisco’s Implementation of IP Multicast Routing 298
Multicast Forwarding Information Base Overview 299
Multicast Group Concept 300
Multicast Boundaries 300
Multicast Routing and Switch Stacks 301
Default Multicast Routing Configuration 301
How to Configure Basic IP Multicast Routing 301
Configuring Basic IP Multicast Routing (CLI) 301
Configuring IP Multicast Forwarding (CLI) 304
Configuring a Static Multicast Route (mroute) (CLI) 305
Configuring sdr Listener Support 307
CHAPTER 18

Configuring the Service Discovery Gateway 321

Finding Feature Information 321

Restrictions for Configuring the Service Discovery Gateway 321

Information about the Service Discovery Gateway and mDNS 322

mDNS 322

mDNS-SD 322

Service Discovery Gateway 323

mDNS Gateway and Subnets 323

Filtering 324

How to Configure the Service Discovery Gateway 325

Configuring the Service List (CLI) 325

Configuring Service List (GUI) 327

Enabling mDNS Gateway and Redistributing Services (CLI) 329

Enabling Multicast DNS Gateway (GUI) 331

Monitoring Service Discovery Gateway 332

Configuration Examples 332

Example: Specify Alternative Source Interface for Outgoing mDNS Packets 332

Example: Redistribute Service Announcements 333

Example: Disable Bridging of mDNS Packets to Wireless Clients 333

Example: Creating a Service-List, Applying a Filter and Configuring Parameters 333
CHAPTER 20

Configuring IPv6 Unicast Routing 353

Finding Feature Information 353
Information About Configuring IPv6 Unicast Routing 353

Understanding IPv6 353
IPv6 Addresses 354
   Supported IPv6 Unicast Routing Features 354
   Unsupported IPv6 Unicast Routing Features 358
IPv6 Feature Limitations 359
IPv6 and Switch Stacks 359

Default IPv6 Configuration 360
Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI) 360
Configuring IPv4 and IPv6 Protocol Stacks (CLI) 363
Configuring Default Router Preference (CLI) 365
Configuring IPv6 ICMP Rate Limiting (CLI) 366
Configuring CEF and dCEF for IPv6 367
Configuring Static Routing for IPv6 (CLI) 368
Configuring RIP for IPv6 (CLI) 370
Configuring OSPF for IPv6 (CLI) 371
Configuring EIGRP for IPv6 374
Displaying IPv6 374

Configuring DHCP for IPv6 Address Assignment 375
   Default DHCPv6 Address Assignment Configuration 375
   DHCPv6 Address Assignment Configuration Guidelines 375
   Enabling DHCPv6 Server Function (CLI) 376
   Enabling DHCPv6 Client Function (CLI) 378

Configuration Examples for IPv6 Unicast Routing 379
   Configuring IPv6 Addressing and Enabling IPv6 Routing: Example 379
   Configuring Default Router Preference: Example 379
   Configuring IPv4 and IPv6 Protocol Stacks: Example 380
   Enabling DHCPv6 Server Function: Example 380
Enabling DHCPv6 Client Function: Example 381
Configuring IPv6 ICMP Rate Limiting: Example 381
Configuring Static Routing for IPv6: Example 381
Configuring RIP for IPv6: Example 381
Displaying IPv6: Example 381

CHAPTER 21
Prerequisites for IPv6 Client Address Learning 383
Information About IPv6 Client Address Learning 383

Configuring IPv6 Client IP Address Learning 383

SLAAC Address Assignment 384
Stateful DHCPv6 Address Assignment 385
Static IP Address Assignment 386
Router Solicitation 386
Router Advertisement 386
Neighbor Discovery 387
Neighbor Discovery Suppression 387
RA Guard 387
RA Throttling 388

Configuring IPv6 Unicast (CLI) 388
Configuring RA Guard Policy (CLI) 389
Applying RA Guard Policy (CLI) 390
Configuring RA Throttle Policy (CLI) 391
Applying RA Throttle Policy on VLAN (CLI) 392
Configuring IPv6 Snooping (CLI) 393
Configuring IPv6 ND Suppress Policy (CLI) 394
Configuring IPv6 Snooping on VLAN/PortChannel 395
Configuring IPv6 on Switch (CLI) 396
Configuring DHCP Pool (CLI) 396
Configuring Stateless Auto Address Configuration Without DHCP (CLI) 397
Configuring Stateless Auto Address Configuration With DHCP (CLI) 399
Configuring Stateful DHCP Locally (CLI) 400
Configuring Stateful DHCP Externally (CLI) 402
Monitoring IPv6 Clients (GUI) 404
Verifying IPv6 Address Learning Configuration 404
CHAPTER 22

Configuring IPv6 WLAN Security 407
- Prerequisites for IPv6 WLAN Security 407
- Restrictions for IPv6 WLAN Security 407
- Information About IPv6 WLAN Security 407
- How to Configure IPv6 WLAN Security 410
  - Configuring Local Authentication 410
    - Creating a Local User 410
    - Creating an Client VLAN and Interface 410
    - Configuring a EAP Profile 412
    - Creating a Local Authentication Model 414
    - Creating a Client WLAN 416
    - Configuring Local Authentication with WPA2+AES 417
  - Configuring External RADIUS Server 421
    - Configuring RADIUS Authentication Server Host 421
    - Configuring RADIUS Authentication Server Group 422
    - Creating a Client VLAN 424
    - Creating 802.1x WLAN Using an External RADIUS Server 425
- Additional References 426
- Feature Information for IPv6 WLAN Security 427

CHAPTER 23

Configuring IPv6 ACL 429
- Prerequisites for IPv6 ACL 429
- Restrictions for IPv6 ACL 429
- Information About IPv6 ACL 430
  - Understanding IPv6 ACLs 430
  - Types of ACL 431
    - Per User IPv6 ACL 431
    - Filter ID IPv6 ACL 431
    - Downloadable IPv6 ACL 431
  - IPv6 ACLs and Switch Stacks 432
- Configuring IPv6 ACLs 432

Additional References 405
Feature Information for IPv6 Client Address Learning 406
CHAPTER 25

Configuring IPv6 Client Mobility 459
- Prerequisites for IPv6 Client Mobility 459
- Restrictions For IPv6 Client Mobility 459
- Information About IPv6 Client Mobility 460
  - Using Router Advertisement 460
  - RA Throttling and NS suppression 461
  - IPv6 Address Learning 462
  - Handling Multiple IP Addresses 462
  - IPv6 Configuration 462
  - High Availability 463
- Verifying IPv6 Client Mobility 463
- Monitoring IPv6 Client Mobility 463
- Additional References 464
- Feature Information For IPv6 Client Mobility 465

CHAPTER 26

Configuring IPv6 Mobility 467
- Pre-requisites for IPv6 Mobility 467
- Information About IPv6 Mobility 467
  - Inter Controller Roaming 467
  - Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming 468
- How to Configure IPv6 Mobility 468
- Monitoring IPv6 Mobility 468
- Additional References 470
- Feature Information for IPv6 Mobility 471

CHAPTER 27

Configuring IPv6 NetFlow 473
- Prerequisites For IPv6 Netflow 473
- Restrictions For IPv6 Netflow 473
- Information About IPv6 Netflow 474
  - Understanding Flexible Netflow 474
  - IPv6 Netflow 475
How To Configure IPv6 Netflow 475
  Configuring a Customized Flow Record 475
  Configuring the Flow Exporters 478
  Configuring a Customized Flow Monitor 480
  Applying a Flow Monitor to an Interface 482
  Configuring and Enabling Flow Sampling 484
  Verifying IPv6 Netflow 486
  Monitoring IPv6 Netflow 486
  Additional References 486
  Feature Information for IPv6 NetFlow 487

PART VI 489

CHAPTER 28 491

Configuring Spanning Tree Protocol 491
  Finding Feature Information 491
  Restrictions for STP 491
  Information About Spanning Tree Protocol 492
    Spanning Tree Protocol 492
      Spanning-Tree Topology and BPDUs 492
      Bridge ID, Device Priority, and Extended System ID 494
      Port Priority Versus Path Cost 495
      Spanning-Tree Interface States 496
      How a Switch or Port Becomes the Root Switch or Root Port 499
      Spanning Tree and Redundant Connectivity 499
      Spanning-Tree Address Management 500
      Accelerated Aging to Retain Connectivity 500
      Spanning-Tree Modes and Protocols 500
      Supported Spanning-Tree Instances 501
      Spanning-Tree Interoperability and Backward Compatibility 501
      STP and IEEE 802.1Q Trunks 502
      VLAN-Bridge Spanning Tree 502
      Spanning Tree and Switch Stacks 502
      Default Spanning-Tree Configuration 503
      How to Configure Spanning-Tree Features 504
CHAPTER 29

Configuring Multiple Spanning-Tree Protocol 519

Finding Feature Information 519
Prerequisites for MSTP 519
Restrictions for MSTP 520
Information About MSTP 521
MSTP Configuration 521
MSTP Configuration Guidelines 521
Root Switch 522
Multiple Spanning-Tree Regions 523
IST, CIST, and CST 523
  Operations Within an MST Region 524
  Operations Between MST Regions 524
IEEE 802.1s Terminology 525
Illustration of MST Regions 525
Hop Count 526
Boundary Ports 527
IEEE 802.1s Implementation 527
  Port Role Naming Change 527
  Interoperation Between Legacy and Standard Switches 528

Consolidated Platform Configuration Guide, Cisco IOS XE 3.3SE (Catalyst 3650 Switches)
CHAPTER 30

Configuring Optional Spanning-Tree Features 553
Finding Feature Information 553
Restriction for Optional Spanning-Tree Features 553
Information About Optional Spanning-Tree Features 554
PortFast 554
# CHAPTER 32

## Configuring Flex Links and the MAC Address-Table Move Update Feature

- Finding Feature Information 611
- Restrictions for Configuring Flex Links and MAC Address-Table Move Update 611
- Information About Flex Links and MAC Address-Table Move Update 612
  - Flex Links 612
    - Flex Links Configuration 612
  - VLAN Flex Links Load Balancing and Support 613
  - Multicast Fast Convergence with Flex Links Failover 613
    - Learning the Other Flex Links Port as the mrouter Port 613
  - Generating IGMP Reports 614
  - Leaking IGMP Reports 614
  - MAC Address-Table Move Update 614
  - Flex Links VLAN Load Balancing Configuration Guidelines 616
  - MAC Address-Table Move Update Configuration Guidelines 616
  - Default Flex Links and MAC Address-Table Move Update Configuration 616
- How to Configure Flex Links and the MAC Address-Table Move Update Feature 616
  - Configuring Flex Links (CLI) 616
    - Configuring a Preemption Scheme for a Pair of Flex Links (CLI) 617
  - Configuring VLAN Load Balancing on Flex Links (CLI) 619
    - Configuring MAC Address-Table Move Update (CLI) 619
      - Configuring a Switch to Obtain and Process MAC Address-Table Move Update Messages (CLI) 621
- Monitoring Flex Links, Multicast Fast Convergence, and MAC Address-Table Move Update 621
  - Configuration Examples for Flex Links 622
    - Configuring Flex Links: Examples 622
      - Configuring VLAN Load Balancing on Flex Links: Examples 622
      - Configuring the MAC Address-Table Move Update: Examples 623
      - Configuring Multicast Fast Convergence with Flex Links Failover: Examples 624
- Additional References for Flex Links and MAC Address-Table Move Update 626
  - Feature Information for Flex Links and MAC Address-Table Move Update 627
CHAPTER 33
Configuring UniDirectional Link Detection 629
Finding Feature Information 629
Restrictions for Configuring UDLD 629
Information About UDLD 630
Modes of Operation 630
Normal Mode 630
Aggressive Mode 630
Methods to Detect Unidirectional Links 631
Neighbor Database Maintenance 631
Event-Driven Detection and Echoing 631
UDLD Reset Options 632
Default UDLD Configuration 632
How to Configure UDLD 632
Enabling UDLD Globally (CLI) 632
Enabling UDLD on an Interface (CLI) 634
Monitoring and Maintaining UDLD 635
Additional References for UDLD 635
Feature Information for UDLD 636

PART VII
Lightweight Access Point 637

CHAPTER 34
Configuring the Switch for Access Point Discovery 639
Finding Feature Information 639
Prerequisites for Configuring the Switch for Access Point Discovery 639
Restrictions for Configuring the Switch for Access Point Discovery 640
Information About Configuring the Switch for Access Point Discovery 640
Access Point Communication Protocols 640
Viewing Access Point Join Information 641
Troubleshooting the Access Point Join Process 641
How to Configure Access Point Discovery 642
Configuring the Syslog Server for Access Points (CLI) 642
Monitoring Access Point Join Information (CLI) 643
Searching for Access Point Radios (GUI) 644
CHAPTER 35  Configuring Data Encryption  647

Finding Feature Information  647
Prerequisites for Configuring Data Encryption  647
Restrictions for Configuring Data Encryption  647
Information About Data Encryption  648
How to Configure Data Encryption  648
  Configuring Data Encryption (CLI)  648
  Configuring Data Encryption (GUI)  649
Configuration Examples for Configuring Data Encryption  649
  Displaying Data Encryption States for all Access Points: Examples  649

CHAPTER 36  Configuring Retransmission Interval and Retry Count  651

Finding Feature Information  651
Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count  651
Information About Retransmission Interval and Retry Count  652
How to Configure Access Point Retransmission Interval and Retry Count  652
  Configuring the Access Point Retransmission Interval and Retry Count (CLI)  652
  Configuring the Access Point Retransmission Interval and Retry Count (GUI)  653
Viewing CAPWAP Maximum Transmission Unit Information (CLI)  654
Viewing CAPWAP Maximum Transmission Unit Information (GUI)  655
Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count  655
  Viewing the CAPWAP Retransmission Details: Example  655
  Viewing Maximum Transmission Unit Information: Example  655

CHAPTER 37  Configuring Adaptive Wireless Intrusion Prevention System  657

Finding Feature Information  657
Prerequisites for Configuring wIPS  657
How to Configure wIPS on Access Points  657
  Configuring wIPS on an Access Point (CLI)  657
CHAPTER 38  Configuring Authentication for Access Points  663

Finding Feature Information  663
Prerequisites for Configuring Authentication for Access Points  663
Restrictions for Configuring Authentication for Access Points  664
Information about Configuring Authentication for Access Points  664
How to Configure Authentication for Access Points  664
   Configuring Global Credentials for Access Points (CLI)  664
   Configuring Global Credentials for Access Points (GUI)  666
   Configuring Authentication for Access Points (CLI)  667
   Configuring Authentication for Access Points (GUI)  669
   Configuring the Switch for Authentication (CLI)  670
Configuration Examples for Configuring Authentication for Access Points  672
   Displaying the Authentication Settings for Access Points: Examples  672

CHAPTER 39  Converting Autonomous Access Points to Lightweight Mode  673

Finding Feature Information  673
Prerequisites for Converting Autonomous Access Points to Lightweight Mode  673
Information About Autonomous Access Points Converted to Lightweight Mode  674
   Reverting from Lightweight Mode to Autonomous Mode  674
   Using DHCP Option 43 and DHCP Option 60  674
   How Converted Access Points Send Crash Information to the Switch  675
   Uploading Memory Core Dumps from Converted Access Points  675
   Displaying MAC Addresses for Converted Access Points  675
   Configuring a Static IP Address for a Lightweight Access Point  675
How to Convert a Lightweight Access Point Back to an Autonomous Access Point  676
   Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)  676
   Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)  676
Authorizing Access Points (CLI) 677
Authorizing Access Points (GUI) 678
Disabling the Reset Button on Converted Access Points (CLI) 679
Monitoring the AP Crash Log Information 680
How to Configure a Static IP Address on an Access Point 680
  Configuring a Static IP Address on an Access Point (CLI) 680
  Configuring a Static IP Address on an Access Point (GUI) 682
Recovering the Access Point Using the TFTP Recovery Procedure 683
Configuration Examples for Converting Autonomous Access Points to Lightweight Mode 683
  Displaying the IP Address Configuration for Access Points: Example 683
  Displaying Access Point Crash File Information: Example 683

CHAPTER 40  Using Cisco Workgroup Bridges 685
  Finding Feature Information 685
  Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges 685
  Monitoring the Status of Workgroup Bridges 686
  Debugging WGB Issues (CLI) 686
  Configuration Examples for Configuring Workgroup Bridges 688
    WGB Configuration: Example 688

CHAPTER 41  Configuring Probe Request Forwarding 689
  Finding Feature Information 689
  Information About Configuring Probe Request Forwarding 689
  How to Configure Probe Request Forwarding (CLI) 689

CHAPTER 42  Optimizing RFID Tracking 691
  Finding Feature Information 691
  Optimizing RFID Tracking on Access Points 691
  How to Optimize RFID Tracking on Access Points 691
    Optimizing RFID Tracking on Access Points (CLI) 691
  Configuration Examples for Optimizing RFID Tracking 693
    Displaying all the Access Points in Monitor Mode: Example 693

CHAPTER 43  Configuring Country Codes 695
CHAPTER 44

Configuring Link Latency  701

Finding Feature Information  701
Prerequisites for Configuring Link Latency  701
Restrictions for Configuring Link Latency  701
Information About Configuring Link Latency  702
  TCP MSS  702
  Link Tests  702
How to Configure Link Latency  703
  Configuring Link Latency (CLI)  703
  Configuring Link Latency (GUI)  705
How to Configure TCP MSS  706
  Configuring TCP MSS (CLI)  706
  Configuring TCP MSS (GUI)  706
Performing a Link Test (CLI)  707
Configuration Examples for Configuring Link Latency  708
  Running a Link Test: Example  708
  Displaying Link Latency Information: Example  708
  Displaying TCP MSS Settings: Example  709

CHAPTER 45

Configuring Power over Ethernet  711

Finding Feature Information  711
Information About Configuring Power over Ethernet  711
How to Configure Power over Ethernet  711
  Configuring Power over Ethernet (CLI)  711
  Configuring Power over Ethernet (GUI)  712
Configuration Examples for Configuring Power over Ethernet  714
  Displaying Power over Ethernet Information: Example  714
## Mobility

### PART VIII

### CHAPTER 46

#### Information About Mobility

- **Overview**
- **Wired and Wireless Mobility**
- **Features of Mobility**
- **Sticky Anchoring for Low Latency Roaming**
- **Bridge Domain ID and L2/L3 Roaming**
- **Link Down Behavior**
- **Platform Specific Scale Requirement for the Mobility Controller**

### CHAPTER 47

#### Mobility Network Elements

- **Mobility Agent**
- **Mobility Controller**
- **Mobility Oracle**
- **Guest Controller**

### CHAPTER 48

#### Mobility Control Protocols

- **About Mobility Control Protocols**
- **Initial Association and Roaming**
- **Initial Association**
- **Intra Switch Handoff**
- **Intra Switch Peer Group Handoff**
- **Inter Switch Peer Group Handoff**
- **Inter Sub Domain Handoff**
- **Inter Mobility Group Handoff**

### CHAPTER 49

#### Configuring Mobility

- **Configuring Mobility Controller**
- **Configuring Converged Access Controllers**
- **Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)**
- **Creating Peer Groups, Peer Group Member, and Bridge Domain ID (GUI)**
- **Configuring Local Mobility Group (CLI)**
CHAPTER 54

Configuring SPAN and RSPAN 823
Finding Feature Information 823
Prerequisites for SPAN and RSPAN 823
Restrictions for SPAN and RSPAN 824
Information About SPAN and RSPAN 825
SPAN and RSPAN 825
  Local SPAN 826
  Remote SPAN 827
  SPAN and RSPAN Concepts and Terminology 827
  SPAN and RSPAN Interaction with Other Features 833
  SPAN and RSPAN and Device Stacks 834
Flow-Based SPAN 834

</table>

**Reader Alert Conventions**

This document may use the following conventions for reader alerts:

- **Note**
  - Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

- **Tip**
  - Means *the following information will help you solve a problem*.

- **Caution**
  - Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

- **Timesaver**
  - Means *the described action saves time*. You can save time by performing the action described in the paragraph.

- **Warning**
  - **IMPORTANT SAFETY INSTRUCTIONS**
    - This warning symbol means danger. You are in a situation that could cause bodily injury. Before you work on any equipment, be aware of the hazards involved with electrical circuitry and be familiar with standard practices for preventing accidents. Use the statement number provided at the end of each warning to locate its translation in the translated safety warnings that accompanied this device. Statement 1071
    - **SAVE THESE INSTRUCTIONS**
Related Documentation

Before installing or upgrading the switch, refer to the switch release notes.

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly What's New in Cisco Product Documentation, which also lists all new and revised Cisco technical documentation, at:

Subscribe to the What's New in Cisco Product Documentation as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS version 2.0.
Using the Command-Line Interface

Information About Using the Command-Line Interface

Command Modes

The Cisco IOS user interface is divided into many different modes. The commands available to you depend on which mode you are currently in. Enter a question mark (?) at the system prompt to obtain a list of commands available for each command mode.

You can start a CLI session through a console connection, through Telnet, a SSH, or by using the browser. When you start a session, you begin in user mode, often called user EXEC mode. Only a limited subset of the commands are available in user EXEC mode. For example, most of the user EXEC commands are one-time commands, such as show commands, which show the current configuration status, and clear commands, which clear counters or interfaces. The user EXEC commands are not saved when the switch reboots.

To have access to all commands, you must enter privileged EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. From this mode, you can enter any privileged EXEC command or enter global configuration mode.

Using the configuration modes (global, interface, and line), you can make changes to the running configuration. If you save the configuration, these commands are stored and used when the switch reboots. To access the various configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and line configuration mode.

This table describes the main command modes, how to access each one, the prompt you see in that mode, and how to exit the mode.
## Table 1: Command Mode Summary

<table>
<thead>
<tr>
<th>Mode</th>
<th>Access Method</th>
<th>Prompt</th>
<th>Exit Method</th>
<th>About This Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>User EXEC</td>
<td>Begin a session using Telnet, SSH, or console.</td>
<td>Switch&gt;</td>
<td>Enter <strong>logout</strong> or <strong>quit</strong>.</td>
<td>Use this mode to • Change terminal settings. • Perform basic tests. • Display system information.</td>
</tr>
<tr>
<td>Privileged EXEC</td>
<td>While in user EXEC mode, enter the <strong>enable</strong> command.</td>
<td>Switch#</td>
<td>Enter <strong>disable</strong> to exit.</td>
<td>Use this mode to verify commands that you have entered. Use a password to protect access to this mode.</td>
</tr>
<tr>
<td>Global configuration</td>
<td>While in privileged EXEC mode, enter the <strong>configure</strong> command.</td>
<td>Switch(config)#</td>
<td>To exit to privileged EXEC mode, enter <strong>exit</strong> or <strong>end</strong>, or press <strong>Ctrl-Z</strong>.</td>
<td>Use this mode to configure parameters that apply to the entire switch.</td>
</tr>
<tr>
<td>VLAN configuration</td>
<td>While in global configuration mode, enter the <strong>vlan vlan-id</strong> command.</td>
<td>Switch(config-vlan)#</td>
<td>To exit to global configuration mode, enter the <strong>exit</strong> command. To return to privileged EXEC mode, press <strong>Ctrl-Z</strong> or enter <strong>end</strong>.</td>
<td>Use this mode to configure VLAN parameters. When VTP mode is transparent, you can create extended-range VLANs (VLAN IDs greater than 1005) and save configurations in the switch startup configuration file.</td>
</tr>
<tr>
<td>Interface configuration</td>
<td>While in global configuration mode, enter the <strong>interface</strong> command (with a specific interface).</td>
<td>Switch(config-if)#</td>
<td>To exit to global configuration mode, enter <strong>exit</strong>. To return to privileged EXEC mode, press <strong>Ctrl-Z</strong> or enter <strong>end</strong>.</td>
<td>Use this mode to configure parameters for the Ethernet ports.</td>
</tr>
<tr>
<td>Line configuration</td>
<td>While in global configuration mode, specify a line with the <strong>line vty</strong> or <strong>line console</strong> command.</td>
<td>Switch(config-line)#</td>
<td>To exit to global configuration mode, enter <strong>exit</strong>. To return to privileged EXEC mode, press <strong>Ctrl-Z</strong> or enter <strong>end</strong>.</td>
<td>Use this mode to configure parameters for the terminal line.</td>
</tr>
</tbody>
</table>
Using the Help System

You can enter a question mark (?) at the system prompt to display a list of commands available for each command mode. You can also obtain a list of associated keywords and arguments for any command.

**SUMMARY STEPS**

1. help
2. abbreviated-command-entry ?
3. abbreviated-command-entry <Tab>
4. ?
5. command ?
6. command keyword ?

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>help</td>
<td>Obtains a brief description of the help system in any command mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# help</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>abbreviated-command-entry ?</td>
<td>Obtains a list of commands that begin with a particular character string.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# di? dir disable disconnect</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>abbreviated-command-entry &lt;Tab&gt;</td>
<td>Completes a partial command name.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# sh conf&lt;tab&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch# show configuration</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>?</td>
<td>Lists all commands available for a particular command mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch&gt; ?</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>command ?</td>
<td>Lists the associated keywords for a command.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch&gt; show ?</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>command keyword ?</td>
<td>Lists the associated arguments for a keyword.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# cdp holdtime ?</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;10–255&gt; Length of time (in sec) that receiver must keep this packet</td>
<td></td>
</tr>
</tbody>
</table>
Understanding Abbreviated Commands

You need to enter only enough characters for the switch to recognize the command as unique.

This example shows how to enter the `show configuration` privileged EXEC command in an abbreviated form:

```
Switch# show conf
```

No and Default Forms of Commands

Almost every configuration command also has a `no` form. In general, use the `no` form to disable a feature or function or reverse the action of a command. For example, the `no shutdown` interface configuration command reverses the shutdown of an interface. Use the command without the keyword `no` to reenable a disabled feature or to enable a feature that is disabled by default.

Configuration commands can also have a `default` form. The `default` form of a command returns the command setting to its default. Most commands are disabled by default, so the `default` form is the same as the `no` form. However, some commands are enabled by default and have variables set to certain default values. In these cases, the `default` command enables the command and sets variables to their default values.

CLI Error Messages

This table lists some error messages that you might encounter while using the CLI to configure your switch.

### Table 2: Common CLI Error Messages

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Meaning</th>
<th>How to Get Help</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Ambiguous command: &quot;show con&quot;</td>
<td>You did not enter enough characters for your switch to recognize the command.</td>
<td>Reenter the command followed by a question mark (?) without any space between the command and the question mark. The possible keywords that you can enter with the command appear.</td>
</tr>
<tr>
<td>% Incomplete command.</td>
<td>You did not enter all of the keywords or values required by this command.</td>
<td>Reenter the command followed by a question mark (?) with a space between the command and the question mark. The possible keywords that you can enter with the command appear.</td>
</tr>
<tr>
<td>% Invalid input detected at <code>^</code> marker.</td>
<td>You entered the command incorrectly. The caret (^) marks the point of the error.</td>
<td>Enter a question mark (?) to display all of the commands that are available in this command mode. The possible keywords that you can enter with the command appear.</td>
</tr>
</tbody>
</table>
Configuration Logging

You can log and view changes to the switch configuration. You can use the Configuration Change Logging and Notification feature to track changes on a per-session and per-user basis. The logger tracks each configuration command that is applied, the user who entered the command, the time that the command was entered, and the parser return code for the command. This feature includes a mechanism for asynchronous notification to registered applications whenever the configuration changes. You can choose to have the notifications sent to the syslog.

Note

Only CLI or HTTP changes are logged.

How to Use the CLI to Configure Features

Configuring the Command History

The software provides a history or record of commands that you have entered. The command history feature is particularly useful for recalling long or complex commands or entries, including access lists. You can customize this feature to suit your needs.

Changing the Command History Buffer Size

By default, the switch records ten command lines in its history buffer. You can alter this number for a current terminal session or for all sessions on a particular line. This procedure is optional.

SUMMARY STEPS

1. **terminal history** [*size number-of-lines*]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Changes the number of command lines that the switch records during the current terminal session in privileged EXEC mode. You can configure the size from 0 to 256.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch# <strong>terminal history size 200</strong></td>
<td></td>
</tr>
</tbody>
</table>

Recalling Commands

To recall commands from the history buffer, perform one of the actions listed in this table. These actions are optional.

Note

The arrow keys function only on ANSI-compatible terminals such as VT100s.
SUMMARY STEPS

1. Ctrl-P or use the up arrow key
2. Ctrl-N or use the down arrow key
3. show history

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Ctrl-P or use the up arrow key</td>
<td>Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall successively older commands.</td>
</tr>
<tr>
<td>Step 2 Ctrl-N or use the down arrow key</td>
<td>Returns to more recent commands in the history buffer after recalling commands with Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands.</td>
</tr>
<tr>
<td>Step 3 show history</td>
<td>Lists the last several commands that you just entered in privileged EXEC mode. The number of commands that appear is controlled by the setting of the terminal history global configuration command and the history line configuration command.</td>
</tr>
</tbody>
</table>

Disabling the Command History Feature

The command history feature is automatically enabled. You can disable it for the current terminal session or for the command line. This procedure is optional.

SUMMARY STEPS

1. terminal no history

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 terminal no history</td>
<td>Disables the feature during the current terminal session in privileged EXEC mode.</td>
</tr>
</tbody>
</table>

Enabling and Disabling Editing Features

Although enhanced editing mode is automatically enabled, you can disable it and reenable it.

SUMMARY STEPS

1. terminal editing
2. terminal no editing
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>terminal editing</td>
<td>Reenables the enhanced editing mode for the current terminal session in privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# terminal editing</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>terminal no editing</td>
<td>Disables the enhanced editing mode for the current terminal session in privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# terminal no editing</td>
<td></td>
</tr>
</tbody>
</table>

### Editing Commands Through Keystrokes

The keystrokes help you to edit the command lines. These keystrokes are optional.

#### Note

The arrow keys function only on ANSI-compatible terminals such as VT100s.

<table>
<thead>
<tr>
<th>Editing Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl-B or use the left arrow key</td>
<td>Moves the cursor back one character.</td>
</tr>
<tr>
<td>Ctrl-F or use the right arrow key</td>

<tr>
<td>Esc L</td>
<td>Changes the word at the cursor to lowercase.</td>
</tr>
<tr>
<td>Esc U</td>
<td>Capitalizes letters from the cursor to the end of the word.</td>
</tr>
<tr>
<td>Ctrl-V or Esc Q</td>
<td>Designates a particular keystroke as an executable command, perhaps as a shortcut.</td>
</tr>
<tr>
<td>Return key</td>
<td>Scrolls down a line or screen on displays that are longer than the terminal screen can display. <strong>Note</strong> The More prompt is used for any output that has more lines than can be displayed on the terminal screen, including <code>show</code> command output. You can use the Return and Space bar keystrokes whenever you see the More prompt.</td>
</tr>
<tr>
<td>Space bar</td>
<td>Scrolls down one screen.</td>
</tr>
<tr>
<td>Ctrl-L or Ctrl-R</td>
<td>Redisplays the current command line if the switch suddenly sends a message to your screen.</td>
</tr>
</tbody>
</table>

---

**Editing Command Lines That Wrap**

You can use a wraparound feature for commands that extend beyond a single line on the screen. When the cursor reaches the right margin, the command line shifts ten spaces to the left. You cannot see the first ten characters of the line, but you can scroll back and check the syntax at the beginning of the command. The keystroke actions are optional.

To scroll back to the beginning of the command entry, press **Ctrl-B** or the left arrow key repeatedly. You can also press **Ctrl-A** to immediately move to the beginning of the line.

**Note**
The arrow keys function only on ANSI-compatible terminals such as VT100s.

The following example shows how to wrap a command line that extends beyond a single line on the screen.

**SUMMARY STEPS**

1. access-list
2. Ctrl-A
3. Return key

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessål</td>
<td>access-list</td>
<td>Displays the global configuration command entry that extends beyond one line.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35</td>
<td>When the cursor first reaches the end of the line, the line is shifted ten spaces to the left and redisplayed. The dollar</td>
</tr>
</tbody>
</table>

---

Consolidated Platform Configuration Guide, Cisco IOS XE 3.3SE (Catalyst 3650 Switches)
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# $101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.255.255.0 131.108.1.20 255.255.255.0 eq</td>
<td>sign ($) shows that the line has been scrolled to the left. Each time the cursor reaches the end of the line, the line is again shifted ten spaces to the left.</td>
</tr>
<tr>
<td>Switch(config)# $! tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.255.255.0</td>
<td>Checks the complete syntax.</td>
</tr>
<tr>
<td>Switch(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.255.255.0 eq 45</td>
<td>Checks the complete syntax.</td>
</tr>
</tbody>
</table>

### Step 2

**Ctrl-A**

**Example:**

Switch(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.255.255.0 eq 45

### Step 3

**Return key**

Execute the commands.

The software assumes that you have a terminal screen that is 80 columns wide. If you have a different width, use the `terminal width` privileged EXEC command to set the width of your terminal.

Use line wrapping with the command history feature to recall and modify previous complex command entries.

### Searching and Filtering Output of show and more Commands

You can search and filter the output for `show` and `more` commands. This is useful when you need to sort through large amounts of output or if you want to exclude output that you do not need to see. Using these commands is optional.

#### SUMMARY STEPS

1. `{show | more} command | {begin | include | exclude} regular-expression`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>{show</td>
<td>more} command</td>
</tr>
<tr>
<td>{begin</td>
<td>include</td>
</tr>
</tbody>
</table>

### Accessing the CLI on a Switch Stack

You can access the CLI through a console connection, through Telnet, a SSH, or by using the browser.
You manage the switch stack and the stack member interfaces through the active switch. You cannot manage stack members on an individual switch basis. You can connect to the active switch through the console port or the Ethernet management port of one or more stack members. Be careful with using multiple CLI sessions on the active switch. Commands that you enter in one session are not displayed in the other sessions. Therefore, it is possible to lose track of the session from which you entered commands.

We recommend using one CLI session when managing the switch stack.

If you want to configure a specific stack member port, you must include the stack member number in the CLI command interface notation.

To debug the standby switch, use the `session standby ios` privileged EXEC command from the active switch to access the IOS console of the standby switch. To debug a specific stack member, use the `session switch stack-member-number` privileged EXEC command from the active switch to access the diagnostic shell of the stack member. For more information about these commands, see the switch command reference.

**Accessing the CLI Through a Console Connection or Through Telnet**

Before you can access the CLI, you must connect a terminal or a PC to the switch console or connect a PC to the Ethernet management port and then power on the switch, as described in the hardware installation guide that shipped with your switch.

If your switch is already configured, you can access the CLI through a local console connection or through a remote Telnet session, but your switch must first be configured for this type of access.

You can use one of these methods to establish a connection with the switch:

**Procedure**

- Connect the switch console port to a management station or dial-up modem, or connect the Ethernet management port to a PC. For information about connecting to the console or Ethernet management port, see the switch hardware installation guide.
- Use any Telnet TCP/IP or encrypted Secure Shell (SSH) package from a remote management station. The switch must have network connectivity with the Telnet or SSH client, and the switch must have an enable secret password configured.
  - The switch supports up to 16 simultaneous Telnet sessions. Changes made by one Telnet user are reflected in all other Telnet sessions.
  - The switch supports up to five simultaneous secure SSH sessions.

After you connect through the console port, through the Ethernet management port, through a Telnet session or through an SSH session, the user EXEC prompt appears on the management station.
Using the Web Graphical User Interface

Prerequisites for Using the Web GUI

- The GUI must be used on a PC running Windows 7, Windows XP SP1 (or later releases), or Windows 2000 SP4 (or later releases).
- The switch GUI is compatible with Microsoft Internet Explorer version 10.x, Mozilla Firefox 20.x, or Google Chrome 26.x.

Information About Using The Web GUI

A web browser, or graphical user interface (GUI), is built into each switch.

You can use either the service port interface or the management interface to access the GUI. We recommend that you use the service-port interface. Click Help at the top of any page in the GUI to display online help. You might need to disable your browser’s pop-up blocker to view the online help.

Web GUI Features

The switch web GUI supports the following:

The Configuration Wizard—After initial configuration of the IP address and the local username/password or auth via the authentication server (privilege 15 needed), the wizard provides a method to complete the initial wireless configuration. Start the wizard through Configuration -> Wizard and follow the nine-step process to configure the following:

- Admin Users
- SNMP System Summary
- Management Port
Wireless Management
RF Mobility and Country code
Mobility configuration
WLANs
802.11 Configuration
Set Time

The Monitor tab:
- Displays summary details of switch, clients, and access points.
- Displays all radio and AP join statistics.
- Displays air quality on access points.
- Displays list of all Cisco Discovery Protocol (CDP) neighbors on all interfaces and the CDP traffic information.
- Displays all rogue access points based on their classification-friendly, malicious, ad hoc, classified, and unclassified.

The Configuration tab:
- Enables you to configure the switch for all initial operation using the web Configuration Wizard. The wizard allows you to configure user details, management interface, and so on.
- Enables you to configure the system, internal DHCP server, management, and mobility management parameters.
- Enables you to configure the switch, WLAN, and radios.
- Enables you to configure and set security policies on your switch.
- Enables you to access the switch operating system software management commands.

The Administration tab enables you to configure system logs.

Connecting the Console Port of the Switch

Before you begin
Before you can configure the switch for basic operations, you need to connect it to a PC that uses a VT-100 terminal emulation program (such as HyperTerminal, ProComm, Minicom, or Tip).

Step 1  Connect one end of a null-modem serial cable to the switch's RJ-45 console port and the other end to your PC's serial port.

Step 2  Plug the AC power cord into the switch and a grounded 100 to 240 VAC, 50/60-Hz electrical outlet. Turn on the power supply. The bootup script displays operating system software initialization (code download and power-on self-test verification) and basic configuration. If the switch passes the power-on self-test, the bootup script runs the configuration wizard, which prompts you for basic configuration input.

Step 3  Enter yes. Proceed with basic initial setup configuration parameters in the CLI setup wizard. Specify the IP address for the service port which is the gigabitethernet 0/0 interface.

After entering the configuration parameters in the configuration wizard, you can access the Web GUI. Now, the switch is configured with the IP address for service port.
Logging On to the Web GUI

Enter the switch IP address in your browser’s address bar. For a secure connection, enter https://ip-address. For a less secure connection, enter http://ip-address.

Enabling Web and Secure Web Modes

Step 1  Choose Configuration > Switch > Management > Protocol Management > HTTP-HTTPS.

The HTTP-HTTPS Configuration page appears.

Step 2  To enable web mode, which allows users to access the switch GUI using “http://ip-address,” choose Enabled from the HTTP Access drop-down list. Otherwise, choose Disabled. Web mode (HTTP) is not a secure connection.

Step 3  To enable secure web mode, which allows users to access the switch GUI using “https://ip-address,” choose Enabled from the HTTPS Access drop-down list. Otherwise, choose Disabled. Secure web mode (HTTPS) is a secure connection.

Step 4  Choose to track the device in the IP Device Tracking check box.

Step 5  Choose to enable the trust point in the Enable check box.

Step 6  Choose the trustpoints from the Trustpoints drop-down list.

Step 7  Enter the amount of time, in seconds, before the web session times out due to inactivity in the HTTP Timeout-policy (1 to 600 sec) text box.

The valid range is from 1 to 600 seconds.

Step 8  Enter the server life time in the Server Life Time (1 to 86400 sec) text box.

The valid range is from 1 to 86400 seconds.

Step 9  Enter the maximum number of connection requests that the server can accept in the Maximum number of Requests (1 to 86400) text box.

The valid range is from 1 to 86400 connections.

Step 10  Click Apply.

Step 11  Click Save Configuration.

Configuring the Switch Web GUI

The configuration wizard enables you to configure basic settings on the switch. You can run the wizard after you receive the switch from the factory or after the switch has been reset to factory defaults. The configuration wizard is available in both GUI and CLI formats.
Step 1: Connect your PC to the service port and configure an IPv4 address to use the same subnet as the switch. The switch is loaded with IOS XE image and the service port interface is configured as gigabitethernet 0/0.

Step 2: Start Internet Explorer 10 (or later), Firefox 2.0.0.11 (or later), or Google Chrome on your PC and enter the management interface IP address on the browser window. The management interface IP address is same as the gigabitethernet 0/0 (also known as service port interface). When you log in for the first time, you need to enter HTTP username and password. By default, the username is admin and the password is cisco.

You can use both HTTP and HTTPS when using the service port interface. HTTPS is enabled by default and HTTP can also be enabled.

When you log in for the first time, the Accessing Cisco Switch &lt;Model Number&gt; &lt;Hostname&gt; page appears.

Step 3: On the Accessing Cisco Switch page, click the Wireless Web GUI link to access switch web GUI Home page.

Step 4: Choose Configuration &gt; Wizard to perform all steps that you need to configure the switch initially.

The Admin Users page appears.

Step 5: On the Admin Users page, enter the administrative username to be assigned to this switch in the User Name text box and the administrative password to be assigned to this switch in the Password and Confirm Password text boxes. Click Next.

The default username is admin and the default password is cisco. You can also create a new administrator user for the switch. You can enter up to 24 ASCII characters for username and password.

The SNMP System Summary page appears.

Step 6: On the SNMP System Summary page, enter the following SNMP system parameters for the switch, and click Next:

- Customer-definable switch location in the Location text box.
- Customer-definable contact details such as phone number with names in the Contact text box.
- Choose enabled to send SNMP notifications for various SNMP traps or disabled not to send SNMP notifications for various SNMP traps from the SNMP Global Trap drop-down list.
- Choose enabled to send system log messages or disabled not to send system log messages from the SNMP Logging drop-down list.

Note: The SNMP trap server, must be reachable through the distribution ports (and not through the gigabitethernet0/0 service or management interface).

The Management Port page appears.

Step 7: In the Management Port page, enter the following parameters for the management port interface (gigabitethernet 0/0) and click Next.

- Interface IP address that you assigned for the service port in the IP Address text box.
- Network mask address of the management port interface in the Netmask text box.
- The IPv4 Dynamic Host Configuration Protocol (DHCP) address for the selected port in the IPv4 DHCP Server text box.

The Wireless Management page appears.

Step 8: In the Wireless Management page, enter the following wireless interface management details, and click Next.
• Choose the interface—VLAN, or Ten Gigabit Ethernet from the Select Interface drop-down list.
• VLAN tag identifier, or 0 for no VLAN tag in the VLAN id text box.
• IP address of wireless management interface where access points are connected in the IP Address text box.
• Network mask address of the wireless management interface in the Netmask text box.
• DHCP IPv4 IP address in the IPv4 DHCP Server text box.

When selecting VLAN as interface, you can specify the ports as –Trunk or Access ports from the selected list displayed in the Switch Port Configuration text box.

The **RF Mobility and Country Code** page appears.

**Step 9**

In the **RF Mobility and Country Code** page, enter the RF mobility domain name in the RF Mobility text box, choose current country code from the Country Code drop-down list, and click **Next**. From the GUI, you can select only one country code.

**Note** Before configuring RF grouping parameters and mobility configuration, ensure that you refer to the relevant conceptual content and then proceed with the configuration.

The **Mobility Configuration** page with mobility global configuration settings appears.

**Step 10**

In the **Mobility Configuration** page, view and enter the following mobility global configuration settings, and click **Next**.

- Choose **Mobility Controller** or **Mobility Agent** from the Mobility Role drop-down list:
  - If Mobility Agent is chosen, enter the mobility controller IP address in the Mobility Controller IP Address text box and mobility controller IP address in the Mobility Controller Public IP Address text box.
  - If Mobility Controller is chosen, then the mobility controller IP address and mobility controller public IP address are displayed in the respective text boxes.

- Displays mobility protocol port number in the Mobility Protocol Port text box.
- Displays the mobility switch peer group name in the Mobility Switch Peer Group Name text box.
- Displays whether DTLS is enabled in the DTLS Mode text box.
  
  DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS.
- Displays mobility domain identifier for 802.11 radios in the Mobility Domain ID for 802.11 radios text box.
- The amount of time (in seconds) between each ping request sent to an peer switch in the Mobility Keepalive Interval (1-30)sec text box.
  
  Valid range is from 1 to 30 seconds, and the default value is 10 seconds.
- Number of times a ping request is sent to an peer switch before the peer is considered to be unreachable in the Mobility Keepalive Count (3-20) text box.
  
  The valid range is from 3 to 20, and the default value is 3.
- The DSCP value that you can set for the mobility switch in the Mobility Control Message DSCP Value (0-63) text box.
  
  The valid range is 0 to 63, and the default value is 0.
Displays the number of mobility switch peer group member configured in the Switch Peer Group Members Configured text box.

The **WLANs** page appears.

**Step 11**  
In the **WLANs** page, enter the following WLAN configuration parameters, and click **Next**.

- WLAN identifier in the WLAN ID text box.
- SSID of the WLAN that the client is associated with in the SSID text box.
- Name of the WLAN used by the client in the Profile Name text box.

The **802.11 Configuration** page appears.

**Step 12**  
In the **802.11 Configuration** page, check either one or both 802.11a/n/ac and 802.11b/g/n check boxes to enable the 802.11 radios, and click **Next**.

The **Set Time** page appears.

**Step 13**  
In the **Set Time** page, you can configure the time and date on the switch based on the following parameters, and click **Next**.

- Displays current timestamp on the switch in the Current Time text box.
- Choose either Manual or NTP from the Mode drop-down list.
  
  On using the NTP server, all access points connected to the switch, synchronizes its time based on the NTP server settings available.
- Choose date on the switch from the Year, Month, and Day drop-down list.
- Choose time from the Hours, Minutes, and Seconds drop-down list.
- Enter the time zone in the Zone text box and select the offset setting required when compared to the current time configured on the switch from the Offset drop-down list.

The **Save Wizard** page appears.

**Step 14**  
In the **Save Wizard** page, you can review the configuration settings performed on the switch using these steps, and if you wish to change any configuration value, click **Previous** and navigate to that page.

You can save the switch configuration created using the wizard only if a success message is displayed for all the wizards. If the **Save Wizard** page displays errors, you must recreate the wizard for initial configuration of the switch.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Flexible NetFlow

The following are prerequisites for your Flexible NetFlow configuration:

- You must configure a source interface. If you do not configure a source interface, the exporter will remain in a disabled state.
- You must configure a valid record name for every flow monitor.

Prerequisites for Wireless Flexible NetFlow

The following are the prerequisites for wireless Flexible NetFlow:

- Ensure that the networking device is running a Cisco release that supports wireless Flexible NetFlow.
- Ensure that the target is connected to a WLAN.
Restrictions for Flexible NetFlow

The following are restrictions for Flexible NetFlow:

- Traditional NetFlow (TNF) accounting is not supported.
- Flexible NetFlow v5 export format is not supported, only NetFlow v9 export format is supported.
- Both ingress and egress NetFlow accounting is supported.
- Microflow policing feature shares the NetFlow hardware resource with FNF.
- Only one flow monitor per interface and per direction is supported.
- Layer 2, IPv4, and IPv6 traffic types are supported; however, the switch can apply a flow monitor to only one of these types at a time for a given direction and interface.
- Layer 2, VLAN, WLAN and Layer 3 interfaces are supported, but the switch does not support SVI and tunnels.

- The following NetFlow table sizes are supported:

<table>
<thead>
<tr>
<th>Trim Level</th>
<th>Ingress NetFlow Table</th>
<th>Egress NetFlow Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAN Base</td>
<td>Not supported</td>
<td>Not supported</td>
</tr>
<tr>
<td>IP Base</td>
<td>8 K</td>
<td>16 K</td>
</tr>
<tr>
<td>IP Services</td>
<td>8 K</td>
<td>16 K</td>
</tr>
</tbody>
</table>

- Depending on the switch type, a switch will have one or two forwarding ASICs. The capacities listed in the above table are on a per-ASIC basis.
- The switch can support either one or two ASICs. Each ASIC has 8K ingress and 16K egress entries.
- The NetFlow tables are on separate compartments and cannot be combined. Depending on which ASIC processed the packet, the flows will be created in the table in the corresponding ASIC.
- Both full flow accounting and sampled NetFlow accounting are supported.
- NetFlow hardware implementation supports four hardware samplers. You can select a sampler rate from 1 out of 2 to 1 out of 1024. Only random sampling mode is supported.
- With the microflow policing feature (which is enabled only for wireless implementation), NetFlow can and should be used only in full flow mode i.e. NetFlow policing cannot be used. For wireless traffic, applying a sampler is not permitted, as it hinders microflow QoS.
- Only full flow accounting is supported for wireless traffic.
- NetFlow hardware uses hash tables internally. Hash collisions can occur in the hardware. Therefore, in spite of the internal overflow Content Addressable Memory (CAM), the actual NetFlow table utilization could be about 80 percent.
Information About NetFlow

NetFlow is a Cisco technology that provides statistics on packets flowing through the switch. NetFlow is the standard for acquiring IP operational data from IP networks. NetFlow provides data to enable network and security monitoring, network planning, traffic analysis, and IP accounting. Flexible NetFlow improves on original NetFlow by adding the capability to customize the traffic analysis parameters for your specific requirements. Flexible NetFlow facilitates the creation of more complex configurations for traffic analysis and data export through the use of reusable configuration components.

Flexible NetFlow Overview

Flexible NetFlow uses flows to provide statistics for accounting, network monitoring, and network planning. A flow is a unidirectional stream of packets that arrives on a source interface and has the same values for the keys. A key is an identified value for a field within the packet. You create a flow using a flow record to define the unique keys for your flow.

The switch supports the Flexible NetFlow feature that enables enhanced network anomalies and security detection. Flexible NetFlow allows you to define an optimal flow record for a particular application by selecting the keys from a large collection of predefined fields.

All key values must match for the packet to count in a given flow. A flow might gather other fields of interest, depending on the export record version that you configure. Flows are stored in the Flexible NetFlow cache.

You can export the data that Flexible NetFlow gathers for your flow by using an exporter and export this data to a remote Flexible NetFlow collector.

You define the size of the data that you want to collect for a flow using a monitor. The monitor combines the flow record and exporter with the Flexible NetFlow cache information.

• Depending on what fields are used for the flow, a single flow could take two consecutive entries. IPv6 flows also take two entries. In these situations, the effective usage of NetFlow entries is half the table size, which is separate from the above hash collision limitation.

• The switch supports up to 16 flow monitors.

• Microflow policing uses a separate set of flow monitors (limit 3).

• SSID-based NetFlow accounting is supported. SSID is treated in a manner similar to an interface. However, certain fields are not supported (such as AP MAC address and user ID).

• NetFlow v9 format NetFlow export is supported.

• The NetFlow software implementation supports distributed NetFlow export, so the flows are exported from the same switch in which the flow was created.

• Ingress flows are present in the ASIC that first received the packets for the flow. Egress flows are present in the ASIC from which the packets actually left the switch setup.

• The reported value for the bytes count field (called “bytes long”) is Layer-2-packet-size—18 bytes. For classic Ethernet traffic (802.3), this will be accurate. For all other Ethernet types, this field will not be accurate. Use the "bytes layer2" field, which always reports the accurate Layer 2 packet size. For information about supported Flexible NetFlow fields, see Supported Flexible NetFlow Fields, on page 27.
Wireless Flexible NetFlow Overview

The wireless Flexible NetFlow infrastructure supports the following:

- Flexible NetFlow Version 9.0
- User-based rate limiting
- Microflow policing
- Voice and video flow monitoring
- Reflexive access control list (ACL)

Microflow Policing and User-Based Rate Limiting

Microflow policing associates a 2-color 1-rate policer and related drop statistics to each flow present in the NetFlow table. When the flow mask comprises all packet fields, this functionality is known as microflow policing. When the flow mask comprises either source or destination only, this functionality is known as user-based rate limiting.

Voice and Video Flow Monitoring

Voice and video flows are full flow mask-based entries. The ASIC provides the flexibility to program the policer parameters, share policers across multiple flows and rewrite the IP address and Layer 4 port numbers of these flows.

Note

For dynamic entries, the NetFlow engine will use the policer parameters that are derived for the flow based on the policy (ACL/QoS-based policies). Dynamic entries cannot share policer across multiple flows.

Reflexive ACL

Reflexive ACLs allow IP packets to be filtered based on upper-layer session information. The ACLs allow outbound traffic and limit inbound traffic in response to the sessions that originate inside the trusted network. The reflexive ACLs are transparent to the filtering mechanism until a data packet that matches the reflexive entry activates it. At this time, a temporary ACL entry is created and added to the IP-named access lists. The information obtained from the data packet to generate the reflexive ACL entry is permit/deny bit, the source IP address and port, the destination IP address, port, and the protocol type. During reflexive ACL entry evaluation, if the protocol type is either TCP or UDP, then the port information must match exactly. For other protocols, there is no port information to match. After this ACL is installed, the firewall is then opened for the reply packets to pass through. At this time, a potential hacker could have access to the network behind the firewall. To narrow this window, an idle timeout period can be defined. However, in the case of TCP, if two FIN bits or an RST is detected, the ACL entry can be removed.

Flow Records

A flow record defines the keys that Flexible NetFlow uses to identify packets in the flow, as well as other fields of interest that Flexible NetFlow gathers for the flow. You can define a flow record with any combination of keys and fields of interest. The switch supports a rich set of keys. A flow record also defines the types of counters gathered per flow. You can configure 64-bit packet or byte counters. The switch enables the following match fields as the defaults when you create a flow record:

- match datalink—Layer 2 attributes
- match flow—Flow identifying attributes
- match interface—Interface attributes
- match ipv4—IPv4 attributes
- match ipv6—IPv6 attributes
- match transport—Transport layer fields

Creating a Flow Record, on page 32

Flexible NetFlow Match Parameters

The following table describes Flexible NetFlow match parameters. You must configure at least one of the following match parameters for the flow records.

Table 4: Match Parameters

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| match datalink \{dot1q | ethertype | mac | vlan \} | Specifies a match to datalink or Layer 2 fields. The following command options are available:
  - dot1q—Matches to the dot1q field.
  - ethertype—Matches to the ethertype of the packet.
  - mac—Matches the source or destination MAC fields.
  - vlan—Matches to the VLAN that the packet is located on (input or output). |
| match flow direction | Specifies a match to the flow identifying fields. |
| match interface \{input | output\} | Specifies a match to the interface fields. The following command options are available:
  - input—Matches to the input interface.
  - output—Matches to the output interface. |
### Flexible NetFlow Collect Parameters

The following table describes the Flexible NetFlow collect parameters.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **match ipv4** {destination | protocol | source | tos | ttl | version} | Specifies a match to the IPv4 fields. The following command options are available:  
  - **destination**—Matches to the IPv4 destination address-based fields.  
  - **protocol**—Matches to the IPv4 protocols.  
  - **source**—Matches to the IPv4 source address based fields.  
  - **tos**—Matches to the IPv4 Type of Service fields.  
  - **ttl**—Matches to the IPv4 Time To Live fields.  
  - **version**—Matches to the IP version from the IPv4 header. |
| **match ipv6** {destination | hop-limit | protocol | source | traffic-class | version} | Specifies a match to the IPv6 fields. The following command options are available:  
  - **destination**—Matches to the IPv6 destination address-based fields.  
  - **hop-limit**—Matches to the IPv6 hop limit fields.  
  - **protocol**—Matches to the IPv6 payload protocol fields.  
  - **source**—Matches to the IPv6 source address based fields.  
  - **traffic-class**—Matches to the IPv6 traffic class.  
  - **version**—Matches to the IP version from the IPv6 header. |
| **match transport** {destination-port | igmp | icmp | source-port} | Specifies a match to the Transport Layer fields. The following command options are available:  
  - **destination-port**—Matches to the transport destination port.  
  - **icmp**—Matches to ICMP fields, including ICMP IPv4 and IPv6 fields.  
  - **igmp**—Matches to IGMP fields.  
  - **source-port**—Matches to the transport source port. |
### Table 5: Collect Parameters

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`collect counter { bytes { layer2 { long }</td>
<td>long }</td>
</tr>
<tr>
<td>`collect interface {input</td>
<td>output}`</td>
</tr>
<tr>
<td>`collect timestamp absolute {first</td>
<td>last}`</td>
</tr>
<tr>
<td><code>collect transport tcp flags</code></td>
<td>Collects the following transport TCP flags:</td>
</tr>
<tr>
<td></td>
<td>• <code>ack</code>—TCP acknowledgement flag</td>
</tr>
<tr>
<td></td>
<td>• <code>cwr</code>—TCP congestion window reduced flag</td>
</tr>
<tr>
<td></td>
<td>• <code>ece</code>—TCP ECN echo flag</td>
</tr>
<tr>
<td></td>
<td>• <code>fin</code>—TCP finish flag</td>
</tr>
<tr>
<td></td>
<td>• <code>psh</code>—TCP push flag</td>
</tr>
<tr>
<td></td>
<td>• <code>rst</code>—TCP reset flag</td>
</tr>
<tr>
<td></td>
<td>• <code>syn</code>—TCP synchronize flag</td>
</tr>
<tr>
<td></td>
<td>• <code>urg</code>—TCP urgent flag</td>
</tr>
</tbody>
</table>

**Note** On the switch, you cannot specify which TCP flag to collect. You can only specify to collect transport TCP flags. All TCP flags will be collected with this command.

### Exporters

An exporter contains network layer and transport layer details for the Flexible NetFlow export packet. The following table lists the configuration options for an exporter.

### Table 6: Flexible NetFlow Exporter Configuration Options

<table>
<thead>
<tr>
<th>Exporter Configuration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Sets a command to its default values.</td>
</tr>
<tr>
<td>description</td>
<td>Provides a description for the flow exporter.</td>
</tr>
<tr>
<td>destination</td>
<td>Export destination.</td>
</tr>
<tr>
<td>dscp</td>
<td>Optional DSCP value.</td>
</tr>
<tr>
<td>exit</td>
<td>Exits from the flow exporter configuration mode.</td>
</tr>
</tbody>
</table>
### Exporter Configuration

<table>
<thead>
<tr>
<th>Exporter Configuration</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>export-protocol</td>
<td>Export protocol version.</td>
</tr>
<tr>
<td>no</td>
<td>Negates the command or its default.</td>
</tr>
<tr>
<td>option</td>
<td>Selects option for exporting.</td>
</tr>
<tr>
<td>source</td>
<td>Originating interface for the net flow.</td>
</tr>
<tr>
<td>template</td>
<td>Flow exporter template configuration.</td>
</tr>
<tr>
<td>transport</td>
<td>Transport protocol.</td>
</tr>
<tr>
<td>ttl</td>
<td>Optional TTL or hop limit.</td>
</tr>
</tbody>
</table>

The switch exports data to the collector whenever a timeout occurs or when the flow is terminated (TCP Fin or Rst received, for example). You can configure the following timers to force a flow export:

- **Active timeout**—The flow continues to have the packets for the past \( m \) seconds since the flow was created.
- **Inactive timeout**—The flow does not have any packets for the past \( n \) seconds.

### Export Formats

The switch supports only NetFlow Version 9 export formats. NetFlow Version 9 export format provides the following features and functionality:

- Variable field specification format
- Support for IPv4 destination address export
- More efficient network utilization

For information about the Version 9 export format, see RFC 3954.

### Monitors

A monitor references the flow record and flow exporter. You apply a monitor to an interface on the switch. Note the following when applying a flow monitor to an interface:

- If you apply a flow monitor in the input direction:
  - Use the `match` keyword and use the input interface as a key field.
  - Use the `collect` keyword and use the output interface as a collect field. This field will be present in the exported records but with a value of 0.

- If you apply a flow monitor in the output direction:
• Use the **match** keyword and use the output interface as a key field.

• Use the **collect** keyword and use the input interface as a collect field. This field will be present in the exported records but with a value of 0.

**Related Topics**

Creating a Flow Monitor, on page 36

---

**Samplers**

If you are using sampled mode, you use the sampler to specify the rate at which packets are sampled.

**Supported Flexible NetFlow Fields**

The following tables provide a consolidated list of supported fields in Flexible NetFlow (FNF) for various traffic types and traffic direction.

<table>
<thead>
<tr>
<th>Field</th>
<th>Layer 2 In</th>
<th>Layer 2 Out</th>
<th>IPv4 In</th>
<th>IPv4 Out</th>
<th>IPv6 In</th>
<th>IPv6 Out</th>
<th>Notes</th>
</tr>
</thead>
</table>
| Key or Collect Fields | Yes | — | — | — | — | — | If you apply a flow monitor in the input direction:  
  • Use the **match** keyword and use the input interface as a key field.  
  • Use the **collect** keyword and use the output interface as a collect field. This field will be present in the exported records but with a value of 0. |
| Interface input | Yes | — | Yes | — | Yes | — | |

—if the packet has a VLAN field, then that length is not accounted for.
**Supported Flexible NetFlow Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Layer 2 In</th>
<th>Layer 2 Out</th>
<th>IPv4 In</th>
<th>IPv4 Out</th>
<th>IPv6 In</th>
<th>IPv6 Out</th>
<th>Notes</th>

**Default Settings**

The following table lists the Flexible NetFlow default settings for the switch.

*Table 7: Default Flexible NetFlow Settings*

<table>
<thead>
<tr>
<th>Setting</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow active timeout</td>
<td>1800 seconds</td>
</tr>
<tr>
<td>Flow timeout inactive</td>
<td>15 seconds</td>
</tr>
</tbody>
</table>

**How to Configure Flexible NetFlow**

To configure Flexible NetFlow, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.
2. Create an optional flow exporter by specifying the protocol and transport destination port, destination, and other parameters.
3. Create a flow monitor based on the flow record and flow exporter.
4. Create an optional sampler.
5. Apply the flow monitor to a Layer 2 port, Layer 3 port, or VLAN.
6. If applicable to your configuration, configure a WLAN to apply a flow monitor to.

Creating a Flow Record

You can create a flow record and add keys to match on and fields to collect in the flow.

SUMMARY STEPS

1. configure terminal
2. flow record name
3. description string
4. match type
5. collect type
6. end
7. show flow record [name record-name]
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 flow record name</td>
<td>Creates a flow record and enters flow record configuration mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# flow record test Switch(config-flow-record)#</td>
<td></td>
</tr>
<tr>
<td>Step 3 description string</td>
<td>(Optional) Describes this flow record as a maximum 63-character string.</td>
</tr>
<tr>
<td>Example: Switch(config-flow-record)# description Ipv4Flow</td>
<td></td>
</tr>
<tr>
<td>Step 4 match type</td>
<td>Specifies a match key. For information about possible match key values, see Flexible NetFlow Match Parameters, on page 23.</td>
</tr>
<tr>
<td>Example: Switch(config-flow-record)# match ipv4 source address</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

| Switch(config-flow-record)# match ipv4 destination address |
| Switch(config-flow-record)# match flow direction |

### Purpose

Specifies the collection field. For information about possible collection field values, see Flexible NetFlow Collect Parameters, on page 24.

### Step 5

**collect type**

**Example:**

```
Switch(config-flow-record)# collect counter bytes layer2 long
Switch(config-flow-record)# collect counter bytes long
Switch(config-flow-record)# collect timestamp absolute first
Switch(config-flow-record)# collect transport tcp flags
```

### Step 6

**end**

**Example:**

```
Switch(config-flow-record)# end
```

### Step 7

**show flow record [name record-name]**

**Example:**

```
Switch show flow record test
```

### Step 8

**copy running-config startup-config**

**Example:**

```
Switch# copy running-config startup-config
```

### What to do next

Define an optional flow exporter by specifying the export format, protocol, destination, and other parameters.

<td>• TenGigabitEthernet—10-Gigabit Ethernet</td>
</tr>
<tr>
<td></td>
<td>• Tunnel—Tunnel interface</td>
</tr>
<tr>
<td></td>
<td>• Vlan—Catalyst VLANs</td>
</tr>
</tbody>
</table>

**Step 7**

**transport udp number**  
*Example:*

Switch(config-flow-exporter)# transport udp 200  
*(Optional) Specifies the UDP port to use to reach the NetFlow collector. The range is from 0 to 65535.*

**Step 8**

**end**  
*Example:*

Switch(config-flow-record)# end  
*Returns to privileged EXEC mode.*

**Step 9**

**show flow exporter [name record-name]**  
*Example:*

Switch show flow exporter ExportTest  
*(Optional) Displays information about NetFlow flow exporters.*

**Step 10**

**copy running-config startup-config**  
*Example:*

Switch# copy running-config startup-config  
*(Optional) Saves your entries in the configuration file.*

---

**What to do next**

Define a flow monitor based on the flow record and flow exporter.

**Related Topics**

[Exporters](#), on page 25
Creating a Flow Monitor

You can create a flow monitor and associate it with a flow record and a flow exporter.

**SUMMARY STEPS**

1. `configure terminal`
2. `flow monitor name`
3. `description string`
4. `exporter name`
5. `record name`
6. `cache { timeout {active | inactive} seconds | type normal }`
7. `end`
8. `show flow monitor [name record-name]`
9. `copy running-config startup-config`

### Creating a Sampler

You can create a sampler to define the NetFlow sampling rate for a flow.

**SUMMARY STEPS**

1. configure terminal
2. sampler name
3. description string
4. mode {random}
5. end
6. `show sampler [name]`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `configure terminal`  
  Example:  
  `Switch# configure terminal` | Enters the global configuration mode. |
| Step 2 | `sampler name`  
  Example:  
  `Switch(config)# sampler SampleTest  
  Switch(config-flow-sampler)#` | Creates a sampler and enters flow sampler configuration mode. |
| Step 3 | `description string`  
  Example:  
  `Switch(config-flow-sampler)# description samples` | (Optional) Describes this flow record as a maximum 63-character string. |
| Step 4 | `mode {random}`  
  Example:  
  `Switch(config-flow-sampler)# mode random 1 out-of 1024` | Defines the random sample mode. |
| Step 5 | `end`  
  Example:  
  `Switch(config-flow-sampler)# end` | Returns to privileged EXEC mode. |
| Step 6 | `show sampler [name]`  
  Example:  
  `Switch show sample SampleTest` | (Optional) Displays information about NetFlow samplers. |
| Step 7 | `copy running-config startup-config`  
  Example:  
  `Switch# copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
What to do next

Apply the flow monitor to a source interface, subinterface, VLAN interface, or a VLAN.

<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Vlan—Catalyst VLANs&lt;br&gt;• Range—Interface range</td>
<td></td>
</tr>
</tbody>
</table>

### Step 3

```
{ip flow monitor | ipv6 flow monitor} name [sampler name] {input |output }
```

**Example:**

```
Switch(config-if)# ip flow monitor MonitorTest input
```

### Step 4

```
end
```

**Example:**

```
Switch(config-flow-monitor)# end
```

### Step 5

```
show flow interface [interface-type number]
```

**Example:**

```
Switch# show flow interface
```

### Step 6

```
copy running-config startup-config
```

**Example:**

```
Switch# copy running-config startup-config
```

---

## Configuring a Bridged NetFlow on a VLAN

You can apply a flow monitor and an optional sampler to a VLAN.

### SUMMARY STEPS

1. configure terminal
2. vlan [configuration] vlan-id
3. ip flow monitor name [sampler name] {input |output}
4. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>

---
### Configuring Layer 2 NetFlow

You can define Layer 2 keys in Flexible NetFlow records that you can use to capture flows in Layer 2 interfaces.

**SUMMARY STEPS**

1. `configure terminal`
2. `flow record name`
3. `match datalink {dot1q | ethertype | mac | vlan}
4. `end`
5. `show flow record [name]`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>flow record name</code></td>
<td>Enters flow record configuration mode.</td>

## Configuring WLAN to Apply Flow Monitor in Data Link Input/Output Direction

### SUMMARY STEPS

1. configure terminal
2. wlan wlan-name
3. datalink flow monitor monitor-name {input | output}
4. end
5. show wlan wlan-name

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

---

### Command or Action

**Example:**

Switch(config)# flow record L2_record
Switch(config-flow-record)#

**Step 3**

match datalink {dot1q | ethertype | mac | vlan}

**Example:**

Switch(config-flow-record)# match datalink ethertype

**Purpose:** Specifies the Layer 2 attribute as a key.

**Step 4**

end

**Example:**

Switch(config-flow-record)# end

**Purpose:** Returns to privileged EXEC mode.

**Step 5**

show flow record [name ]

**Example:**

Switch# show flow record

(Optional) Displays information about NetFlow on an interface.

**Step 6**

copy running-config startup-config

**Example:**

Switch# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
### Purpose

**Command or Action**

**Step 2**

`wlan wlan-name`

*Example:*

Switch (config) # wlan mywlan

Enters WLAN configuration submode. For `wlan-name`, enter the profile name. The range is 1 to 32 characters.

**Step 3**

`datalink flow monitor monitor-name {input | output}`

*Example:*

Switch (config-wlan) # datalink flow monitor
flow-monitor-1 {input | output}

Applies flow monitor to Layer 2 traffic in the direction of interest.

**Step 4**

`end`

*Example:*

Switch (config) # end

Returns to privileged EXEC mode.

**Step 5**

`show wlan wlan-name`

*Example:*

Switch # show wlan mywlan

(Optional) Verifies your configuration.

---

### Example

**Configuring WLAN to Apply Flow Monitor in IPV4 and IPv6 Input/Output Direction**

**SUMMARY STEPS**

1. configure terminal
2. wlan wlan-id
3. {ip | ipv6} flow monitor monitor-name {input | output}
4. end
5. show wlan wlan-name

## Configuration Examples for Flexible NetFlow

### Example: Configuring a Flow

This example shows how to create a flow and apply it to an interface:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch(config)# flow export export1
Switch(config-flow-exporter)# destination 10.0.101.254
Switch(config-flow-exporter)# transport udp 2055
Switch(config-flow-exporter)# exit
Switch(config)# flow record record1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match ipv4 protocol
Switch(config-flow-record)# match transport source-port
Switch(config-flow-record)# match transport destination-port
Switch(config-flow-record)# collect counter byte long
Switch(config-flow-record)# collect counter packet long
Switch(config-flow-record)# collect timestamp absolute first
Switch(config-flow-record)# collect timestamp absolute last
Switch(config-flow-record)# exit
Switch(config)# flow monitor monitor1
Switch(config-flow-monitor)# record record1
Switch(config-flow-monitor)# exporter export1
Switch(config-flow-monitor)# exit
Switch(config)# interface tenGigabitEthernet 1/0/1
Switch(config-if)# ip flow monitor monitor1 input
Switch(config-if)# end
```
Example: Configuring IPv4 Flexible NetFlow in WLAN (Ingress Direction)

The following example shows how to configure IPv4 Flexible NetFlow on WLAN ingress direction:

Switch# configure terminal
Switch(config)# flow record fr_v4
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 protocol
Switch(config-flow-record)# match ipv4 tos
Switch(config-flow-record)# match ipv4 ttl
Switch(config-flow-record)# match ipv4 version
Switch(config-flow-record)# match wireless ssid
Switch(config-flow-record)# collect wireless ap mac address
Switch(config-flow-record)# collect counter packets long
Switch(config-flow-record)# collect counter bytes long
Switch(config-flow-record)# collect timestamp absolute first
Switch(config-flow-record)# exit

Switch(config)# flow monitor fm_v4
Switch(config-flow-monitor)# record fr_v4
Switch(config-flow-record)# exit

Switch(config)# wlan 1
Switch(config-wlan)# ip flow monitor fm_v4 in
Switch(config-wlan)# end

Switch# show flow monitor fm_v4 cache

Related Topics

- Wireless Flexible NetFlow Overview, on page 22

Example: Configuring IPv6 and Transport Flag Flexible NetFlow in WLAN (Egress Direction)

The following example shows how to configure IPv6 and transport flag Flexible NetFlow on WLAN egress direction:

Switch# configure terminal
Switch(config)# flow record fr_v6
Switch(config-flow-record)# match ipv6 destination address
Switch(config-flow-record)# match ipv6 source address
Switch(config-flow-record)# match ipv6 hop-limit
Switch(config-flow-record)# match ipv6 protocol
Switch(config-flow-record)# match ipv6 traffic
Switch(config-flow-record)# match ipv6 version
Switch(config-flow-record)# match wireless ssid
Switch(config-flow-record)# collect wireless ap mac address
Switch(config-flow-record)# collect counter bytes long
Switch(config-flow-record)# collect transport tcp flags
Switch(config-flow-record)# exit
Switch(config)# flow monitor fm_v6
Switch(config-flow-monitor)# record fr_v6
Switch(config-flow-monitor)# exit

Switch(config)# wlan 1
Switch(config-wlan)# ipv6 flow monitor fm_v6 out
Switch(config-wlan)# end

Switch# show flow monitor fm_v6 cache

**Note**

On the switch, you cannot specify which TCP flag to collect. You can only specify to collect transport TCP flags.

### Example: Configuring IPv6 Flexible NetFlow in WLAN (Both Ingress and Egress Directions)

The following example shows how to configure IPv6 Flexible NetFlow on WLAN in both directions:

Switch# configure terminal
Switch (config)# flow record fr_v6
Switch (config-flow-record)# match ipv6 destination address
Switch (config-flow-record)# match ipv6 source address
Switch (config-flow-record)# match ipv6 hop-limit
Switch (config-flow-record)# match ipv6 protocol
Switch (config-flow-record)# match ipv6 traffic
Switch (config-flow-record)# match ipv6 version
Switch (config-flow-record)# match wireless ssid
Switch (config-flow-record)# collect wireless ap mac address
Switch (config-flow-record)# collect counter packets long
Switch (config-flow-record)# exit

Switch (config)# flow monitor fm_v6
Switch (config-flow-monitor)# record fr_v6
Switch (config-flow-monitor)# exit

Switch (config)# wlan 1
Switch (config-wlan)# ipv6 flow monitor fm_v6 in
Switch (config-wlan)# ipv6 flow monitor fm_v6 out
Switch (config-wlan)# end

Switch# show flow monitor fm_v6 cache

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for CleanAir

You can configure Cisco CleanAir only on CleanAir-enabled access points.

Only Cisco CleanAir-enabled access points using the following access point modes can perform Cisco CleanAir spectrum monitoring:

- Local—In this mode, each Cisco CleanAir-enabled access point radio provides air quality and interference detection reports for the current operating channel only.

- Monitor—When Cisco CleanAir is enabled in monitor mode, the access point provides air quality and interference detection reports for all monitored channels.

The following options are available:
Restrictions for CleanAir

- Access points in monitor mode do not transmit Wi-Fi traffic or 802.11 packets. They are excluded from radio resource management (RRM) planning and are not included in the neighbor access point list. IDR clustering depends on the switch’s ability to detect neighboring in-network access points. Correlating interference device detections from multiple access points is limited between monitor-mode access points.

- Cisco recommends a ratio of 1 monitor mode access point for every 5 local mode access points, this may also vary based on the network design and expert guidance for best coverage.

- Spectrum Expert (Windows XP laptop client) and AP should be pingable, otherwise; it will not work.

Note

The access point does not participate in AQ HeatMap in Prime Infrastructure.
Information About CleanAir

Cisco CleanAir is a spectrum intelligence solution designed to proactively manage the challenges of a shared wireless spectrum. All of the users of the shared spectrum can be seen (both native devices and foreign interferers). It also enables the network to act upon this information. For example, the interfering device can be manually removed or the system can automatically change the channel away from the interference.

A Cisco CleanAir system consists of CleanAir-enabled access points, wireless controller modules, mobility controllers, mobility anchors and next generation switches. The access points join the mobility controller directly or through the mobility anchor. They collect information about all devices that operate in the industrial, scientific, and medical (ISM) bands, identify and evaluate the information as a potential interference source, and forward it to the switch. The switch controls the access points, collects spectrum data, and forwards information to Cisco Prime Infrastructure (PI) or a Cisco Mobility Services Engine (MSE) upon request.

Any networking configurations can be performed only on the mobility controller, configurations cannot be performed in the MA mode. However, any radio level CleanAir configurations can be done using mobility anchor.

For every device operating in the unlicensed band, Cisco CleanAir tells what it is, where it is, how it is impacting the wireless network, and what actions should be taken. It simplifies RF.

Wireless LAN systems operate in unlicensed 2.4-GHz and 5-GHz ISM bands. Many devices like microwave ovens, cordless phones, and Bluetooth devices also operate in these bands and can negatively affect the Wi-Fi operations.

Some of the most advanced WLAN services, such as voice over wireless and IEEE 802.11n radio communications, could be significantly impaired by the interference caused by other legal users of the ISM bands. The integration of Cisco CleanAir functionality addresses this problem of radio frequency (RF) interference.

Cisco CleanAir Components

The basic Cisco CleanAir architecture consists of Cisco CleanAir-enabled APs and switch. Cisco Prime Infrastructure (PI), Mobility Services Engine (MSE) and Cisco Spectrum Expert are optional system components. Cisco PI and MSE provide user interfaces for advanced spectrum capabilities such as historic charts, tracking interference devices, location services and impact analysis.
An access point equipped with Cisco CleanAir technology collects information about non-Wi-Fi interference sources, processes it, and forwards it to the MA. The access point sends AQR and IDR reports to the controller.

The mobility controller (MC) controls and configures CleanAir-capable access points, collects and processes spectrum data, and provides it to the PI and/or the MSE. The MC provides local user interfaces (GUI and CLI) to configure basic CleanAir features and services and display current spectrum information. The MC also does detection, merging and mitigation of interference devices using RRM TPC and DCM. For details on Interference Device Merging, see Interference Device Merging, on page 58.

Cisco PI provides advanced user interfaces for CleanAir that include feature enabling and configuration, consolidated display information, historic AQ records and reporting engines. PI also shows charts of interference devices, AQ trends, and alerts.

Cisco MSE is required for location and historic tracking of interference devices, and provides coordination and consolidation of interference reports across multiple controllers. MSE also provides adaptive Wireless Intrusion Prevention System (WIPS) service that provides comprehensive over-the-air threat detection, location and mitigation. MSE also merges all the interference data.

To obtain detailed spectrum data that can be used to generate RF analysis plots similar to those provided by a spectrum analyzer, you can configure a Cisco CleanAir-enabled access point to connect directly to a Microsoft Windows XP or Vista PC running the Cisco Spectrum Expert application.

The switch performs the following tasks in a Cisco CleanAir system:

- Configures Cisco CleanAir capabilities on the access point.
- Provides interfaces (GUI, CLI, and SNMP) for configuring Cisco CleanAir features and retrieving data.
- Displays spectrum data.
- Collects and processes AQRs from the access point and stores them in the air quality database. AQRs contain information about the total interference from all identified sources represented by Air Quality Index (AQI) and summary for the most severe interference categories. The CleanAir system can also
include unclassified interference information under per interference type reports which enable you to take action in cases where the interference due to unclassified interfering devices is frequent.

- Collects and processes Interference Device Reports (IDRs) from the access point and stores them in the interference device database.
- Forwards spectrum data to Prime Infrastructure and the MSE.

**Terms Used in Cisco CleanAir**

**Table 9: CleanAir-related Terms**

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AQI</td>
<td>Air Quality Index. The AQI is an indicator of air quality, based on the air pollutants. An AQI of 0 is bad and an AQI &gt; 85 is good.</td>
</tr>
<tr>
<td>AQR</td>
<td>Air Quality Report. AQRs contain information about the total interference from all identified sources represented by AQI and summary of the most severe interference categories. AQRs are sent every 15 minutes to the Mobility Controller and every 30 seconds in the Rapid mode.</td>
</tr>
<tr>
<td>DC</td>
<td>Duty Cycle. Percentage of time that the channel is utilized by a device.</td>
</tr>
<tr>
<td>EDRRM</td>
<td>EDRRM Event Driven RRM. EDRRM allows an access point in distress to bypass normal RRM intervals and immediately change channels.</td>
</tr>
<tr>
<td>IDR</td>
<td>Interference Device Reports that the access point sends to the controller.</td>
</tr>
<tr>
<td>ISI</td>
<td>Interference Severity Index. The ISI is an indicator of the severity of the interference.</td>
</tr>
<tr>
<td>MA</td>
<td>Mobility Agent. An MA is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. An MA is the wireless component that maintains client mobility state machine for a mobile client that is connected to an access point to the device that the MA is running on.</td>
</tr>
<tr>
<td>MC</td>
<td>Mobility Controller. An MC provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members.</td>
</tr>
<tr>
<td>RSSI</td>
<td>Received Signal Strength Indicator. RSSI is a measurement of the power present in a received radio signal. It is the power at which an access point sees the interferer device.</td>
</tr>
</tbody>
</table>

**Interference Types that Cisco CleanAir can Detect**

Cisco CleanAir can detect interference, report on the location and severity of the interference, and recommend different mitigation strategies. Two such mitigation strategies are persistent device avoidance and spectrum event-driven RRM. New

Wi-Fi chip-based RF management systems share these characteristics:

- Any RF energy that cannot be identified as a Wi-Fi signal is reported as noise.
- Noise measurements that are used to assign a channel plan tend to be averaged over a period of time to avoid instability or rapid changes that can be disruptive to certain client devices.
- Averaging measurements reduces the resolution of the measurement. As such, a signal that disrupts clients might not look like it needs to be mitigated after averaging.
• All RF management systems available today are reactive in nature.

Cisco CleanAir is different and can positively identify not only the source of the noise but also its location and potential impact to a WLAN. Having this information allows you to consider the noise within the context of the network and make intelligent and, where possible, proactive decisions. For CleanAir, two types of interference events are common:

• Persistent interference
• Spontaneous interference

Persistent interference events are created by devices that are stationary in nature and have intermittent but largely repeatable patterns of interference. For example, consider the case of a microwave oven located in a break room. Such a device might be active for only 1 or 2 minutes at a time. When operating, however, it can be disruptive to the performance of the wireless network and associated clients. Using Cisco CleanAir, you can positively identify the device as a microwave oven rather than indiscriminate noise. You can also determine exactly which part of the band is affected by the device, and because you can locate it, you can understand which access points are most severely affected. You can then use this information to direct RRM in selecting a channel plan that avoids this source of interference for the access points within its range. Because this interference is not active for a large portion of the day, existing RF management applications might attempt to again change the channels of the affected access points. Persistent device avoidance is unique, however, in that it remains in effect as long as the source of interference is periodically detected to refresh the persistent status. The Cisco CleanAir system knows that the microwave oven exists and includes it in all future planning.

If you move either the microwave oven or the surrounding access points, the algorithm updates RRM automatically.

Spectrum event-driven RRM can be triggered only by Cisco CleanAir-enabled access points in local mode.

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a threshold for air quality (AQ) that, if exceeded, triggers an immediate channel change for the affected access point. Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an access point detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active. Cisco CleanAir also identifies and locates the source of interference so that more permanent mitigation of the device can be performed at a later time.

In the case of Bluetooth devices, Cisco CleanAir-enabled access points can detect and report interference only if the devices are actively transmitting. Bluetooth devices have extensive power save modes. For example, interference can be detected when data or voice is being streamed between the connected devices.

Interference Device Merging

The Interference Devices (ID) messages are processed on a Mobility Controller (MC). The Mobility Anchor (MA) forwards the ID messages from APs and hence they are processed on the MC. The MC has visibility of the neighbor information across APs connected to different MAs.

ID merging logic requires AP neighbor information. Neighbor information is obtained from the RRM module. This api only gives neighbor information to the APs directly connected to MC.

Currently the AP neighbor list on MA is synced to MC once every 3 minutes; hence the AP neighbor list obtained by this api could be at most 3 mins old. This delay results in delay in merging of Devices as they
are discovered. The subsequent periodic merge will pick up the updated neighbor information and merge is performed

**Persistent Devices**

Some interference devices such as outdoor bridges and Microwave Ovens only transmit when needed. These devices can cause significant interference to the local WLAN due to short duration and periodic operation remain largely undetected by normal RF management metrics. With CleanAir the RRM DCA algorithm can detect, measure, register and remember the impact and adjust the DCA algorithm. This minimizes the use of channels affected by the persistent devices in the channel plan local to the interference source. Cisco CleanAir detects and stores the persistent device information in the switch and this information is used to mitigate interfering channels.

**Persistent Devices Detection**

CleanAir-capable Monitor Mode access point collects information about persistent devices on all configured channels and store the information in controller. Local/Bridge mode AP detects interference devices on the serving channels only.

**Persistent Device Avoidance**

When a Persistent Device (PD) is detected in the CleanAir module, it is reported to the RRM module on the MA. This information is used in the channel selection by the subsequent EDRRM Event Driven RRM (ED-RRM) signal sent to the RRM module.

**EDRRM and AQR Update Mode**

EDRRM is a feature that allows an access point that is in distress to bypass normal RRM intervals and immediately change channels. A CleanAir access point always monitors AQ and reports the AQ every 15 minutes. AQ only reports classified interference devices. The key benefit of EDRRM is very fast action time. If an interfering device is operating on an active channel and causes enough AQ degradation to trigger an EDRRM, then no clients will be able to use that channel or the access point. You must remove the access point from the channel. EDRRM is not enabled by default, you must first enable CleanAir and then enable EDRRM.

AQRs are only available on the MC. The mode configuration and timers are held in Radio Control Block (RCB) on MA (for APs connected to MA). There is no change to the current API available for EMS/NMS. No change is required for directly connected APs as RCB (spectrum config and timers) is available locally. For remote APs (APs connected to MA), three new control messages are added. These three messages are for enable, restart timer and disable rapid update mode for a given AP MAC address and slot.

**Related Topics**

Configuring EDRRM for CleanAir-Events, on page 67

**CleanAir High Availability**

CleanAir configuration (network and radio) is stateful during the switchover. On the MC, Embedded Instrumentation Core (EICORE) provides the sync on network configurations across active and standby nodes. The radio configurations are synced using the HA Infrastructure. The CleanAir configurations on MA are pulled from the MC upon joining. The network configuration is not stored in the EICORE on MA, hence it is synced using HA Infrastructure.
CleanAir Data (AQ and IDR) reports are not stateful, that is, the standby and active nodes are not synced. On switchover, the APs send the reports to the current active slot. The RRM Client (HA Infra Client) is used for CleanAir HA sync.

# How to Configure CleanAir

## Enabling CleanAir for 2.4-GHz Band

### SUMMARY STEPS

1. configure terminal
2. `ap dot11 24ghz cleanair`
3. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>

<tr>
<td></td>
<td>Step 2</td>
<td>Command or Action</td>
</tr>
<tr>
<td></td>
<td>ap dot11 5ghz cleanair alarm air-quality threshold threshold_value</td>
<td>Configures the alarm for the threshold value for air-quality for all the 5-GHz devices. Add the No form of the command to disable the alarm.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)#ap dot11 5ghz cleanair alarm air-quality threshold 50</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose
Command or Action | Purpose
--- | ---
Step 3 | `ap dot11 5ghz cleanair alarm device {canopy | cont-tx | dect-like | inv | jammer | nonstd | radar | report | superag | tdd-tx | video | wimax-fixed | wimax-mobile}`

Configures the alarm for the 5-GHz devices. Add the `no` form of the command to disable the alarm.
- **canopy** — Canopy devices.
- **cont-tx** — Continuous Transmitter.
- **dect-like** — Digital Enhanced Cordless Communication (DECT) like phone.
- **fh** — 802.11 frequency hopping devices.
- **inv** — Devices using spectrally inverted WiFi signals.
- **jammer** — Jammer.
- **nonstd** — Devices using non-standard WiFi channels.
- **radar** — Radars.
- **report** — Interference device reporting.
- **superag** — 802.11 SuperAG devices.
- **tdd-tx** — TDD Transmitter.
- **video** — Video cameras.
- **wimax-fixed** — WiMax Fixed.
- **wimax-mobile** — WiMax Mobile.

Example:
```
Switch(config)#ap dot11 5ghz cleanair alarm device
```

Step 4 | `end`

Returns to privileged EXEC mode. Alternatively, you can also press `Ctrl-Z` to exit global configuration mode.

Example:
```
Switch(config)#end
```

Configuring Cisco CleanAir using the Controller GUI

Configuring Cisco CleanAir on the Cisco Wireless LAN Controller (GUI)

**Step 1** Choose **Configuration > Wireless > 802.11a/n or 802.11b/g/n > CleanAir** to open the **802.11a (or 802.11b) > CleanAir** page.

**Step 2** Select the **CleanAir** check box to enable Cisco CleanAir functionality on the 802.11a/n or 802.11b/g/n network, or unselect it to prevent the switch from detecting spectrum interference. By default, the Cisco CleanAir is disabled.

**Step 3** Select the **Report Interferers** check box to enable the Cisco CleanAir system to report any detected sources of interference, or unselect it to prevent the switch from reporting interferers. The default value is selected.

**Note** Device Security alarms, Event Driven RRM, and the Persistence Device Avoidance algorithm do not work if Report Interferers are disabled.

**Step 4** Select the **Persistent Device Propagation** check box to enable propagation of information about persistent devices that can be detected by CleanAir. Persistent device propagation enables you to propagate information about persistent devices to the neighboring access points connected to the same switch. Persistent interferers are present at the location and interfere with the WLAN operations even if they are not detectable at all times.

**Step 5** Ensure that any sources of interference that need to be detected and reported by the Cisco CleanAir system appear in the Interferences to Detect box and any that do not need to be detected appear in the Interferences to Ignore box. Use the > and < buttons to move interference sources between these two boxes. By default, all interference sources are detected. The sources of interference that you can choose depend on the type of radio, 802.11a/n/ac or 802.11b/g/n, and are as follows:

- **802.11 FH**—A 802.11 FH device
• **802.15.4**—A 802.15.4 or ZigBee device
• **Continuous Transmitter**—A continuous transmitter
• **Bluetooth Discovery**—A Bluetooth device
• **DECT-like Phone**—A digital enhanced cordless communication (DECT)-compatible phone
• **Microsoft**—A Microsoft device
• **SuperAG**—A 802.11a/g SuperAG device
• **Microwave Phone**—A microwave phone
• **Jammer**—A jamming device
• **Canopy**—A canopy bridge device
• **TDD Transmitter**—A time division duplex (TDD) transmitter device
• **Video Camera**—An analog video camera
• **WiFi Invalid Channel**—A WiFi invalid channel
• **WiFi Inverted**—A device using spectrally inverted Wi-Fi signals (I and Q signals of the RF signal are inverted)
• **WiMAX Fixed**—A WiMAX fixed device (802.11a/n only)
• **WiMAX Mobile**—A WiMAX mobile device (802.11a/n only)

**Note**
Access points that are associated to the switch send interference reports only for the interferers that appear in the Interferences to Detect box. This functionality allows you to filter out interferers that you do not want as well as any that may be flooding the network and causing performance problems for the switch or Prime Infrastructure. Filtering allows the system to resume normal performance levels.

**Step 6**
Configure Cisco CleanAir alarms as follows:

a) Select the **Enable AQI (Air Quality Index) Trap** check box to enable the triggering of air quality alarms, or unselect the box to disable this feature. The default value is selected.

b) If you selected the **Enable AQI Trap** check box in Step a, enter a value between 1 and 100 (inclusive) in the AQI Alarm Threshold text box to specify the threshold at which you want the air quality alarm to be triggered. When the air quality falls below the threshold level, the alarm is triggered. A value of 1 represents the worst air quality, and 100 represents the best. The default value is 35.

c) Enter the AQI threshold in the **AQI Alarm Threshold** text box. An alarm is generated when the air quality reaches a threshold value. The default is 35. The range is from 1 and 100.

d) Select the **Enable Interference For Security Alarm** check box to trigger interferer alarms when the switch detects specified device types, or unselect it to disable this feature. The default value is selected.

e) Make sure that any sources of interference that need to trigger interferer alarms appear in the **Trap on These Types** box and any that do not need to trigger interferer alarms appear in the **Do Not Trap on These Types** box. Use the > and < buttons to move interference sources between these two boxes. By default, all interference sources trigger interferer alarms.

For example, if you want the switch to send an alarm when it detects a jamming device, select the **Enable Interference For Security Alarm** check box and move the jamming device to the **Trap on These Types** box.

**Step 7**
Click **Apply**.

**Step 8**
Trigger spectrum event-driven radio resource management (RRM) to run when a Cisco CleanAir-enabled access point detects a significant level of interference as follows:

a) Look at the **EDRRM** field to see the current status of spectrum event-driven RRM and, if enabled, the Sensitivity Threshold field to see the threshold level at which event-driven RRM is invoked.

b) If you want to change the current status of event-driven RRM or the sensitivity level, go to the **802.11a (or 802.11b) > RRM > Dynamic Channel Assignment (DCA)** page.

c) Select the **EDRRM** check box to trigger RRM to run when an access point detects a certain level of interference, or unselect it to disable this feature. The default value is selected.
d) If you selected the **EDRRM** check box in *Step c*, choose **Low**, **Medium**, **High**, or **Custom** from the Sensitivity Threshold drop-down list to specify the threshold at which you want RRM to be triggered. When the interference for the access point rises above the threshold level, RRM initiates a local dynamic channel assignment (DCA) run and changes the channel of the affected access point radio if possible to improve network performance. EDRRM prevents the access point from returning to the original channel for three hours after the event.

High—Represents an increased sensitivity to changes in the environment.

Custom—Allows you to set a threshold value in the Custom Sensitivity Threshold field. The default sensitivity is 35.

Low—Represents a decreased sensitivity to changes in the environment.

The EDRRM AQ threshold value for low sensitivity is 35, medium sensitivity is 50, and high sensitivity is 60.

e) Click **Apply**.

**Step 9**  
Click **Save Configuration**.

---

## Configuring Cisco CleanAir on an Access Point (GUI)

**Step 1**  
Choose **Configuration > Wireless > Access Points > Radios > 802.11a/n or 802.11b/g/n** to open the 802.11a/n (or 802.11b/g/n) Radios page.

**Step 2**  
Select the check box adjacent to the desired access point and click **Configure**. The 802.11a/n (or 802.11b/g/n) Radios page appears.

The **CleanAir Capable** field shows whether this access point can support CleanAir functionality. If it can, go to the next step to enable or disable CleanAir for this access point. If the access point cannot support CleanAir functionality, you cannot enable CleanAir for this access point.

**Note**  
By default, the Cisco CleanAir functionality is enabled on the radios.

**Step 3**  
Enable Cisco CleanAir functionality for this access point by choosing **Enable** from the CleanAir Admin Status drop-down list. To disable CleanAir functionality for this access point, choose **Disable**. The default value is Enable. This setting overrides the global CleanAir configuration for this access point.

**Step 4**  
Click **Apply**.

**Step 5**  
Click **Save Configuration**.

---

## Configuring Cisco Spectrum Expert

### Configuring Spectrum Expert (GUI)

**Before you begin**

- Spectrum Expert (Windows XP laptop client) and access point should be pingable, otherwise; it will not work.
Prior to establishing a connection between the Spectrum Expert console and the access point, make sure that IP address routing is properly configured and the network spectrum interface (NSI) ports are open in any intervening firewalls.

The access point must be a TCP server listening on ports 37540 for 2.4 GHz and 37550 for 5 GHz frequencies. These ports must be opened for the spectrum expert application to connect to the access point using the NSI protocol.

You can view the NSI key from the switch CLI by using the `show ap name ap_name config dot11 {24ghz | 5ghz}` command.

---

**Step 1**
Ensure that Cisco CleanAir functionality is enabled for the access point that will be connected to the Spectrum Expert console.

*Note* The SE-Connect mode is set for the entire access point, not just a single radio. However, the Spectrum Expert console connects to a single radio at a time.

**Step 2**
Choose Configuration > Wireless > Access Points > All APs to open the All APs page.

**Step 3**
Click the name of the desired access point to open the All APs > Details page.

**Step 4**
Choose SE-Connect from the AP Mode drop-down list. This mode is available only for access points that are capable of supporting Cisco CleanAir functionality. For the SE-Connect mode to appear as an available option, the access point must have at least one spectrum-capable radio in the Enable state.

**Step 5**
Click Apply to commit your changes.

**Step 6**
Click OK when prompted to reboot the access point.

**Step 7**
On the Windows PC, access the Cisco Software Center from this URL:

**Step 8**
Click Product > Wireless > Cisco Spectrum Intelligence > Cisco Spectrum Expert > Cisco Spectrum Expert Wi-Fi, and then download the Spectrum Expert 4.1.11 executable (*.exe) file.

**Step 9**
Run the Spectrum Expert application on the PC.

**Step 10**
When the Connect to Sensor dialog box appears, enter the IP address of the access point, choose the access point radio, and enter the 16-byte network spectrum interface (NSI) key to authenticate. The Spectrum Expert application opens a TCP/IP connection directly to the access point using the NSI protocol.

When an access point in SE-Connect mode joins a switch, it sends a Spectrum Capabilities notification message, and the switch responds with a Spectrum Configuration Request. The request contains the 16-byte random NSI key generated by the switch for NSI authentication. The switch generates one key per access point, which the access point stores until it is rebooted.

*Note* You can establish up to three Spectrum Expert console connections per access point radio.

**Step 11**
Verify that the Spectrum Expert console is connected to the access point by selecting the Slave Remote Sensor text box in the bottom right corner of the Spectrum Expert application. If the two devices are connected, the IP address of the access point appears in this text box.

**Step 12**
Use the Spectrum Expert application to view and analyze spectrum data from the access point.
Configuring Spectrum Expert (CLI)

Before you begin

- Spectrum Expert (Windows XP laptop client) and access point should be pingable, otherwise; it will not work.
- Prior to establishing a connection between the Spectrum Expert console and the access point, make sure that IP address routing is properly configured and the network spectrum interface (NSI) ports are open in any intervening firewalls.
- The access point must be a TCP server listening on ports 37540 for 2.4-GHz and 37550 for 5-GHz frequencies. These ports must be opened for the spectrum expert application to connect to the access point using the NSI protocol.
- You can view the NSI key from the switch CLI by using the `show ap name ap_name config dot11 {24ghz | 5ghz}` command.

Step 1
To configure the access point for SE-Connect mode, enter this command:

```
ap name ap_name mode se-connect
```

Example:

```
Switch#ap name Cisco_AP3500 mode se-connect
```

Step 2
When prompted to reboot the access point, enter Y.

Step 3
To view the NSI key for the access point, enter this command:

```
show ap name ap_name config dot11 {24ghz | 5ghz}
```

Example:

```
Switch#show ap name Cisco_AP3500 config dot11 24ghz
```

What to do next

On the Windows PC, download Cisco Spectrum Expert:

- Access the Cisco Software Center from this URL: [http://www.cisco.com/cisco/software/navigator.html](http://www.cisco.com/cisco/software/navigator.html)
- Click **Product > Wireless > Cisco Spectrum Intelligence > Cisco Spectrum Expert > Cisco Spectrum Expert Wi-Fi**, and then download the Spectrum Expert 4.1.11 executable (*.exe) file.
- Run the Spectrum Expert application on the PC.
When the Connect to Sensor dialog box appears, enter the IP address of the access point, choose the access point radio, and enter the 16-byte network spectrum interface (NSI) key to authenticate. The Spectrum Expert application opens a TCP/IP connection directly to the access point using the NSI protocol.

When an access point in SE-Connect mode joins a switch, it sends a Spectrum Capabilities notification message, and the switch responds with a Spectrum Configuration Request. The request contains the 16-byte random NSI key generated by the switch for use in NSI authentication. The switch generates one key per access point, which the access point stores until it is rebooted.

Note: You can establish up to three Spectrum Expert console connections per access point radio.

Verify that the Spectrum Expert console is connected to the access point by selecting the Slave Remote Sensor text box in the bottom right corner of the Spectrum Expert application. If the two devices are connected, the IP address of the access point appears in this text box.

Use the Spectrum Expert application to view and analyze spectrum data from the access point.

## Monitoring CleanAir Parameters

You can monitor CleanAir parameters using the following commands:

### Table 10: Commands for Monitoring CleanAir

<table>
<thead>
<tr>
<th>Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ap dot11 24ghz cleanair-air-quality summary</code></td>
<td>Displays CleanAir Air Quality (AQ) data for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-air-quality worst</code></td>
<td>Displays CleanAir Air Quality (AQ) worst data for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-config</code></td>
<td>Displays CleanAir Configuration for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-device-type all</code></td>
<td>Displays all CleanAir Interferers for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-device-type bt-discovery</code></td>
<td>Displays CleanAir Interferers of type BT Discovery for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-device-type bt-link</code></td>
<td>Displays CleanAir Interferers of type BT Link for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-device-type canopy</code></td>
<td>Displays CleanAir Interferers of type Canopy for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-device-type cont-tx</code></td>
<td>Displays CleanAir Interferers of type Continuous transmitter for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz cleanair-device-type dect-like</code></td>
<td>Displays CleanAir Interferers of type DECT Like for 2.4-GHz band</td>

<tr>
<td><code>show ap dot11 24ghz clean device type fh</code></td>
<td>Displays CleanAir Interferers of type 802.11FH for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type inv</code></td>
<td>Displays CleanAir Interferers of type WiFi Inverted for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type jammer</code></td>
<td>Displays CleanAir Interferers of type Jammer for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type mw-oven</code></td>
<td>Displays CleanAir Interferers of type MW Oven for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type nonstd persistent</code></td>
<td>Displays CleanAir Interferers of type WiFi Inv. Ch for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type superag</code></td>
<td>Displays CleanAir Interferers of type SuperAG for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type tdd-tx</code></td>
<td>Displays CleanAir Interferers of type TDD Transmit for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type video</code></td>
<td>Displays CleanAir Interferers of type Video Camera for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type wimax-fixed</code></td>
<td>Displays CleanAir Interferers of type WiMax Fixed for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type wimax-mobile</code></td>
<td>Displays CleanAir Interferers of type WiMax Mobile for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type xbox</code></td>
<td>Displays CleanAir Interferers of type Xbox for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 24ghz clean device type zigbee</code></td>
<td>Displays CleanAir Interferers of type zigbee for 2.4-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 5ghz clean air-quality summary</code></td>
<td>Displays CleanAir Air Quality (AQ) data for 5-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 5ghz clean air-quality worst</code></td>
<td>Displays CleanAir Air Quality (AQ) worst data for 5-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 5ghz clean config</code></td>
<td>Displays CleanAir Configuration for 5-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 5ghz clean device type all</code></td>
<td>Displays all CleanAir Interferers for 5-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 5ghz clean device type canopy</code></td>
<td>Displays CleanAir Interferers of type Canopy for 5-GHz band</td>
</tr>
<tr>
<td><code>show ap dot11 5ghz clean device type cont-tx</code></td>
<td>Displays CleanAir Interferers of type Continuous TX for 5-GHz band</td>
</tr>
<tr>
<td>Commands</td>
<td>Description</td>

<td>Displays CleanAir Interferers of type Video Camera for 5-GHz band</td>
</tr>
<tr>
<td>show ap dot11 5ghz cleanair device type wimax-fixed</td>
<td>Displays CleanAir Interferers of type WiMax Fixed for 5-GHz band</td>
</tr>
<tr>
<td>show ap dot11 5ghz cleanair device type wimax-mobile</td>
<td>Displays CleanAir Interferers of type WiMax Mobile for 5-GHz band</td>
</tr>
</tbody>
</table>

You can also check the CleanAir status of the access points using the switch GUI:

Choose **Monitor > Wireless > Access Points > 802.11 a/n/ac or 802.11 b/g/n**.

The **Radios** page is displayed showing a list of access points that are associated with the switch. You can see the CleanAir Admin and CleanAir Status.

The Cisco CleanAir status is one of the following:

- **UP**—The spectrum sensor for the access point radio is currently operational (error code 0).
- **DOWN**—The spectrum sensor for the access point radio is currently not operational because an error has occurred. The most likely reason for the error is that the access point radio is disabled (error code 8). To correct this error, enable the radio.
- **ERROR**—The spectrum sensor for the access point radio has crashed (error code 128), making CleanAir monitoring nonoperational for this radio. If this error occurs, reboot the access point. If the error continues to appear, you might want to disable Cisco CleanAir functionality on the radio.
- **N/A**—This access point radio is not capable of supporting Cisco CleanAir functionality.
Monitoring the Interference Devices

When a CleanAir-enabled access point detects interference devices, detections of the same device from multiple sensors are merged together to create clusters. Each cluster is given a unique ID. Some devices conserve power by limiting the transmit time until actually needed which results in the spectrum sensor to temporarily stop detecting the device. This device is then correctly marked as down. A down device is correctly removed from the spectrum database. In cases when all the interferer detections for a specific devices are reported, the cluster ID is kept alive for an extended period of time to prevent possible device detection bouncing. If the same device is detected again, it is merged with the original cluster ID and the device detection history is preserved.

For example, some Bluetooth headsets operate on battery power. These devices employ methods to reduce power consumption, such as turning off the transmitter when not actually needed. Such devices can appear to come and go from the classification. To manage these devices, CleanAir keeps the cluster IDs longer and they are remerged into a single record upon detection. This process smoothens the user records and accurately represents the device history.

Monitoring the Interference Devices (GUI)

Before you begin

You can configure Cisco CleanAir only on CleanAir-enabled access points.

Step 1

Choose Monitor > Interferers > Cisco CleanAir > 802.11a/n or 802.11b/g/n > Interference Devices to open the Cisco APs > Interference Devices page.

This page shows the following information:

- **AP Name**—The name of the access point where the interference device is detected.
- **Interferer Type**—Type of the interferer.
- **Affected Channel**—Channel that the device affects.
- **Severity**—Severity index of the interfering device.
- **Duty Cycle (%)**—Proportion of time during which the interfering device was active.
- **RSSI**—Receive signal strength indicator (RSSI) of the access point.
- **DevID**—Device identification number that uniquely identified the interfering device.
- **ClusterID**—Cluster identification number that uniquely identifies the type of the devices.

Step 2

Click the **Filter** icon or choose the **Quick Filter** option from the Show drop-down list to display the information about interference devices based on a particular criteria.

- Configuring Interference Reporting for 5-GHz devices, on page 65
Monitoring the Worst Air Quality of Radio Bands (GUI)

Choose Monitor > Cisco CleanAir > Worst Air-Quality to open the Air Quality Report page.

This page shows the air quality of both the 802.11a/n and 802.11b/g/n radio bands. This page displays the following information:

- **AP Name**—Name of the access point that reported the worst air quality for the 802.11 radio band.
- **Channel Number**—Radio channel with the worst reported air quality.
- **Minimum Air Quality Index**—Minimum air quality for this radio channel. The range is from 1 to 100. An air quality index (AQI) value of 100 is the best, and 1 is the worst.
- **Average Air Quality Index**—Average air quality for this radio channel. The range is from 1 to 100. An air quality index (AQI) value of 100 is the best, and 1 is the worst.
- **Interference Device Count**—Number of interferers detected by the radios on the 802.11 radio band.

**Configuration Examples for Configuring CleanAir**

**Enabling CleanAir on 2.4-GHz Band and an Access Point: Example**

This example shows how to enable CleanAir on the 2.4-GHz band and an access point operating in the channel:

```
Switch# configure terminal
Switch(config)# ap dot11 24ghz cleanair
Switch(config)# exit
Switch# ap name TAP1 dot11 24ghz cleanair
Switch# end
```

**Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices: Example**

This example shows how to configure a CleanAir Alarm for 2.4-GHz Air-Quality threshold of 50 dBm and an Xbox device:

```
Switch# configure terminal
Switch(config)# ap dot11 24ghz cleanair alarm air-quality threshold 50
Switch(config)# ap dot11 24ghz cleanair alarm device xbox
Switch(config)# end
```

**Configuring Interference Reporting for 5-GHz Devices: Example**

This example shows how to configure interference reporting for 5-GHz devices:

```
Switch# configure terminal
Switch(config)# ap dot11 5ghz cleanair alarm device xbox
Switch(config)# end
```
Configuring EDRRM for CleanAir-Events: Example

This example shows how to enable an EDRRM clean-air-event in the 2.4-GHz band and configure high sensitivity to non Wi-Fi interference:

Switch# configure terminal
Switch(config)# ap dot11 24ghz rrm channel cleanair-event
Switch(config)# ap dot11 24ghz rrm channel cleanair-event sensitivity high
Switch(config)# end

Configuring Persistent Device Avoidance: Example

This example shows how to enable persistent non Wi-Fi device avoidance in the 2.4-GHz band:

Switch# configure terminal
Switch(config)# ap dot11 24ghz rrm channel device
Switch(config)# end

Configuring an Access Point for SE-Connect Mode: Example

This example shows how to configure an access point in the SE-Connect mode:

Switch# ap name Cisco_AP3500 mode se-connect

CleanAir FAQs

Q. How do I check if my MC is up?
A. To check if the MC is up, use the command: show wireless mobility summary.

This example shows how to display the mobility summary:

Switch# show wireless mobility summary

Mobility Controller Summary:
- Mobility Role: Mobility Controller
- Mobility Protocol Port: 16666
- Mobility Group Name: MG-AK
- Mobility Oracle: Disabled
- Mobility Oracle IP Address: 0.0.0.0
- DTLS Mode: Enabled
- Mobility Domain ID for 802.11r: 0x39b2
- Mobility Keepalive Interval: 10
- Mobility Keepalive Count: 3
- Mobility Control Message DSCP Value: 48
- Mobility Domain Member Count: 2
- Link Status is Control Link Status: Data Link Status

Controllers configured in the Mobility Domain:
- IP Public IP Group Name Multicast IP Link Status
  9.6.136.10 - MG-AK 0.0.0.0 UP : UP

Q. Multiple access points detect the same interference device, however, the switch shows them as separate clusters or different suspected devices clustered together. Why does this happen?
A. Access points must be RF neighbors for the switch to consider the merging of devices that are detected by these access points. The access point takes time to establish neighbor relationships. A few minutes...
after the switch reboots or a change in the RF group and similar events, clustering will not be very accurate.

Q. Can I merge two monitor mode access points using a switch?
A. No, you cannot merge two monitor mode access points using a switch. You can merge the monitor mode access points only using MSE.

Q. How do I view neighbor access points?
A. To view neighbor access points, use the command: `show ap ap_name auto-rf dot11 {24ghz | 5ghz}

This example shows how to display the neighbor access points:

```
Switch#show ap name AS-5508-5-AP3 auto-rf dot11 24ghz
Nearby APs
 AP 0C85.259E.C350 slot 0 : -12 dBm on 1 (10.10.0.5)
 AP 0C85.25AB.CCA0 slot 0 : -24 dBm on 6 (10.10.0.5)
 AP 0C85.25C7.B7A0 slot 0 : -26 dBm on 11 (10.10.0.5)
 AP 0C85.25DE.2C10 slot 0 : -24 dBm on 6 (10.10.0.5)
 AP 0C85.25DE.C8E0 slot 0 : -14 dBm on 11 (10.10.0.5)
 AP 0C85.25DF.3280 slot 0 : -31 dBm on 6 (10.10.0.5)
 AP 0CD9.96BA.5600 slot 0 : -44 dBm on 6 (10.0.0.2)
 AP 24B6.5734.C570 slot 0 : -48 dBm on 11 (10.0.0.2)
```

Q. What are the debug commands available for CleanAir?
A. The debug commands for CleanAir are:

```
dump cleanair { all | error | event | internal-event | nmsp | packet }

dump rrm { all | channel | detail | error | group | ha | manager | message | packet |
| power | prealarm | profile | radar | rf-change | scale | spectrum }
```

Q. Why are CleanAir Alarms not generated for interferer devices?
A. Verify that the access points are CleanAir-capable and CleanAir is enabled both on the access point and the switch.

Q. Can the Cisco Catalyst 3850 and 3650 Series Switches function as a Mobility Agent (MA)?
A. Yes, the Cisco Catalyst 3850 and 3650 Series Switches can function as an MA.

Q. Are CleanAir configurations available on the MA?
A. From Release 3.3 SE, CleanAir configurations are available on the MA. You can use the following two CleanAir commands on the MA:

```
• show ap dot11 5ghz cleanair config
• show ap dot11 24ghz cleanair config
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Interface Characteristics

Interface Types

This section describes the different types of interfaces supported by the switch. The rest of the chapter describes configuration procedures for physical interface characteristics.

Note

The stack ports on the rear of the stacking-capable switches are not Ethernet ports and cannot be configured.

Port-Based VLANs

A VLAN is a switched network that is logically segmented by function, team, or application, without regard to the physical location of the users. Packets received on a port are forwarded only to ports that belong to the
same VLAN as the receiving port. Network devices in different VLANs cannot communicate with one another without a Layer 3 device to route traffic between the VLANs.

VLAN partitions provide hard firewalls for traffic in the VLAN, and each VLAN has its own MAC address table. A VLAN comes into existence when a local port is configured to be associated with the VLAN, when the VLAN Trunking Protocol (VTP) learns of its existence from a neighbor on a trunk, or when a user creates a VLAN. VLANs can be formed with ports across the stack.

To configure VLANs, use the `vlan vlan-id` global configuration command to enter VLAN configuration mode. The VLAN configurations for normal-range VLANs (VLAN IDs 1 to 1005) are saved in the VLAN database. If VTP is version 1 or 2, to configure extended-range VLANs (VLAN IDs 1006 to 4094), you must first set VTP mode to transparent. Extended-range VLANs created in transparent mode are not added to the VLAN database but are saved in the switch running configuration. With VTP version 3, you can create extended-range VLANs in client or server mode. These VLANs are saved in the VLAN database.

In a switch stack, the VLAN database is downloaded to all switches in a stack, and all switches in the stack build the same VLAN database. The running configuration and the saved configuration are the same for all switches in a stack.

Add ports to a VLAN by using the `switchport` interface configuration commands:

- Identify the interface.
- For a trunk port, set trunk characteristics, and, if desired, define the VLANs to which it can belong.
- For an access port, set and define the VLAN to which it belongs.

**Switch Ports**

Switch ports are Layer 2-only interfaces associated with a physical port. Switch ports belong to one or more VLANs. A switch port can be an access port or a trunk port. You can configure a port as an access port or trunk port or let the Dynamic Trunking Protocol (DTP) operate on a per-port basis to set the switchport mode by negotiating with the port on the other end of the link. Switch ports are used for managing the physical interface and associated Layer 2 protocols and do not handle routing or bridging.

Configure switch ports by using the `switchport` interface configuration commands.

**Access Ports**

An access port belongs to and carries the traffic of only one VLAN (unless it is configured as a voice VLAN port). Traffic is received and sent in native formats with no VLAN tagging. Traffic arriving on an access port is assumed to belong to the VLAN assigned to the port. If an access port receives a tagged packet (Inter-Switch Link [ISL] or IEEE 802.1Q tagged), the packet is dropped, and the source address is not learned.

The types of access ports supported are:

- Static access ports are manually assigned to a VLAN (or through a RADIUS server for use with IEEE 802.1x).

You can also configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.

**Trunk Ports**

A trunk port carries the traffic of multiple VLANs and by default is a member of all VLANs in the VLAN database.
Although by default, a trunk port is a member of every VLAN known to the VTP, you can limit VLAN membership by configuring an allowed list of VLANs for each trunk port. The list of allowed VLANs does not affect any other port but the associated trunk port. By default, all possible VLANs (VLAN ID 1 to 4094) are in the allowed list. A trunk port can become a member of a VLAN only if VTP knows of the VLAN and if the VLAN is in the enabled state. If VTP learns of a new, enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of that VLAN and traffic is forwarded to and from the trunk port for that VLAN. If VTP learns of a new, enabled VLAN that is not in the allowed list for a trunk port, the port does not become a member of the VLAN, and no traffic for the VLAN is forwarded to or from the port.

### Tunnel Ports

Tunnel ports are used in IEEE 802.1Q tunneling to segregate the traffic of customers in a service-provider network from other customers who are using the same VLAN number. You configure an asymmetric link from a tunnel port on a service-provider edge switch to an IEEE 802.1Q trunk port on the customer switch. Packets entering the tunnel port on the edge switch, already IEEE 802.1Q-tagged with the customer VLANs, are encapsulated with another layer of an IEEE 802.1Q tag (called the metro tag), containing a VLAN ID unique in the service-provider network, for each customer. The double-tagged packets go through the service-provider network keeping the original customer VLANs separate from those of other customers. At the outbound interface, also a tunnel port, the metro tag is removed, and the original VLAN numbers from the customer network are retrieved.

Tunnel ports cannot be trunk ports or access ports and must belong to a VLAN unique to each customer.

### Routed Ports

A routed port is a physical port that acts like a port on a router; it does not have to be connected to a router. A routed port is not associated with a particular VLAN, as is an access port. A routed port behaves like a regular router interface, except that it does not support VLAN subinterfaces. Routed ports can be configured with a Layer 3 routing protocol. A routed port is a Layer 3 interface only and does not support Layer 2 protocols, such as DTP and STP.

Configure routed ports by putting the interface into Layer 3 mode with the no switchport interface configuration command. Then assign an IP address to the port, enable routing, and assign routing protocol characteristics by using the ip routing and router protocol global configuration commands.

**Note**

Entering a no switchport interface configuration command shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost.

The number of routed ports that you can configure is not limited by software. However, the interrelationship between this number and the number of other features being configured might impact CPU performance because of hardware limitations.

**Note**

The IP base feature set supports static routing and the Routing Information Protocol (RIP). For full Layer 3 routing or for fallback bridging, you must enable the IP services feature set on the standalone switch, or the active switch.
Switch Virtual Interfaces

A switch virtual interface (SVI) represents a VLAN of switch ports as one interface to the routing or bridging function in the system. You can associate only one SVI with a VLAN. You configure an SVI for a VLAN only to route between VLANs or to provide IP host connectivity to the switch. By default, an SVI is created for the default VLAN (VLAN 1) to permit remote switch administration. Additional SVIs must be explicitly configured.

**Note**

You cannot delete interface VLAN 1.

SVIs provide IP host connectivity only to the system.

Although the switch stack or switch supports a total of 1005 VLANs and SVIs, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might impact CPU performance because of hardware limitations.

SVIs are created the first time that you enter the `vlan` interface configuration command for a VLAN interface. The VLAN corresponds to the VLAN tag associated with data frames on an ISL or IEEE 802.1Q encapsulated trunk or the VLAN ID configured for an access port. Configure a VLAN interface for each VLAN for which you want to route traffic, and assign it an IP address.

**Note**

When you create an SVI, it does not become active until it is associated with a physical port.

**SVI Autostate Exclude**

The line state of an SVI with multiple ports on a VLAN is in the up state when it meets these conditions:

- The VLAN exists and is active in the VLAN database on the switch
- The VLAN interface exists and is not administratively down.
- At least one Layer 2 (access or trunk) port exists, has a link in the up state on this VLAN, and is in the spanning-tree forwarding state on the VLAN.

**Note**

The protocol link state for VLAN interfaces come up when the first switchport belonging to the corresponding VLAN link comes up and is in STP forwarding state.

The default action, when a VLAN has multiple ports, is that the SVI goes down when all ports in the VLAN go down. You can use the SVI autostate exclude feature to configure a port so that it is not included in the SVI line-state up-or-down calculation. For example, if the only active port on the VLAN is a monitoring port, you might configure autostate exclude on that port so that the VLAN goes down when all other ports go down. When enabled on a port, autostate exclude applies to all VLANs that are enabled on that port.

The VLAN interface is brought up when one Layer 2 port in the VLAN has had time to converge (transition from STP listening-learning state to forwarding state). This prevents features such as routing protocols from using the VLAN interface as if it were fully operational and minimizes other problems, such as routing black holes.
EtherChannel Port Groups

EtherChannel port groups treat multiple switch ports as one switch port. These port groups act as a single logical port for high-bandwidth connections between switches or between switches and servers. An EtherChannel balances the traffic load across the links in the channel. If a link within the EtherChannel fails, traffic previously carried over the failed link changes to the remaining links. You can group multiple trunk ports into one logical trunk port, group multiple access ports into one logical access port, group multiple tunnel ports into one logical tunnel port, or group multiple routed ports into one logical routed port. Most protocols operate over either single ports or aggregated switch ports and do not recognize the physical ports within the port group. Exceptions are the DTP, the Cisco Discovery Protocol (CDP), and the Port Aggregation Protocol (PAgP), which operate only on physical ports.

When you configure an EtherChannel, you create a port-channel logical interface and assign an interface to the EtherChannel. For Layer 3 interfaces, you manually create the logical interface by using the `interface port-channel` global configuration command. Then you manually assign an interface to the EtherChannel by using the `channel-group` interface configuration command. For Layer 2 interfaces, use the `channel-group` interface configuration command to dynamically create the port-channel logical interface. This command binds the physical and logical ports together.

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the switch senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device
- an IEEE 802.3at-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

After the switch detects a powered device, the switch determines the device power requirements and then grants or denies power to the device. The switch can also sense the real-time power consumption of the device by monitoring and policing the power usage.

Using the Switch USB Ports

USB Mini-Type B Console Port

The switch has the following console ports available on its front panel:

- USB mini-Type B console connection
- RJ-45 console port

Console output appears on devices connected to both ports, but console input is active on only one port at a time. By default, the USB connector takes precedence over the RJ-45 connector.

Note

Windows PCs require a driver for the USB port. See the hardware installation guide for driver installation instructions.
Use the supplied USB Type A-to-USB mini-Type B cable to connect a PC or other device to the switch. The connected device must include a terminal emulation application. When the switch detects a valid USB connection to a powered-on device that supports host functionality (such as a PC), input from the RJ-45 console is immediately disabled, and input from the USB console is enabled. Removing the USB connection immediately reenables input from the RJ-45 console connection. An LED on the switch shows which console connection is in use.

**Console Port Change Logs**

At software startup, a log shows whether the USB or the RJ-45 console is active. Each switch in a stack issues this log. Every switch always first displays the RJ-45 media type.

In the sample output, switch 1 has a connected USB console cable. Because the bootloader did not change to the USB console, the first log from switch 1 shows the RJ-45 console. A short time later, the console changes and the USB console log appears. Switch 2 and switch 3 have connected RJ-45 console cables.

```
switch-stack-1
*Mar 1 00:01:00.171: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
*Mar 1 00:01:00.431: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.
```

```
switch-stack-2
*Mar 1 00:01:09.835: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

```
switch-stack-3
*Mar 1 00:01:10.523: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

When the USB cable is removed or the PC de-activates the USB connection, the hardware automatically changes to the RJ-45 console interface:

```
switch-stack-1
Mar 1 00:20:48.635: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

You can configure the console type to always be RJ-45, and you can configure an inactivity timeout for the USB connector.

**Interface Connections**

Devices within a single VLAN can communicate directly through any switch. Ports in different VLANs cannot exchange data without going through a routing device. With a standard Layer 2 switch, ports in different VLANs have to exchange information through a router. By using the switch with routing enabled, when you configure both VLAN 20 and VLAN 30 with an SVI to which an IP address is assigned, packets can be sent from Host A to Host B directly through the switch with no need for an external router.
Switches running the LAN base feature set support configuring only 16 static routes on SVIs.

## Default Ethernet Interface Configuration

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

This table shows the Ethernet interface default configuration, including some features that apply only to Layer 2 interfaces.

### Table 11: Default Layer 2 Ethernet Interface Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operating mode</td>
<td>Layer 2 or switching mode (<code>switchport</code> command).</td>

<tr>
<td>Allowed VLAN range</td>
<td>VLANs 1–4094.</td>
</tr>
<tr>
<td>Default VLAN (for access ports)</td>
<td>VLAN 1 (Layer 2 interfaces only).</td>
</tr>
<tr>
<td>Native VLAN (for IEEE 802.1Q trunks)</td>
<td>VLAN 1 (Layer 2 interfaces only).</td>
</tr>
<tr>
<td>VLAN trunking</td>
<td>Switchport mode dynamic auto (supports DTP) (Layer 2 interfaces only).</td>
</tr>
<tr>
<td>Port enable state</td>
<td>All ports are enabled.</td>
</tr>
<tr>
<td>Port description</td>
<td>None defined.</td>
</tr>
<tr>
<td>Speed</td>
<td>Autonegotiate. (Not supported on the 10-Gigabit interfaces.)</td>
</tr>
</tbody>
</table>
Interface Speed and Duplex Mode

Ethernet interfaces on the switch operate at 10, 100, 1000, or 10,000 Mb/s and in either full- or half-duplex mode. In full-duplex mode, two stations can send and receive traffic at the same time. Normally, 10-Mb/s ports operate in half-duplex mode, which means that stations can either receive or send traffic.

Switch models include Gigabit Ethernet (10/100/1000-Mb/s) ports, 10-Gigabit Ethernet ports, and small form-factor pluggable (SFP) module slots supporting SFP modules.

Speed and Duplex Configuration Guidelines

When configuring an interface speed and duplex mode, note these guidelines:

- The 10-Gigabit Ethernet ports do not support the speed and duplex features. These ports operate only at 10,000 Mb/s and in full-duplex mode.

- Gigabit Ethernet (10/100/1000-Mb/s) ports support all speed options and all duplex options (auto, half, and full). However, Gigabit Ethernet ports operating at 1000 Mb/s do not support half-duplex mode.

- For SFP module ports, the speed and duplex CLI options change depending on the SFP module type:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duplex mode</td>
<td>Autonegotiate. (Not supported on the 10-Gigabit interfaces.)</td>
</tr>
<tr>
<td>Flow control</td>
<td>Flow control is set to receive: off. It is always off for sent packets.</td>
</tr>
<tr>
<td>EtherChannel (PAgP)</td>
<td>Disabled on all Ethernet ports.</td>
</tr>
<tr>
<td>Port blocking (unknown multicast and unknown unicast traffic)</td>
<td>Disabled (not blocked) (Layer 2 interfaces only).</td>
</tr>
<tr>
<td>Broadcast, multicast, and unicast storm control</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Protected port</td>
<td>Disabled (Layer 2 interfaces only).</td>
</tr>
<tr>
<td>Port security</td>
<td>Disabled (Layer 2 interfaces only).</td>
</tr>
<tr>
<td>Port Fast</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Auto-MDIX</td>
<td>Enabled. Note: The switch might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the switch through a crossover cable. This is regardless of whether auto-MIDX is enabled on the switch port.</td>
</tr>
<tr>
<td>Power over Ethernet (PoE)</td>
<td>Enabled (auto).</td>
</tr>
</tbody>
</table>
• The 1000BASE-x (where x is -BX, -CWDM, -LX, -SX, and -ZX) SFP module ports support the nonegotiate keyword in the speed interface configuration command. Duplex options are not supported.

• The 1000BASE-T SFP module ports support the same speed and duplex options as the 10/100/1000-Mb/s ports.

For information about which SFP modules are supported on your switch, see the product release notes.

• If both ends of the line support autonegotiation, we highly recommend the default setting of auto negotiation.

• If one interface supports autonegotiation and the other end does not, configure duplex and speed on both interfaces; do not use the auto setting on the supported side.

• When STP is enabled and a port is reconfigured, the switch can take up to 30 seconds to check for loops. The port LED is amber while STP reconfigures.

Caution

Changing the interface speed and duplex mode configuration might shut down and re-enable the interface during the reconfiguration.

IEEE 802.3x Flow Control

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If one port experiences congestion and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note

Flow control is not supported on Catalyst 3850 and Catalyst 3650 Series Switches (CSCul33405).

Note

The switch ports can receive, but not send, pause frames.

You use the flowcontrol interface configuration command to set the interface’s ability to receive pause frames to on, off, or desired. The default state is off.

When set to desired, an interface can operate with an attached device that is required to send flow-control packets or with an attached device that is not required to but can send flow-control packets.

These rules apply to flow control settings on the device:

• receive on (or desired): The port cannot send pause frames but can operate with an attached device that is required to or can send pause frames; the port can receive pause frames.

• receive off: Flow control does not operate in either direction. In case of congestion, no indication is given to the link partner, and no pause frames are sent or received by either device.
Layer 3 Interfaces

The switch supports these types of Layer 3 interfaces:

- **SVIs**: You should configure SVIs for any VLANs for which you want to route traffic. SVIs are created when you enter a VLAN ID following the `interface vlan` global configuration command. To delete an SVI, use the `no interface vlan` global configuration command. You cannot delete interface VLAN 1.

  **Note** When you create an SVI, it does not become active until it is associated with a physical port.

When configuring SVIs, you can also configure SVI autostate exclude on a port in the SVI to exclude that port from being included in determining SVI line-state status.

- **Routed ports**: Routed ports are physical ports configured to be in Layer 3 mode by using the `no switchport` interface configuration command.

- **Layer 3 EtherChannel ports**: EtherChannel interfaces made up of routed ports.

A Layer 3 switch can have an IP address assigned to each routed port and SVI.

There is no defined limit to the number of SVIs and routed ports that can be configured in a switch or in a switch stack. However, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might have an impact on CPU usage because of hardware limitations. If the switch is using its maximum hardware resources, attempts to create a routed port or SVI have these results:

- If you try to create a new routed port, the switch generates a message that there are not enough resources to convert the interface to a routed port, and the interface remains as a switchport.

- If you try to create an extended-range VLAN, an error message is generated, and the extended-range VLAN is rejected.

- If the switch is notified by VLAN Trunking Protocol (VTP) of a new VLAN, it sends a message that there are not enough hardware resources available and shuts down the VLAN. The output of the `show vlan` user EXEC command shows the VLAN in a suspended state.

- If the switch attempts to boot up with a configuration that has more VLANs and routed ports than hardware can support, the VLANs are created, but the routed ports are shut down, and the switch sends a message that this was due to insufficient hardware resources.

All Layer 3 interfaces require an IP address to route traffic. This procedure shows how to configure an interface as a Layer 3 interface and how to assign an IP address to an interface.

**Note** If the physical port is in Layer 2 mode (the default), you must enter the `no switchport` interface configuration command to put the interface into Layer 3 mode. Entering a `no switchport` command disables and then re-enables the interface, which might generate messages on the device to which the interface is connected.

Furthermore, when you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.
How to Configure Interface Characteristics

Configuring Interfaces Procedure

These general instructions apply to all interface configuration processes.

</tbody>
</table>

**Configuring a Range of Interfaces**

To configure multiple interfaces with the same configuration parameters, use the **interface range** global configuration command. When you enter the interface-range configuration command, all command parameters that you enter are attributed to all interfaces within that range until you exit this mode.

**SUMMARY STEPS**

1. configure terminal
2. interface range {port-range | macro macro_name}
3. end
4. show interfaces [interface-id]
## DETAILED STEPS

<table>

### Configuring and Using Interface Range Macros

You can create an interface range macro to automatically select a range of interfaces for configuration. Before you can use the `macro` keyword in the `interface range macro` global configuration command string, you must use the `define interface-range` global configuration command to define the macro.
### SUMMARY STEPS

1. `configure terminal`
2. `define interface-range macro_name interface-range`
3. `interface range macro macro_name`
4. `end`
5. `show running-config | include define`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Defines the interface-range macro, and save it in NVRAM.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td>• The <code>macro_name</code> is a 32-character maximum character string.</td>
</tr>
<tr>
<td></td>
<td>• A macro can contain up to five comma-separated interface ranges.</td>
</tr>
<tr>
<td></td>
<td>• Each <code>interface-range</code> must consist of the same port type.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Before you can use the <code>macro</code> keyword in the <code>interface range macro</code> global configuration command string, you must use the <code>define interface-range</code> global configuration command to define the macro.</td>
</tr>
</tbody>
</table>

| **Step 2** | Selects the interface range to be configured using the values saved in the interface-range macro called `macro_name`. |
| `define interface-range macro_name interface-range` | You can now use the normal configuration commands to apply the configuration to all interfaces in the defined macro. |
| `Example:` | `Switch(config)# define interface-range enet_list gigabitethernet1/0/1 - 2` |

| **Step 3** | Returns to privileged EXEC mode. |
| `interface range macro macro_name` | `Switch(config)# interface range macro enet_list` |
| `Example:` | `Switch(config)# end` |

| **Step 4** | Shows the defined interface range macro configuration. |
| `show running-config | include define` | `Switch# show running-config | include define` |
Configuring Ethernet Interfaces

Setting the Interface Speed and Duplex Parameters

### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `speed {10 | 100 | 1000 | auto [10 | 100 | 1000] | nonegotiate}`
4. `duplex {auto | full | half}`
5. `end`
6. `show interfaces interface-id`
7. `copy running-config startup-config`

### DETAILED STEPS

```

**Example:**

Switch(config)# interface gigabitethernet1/0/1

**Purpose:**

Specifies the physical interface to be configured, and enter interface configuration mode.

**Step 3**

```
flowcontrol {receive} {on | off | desired}
```

**Example:**

Switch(config-if)# flowcontrol receive on

**Purpose:**

Configures the flow control mode for the port.

**Step 4**

```
end
```

**Example:**

Switch(config-if)# end

**Purpose:**

Returns to privileged EXEC mode.

**Step 5**

```
show interfaces interface-id
```

**Example:**

Switch# show interfaces gigabitethernet1/0/1

**Purpose:**

Verifies the interface flow control settings.

### Configuring Logical Layer 3 GRE Tunnel Interfaces

#### Before you begin

Generic Routing Encapsulation (GRE) is a tunneling protocol used to encapsulate network layer protocols inside virtual point-to-point links. A GRE tunnel only provides encapsulation and not encryption.

#### Attention

Beginning in Cisco IOS XE Release 3.7.2E, GRE tunnels are supported on the hardware on Cisco Catalyst switches. When GRE is configured without tunnel options, packets are hardware-switched. When GRE is configured with tunnel options (such as key, checksum, etc.), packets are switched in the software. A maximum of 10 GRE tunnels are supported.
Other features like Access Control Lists (ACL) and Quality of Service (QoS) are not supported for the GRE tunnels.

To configure a GRE tunnel, perform this task:

**SUMMARY STEPS**

1. `interface tunnel number`
2. `ip address ip_address subnet_mask`
3. `tunnel source {ip_address | type_number}`
4. `tunnel destination {host_name | ip_address}`
5. `tunnel mode gre ip`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables tunneling on the interface.</td>
</tr>
<tr>

</table>
Configuring SVI Autostate Exclude

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. switchport autostate exclude
4. end
5. show running config interface interface-id

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td>Specifies a Layer 2 interface (physical port or port channel), and enter interface configuration mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# interface gigabitethernet1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> switchport autostate exclude</td>
<td>Excludes the access or trunk port when defining the status of an SVI line state (up or down)</td>
</tr>
<tr>
<td>Example: Switch(config-if)# switchport autostate exclude</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Switch(config-if)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show running config interface interface-id</td>
<td>(Optional) Shows the running configuration.</td>
</tr>
<tr>
<td>Example: Verifies the configuration.</td>
<td></td>
</tr>
</tbody>
</table>

Shutting Down and Restarting the Interface

Shutting down an interface disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface is not mentioned in any routing updates.
### SUMMARY STEPS

1. `configure terminal`
2. `interface {vlan vlan-id} | {gigabitethernet interface-id} | {port-channel port-channel-number}`
3. `shutdown`
4. `no shutdown`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>`interface {vlan vlan-id}</td>
<td>{gigabitethernet interface-id}</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# <code>interface gigabitethernet1/0/2</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>shutdown</code></td>
<td>Shuts down an interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config-if)# <code>shutdown</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>no shutdown</code></td>
<td>Restarts an interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config-if)# <code>no shutdown</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config-if)# <code>end</code></td>
<td></td>
</tr>
</tbody>
</table>

### Configuring the Console Media Type

Beginning in privileged EXEC mode, follow these steps to set the console media type to RJ-45. If you configure the console as RJ-45, USB console operation is disabled, and input comes only through the RJ-45 connector.

This configuration applies to all switches in a stack.
SUMMARY STEPS

1. configure terminal
2. line console 0
3. media-type rj45
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 line console 0</td>
<td>Configures the console and enters line configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# line console 0</td>
<td></td>
</tr>
<tr>
<td>Step 3 media-type rj45</td>
<td>Configures the console media type to be only RJ-45 port. If you do not enter this command and both types are connected, the USB port is used by default.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config-line)# media-type rj45</td>
<td></td>
</tr>
<tr>
<td>Step 4 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Configuring the USB Inactivity Timeout

The configurable inactivity timeout reactivates the RJ-45 console port if the USB console port is activated but no input activity occurs on it for a specified time period. When the USB console port is deactivated due to a timeout, you can restore its operation by disconnecting and reconnecting the USB cable.

Note

The configured inactivity timeout applies to all switches in a stack. However, a timeout on one switch does not cause a timeout on other switches in the stack.

Beginning in privileged EXEC mode, follow these steps to configure an inactivity timeout.

SUMMARY STEPS

1. configure terminal
2. line console 0
3. usb-inactivity-timeout  timeout-minutes

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode. Example: Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>line console 0</td>
<td>Configures the console and enters line configuration mode. Example: Switch(config)# line console 0</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>usb-inactivity-timeout  timeout-minutes</td>
<td>Specify an inactivity timeout for the console port. The range is 1 to 240 minutes. The default is to have no timeout configured. Example: Switch(config-line)# usb-inactivity-timeout 30</td>
</tr>
</tbody>
</table>

**Monitoring Interface Characteristics**

**Monitoring Interface Status**

Commands entered at the privileged EXEC prompt display information about the interface, including the versions of the software and the hardware, the configuration, and statistics about the interfaces.

This table lists some of the available interface monitoring commands.

**Table 12: Show Commands for Interfaces**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show interfaces [interface-id]</td>
<td>Displays the status and configuration of all interfaces or a specific interface.</td>
</tr>
<tr>
<td>show interfaces interface-id status [err-disabled]</td>
<td>Displays interface status or a list of interfaces in the error-disabled state.</td>
</tr>
<tr>
<td>show interfaces [interface-id] switchport</td>
<td>Displays administrative and operational status of switching (nonrouting) ports. You can use this command to find out if a port is in routing or in switching mode.</td>
</tr>
<tr>
<td>show interfaces [interface-id] description</td>
<td>Displays the description configured on an interface or all interfaces and the interface status.</td>
</tr>
<tr>
<td>Command</td>
<td>Purpose</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>show ip interface [interface-id]</td>
<td>Displays the usability status of all interfaces configured for IP routing or the specified interface.</td>
</tr>
<tr>
<td>show interface [interface-id] stats</td>
<td>Displays the input and output packets by the switching path for the interface.</td>
</tr>
<tr>
<td>show interfaces interface-id</td>
<td>(Optional) Displays speed and duplex on the interface.</td>
</tr>
<tr>
<td>show interfaces transceiver dom-supported-list</td>
<td>(Optional) Displays Digital Optical Monitoring (DOM) status on the connect SFP modules.</td>
</tr>
<tr>
<td>show interfaces transceiver properties</td>
<td>(Optional) Displays temperature, voltage, or amount of current on the interface.</td>
</tr>
<tr>
<td>show interfaces [interface-id] [{transceiver properties</td>
<td>detail; }] module number</td>
</tr>
<tr>
<td>show running-config interface [interface-id]</td>
<td>Displays the running configuration in RAM for the interface.</td>
</tr>
<tr>
<td>show version</td>
<td>Displays the hardware configuration, software version, the names and sources of configuration files, and the boot images.</td>
</tr>
<tr>
<td>show controllers ethernet-controller interface-id phy</td>
<td>Displays the operational state of the auto-MDIX feature on the interface.</td>
</tr>
</tbody>
</table>

### Clearing and Resetting Interfaces and Counters

**Table 13: Clear Commands for Interfaces**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear counters [interface-id]</td>
<td>Clears interface counters.</td>
</tr>
<tr>
<td>clear interface interface-id</td>
<td>Resets the hardware logic on an interface.</td>
</tr>
<tr>
<td>clear line [number</td>
<td>console 0</td>
</tr>
</tbody>
</table>

**Note**

The **clear counters** privileged EXEC command does not clear counters retrieved by using Simple Network Management Protocol (SNMP), but only those seen with the **show interface** privileged EXEC command.
Configuration Examples for Interface Characteristics

Adding a Description to an Interface: Example

Switch# configure terminal
Enter configuration commands, one per line. End with CNTRL/Z.
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# description Connects to Marketing
Switch(config-if)# end
Switch# show interfaces gigabitethernet1/0/2 description
Interface Status Protocol Description
Gi1/0/2 admin down down Connects to Marketing

Configuring a Range of Interfaces: Examples

This example shows how to use the interface range global configuration command to set the speed to 100 Mb/s on ports 1 to 4 on switch 1:

Switch# configure terminal
Switch(config)# interface range gigabitethernet1/0/1 - 4
Switch(config-if-range)# speed 100

This example shows how to use a comma to add different interface type strings to the range to enable Gigabit Ethernet ports 1 to 3 and 10-Gigabit Ethernet ports 1 and 2 to receive flow-control pause frames:

Switch# configure terminal
Switch(config)# interface range gigabitethernet1/0/1 - 3 , tengigabitethernet1/0/1 - 2
Switch(config-if-range)# flowcontrol receive on

If you enter multiple configuration commands while you are in interface-range mode, each command is executed as it is entered. The commands are not batched and executed after you exit interface-range mode. If you exit interface-range configuration mode while the commands are being executed, some commands might not be executed on all interfaces in the range. Wait until the command prompt reappears before exiting interface-range configuration mode.

Configuring and Using Interface Range Macros: Examples

This example shows how to define an interface-range named enet_list to include ports 1 and 2 on switch 1 and to verify the macro configuration:

Switch# configure terminal
Switch(config)# define interface-range enet_list gigabitethernet1/0/1 - 2
Switch(config)# end
Switch# show running-config | include define
define interface-range enet_list GigabitEthernet1/0/1 - 2

This example shows how to create a multiple-interface macro named macro1:
Switch# configure terminal
Switch(config)# define interface-range macro1 gigabitethernet1/0/1 - 2, gigabitethernet1/0/5 - 7, tengigabitethernet1/0/1 -2
Switch(config)# end

This example shows how to enter interface-range configuration mode for the interface-range macro enet_list:

Switch# configure terminal
Switch(config)# interface range macro enet_list
Switch(config-if-range)#

This example shows how to delete the interface-range macro enet_list and to verify that it was deleted.

Switch# configure terminal
Switch(config)# no define interface-range enet_list
Switch(config)# end
Switch# show run | include define
Switch#

Setting Interface Speed and Duplex Mode: Example

This example shows how to set the interface speed to 100 Mb/s and the duplex mode to half on a 10/100/1000 Mb/s port:

Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/3
Switch(config-if)# speed 10
Switch(config-if)# duplex half

This example shows how to set the interface speed to 100 Mb/s on a 10/100/1000 Mb/s port:

Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# speed 100

Configuring Layer 3 Interfaces: Example

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# no switchport
Switch(config-if)# ip address 192.20.135.21 255.255.255.0
Switch(config-if)# no shutdown

Configuring the Console Media Type: Example

This example disables the USB console media type and enables the RJ-45 console media type.
This configuration terminates any active USB console media type in the stack. A log shows that this termination has occurred. This example shows that the console on switch 1 reverted to RJ-45.

*Mar 1 00:25:36.860: %USB_CONSOLE-6-CONFIG_DISABLE: Console media-type USB disabled by system configuration, media-type reverted to RJ45.

At this point no switches in the stack allow a USB console to have input. A log entry shows when a console cable is attached. If a USB console cable is connected to switch 2, it is prevented from providing input.

*Mar 1 00:34:27.498: %USB_CONSOLE-6-CONFIG_DISALLOW: Console media-type USB is disallowed by system configuration, media-type remains RJ45. (switch-stk-2)

This example reverses the previous configuration and immediately activates any USB console that is connected.

Switch# configure terminal
Switch(config)# line console 0
Switch(config-line)# no media-type rj45

**Configuring the USB Inactivity Timeout: Example**

This example configures the inactivity timeout to 30 minutes:

Switch# configure terminal
Switch(config)# line console 0
Switch(config-line)# usb-inactivity-timeout 30

To disable the configuration, use these commands:

Switch# configure terminal
Switch(config)# line console 0
Switch(config-line)# no usb-inactivity-timeout

If there is no (input) activity on a USB console port for the configured number of minutes, the inactivity timeout setting applies to the RJ-45 port, and a log shows this occurrence:

*Mar 1 00:47:25.625: %USB_CONSOLE-6-INACTIVITY_DISABLE: Console media-type USB disabled due to inactivity, media-type reverted to RJ45.

At this point, the only way to reactivate the USB console port is to disconnect and reconnect the cable. When the USB cable on the switch has been disconnected and reconnected, a log similar to this appears:

*Mar 1 00:48:28.640: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.

**Configuring Auto-MDIX**

- Prerequisites for Auto-MDIX, on page 111
- Restrictions for Auto-MDIX, on page 111
- Information about Configuring Auto-MDIX, on page 112
- How to Configure Auto-MDIX, on page 112
- Monitoring Auto-MDIX, on page 114
- Example for Configuring Auto-MDIX, on page 114
- Additional References, on page 114
- Feature History and Information for Auto-MDIX, on page 115

**Prerequisites for Auto-MDIX**

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

Automatic medium-dependent interface crossover (auto-MDI) is enabled by default.

Auto-MDIX is supported on all 10/100/1000-Mb/s and on 10/100/1000BASE-TX small form-factor pluggable (SFP)-module interfaces. It is not supported on 1000BASE-SX or -LX SFP module interfaces.

**Restrictions for Auto-MDIX**

The switch might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the switch through a crossover cable. This is regardless of whether auto-MDI is enabled on the switch port.
Information about Configuring Auto-MDIX

Auto-MDIX on an Interface

When automatic medium-dependent interface crossover (auto-MDIX) is enabled on an interface, the interface automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting switches without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other switches or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

This table shows the link states that result from auto-MDIX settings and correct and incorrect cabling.

CHAPTER 7

Configuring Ethernet Management Port

• Finding Feature Information, on page 117
• Prerequisites for Ethernet Management Ports, on page 117
• Information about the Ethernet Management Port, on page 117
• How to Configure the Ethernet Management Port, on page 120
• Additional References, on page 121
• Feature Information for Ethernet Management Ports, on page 122

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature
information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support.
To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not
required.

Prerequisites for Ethernet Management Ports

When connecting a PC to the Ethernet management port, you must first assign an IP address.

Information about the Ethernet Management Port

The Ethernet management port, also referred to as the Gi0/0 or GigabitEthernet0/0 port, is a VRF (VPN
routing/forwarding) interface to which you can connect a PC. You can use the Ethernet management port
instead of the switch console port for network management. When managing a switch stack, connect the PC
to the Ethernet management port on a stack member.
Ethernet Management Port Direct Connection to a Switch

This figure displays how to connect the Ethernet management port to the PC for a switch or a standalone switch.

Ethernet Management Port Connection to Stack Switches using a Hub

In a stack with only stack switches, all the Ethernet management ports on the stack members are connected to a hub to which the PC is connected. The active link is from the Ethernet management port on the active switch through the hub, to the PC. If the active switch fails and a new active switch is elected, the active link is now from the Ethernet management port on the new active switch to the PC.

Ethernet Management Port and Routing

By default, the Ethernet management port is enabled. The switch cannot route packets from the Ethernet management port to a network port, and the reverse. Even though the Ethernet management port does not support routing, you may need to enable routing protocols on the port.

In the following figure, you must enable routing protocols on the Ethernet management port when the PC is multiple hops away from the switch and the packets must pass through multiple Layer 3 devices to reach the PC.

In the above figure, if the Ethernet management port and the network ports are associated with the same routing process, the routes are propagated as follows:
• The routes from the Ethernet management port are propagated through the network ports to the network.
• The routes from the network ports are propagated through the Ethernet management port to the network.

Because routing is not supported between the Ethernet management port and the network ports, traffic between these ports cannot be sent or received. If this happens, data packet loops occur between the ports, which disrupt the switch and network operation. To prevent the loops, configure route filters to avoid routes between the Ethernet management port and the network ports.

**Supported Features on the Ethernet Management Port**

The Ethernet management port supports these features:

- Express Setup (only in switch stacks)
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SMNP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features
  - Speed—10 Mb/s, 100 Mb/s, and autonegotiation
  - Duplex mode—Full, half, and autonegotiation
  - Loopback detection
- Cisco Discovery Protocol (CDP)
- DHCP relay agent
- IPv4 and IPv6 access control lists (ACLs)
- Routing protocols

**Caution**

Before enabling a feature on the Ethernet management port, make sure that the feature is supported. If you try to configure an unsupported feature on the Ethernet Management port, the feature might not work properly, and the switch might fail.
How to Configure the Ethernet Management Port

Disabling and Enabling the Ethernet Management Port

To disable or enable the Ethernet management port in the CLI, follow this procedure.

**SUMMARY STEPS**

1. configure terminal
2. interface gigabitethernet0/0
3. shutdown
4. no shutdown
5. exit
6. show interfaces gigabitethernet0/0

**DETAILED STEPS**

<table>

<td></td>
</tr>
<tr>
<td>Switch# show interfaces gigabitethernet0/0</td>
<td>To find out the link status to the PC, you can monitor the LED for the Ethernet management port. The LED is green (on) when the link is active, and the LED is off when the link is down. The LED is amber when there is a POST failure.</td>
</tr>
</tbody>
</table>
What to do next
Proceed to manage or configure your switch using the Ethernet management port. Refer to the *Network Management Configuration Guide (Catalyst 3650 Switches)*.

Configuring LLDP, LLDP-MED, and Wired Location Service

- Finding Feature Information, on page 123
- LLDP, LLDP-MED, and Wired Location Service Overview, on page 123
- How to Configure LLDP, LLDP-MED, and Wired Location Service, on page 127
- Configuration Examples for LLDP, LLDP-MED, and Wired Location Service, on page 138
- Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service, on page 138
- Additional References for LLDP, LLDP-MED, and Wired Location Service, on page 140
- Feature Information for LLDP, LLDP-MED, and Wired Location Service, on page 140

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

LLDP, LLDP-MED, and Wired Location Service Overview

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, and switches). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the switch supports the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.
LLDP Supported TLVs

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. This protocol can advertise details such as configuration information, device capabilities, and device identity.

The switch supports these basic management TLVs. These are mandatory LLDP TLVs.

- Port description TLV
- System name TLV
- System description TLV
- System capabilities TLV
- Management address TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

- Port VLAN ID TLV (IEEE 802.1 organizationally specific TLVs)
- MAC/PHY configuration/status TLV (IEEE 802.3 organizationally specific TLVs)

LLDP and Cisco Switch Stacks

A switch stack appears as a single switch in the network. Therefore, LLDP discovers the switch stack, not the individual stack members.

LLDP and Cisco Medianet

When you configure LLDP or CDP location information on a per-port basis, remote devices can send Cisco Medianet location information to the switch. For information, go to http://www.cisco.com/en/US/docs/ios/netmgmt/configuration/guide/nm_cdp_discover.html.

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices such as switches. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet, inventory management and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED Supported TLVs

LLDP-MED supports these TLVs:

- LLDP-MED capabilities TLV
  Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and has enabled.
- Network policy TLV
  Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify
a phone of the VLAN number that it should use. The phone can connect to any switch, obtain its VLAN number, and then start communicating with the call control.

By defining a network-policy profile TLV, you can create a profile for voice and voice-signaling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

• Power management TLV

Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows switches and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

LLDP-MED also supports an extended power TLV to advertise fine-grained power requirements, end-point power priority, and end-point and network connectivity-device power status. LLDP is enabled and power is applied to a port, the power TLV determines the actual power requirement of the endpoint device so that the system power budget can be adjusted accordingly. The switch processes the requests and either grants or denies power based on the current power budget. If the request is granted, the switch updates the power budget. If the request is denied, the switch turns off power to the port, generates a syslog message, and updates the power budget. If LLDP-MED is disabled or if the endpoint does not support the LLDP-MED power TLV, the initial allocation value is used throughout the duration of the connection.

You can change power settings by entering the `power inline {auto [max max-wattage] | never | static [max max-wattage]} interface configuration command. By default the PoE interface is in auto mode; If no value is specified, the maximum is allowed (30 W).

• Inventory management TLV

Allows an endpoint to send detailed inventory information about itself to the switch, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

• Location TLV

Provides location information from the switch to the endpoint device. The location TLV can send this information:

• Civic location information

  Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

• ELIN location information

  Provides the location information of a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

• Geographic location information

  Provides the geographical details of a switch location such as latitude, longitude, and altitude of a switch.

• custom location

  Provides customized name and value of a switch location.
Wired Location Service

The switch uses the location service feature to send location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired switch or controller. The switch notifies the MSE of device link up and link down events through the Network Mobility Services Protocol (NMSP) location and attachment notifications.

The MSE starts the NMSP connection to the switch, which opens a server port. When the MSE connects to the switch there is a set of message exchanges to establish version compatibility and service exchange information followed by location information synchronization. After connection, the switch periodically sends location and attachment notifications to the MSE. Any link up or link down events detected during an interval are aggregated and sent at the end of the interval.

When the switch determines the presence or absence of a device on a link-up or link-down event, it obtains the client-specific information such as the MAC address, IP address, and username. If the client is LLDP-MED- or CDP-capable, the switch obtains the serial number and UDI through the LLDP-MED location TLV or CDP.

Depending on the device capabilities, the switch obtains this client information at link up:

- Slot and port specified in port connection
- MAC address specified in the client MAC address
- IP address specified in port connection
- 802.1X username if applicable
- Device category is specified as a wired station
- State is specified as new
- Serial number, UDI
- Model number
- Time in seconds since the switch detected the association

Depending on the device capabilities, the switch obtains this client information at link down:

- Slot and port that was disconnected
- MAC address
- IP address
- 802.1X username if applicable
- Device category is specified as a wired station
- State is specified as delete
- Serial number, UDI
- Time in seconds since the switch detected the disassociation

When the switch shuts down, it sends an attachment notification with the state delete and the IP address before closing the NMSP connection to the MSE. The MSE interprets this notification as disassociation for all the wired clients associated with the switch.
If you change a location address on the switch, the switch sends an NMSP location notification message that identifies the affected ports and the changed address information.

**Default LLDP Configuration**

**Table 15: Default LLDP Configuration**

<table>
<thead>

</tr>
<tr>
<td>LLDP med-tlv-select</td>
<td>Disabled to send all LLDP-MED TLVs. When LLDP is globally enabled, LLDP-MED-TLV is also enabled.</td>
</tr>
</tbody>
</table>

**Configuration Guidelines**

- If the interface is configured as a tunnel port, LLDP is automatically disabled.
- If you first configure a network-policy profile on an interface, you cannot apply the `switchport voice vlan` command on the interface. If the `switchport voice vlan vlan-id` is already configured on an interface, you can apply a network-policy profile on the interface. This way the interface has the voice or voice-signaling VLAN network-policy profile applied on the interface.
- You cannot configure static secure MAC addresses on an interface that has a network-policy profile.
- You cannot configure a network-policy profile on a private-VLAN port.
- For wired location to function, you must first enter the `ip device tracking` global configuration command.

**How to Configure LLDP, LLDP-MED, and Wired Location Service**

**Enabling LLDP**

Beginning in privileged EXEC mode, follow these steps to enable LLDP:
## SUMMARY STEPS

1. `configure terminal`
2. `lldp run`
3. `interface interface-id`
4. `lldp transmit`
5. `lldp receive`
6. `end`
7. `show lldp`
8. `copy running-config startup-config`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
</tbody>
</table>
### Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, and the initialization delay time. You can also select the LLDP and LLDP-MED TLVs to send and receive.

Beginning in privileged EXEC mode, follow these steps to configure the LLDP characteristics.

#### Note
Steps 2 through 5 are optional and can be performed in any order.

#### SUMMARY STEPS

1. configure terminal
2. lldp holdtime seconds
3. lldp reinit delay
4. lldp timer rate
5. lldp tlv-select
6. interface interface-id
7. lldp med-tlv-select
8. end
9. show lldp
10. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>

<td><strong>end</strong>  &lt;br&gt; Example: <code>Switch (config-if)# end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 9</td>
<td><strong>show lldp</strong>  &lt;br&gt; Example: <code>Switch# show lldp</code></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>
## Configuring LLDP-MED TLVs

By default, the switch only sends LLDP packets until it receives LLDP-MED packets from the end device. It then sends LLDP packets with MED TLVs, as well. When the LLDP-MED entry has been aged out, it again only sends LLDP packets.

By using the `lldp` interface configuration command, you can configure the interface not to send the TLVs listed in the following table.

### Table 16: LLDP-MED TLVs

<table>
<thead>
<tr>
<th>LLDP-MED TLV</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inventory-management</td>
<td>LLDP-MED inventory management TLV</td>
</tr>
<tr>
<td>location</td>
<td>LLDP-MED location TLV</td>
</tr>
<tr>
<td>network-policy</td>
<td>LLDP-MED network policy TLV</td>
</tr>
<tr>
<td>power-management</td>
<td>LLDP-MED power management TLV</td>
</tr>
</tbody>
</table>

Beginning in privileged EXEC mode, follow these steps to enable a TLV on an interface:

### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `lldp med-tlv-select`
4. `end`
5. `copy running-config startup-config`

### DETAILED STEPS

<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>

(Optional) Saves your entries in the configuration file.
### Configuring Network-Policy TLV

Beginning in privileged EXEC mode, follow these steps to create a network-policy profile, configure the policy attributes, and apply it to an interface.

#### SUMMARY STEPS

1. configure terminal
2. network-policy profile `profile number`
3. `{voice | voice-signaling} vlan [vlan-id {cos `cvalue` | dscp `dvalue`}] | [[dot1p `{cos `cvalue` | dscp `dvalue`}]]`
   | none | untagged
4. exit
5. interface `interface-id`
6. network-policy `profile number`
7. lldp med-tlv-select network-policy
8. end
9. show network-policy profile
10. copy running-config startup-config

**Configuring Location TLV and Wired Location Service**

Beginning in privileged EXEC mode, follow these steps to configure location information for an endpoint and to apply it to an interface.
SUMMARY STEPS

1. configure terminal
2. location {admin-tag string | civic-location identifier {id | host} | elin-location string identifier id | custom-location identifier {id | host} | geo-location identifier {id | host} }
3. exit
4. interface interface-id
5. location {additional-location-information word | civic-location-id {id | host} | elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host} }
6. end
7. Use one of the following:
   - show location admin-tag string
   - show location civic-location identifier id
   - show location elin-location identifier id
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>location {admin-tag string</td>
<td>civic-location identifier {id</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch(config)# location civic-location identifier 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# number 3550</td>
<td>• admin-tag—Specifies an administrative tag or site information.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# primary-road-name &quot;Cisco Way&quot;</td>
<td>• civic-location—Specifies civic location information.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# city &quot;San Jose&quot;</td>
<td>• elin-location—Specifies emergency location information (ELIN).</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# state CA</td>
<td>• custom-location—Specifies custom location information.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# building 19</td>
<td>• geo-location—Specifies geo-spatial location information.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# room C6</td>
<td>• identifier id—Specifies the ID for the civic, ELIN, custom, or geo location.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# county &quot;Santa Clara&quot;</td>
<td>• host—Specifies the host civic, custom, or geo location.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-civic)# country US</td>
<td>• string—Specifies the site or location information in alphanumeric format.</td>
</tr>
<tr>
<td>Step 3</td>
<td>exit</td>
<td>Returns to global configuration mode.</td>
</tr>
</tbody>
</table>
### Configuring Location TLV and Wired Location Service

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config-civic)# exit</code></td>
<td>Specifies the interface on which you are configuring the location information, and enter interface configuration mode.</td>
</tr>
</tbody>
</table>

**Step 4**

**interface interface-id**

**Example:**

```
Switch (config)# interface gigabitethernet2/0/1
```

**Step 5**

**location {additional-location-information word | civic-location-id {id | host} | clin-location-id {id | host} | geo-location-id {id | host}}**

**Example:**

```
Switch(config-if)# location elin-location-id 1
```

**Step 6**

**end**

**Example:**

```
Switch(config-if)# end
```

**Step 7**

Use one of the following:

- `show location admin-tag string`
- `show location civic-location identifier id`
- `show location elin-location identifier id`

**Example:**

```
Switch# show location admin-tag
```

or

Verifies the configuration.
### Enabling Wired Location Service on the Switch

Beginning in privileged EXEC mode, follow these steps to enable wired location service on the switch.

#### SUMMARY STEPS

1. `configure terminal`
2. `nmsp notification interval {attachment | location} interval-seconds`
3. `end`
4. `show network-policy profile`
5. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
| **Example:** 
  Switch# `configure terminal` | |
| **Step 2** `nmsp notification interval {attachment | location} interval-seconds` | Specifies the NMSP notification interval. |
| **Example:** 
  Switch(config)# `nmsp notification interval location 10` | `attachment`—Specifies the attachment notification interval. |
<p>| <code>location</code>—Specifies the location notification interval. |
| <code>interval-seconds</code>—Duration in seconds before the switch sends the MSE the location or attachment updates. The range is 1 to 30; the default is 30. | |
| <strong>Step 3</strong> <code>end</code> | Returns to privileged EXEC mode. |
| <strong>Example:</strong> | |</p>
<table>

<tr>
<td><code>Switch(config)# end</code></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

**Step 4**

`show network-policy profile`  
Example:  
`Switch# show network-policy profile`

**Step 5**

`copy running-config startup-config`  
Example:  
`Switch# copy running-config startup-config`

---

**Configuration Examples for LLDP, LLDP-MED, and Wired Location Service**

**Configuring Network-Policy TLV: Examples**

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
Switch# configure terminal  
Switch(config)# network-policy 1  
Switch(config-network-policy)# voice vlan 100 cos 4  
Switch(config-network-policy)# exit  
Switch(config)# interface gigabitethernet1/0/1  
Switch(config-if)# network-policy profile 1  
Switch(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
Switch(config-network-policy)# voice vlan dot1p cos 4  
Switch(config-network-policy)# voice vlan dot1p dscp 34
```

---

**Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service**

Commands for monitoring and maintaining LLDP, LLDP-MED, and wired location service.
<table>
<thead>
<tr>

Configuring System MTU

This module describes how to configure the Maximum Transmission Unit for a system on Catalyst 3650 Series Switches and Catalyst 3850 Series Switches.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about the MTU

The default maximum transmission unit (MTU) size for frames received and sent on all switch interfaces is 1500 bytes.

Restrictions for System MTU

When configuring the system MTU values, follow these guidelines:

• The switch does not support the MTU on a per-interface basis.
• If you enter the system mtu bytes global configuration command, the command does not take effect on the switch. This command only affects the system MTU size on Fast Ethernet switch ports.

System MTU Value Application

In a switch stack, the MTU values applied to member switches depends upon the stack configuration. The following stack configurations are supported:
The upper limit of the IP or IPv6 MTU value is based on the switch or switch stack configuration and refers to the currently applied system MTU or the system jumbo MTU value. For more information about setting the MTU sizes, see the `system mtu` global configuration command in the command reference for this release.

## Configuring the System MTU

### Configuring the System MTU

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `system mtu bytes`
4. `exit`
5. `show system mtu`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | Enables privileged EXEC mode.  
| `enable` | • Enter your password if prompted.  
| **Example:**  
| Switch> enable | |
| **Step 2** | Enters global configuration mode.  
| `configure terminal` |  
| **Example:**  
| Switch# configure terminal | |
| **Step 3** | Applies the Maximum Transmission Unit (MTU) size for all Ethernet interfaces on the switch or the switch stack.  
| `system mtu bytes` | • The MTU range is from 1500 to 9198. The default is 1500.  
| **Example:**  
| Switch(config)# system mtu 1600 | |
| **Step 4** | Exits global configuration mode and returns to privileged EXEC mode.  
| `exit` |  
| **Example:**  
| Switch(config)# exit | |
| **Step 5** | Displays the configured global MTU size.  
| `show system mtu` |  
| **Example:**  
| Switch# show system mtu | |

### Configuring Protocol-Specific MTU

When system MTU changes, the range for the `ip mtu` command for interface also changes.

#### SUMMARY STEPS

1. `enable`
2. configure terminal
3. interface type number
4. ip mtu bytes
5. ipv6 mtu bytes
6. end
7. show system mtu

### DETAILED STEPS

<table>

Information About Internal Power Supplies

See the switch installation guide for information about the power supplies.

How to Configure Internal Power Supplies

Configuring an Internal Power Supply

You can use the `powersupply` EXEC command to configure and manage the internal power supply on the switch. The switch does not support the `nopowersupply` EXEC command.

SUMMARY STEPS

1. `powersupply switch_number slot{A | B} {off | on}`
2. `show environment power`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>`powersupply switch_number slot{A</td>
<td>B} {off</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch# power supply 1 slot A on</code></td>
<td>• A — Selects the power supply in slot A.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• B — Selects power supply in slot B.</td>
</tr>
</tbody>
</table>
Table 17: Show Commands for Power Supplies

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>

</thead>
<tbody>
<tr>
<td><code>show environment power</code> [ all</td>
<td>switch switch_number ]</td>
</tr>
</tbody>
</table>

Configuration Examples for Internal Power Supplies

This example shows how to set the power supply in slot A to off:

```
Switch# power supply 1 slot A off
Disabling Power supply A may result in a power loss to PoE devices and/or switches ...
Continue? (yes/no)): yes
Switch#  
Jun 10 04:52:54.389: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered off
Jun 10 04:52:56.717: %PLATFORM_ENV-1-FAN_NOT_PRESENT: Fan is not present
Switch#  
```

This example shows how to set the power supply in slot A to on:

```
Switch# power supply 1 slot A on
Switch#  
Jun 10 04:54:39.600: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered on

This example shows the output of the `show env power` command:

```
Switch# show env power
```
### Table 18: show env power Status Descriptions

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about PoE

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the switch senses that there is no power on the circuit:

• a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
• an IEEE 802.3af-compliant powered device
• an IEEE 802.3at-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

After the switch detects a powered device, the switch determines the device power requirements and then grants or denies power to the device. The switch can also sense the real-time power consumption of the device by monitoring and policing the power usage.
Supported Protocols and Standards

The switch uses these protocols and standards to support PoE:

- **CDP with power consumption**—The powered device notifies the switch of the amount of power it is consuming. The switch does not reply to the power-consumption messages. The switch can only supply power to or remove power from the PoE port.

- **Cisco intelligent power management**—The powered device and the switch negotiate through power-negotiation CDP messages for an agreed-upon power-consumption level. The negotiation allows a high-power Cisco powered device, which consumes more than 7 W, to operate at its highest power mode. The powered device first boots up in low-power mode, consumes less than 7 W, and negotiates to obtain enough power to operate in high-power mode. The device changes to high-power mode only when it receives confirmation from the switch.

High-power devices can operate in low-power mode on switches that do not support power-negotiation CDP.

Cisco intelligent power management is backward-compatible with CDP with power consumption; the switch responds according to the CDP message that it receives. CDP is not supported on third-party powered devices; therefore, the switch uses the IEEE classification to determine the power usage of the device.

- **IEEE 802.3af**—The major features of this standard are powered-device discovery, power administration, disconnect detection, and optional powered-device power classification. For more information, see the standard.

- **IEEE 802.3at**—The PoE+ standard increases the maximum power that can be drawn by a powered device from 15.4 W per port to 30 W per port.

Powered-Device Detection and Initial Power Allocation

The switch detects a Cisco pre-standard or an IEEE-compliant powered device when the PoE-capable port is in the no-shutdown state, PoE is enabled (the default), and the connected device is not being powered by an AC adaptor.

After device detection, the switch determines the device power requirements based on its type:

- **A Cisco prestandard powered device** does not provide its power requirement when the switch detects it, so the switch allocates 15.4 W as the initial allocation for power budgeting.

  The initial power allocation is the maximum amount of power that a powered device requires. The switch initially allocates this amount of power when it detects and powers the powered device. As the switch receives CDP messages from the powered device and as the powered device negotiates power levels with the switch through CDP power-negotiation messages, the initial power allocation might be adjusted.

- **The switch classifies the detected IEEE device** within a power consumption class. Based on the available power in the power budget, the switch determines if a port can be powered. Table 19: IEEE Power Classifications, on page 152 lists these levels.

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum Power Level Required from the Switch</th>

</tr>
</tbody>
</table>

The switch monitors and tracks requests for power and grants power only when it is available. The switch tracks its power budget (the amount of power available on the switch for PoE). The switch performs power-accounting calculations when a port is granted or denied power to keep the power budget up to date.

After power is applied to the port, the switch uses CDP to determine the CDP-specific power consumption requirement of the connected Cisco powered devices, which is the amount of power to allocate based on the CDP messages. The switch adjusts the power budget accordingly. This does not apply to third-party PoE devices. The switch processes a request and either grants or denies power. If the request is granted, the switch updates the power budget. If the request is denied, the switch ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. Powered devices can also negotiate with the switch for more power.

With PoE+, powered devices use IEEE 802.3at and LLDP power with media dependent interface (MDI) type, length, and value descriptions (TLVs), Power-via-MDI TLVs, for negotiating power up to 30 W. Cisco pre-standard devices and Cisco IEEE powered devices can use CDP or the IEEE 802.3at power-via-MDI power negotiation mechanism to request power levels up to 30 W.

Note The initial allocation for Class 0, Class 3, and Class 4 powered devices is 15.4 W. When a device starts up and uses CDP or LLDP to send a request for more than 15.4 W, it can be allocated up to the maximum of 30 W.

Note The CDP-specific power consumption requirement is referred to as the actual power consumption requirement in the software configuration guides and command references.

If the switch detects a fault caused by an undervoltage, overvoltage, overtemperature, oscillator-fault, or short-circuit condition, it turns off power to the port, generates a syslog message, and updates the power budget and LEDs.

The PoE feature operates the same whether or not the switch is a stack member. The power budget is per-switch and independent of any other switch in the stack. Election of a new active switch does not affect PoE operation. The active switch keeps track of the PoE status for all switches and ports in the stack and includes the status in output displays.

Power Management Modes

The switch supports these PoE modes:

- **auto**—The switch automatically detects if the connected device requires power. If the switch discovers a powered device connected to the port and if the switch has enough power, it grants power, updates the
power budget, turns on power to the port on a first-come, first-served basis, and updates the LEDs. For LED information, see the hardware installation guide.

If the switch has enough power for all the powered devices, they all come up. If enough power is available for all powered devices connected to the switch, power is turned on to all devices. If there is not enough available PoE, or if a device is disconnected and reconnected while other devices are waiting for power, it cannot be determined which devices are granted or are denied power.

If granting power would exceed the system power budget, the switch denies power, ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. After power has been denied, the switch periodically rechecks the power budget and continues to attempt to grant the request for power.

If a device being powered by the switch is then connected to wall power, the switch might continue to power the device. The switch might continue to report that it is still powering the device whether the device is being powered by the switch or receiving power from an AC power source.

If a powered device is removed, the switch automatically detects the disconnect and removes power from the port. You can connect a nonpowered device without damaging it.

You can specify the maximum wattage that is allowed on the port. If the IEEE class maximum wattage of the powered device is greater than the configured maximum value, the switch does not provide power to the port. If the switch powers a powered device, but the powered device later requests through CDP messages more than the configured maximum value, the switch removes power to the port. The power that was allocated to the powered device is reclaimed into the global power budget. If you do not specify a wattage, the switch delivers the maximum value. Use the auto setting on any PoE port. The auto mode is the default setting.

- **static**—The switch pre-allocates power to the port (even when no powered device is connected) and guarantees that power will be available for the port. The switch allocates the port configured maximum wattage, and the amount is never adjusted through the IEEE class or by CDP messages from the powered device. Because power is pre-allocated, any powered device that uses less than or equal to the maximum wattage is guaranteed to be powered when it is connected to the static port. The port no longer participates in the first-come, first-served model.

  However, if the powered-device IEEE class is greater than the maximum wattage, the switch does not supply power to it. If the switch learns through CDP messages that the powered device is consuming more than the maximum wattage, the switch shuts down the powered device.

  If you do not specify a wattage, the switch pre-allocates the maximum value. The switch powers the port only if it discovers a powered device. Use the static setting on a high-priority interface.

- **never**—The switch disables powered-device detection and never powers the PoE port even if an unpowered device is connected. Use this mode only when you want to make sure that power is never applied to a PoE-capable port, making the port a data-only port.

For most situations, the default configuration (auto mode) works well, providing plug-and-play operation. No further configuration is required. However, perform this task to configure a PoE port for a higher priority, to make it data only, or to specify a maximum wattage to disallow high-power powered devices on a port.

When you make PoE configuration changes, the port being configured drops power. Depending on the new configuration, the state of the other PoE ports, and the state of the power budget, the port might not be powered up again. For example, port 1 is in the auto and on state, and you configure it for static mode. The switch removes power from port 1, detects the powered device, and repowers the port. If port 1 is in the auto and on state and you configure it with a maximum wattage of 10 W, the switch removes power from the port and then redetects the powered device. The switch repowers the port only if the powered device is a class 1, class 2, or a Cisco-only powered device.
Power Monitoring and Power Policing

When policing of the real-time power consumption is enabled, the switch takes action when a powered device consumes more power than the maximum amount allocated, also referred to as the cutoff-power value.

When PoE is enabled, the switch senses the real-time power consumption of the powered device. The switch monitors the real-time power consumption of the connected powered device; this is called power monitoring or power sensing. The switch also polices the power usage with the power policing feature.

Power monitoring is backward-compatible with Cisco intelligent power management and CDP-based power consumption. It works with these features to ensure that the PoE port can supply power to the powered device.

The switch senses the real-time power consumption of the connected device as follows:

1. The switch monitors the real-time power consumption on individual ports.
2. The switch records the power consumption, including peak power usage. The switch reports the information through the CISCO-POWER-ETHERNET-EXT-MIB.
3. If power policing is enabled, the switch polices power usage by comparing the real-time power consumption to the maximum power allocated to the device. The maximum power consumption is also referred to as the cutoff power on a PoE port.

If the device uses more than the maximum power allocation on the port, the switch can either turn off power to the port, or the switch can generate a syslog message and update the LEDs (the port LED is now blinking amber) while still providing power to the device based on the switch configuration. By default, power-usage policing is disabled on all PoE ports.

If error recovery from the PoE error-disabled state is enabled, the switch automatically takes the PoE port out of the error-disabled state after the specified amount of time.

If error recovery is disabled, you can manually re-enable the PoE port by using the shutdown and no shutdown interface configuration commands.

4. If policing is disabled, no action occurs when the powered device consumes more than the maximum power allocation on the PoE port, which could adversely affect the switch.

Power Consumption Values

You can configure the initial power allocation and the maximum power allocation on a port. However, these values are only the configured values that determine when the switch should turn on or turn off power on the PoE port. The maximum power allocation is not the same as the actual power consumption of the powered device. The actual cutoff power value that the switch uses for power policing is not equal to the configured power value.

When power policing is enabled, the switch polices the power usage at the switch port, which is greater than the power consumption of the device. When you are manually set the maximum power allocation, you must consider the power loss over the cable from the switch port to the powered device. The cutoff power is the sum of the rated power consumption of the powered device and the worst-case power loss over the cable.

We recommend that you enable power policing when PoE is enabled on your switch. For example, if policing is disabled and you set the cutoff-power value by using the power inline auto max 6300 interface configuration command, the configured maximum power allocation on the PoE port is 6.3 W (6300 mW). The switch provides power to the connected devices on the port if the device needs up to 6.3 W. If the CDP-power negotiated value or the IEEE classification value exceeds the configured cutoff value, the switch does not provide power to the connected device. After the switch turns on power on the PoE port, the switch does not police the real-time power consumption of the device, and the device can consume more power than the
maximum allocated amount, which could adversely affect the switch and the devices connected to the other PoE ports.

Because a standalone switch supports internal power supplies, the total amount of power available for the powered devices varies depending on the power supply configuration.

- If a power supply is removed and replaced by a new power supply with less power and the switch does not have enough power for the powered devices, the switch denies power to the PoE ports in auto mode in descending order of the port numbers. If the switch still does not have enough power, the switch then denies power to the PoE ports in static mode in descending order of the port numbers.

- If the new power supply supports more power than the previous one and the switch now has more power available, the switch grants power to the PoE ports in static mode in ascending order of the port numbers. If it still has power available, the switch then grants power to the PoE ports in auto mode in ascending order of the port numbers.

## How to Configure PoE

### Configuring a Power Management Mode on a PoE Port

#### SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. power inline {auto [max max-wattage] | never | static [max max-wattage]}
4. end
5. show power inline [interface-id | module switch-number]

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>interface interface-id</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# interface gigabitethernet2/0/1</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>power inline {auto [max max-wattage]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config-if)# power inline auto</td>
</tr>
</tbody>
</table>

**Purpose**

- **Step 1**: Enters global configuration mode.
- **Step 2**: Specifies the physical port to be configured, and enters interface configuration mode.
- **Step 3**: Configures the PoE mode on the port. The keywords have these meanings:
  - **auto**: Enables powered-device detection. If enough power is available, automatically allocates power to the PoE port after device detection. This is the default setting.
### Configuring Power Policing

By default, the switch monitors the real-time power consumption of connected powered devices. You can configure the switch to police the power usage. By default, policing is disabled.

#### SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. power inline police [action {log | errdisable}]
4. exit
5. Use one of the following:
   - errdisable detect cause inline-power
   - errdisable recovery cause inline-power

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| • **max** max-wattage — Limits the power allowed on the port. The range for PoE+ ports is 4000 to 30000 mW. If no value is specified, the maximum is allowed.  
• **never** — Disables device detection, and disable power to the port. |
| **Note** | If a port has a Cisco powered device connected to it, do not use the **power inline never** command to configure the port. A false link-up can occur, placing the port into the error-disabled state.  
• **static** — Enables powered-device detection. Pre-allocate (reserve) power for a port before the switch discovers the powered device. The switch reserves power for this port even when no device is connected and guarantees that power will be provided upon device detection.  
The switch allocates power to a port configured in static mode before it allocates power to a port configured in auto mode. |

---

**Step 4**

end

*Example:*

Switch(config-if)# end

**Step 5**

**show power inline** [**interface-id** | **module switch-number**]

*Example:*

Switch# show power inline

Displays PoE status for a switch or a switch stack, for the specified interface, or for a specified stack member.  
The **module switch-number** keywords are supported only on stacking-capable switches.
**Configuring Power Policing**

6. `exit`

7. Use one of the following:
   - `show power inline police`
   - `show errdisable recovery`

### DETAILED STEPS

<table>
<thead>
<tr>

<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td><code>interface interface-id</code></td>
<td>Specifies the physical port to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> <code>interface gigabitethernet2/0/1</code></td>
<td></td>
</tr>
</tbody>
</table>
| 3    | `power inline police [action\{log | errdisable\}]` | If the real-time power consumption exceeds the maximum power allocation on the port, configures the switch to take one of these actions:
   - `power inline police`—Shuts down the PoE port, turns off power to it, and puts it in the error-disabled state.

   **Note** You can enable error detection for the PoE error-disabled cause by using the `errdisable detect cause inline-power` global configuration command. You can also enable the timer to recover from the PoE error-disabled state by using the `errdisable recovery cause inline-power interval interval` global configuration command.

   - `power inline police action errdisable`—Turns off power to the port if the real-time power consumption exceeds the maximum power allocation on the port.
   - `power inline police action log`—Generates a syslog message while still providing power to the port.

   If you do not enter the `action log` keywords, the default action shuts down the port and puts the port in the error-disabled state. |
|      | **Example:** `power inline police` | |
| 4    | `exit` | Returns to global configuration mode. |
|      | **Example:** `exit` | |
Purpose

Command or Action

Step 5

Use one of the following:

- `errdisable detect cause inline-power`
- `errdisable recovery cause inline-power`
- `errdisable recovery interval interval`

Example:

Switch(config)# errdisable detect cause inline-power

Switch(config)# errdisable recovery cause inline-power

Switch(config)# errdisable recovery interval 100

Purpose

(Optional) Enables error recovery from the PoE error-disabled state, and configures the PoE recovery mechanism variables.

By default, the recovery interval is 300 seconds.

For `interval interval`, specifies the time in seconds to recover from the error-disabled state. The range is 30 to 86400.

Step 6

exit

Example:

Switch(config)# exit

Purpose

Returns to privileged EXEC mode.

Step 7

Use one of the following:

- `show power inline police`
- `show errdisable recovery`

Example:

Switch# show power inline police

Switch# show errdisable recovery

Purpose

Displays the power monitoring status, and verify the error recovery settings.

Monitoring Power Status

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About EEE

EEE Overview

Energy Efficient Ethernet (EEE) is an IEEE 802.3az standard that is designed to reduce power consumption in Ethernet networks during idle periods.

EEE can be enabled on devices that support low power idle (LPI) mode. Such devices can save power by entering LPI mode during periods of low utilization. In LPI mode, systems on both ends of the link can save power by shutting down certain services. EEE provides the protocol needed to transition into and out of LPI mode in a way that is transparent to upper layer protocols and applications.

Default EEE Configuration

EEE is disabled by default.
Restrictions for EEE

EEE has the following restrictions:

- Changing the EEE configuration resets the interface because the device has to restart Layer 1 autonegotiation.
- You might want to enable the Link Layer Discovery Protocol (LLDP) for devices that require longer wakeup times before they are able to accept data on their receive paths. Doing so enables the device to negotiate for extended system wakeup times from the transmitting link partner.

How to Configure EEE

You can enable or disable EEE on an interface that is connected to an EEE-capable link partner.

Enabling or Disabling EEE

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. power efficient-ethernet auto
4. no power efficient-ethernet auto
5. end
6. copy running-config startup-config

DETAILED STEPS

<td>show eee capabilities interface interface-id</td>
<td>Displays EEE capabilities for the specified interface.</td>
</tr>
<tr>
<td>show eee status interface interface-id</td>
<td>Displays EEE status information for the specified interface.</td>
</tr>
</tbody>
</table>

## Configuration Examples for Configuring EEE

This example shows how to enable EEE for an interface:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# power efficient-ethernet auto
```

This example shows how to disable EEE for an interface:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# no power efficient-ethernet auto
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring IGMP

The following are the restrictions for configuring IGMP:

• The switch supports IGMP Versions 1, 2, and 3.

**Note** For IGMP Version 3, only IGMP Version 3 BISS (Basic IGMPv3 Snooping Support) is supported.

• IGMP Version 3 uses new membership report messages that might not be correctly recognized by older IGMP snooping switches.

• IGMP filtering and throttling is not supported under the WLAN.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
Information About IGMP

To participate in IP multicasting, multicast hosts, routers, and multilayer switches must have the Internet Group Management Protocol (IGMP) operating. This protocol defines the querier and host roles:

- A querier is a network device that sends query messages to discover which network devices are members of a given multicast group.
- A host is a receiver that sends report messages (in response to query messages) to inform a querier of a host membership.

A set of queriers and hosts that receive multicast data streams from the same source is called a multicast group. Queriers and hosts use IGMP messages to join and leave multicast groups.

Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message. Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time. How active a multicast group is and what members it has can vary from group to group and from time to time. A multicast group can be active for a long time, or it can be very short-lived. Membership in a group can constantly change.

IP Multicast Group Addresses

IP multicast traffic uses group addresses, which are class D addresses. The high-order bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 through 239.255.255.255. Multicast addresses in the range 224.0.0.0 to 224.0.0.255 are reserved for use by routing protocols and other network control traffic. The address 224.0.0.0 is guaranteed not to be assigned to any group.

IGMP packets are sent using these IP multicast group addresses:

- IGMP general queries are destined to the address 224.0.0.1 (all systems on a subnet).
- IGMP group-specific queries are destined to the group IP address for which the switch is querying.
- IGMP group membership reports are destined to the group IP address for which the switch is reporting.
- IGMP Version 2 (IGMPv2) leave messages are destined to the address 224.0.0.2 (all multicast routers on a subnet). In some old host IP stacks, leave messages might be destined to the group IP address rather than to the all-routers address.

Related Topics

- Configuring the Switch as a Member of a Group (CLI), on page 176
- Example: Configuring the Switch as a Member of a Multicast Group, on page 215

IGMP Versions

The switch supports IGMP version 1, IGMP version 2, and IGMP version 3. These versions are interoperable on the switch. For example, if IGMP snooping is enabled and the querier's version is IGMPv2, and the switch receives an IGMPv3 report from a host, then the switch can forward the IGMPv3 report to the multicast router.
IGMP Version 1

IGMP version 1 (IGMPv1) primarily uses a query-response model that enables the multicast router and multilayer switch to find which multicast groups are active (have one or more hosts interested in a multicast group) on the local subnet. IGMPv1 has other processes that enable a host to join and leave a multicast group. For more information, see RFC 1112.

IGMP Version 2

IGMPv2 extends IGMP functionality by providing such features as the IGMP leave process to reduce leave latency, group-specific queries, and an explicit maximum query response time. IGMPv2 also adds the capability for routers to elect the IGMP querier without depending on the multicast protocol to perform this task. For more information, see RFC 2236.

Note

IGMP version 2 is the default version for the switch.

IGMP Version 3

The switch supports IGMP version 3. The following are considerations for the switch and IGMP version 3:

- An IGMPv3 switch supports Basic IGMPv3 Snooping Support (BISS), which includes support for the snooping features on IGMPv1 and IGMPv2 switches and for IGMPv3 membership report messages. BISS constrains the flooding of multicast traffic when your network includes IGMPv3 hosts. It constrains traffic to approximately the same set of ports as the IGMP snooping feature on IGMPv2 or IGMPv1 hosts.

- The switch supports IGMPv3 snooping based only on the destination multicast IP address. It does not support snooping based on a source IP address or proxy report.

- IGMPv3 join and leave messages are not supported on switches running IGMP filtering or Multicast VLAN registration (MVR).

- An IGMPv3 switch can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

IGMPv3 Host Signalling

In IGMPv3, hosts signal membership to last hop routers of multicast groups. Hosts can signal group membership with filtering capabilities with respect to sources. A host can either signal that it wants to receive traffic from all sources sending to a group except for some specific sources (called exclude mode), or that it wants to receive traffic only from some specific sources sending to the group (called include mode).

IGMPv3 can operate with both Internet Standard Multicast (ISM) and Source Specific Multicast (SSM). In ISM, both exclude and include mode reports are applicable. In SSM, only include mode reports are accepted by the last-hop router. Exclude mode reports are ignored.

IGMP Snooping

Layer 2 switches can use IGMP snooping to constrain the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. As the name implies, IGMP snooping requires the LAN switch to snoop on the IGMP
transmissions between the host and the router and to keep track of multicast groups and member ports. When the switch receives an IGMP report from a host for a particular multicast group, the switch adds the host port number to the forwarding table entry; when it receives an IGMP Leave Group message from a host, it removes the host port from the table entry. It also periodically deletes entries if it does not receive IGMP membership reports from the multicast clients.

For more information on IP multicast and IGMP, see RFC 1112 and RFC 2236.

The multicast router (which could be a switch with the IP services feature set on the active switch) sends out periodic general queries to all VLANs. All hosts interested in this multicast traffic send join requests and are added to the forwarding table entry. The switch creates one entry per VLAN in the IGMP snooping IP multicast forwarding table for each group from which it receives an IGMP join request.

The switch supports IP multicast group-based bridging, instead of MAC-addressed based groups. With multicast MAC address-based groups, if an IP address being configured translates (aliases) to a previously configured MAC address or to any reserved multicast MAC addresses (in the range 224.0.0.xxx), the command fails. Because the switch uses IP multicast groups, there are no address aliasing issues.

The IP multicast groups learned through IGMP snooping are dynamic. However, you can statically configure multicast groups by using the `ip igmp snooping vlan vlan-id static ip_address interface interface-id` global configuration command. If you specify group membership for a multicast group address statically, your setting supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can consist of both user-defined and IGMP snooping-learned settings.

You can configure an IGMP snooping querier to support IGMP snooping in subnets without multicast interfaces because the multicast traffic does not need to be routed.

If a port spanning-tree, a port group, or a VLAN ID change occurs, the IGMP snooping-learned multicast groups from this port on the VLAN are deleted.

**Joining a Multicast Group**

*Figure 6: Initial IGMP Join Message*

When a host connected to the switch wants to join an IP multicast group and it is an IGMP version 2 client, it sends an unsolicited IGMP join message, specifying the IP multicast group to join. Alternatively, when the switch receives a general query from the router, it forwards the query to all ports in the VLAN. IGMP version 1 or version 2 hosts wanting to join the multicast group respond by sending a join message to the switch. The switch CPU creates a multicast forwarding-table entry for the group if it is not already present. The CPU also adds the interface where the join message was received to the forwarding-table entry. The host associated with that interface receives multicast traffic for that multicast group.
Router A sends a general query to the switch, which forwards the query to ports 2 through 5, which are all members of the same VLAN. Host 1 wants to join multicast group 224.1.2.3 and multicasts an IGMP membership report (IGMP join message) to the group. The switch CPU uses the information in the IGMP report to set up a forwarding-table entry that includes the port numbers connected to Host 1 and to the router.

**Table 22: IGMP Snooping Forwarding Table**

<table>
<thead>
<tr>
<th>Destination Address</th>
<th>Type of Packet</th>
<th>Ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>224.1.2.3</td>
<td>IGMP</td>
<td>1, 2</td>
</tr>
</tbody>
</table>

The switch hardware can distinguish IGMP information packets from other packets for the multicast group. The information in the table tells the switching engine to send frames addressed to the 224.1.2.3 multicast IP address that are not IGMP packets to the router and to the host that has joined the group.

**Figure 7: Second Host Joining a Multicast Group**

If another host (for example, Host 4) sends an unsolicited IGMP join message for the same group, the CPU receives that message and adds the port number of Host 4 to the forwarding table. Because the forwarding table directs IGMP messages only to the CPU, the message is not flooded to other ports on the switch. Any
known multicast traffic is forwarded to the group and not to the

**Leaving a Multicast Group**

The router sends periodic multicast general queries, and the switch forwards these queries through all ports in the VLAN. Interested hosts respond to the queries. If at least one host in the VLAN wants to receive multicast traffic, the router continues forwarding the multicast traffic to the VLAN. The switch forwards multicast group traffic only to those hosts listed in the forwarding table for that IP multicast group maintained by IGMP snooping.

When hosts want to leave a multicast group, they can silently leave, or they can send a leave message. When the switch receives a leave message from a host, it sends a group-specific query to learn if any other devices connected to that interface are interested in traffic for the specific multicast group. The switch then updates the forwarding table for that MAC group so that only those hosts interested in receiving multicast traffic for the group are listed in the forwarding table. If the router receives no reports from a VLAN, it removes the group for the VLAN from its IGMP cache.

**Immediate Leave**

The switch uses IGMP snooping Immediate Leave to remove from the forwarding table an interface that sends a leave message without the switch sending group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original leave message. Immediate
Leave ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are simultaneously in use.

Immediate Leave is only supported on IGMP version 2 hosts. IGMP version 2 is the default version for the switch.

---

**Note**

You should only use the Immediate Leave feature on VLANs where a single host is connected to each port. If Immediate Leave is enabled in VLANs where more than one host is connected to a port, some hosts might inadvertently be dropped.

---

**IGMP Configurable-Leave Timer**

You can configure the time that the switch waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 5000 milliseconds. The timer can be set either globally or on a per-VLAN basis. The VLAN configuration of the leave time overrides the global configuration.

- [Configuring the IGMP Leave Timer (CLI)], on page 200

---

**IGMP Report Suppression**

---

**Note**

IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

The switch uses IGMP report suppression to forward only one IGMP report per multicast router query to multicast devices. When IGMP report suppression is enabled (the default), the switch sends the first IGMP report from all hosts for a group to all the multicast routers. The switch does not send the remaining IGMP reports for the group to the multicast routers. This feature prevents duplicate reports from being sent to the multicast devices.

If the multicast router query includes requests only for IGMPv1 and IGMPv2 reports, the switch forwards only the first IGMPv1 or IGMPv2 report from all hosts for a group to all the multicast routers.

If the multicast router query also includes requests for IGMPv3 reports, the switch forwards all IGMPv1, IGMPv2, and IGMPv3 reports for a group to the multicast devices.

If you disable IGMP report suppression, all IGMP reports are forwarded to the multicast routers.

---

**IGMP Snooping and Switch Stacks**

IGMP snooping functions across the switch stack; that is, IGMP control information from one switch is distributed to all switches in the stack. Regardless of the stack member through which IGMP multicast data enters the stack, the data reaches the hosts that have registered for that group.

If a switch in the stack fails or is removed from the stack, only the members of the multicast group that are on that switch will not receive the multicast data. All other members of a multicast group on other switches in the stack continue to receive multicast data streams. However, multicast groups that are common for both Layer 2 and Layer 3 (IP multicast routing) might take longer to converge if the active switch is removed.

---

**IGMP Configurable-Leave Timer**

You can configure the time that the switch waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 5000 milliseconds. The timer can be set either globally or on a per-VLAN basis. The VLAN configuration of the leave time overrides the global configuration.

**IGMP Report Suppression**

---

**Note**

IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

The switch uses IGMP report suppression to forward only one IGMP report per multicast router query to multicast devices. When IGMP report suppression is enabled (the default), the switch sends the first IGMP report from all hosts for a group to all the multicast routers. The switch does not send the remaining IGMP reports for the group to the multicast routers. This feature prevents duplicate reports from being sent to the multicast devices.

If the multicast router query includes requests only for IGMPv1 and IGMPv2 reports, the switch forwards only the first IGMPv1 or IGMPv2 report from all hosts for a group to all the multicast routers.

If the multicast router query also includes requests for IGMPv3 reports, the switch forwards all IGMPv1, IGMPv2, and IGMPv3 reports for a group to the multicast devices.

If you disable IGMP report suppression, all IGMP reports are forwarded to the multicast routers.

---

**IGMP Snooping and Switch Stacks**

IGMP snooping functions across the switch stack; that is, IGMP control information from one switch is distributed to all switches in the stack. Regardless of the stack member through which IGMP multicast data enters the stack, the data reaches the hosts that have registered for that group.

If a switch in the stack fails or is removed from the stack, only the members of the multicast group that are on that switch will not receive the multicast data. All other members of a multicast group on other switches in the stack continue to receive multicast data streams. However, multicast groups that are common for both Layer 2 and Layer 3 (IP multicast routing) might take longer to converge if the active switch is removed.
IGMP Filtering and Throttling Overview

In some environments, for example, metropolitan or multiple-dwelling unit (MDU) installations, you might want to control the set of multicast groups to which a user on a switch port can belong. You can control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan. You might also want to limit the number of multicast groups to which a user on a switch port can belong.

With the IGMP filtering feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual switch ports. An IGMP profile can contain one or more multicast groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a switch port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing. You can also set the maximum number of IGMP groups that a Layer 2 interface can join.

IGMP filtering controls only group-specific query and membership reports, including join and leave reports. It does not control general IGMP queries. IGMP filtering has no relationship with the function that directs the forwarding of IP multicast traffic. The filtering feature operates in the same manner whether CGMP or MVR is used to forward the multicast traffic.

IGMP filtering applies only to the dynamic learning of IP multicast group addresses, not static configuration.

With the IGMP throttling feature, you can set the maximum number of IGMP groups that a Layer 2 interface can join. If the maximum number of IGMP groups is set, the IGMP snooping forwarding table contains the maximum number of entries, and the interface receives an IGMP join report, you can configure an interface to drop the IGMP report or to replace the randomly selected multicast entry with the received IGMP report.

---

**Note**

IGMPv3 join and leave messages are not supported on switches running IGMP filtering.

How to Configure IGMP

Configuring the Switch as a Member of a Group (CLI)

You can configure the switch as a member of a multicast group and discover multicast reachability in a network. If all the multicast-capable routers and multilayer switches that you administer are members of a multicast group, pinging that group causes all of these devices to respond. The devices respond to ICMP echo-request packets addressed to a group of which they are members. Another example is the multicast trace-route tools provided in the software.

⚠️ Caution
Performing this procedure might impact the CPU performance because the CPU will receive all data traffic for the group address.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp join-group group-address
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

DETAILED STEPS

For a configuration example, see Example: Interface Configuration as an SVI, on page 218.</td>
<td></td>
</tr>
<tr>
<td>These interfaces must have IP addresses assigned to them.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 4

**ip igmp join-group** *group-address*

**Example:**

```
Switch(config-if)# ip igmp
join-group 225.2.2.2
```

Configures the switch to join a multicast group.

By default, no group memberships are defined.

For *group-address*, specify the multicast IP address in dotted decimal notation.

### Step 5

**end**

**Example:**

```
Switch(config-if)# end
```

Returns to privileged EXEC mode.

### Step 6

**show ip igmp interface** *[interface-id]*

**Example:**

```
Switch# show ip igmp interface
```

Verifies your entries.

### Step 7

**copy running-config startup-config**

**Example:**

```
Switch# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

- IP Multicast Group Addresses, on page 168
## Controlling Access to IP Multicast Group (CLI)

The switch sends IGMP host-query messages to find which multicast groups have members on attached local networks. The switch then forwards to these group members all packets addressed to the multicast group. You can place a filter on each interface to restrict the multicast groups that hosts on the subnet serviced by the interface can join.

To limit the number of joins on the interface, configure the port for the filter which associates with the IGMP profile.

This procedure is optional.

### SUMMARY STEPS

1. `enable`  
2. `configure terminal`  
3. `ip igmp profile`  
4. `permit`  
5. `exit`  
6. `interface interface-id`  
7. `ip igmp filter filter_number`  
8. `end`

**Modifying the IGMP Host-Query Message Interval (CLI)**

The switch periodically sends IGMP host-query messages to discover which multicast groups are present on attached networks. These messages are sent to the all-hosts multicast group (224.0.0.1) with a time-to-live (TTL) of 1. The switch sends host-query messages to refresh its knowledge of memberships present on the network. If, after some number of queries, the software discovers that no local hosts are members of a multicast group, the software stops forwarding multicast packets to the local network from remote origins for that group and sends a prune message upstream toward the source.
The switch elects a PIM designated router (DR) for the LAN (subnet). The DR is the router or multilayer switch with the highest IP address for IGMPv2. For IGMPv1, the DR is elected according to the multicast routing protocol that runs on the LAN. The designated router is responsible for sending IGMP host-query messages to all hosts on the LAN. In sparse mode, the designated router also sends PIM register and PIM join messages toward the RP router.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp query-interval seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

</tbody>
</table>
Changing the IGMP Query Timeout for IGMPv2 (CLI)

If you are using IGMPv2, you can specify the period of time before the switch takes over as the querier for the interface. By default, the switch waits twice the query interval period controlled by the `ip igmp query-interval` interface configuration command. After that time, if the switch has received no queries, it becomes the querier.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp querier-timeout seconds`

---

**Purpose**

and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218.

These interfaces must have IP addresses assigned to them.

### Step 4

**Command or Action**

- `ip igmp query-interval seconds`

**Example:**

Switch(config-if)# ip igmp query-interval 75

Configures the frequency at which the designated router sends IGMP host-query messages.

By default, the designated router sends IGMP host-query messages every 60 seconds to keep the IGMP overhead very low on hosts and networks.

The range is 1 to 65535.

### Step 5

**Command or Action**

- `end`

**Example:**

Switch(config-if)# end

Returns to privileged EXEC mode.

### Step 6

**Command or Action**

- `show ip igmp interface [interface-id]`

**Example:**

Switch# show ip igmp interface

Verifies your entries.

### Step 7

**Command or Action**

- `copy running-config startup-config`

**Example:**

Switch# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
5. **end**  
6. **show ip igmp interface [interface-id]**  
7. **copy running-config startup-config**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
• Enter your password if prompted.  |
| Example: Switch> enable | |
| **Step 2** configure terminal | Enters the global configuration mode.  |
| Example: Switch# configure terminal | |
| **Step 3** interface interface-id | Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode.  
The specified interface must be one of the following:  
• A routed port—A physical port that has been configured as a Layer 3 port by entering the **no switchport** interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217.  
• An SVI—A VLAN interface created by using the **interface vlan vlan-id** global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218.  
These interfaces must have IP addresses assigned to them.  |
| Example: Switch(config)# interface gigabitethernet 1/0/1 | |
| **Step 4** ip igmp querier-timeout seconds | Specifies the IGMP query timeout.  
The default is 60 seconds (twice the query interval). The range is 60 to 300.  |
| Example: Switch(config-if)# ip igmp querier-timeout 120 | |
Changing the Maximum Query Response Time for IGMPv2 (CLI)

If you are using IGMPv2, you can change the maximum query response time advertised in IGMP queries. The maximum query response time enables the switch to quickly detect that there are no more directly connected group members on a LAN. Decreasing the value enables the switch to prune groups faster. This procedure is optional.

SUMMARY STEPS

1.  enable
2.  configure terminal
3.  interface interface-id
4.  ip igmp query-max-response-time seconds
5.  end
6.  show ip igmp interface [interface-id]
7.  copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 3** interface interface-id | Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode. |
| Example:                          |                                                                         |
| Switch(config)# interface        |                                                                         |
| gigabitethernet 1/0/1             |                                                                         |

- The specified interface must be one of the following:
  - A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217.
  - An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218.

These interfaces must have IP addresses assigned to them.

| **Step 4** ip igmp query-max-response-time seconds | Changes the maximum query response time advertised in IGMP queries. The default is 10 seconds. The range is 1 to 25. |
| Example:                                          |                                                                         |
| Switch(config-if)# ip igmp query-max-response-time 15 |                                                                         |

| **Step 5** end                                 | Returns to privileged EXEC mode.                                      |
| Example:                                        |                                                                         |
| Switch(config-if)# end                         |                                                                         |

| **Step 6** show ip igmp interface [interface-id] | Verifies your entries.                                                |
| Example:                                        |                                                                         |
| Switch# show ip igmp interface                 |                                                                         |
Configuring the Switch as a Statically Connected Member (CLI)

At various times, either there is not a group member on a network segment or a host that cannot report its group membership by using IGMP. However, you may want multicast traffic to be sent to that network segment. The following commands are used to pull multicast traffic down to a network segment:

- **ip igmp join-group** — The switch accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the switch from fast switching.

- **ip igmp static-group** — The switch does not accept the packets itself, but only forwards them. This method enables fast switching. The outgoing interface appears in the IGMP cache, but the switch itself is not a member, as evidenced by lack of an L (local) flag in the multicast route entry.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp static-group group-address
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>

</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 3**

`interface interface-id`

**Example:**

```
Switch(config)# interface gigabitethernet 1/0/1
```

**Purpose:** Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode.

The specified interface must be one of the following:

- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217.

- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218.

These interfaces must have IP addresses assigned to them.

**Step 4**

`ip igmp static-group group-address`

**Example:**

```
Switch(config-if)# ip igmp static-group 239.100.100.101
```

**Purpose:** Configures the switch as a statically connected member of a group.

By default, this feature is disabled.

**Step 5**

`end`

**Example:**

```
Switch(config-if)# end
```

**Purpose:** Returns to privileged EXEC mode.

**Step 6**

`show ip igmp interface [interface-id]`

**Example:**

```
Switch# show ip igmp interface gigabitethernet 1/0/1
```

**Purpose:** Verifies your entries.

**Step 7**

`copy running-config startup-config`

**Example:**

```
Switch# copy running-config
```

**Purpose:** (Optional) Saves your entries in the configuration file.
Configuring IGMP Profiles (CLI)

To configure an IGMP profile, use the `ip igmp profile` global configuration command with a profile number to create an IGMP profile and to enter IGMP profile configuration mode. From this mode, you can specify the parameters of the IGMP profile to be used for filtering IGMP join requests from a port. When you are in IGMP profile configuration mode, you can create the profile by using these commands:

- `deny` — Specifies that matching addresses are denied; this is the default.
- `exit` — Exits from igmp-profile configuration mode.
- `no` — Negates a command or returns to its defaults.
- `permit` — Specifies that matching addresses are permitted.
- `range` — Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with a start and an end address.

The default is for the switch to have no IGMP profiles configured. When a profile is configured, if neither the `permit` nor `deny` keyword is included, the default is to deny access to the range of IP addresses.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp profile profile number`
4. `permit | deny`
5. `range ip multicast address`
6. `end`
7. `show ip igmp profile profile number`
8. `copy running-config startup-config`

**DETAILED STEPS**

</tbody>
</table>
Setting the Maximum Number of IGMP Groups (CLI)

You can set the maximum number of IGMP groups that a Layer 2 interface can join by using the `ip igmp max-groups` interface configuration command. Use the `no` form of this command to set the maximum back to the default, which is no limit.

This restriction can be applied to Layer 2 ports only; you cannot set a maximum number of IGMP groups on routed ports or SVIs. You also can use this command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

Beginning in privileged EXEC mode, follow these steps to set the maximum number of IGMP groups in the forwarding table:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp max-groups number
5. end
6. show running-config interface interface-id
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>

<th>Purpose</th>
</tr>
</thead>
</table>
| 3    | `interface interface-id` | Specifies the interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or a EtherChannel interface. **Example:**

```bash
Switch(config)# interface gigabitethernet1/0/2
```
| 4    | `ip igmp max-groups number` | Sets the maximum number of IGMP groups that the interface can join. The range is 0 to 4294967294. The default is to have no maximum set. **Note** The switch supports a maximum number of 4096 Layer 2 IGMP groups and 2048 Layer 3 IGMP groups. **Example:**

```bash
Switch(config-if)# ip igmp max-groups 20
```
| 5    | `end` | Returns to privileged EXEC mode. **Example:**

```bash
Switch(config-if)# end
```
| 6    | `show running-config interface interface-id` | Verifies your entries. **Example:**

```bash
Switch# show running-config interface gigabitethernet1/0/1
```
| 7    | `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. **Example:**

```bash
Switch# copy running-config startup-config
```

### Configuring the IGMP Throttling Action (CLI)

After you set the maximum number of IGMP groups that a Layer 2 interface can join, you can configure an interface to replace the existing group with the new group for which the IGMP report was received by using the `ip igmp max-groups action replace` interface configuration command. Use the `no` form of this command to return to the default, which is to drop the IGMP join report.

Follow these guidelines when configuring the IGMP throttling action:

- This restriction can be applied only to Layer 2 ports. You can use this command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

- When the maximum group limitation is set to the default (no maximum), entering the `ip igmp max-groups action {deny | replace}` command has no effect.
• If you configure the throttling action and set the maximum group limitation after an interface has added multicast entries to the forwarding table, the forwarding-table entries are either aged out or removed, depending on the throttling action.

• If you configure the throttling action as **deny**, the entries that were previously in the forwarding table are not removed but are aged out. After these entries are aged out and the maximum number of entries is in the forwarding table, the switch drops the next IGMP report received on the interface.

• If you configure the throttling action as **replace**, the entries that were previously in the forwarding table are removed. When the maximum number of entries is in the forwarding table, the switch replaces a randomly selected entry with the received IGMP report.

To prevent the switch from removing the forwarding-table entries, you can configure the IGMP throttling action before an interface adds entries to the forwarding table.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface interface-id**
4. **ip igmp max-groups action {deny | replace}**
5. **end**
6. **show running-config interface interface-id**
7. **copy running-config startup-config**

**DETAILED STEPS**

### How to Configure IGMP Snooping

#### Enabling or Disabling IGMP Snooping on a Switch (CLI)

By default, IGMP snooping is globally enabled on the switch. When globally enabled or disabled, it is also enabled or disabled in all existing VLAN interfaces. IGMP snooping is by default enabled on all VLANs, but can be enabled and disabled on a per-VLAN basis.

Global IGMP snooping overrides the VLAN IGMP snooping. If global snooping is disabled, you cannot enable VLAN snooping. If global snooping is enabled, you can enable or disable VLAN snooping.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping
4. end
5. copy running-config startup-config

### Setting the Snooping Method (CLI)

Multicast-capable router ports are added to the forwarding table for every Layer 2 multicast entry. The switch learns of the ports through one of these methods:

- Snooping on IGMP queries
- Statically connecting to a multicast router port using the `ip igmp snooping mrouting` global configuration command

Beginning in privileged EXEC mode, follow these steps to alter the method in which a VLAN interface accesses a multicast router:
SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp snooping vlan vlan-id mrouter interface {GigabitEthernet | Port-Channel | TenGigabitEthernet}
4. end
5. show ip igmp snooping
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  enable</td>
<td>Enables privileged EXEC mode. • Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Switch&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2  configure terminal</td>
<td>Enters the global configuration mode.</td>

<td></td>
</tr>
<tr>
<td>Step 5  show ip igmp snooping</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td>Example: Switch# show ip igmp snooping</td>
<td></td>
</tr>
<tr>
<td>Step 6  copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example: Switch# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
Configuring a Multicast Router Port (CLI)

To add a multicast router port (add a static connection to a multicast router), use the `ip igmp snooping vlan mrouter` global configuration command on the switch.

**Note**
Static connections to multicast routers are supported only on switch ports.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id mrouter interface interface-id`
4. `end`
5. `show ip igmp snooping mrouter [vlan vlan-id]`
6. `copy running-config startup-config`

### Configuring a Host Statically to Join a Group (CLI)

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure a host on an interface.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id static ip_address interface interface-id`
4. `end`
5. `show ip igmp snooping groups`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: <code>Switch&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: <code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip igmp snooping vlan vlan-id static ip_address interface interface-id</code></td>
<td>Statically configures a Layer 2 port as a member of a multicast group:</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

| Switch(config)# ip igmp snooping vlan 105 static 230.0.0.1 interface gigabitethernet1/0/1 |

**Purpose**

- **vlan-id** is the multicast group VLAN ID. The range is 1 to 1001 and 1006 to 4094.
- **ip-address** is the group IP address.
- **interface-id** is the member port. It can be a physical interface or a port channel (1 to 128).

**Note**

To remove the Layer 2 port from the multicast group, use the `no ip igmp snooping vlan vlan-id static mac-address interface interface-id` global configuration command.

### Step 4

**end**

**Example:**

Switch(config)# end

**Purpose**

Returns to privileged EXEC mode.

### Step 5

**show ip igmp snooping groups**

**Example:**

Switch# show ip igmp snooping groups

**Purpose**

Verifies the member port and the IP address.

### Step 6

**copy running-config startup-config**

**Example:**

Switch# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

### Enabling IGMP Immediate Leave (CLI)

When you enable IGMP Immediate Leave, the switch immediately removes a port when it detects an IGMP Version 2 leave message on that port. You should only use the Immediate-Leave feature when there is a single receiver present on every port in the VLAN.

**Note**

Immediate Leave is supported only on IGMP Version 2 hosts. IGMP Version 2 is the default version for the switch.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip igmp snooping vlan vlan-id immediate-leave**
4. **end**
5. **show ip igmp snooping vlan vlan-id**
### Configuring the IGMP Leave Timer (CLI)

Follow these guidelines when configuring the IGMP leave timer:

- You can configure the leave time globally or on a per-VLAN basis.
- Configuring the leave time on a VLAN overrides the global setting.
- The default leave time is 1000 milliseconds.

---

#### 6. copy running-config startup-config

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters the global configuration mode. |
| configure terminal|         |
| **Example:**      |         |
| Switch# configure terminal |         |

| **Step 3**        | Enables IGMP Immediate Leave on the VLAN interface. |
| ip igmp snooping vlan vlan-id immediate-leave |         |
| **Example:**      | To disable IGMP Immediate Leave on a VLAN, use the **no ip igmp snooping vlan vlan-id immediate-leave** global configuration command. |
| Switch(config)# ip igmp snooping vlan 21 immediate-leave |         |

| **Step 4**        | Returns to privileged EXEC mode. |
| end               |         |
| **Example:**      |         |
| Switch(config)# end |         |

| **Step 5**        | Verifies that Immediate Leave is enabled on the VLAN interface. |
| show ip igmp snooping vlan vlan-id |         |
| **Example:**      |         |
| Switch# show ip igmp snooping vlan 21 |         |

| **Step 6**        | (Optional) Saves your entries in the configuration file. |
| copy running-config startup-config |         |
| **Example:**      |         |
| Switch# copy running-config startup-config |         |
• The IGMP configurable leave time is only supported on hosts running IGMP Version 2. IGMP version 2 is the default version for the switch.

• The actual leave latency in the network is usually the configured leave time. However, the leave time might vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp snooping last-member-query-interval time
4. ip igmp snooping vlan vlan-id last-member-query-interval time
5. end
6. show ip igmp snooping
7. copy running-config startup-config

<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**  
To remove the configured IGMP leave-time setting from the specified VLAN, use the `no ip igmp snooping vlan vlan-id last-member-query-interval` global configuration command.

**Note**

- **Step 5**
  - `end`
  - *Example:*
  
  `Switch(config)# end`

- **Step 6**
  - `show ip igmp snooping`
  - *Example:*
  
  `Switch# show ip igmp snooping`

- **Step 7**
  - `copy running-config startup-config`
  - *Example:*
  
  `Switch# copy running-config startup-config`

### Configuring TCN-Related Commands

**Controlling the Multicast Flooding Time After a TCN Event (CLI)**

You can control the time that multicast traffic is flooded after a topology change notification (TCN) event by using the `ip igmp snooping tcn flood query count` global configuration command. This command configures the number of general queries for which multicast data traffic is flooded after a TCN event. Some examples of TCN events are when the client changed its location and the receiver is on same port that was blocked but is now forwarding, and when a port went down without sending a leave message.

If you set the TCN flood query count to 1 by using the `ip igmp snooping tcn flood query count` command, the flooding stops after receiving 1 general query. If you set the count to 7, the flooding continues until 7 general queries are received. Groups are relearned based on the general queries received during the TCN event.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip igmp snooping tcn flood query count count`
4. `end`
5. `show ip igmp snooping`
6. `copy running-config startup-config`

#### DETAILED STEPS

</tbody>
</table>

**Recovering from Flood Mode (CLI)**

When a topology change occurs, the spanning-tree root sends a special IGMP leave message (also known as global leave) with the group multicast address 0.0.0.0. However, when you enable the `ip igmp snooping tcn query solicit` global configuration command, the switch sends the global leave message whether or not it is the spanning-tree root. When the router receives this special leave, it immediately sends general queries, which expedite the process of recovering from the flood mode during the TCN event. Leaves are always sent if the switch is the spanning-tree root regardless of this configuration command. By default, query solicitation is disabled.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping tcn query solicit
4. end
5. show ip igmp snooping
6. copy running-config startup-config
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables privileged EXEC mode.</td>
<td><code>enable</code></td>
<td>Switch&gt; <code>enable</code></td>
</tr>
<tr>
<td>Enters the global configuration mode.</td>
<td><code>configure terminal</code></td>
<td>Switch# <code>configure terminal</code></td>
</tr>
<tr>
<td>Sends an IGMP leave message (global leave) to speed the process of recovering from the flood mode caused during a TCN event. By default, query solicitation is disabled. To return to the default query solicitation, use the <code>no ip igmp snooping tcn query solicit</code> global configuration command.</td>
<td><code>ip igmp snooping tcn query solicit</code></td>

<td><code>copy running-config startup-config</code></td>
<td>Switch# <code>copy running-config startup-config</code></td>
</tr>
</tbody>
</table>

### Disabling Multicast Flooding During a TCN Event (CLI)

When the switch receives a TCN, multicast traffic is flooded to all the ports until 2 general queries are received. If the switch has many ports with attached hosts that are subscribed to different multicast groups, this flooding might exceed the capacity of the link and cause packet loss. You can use the `ip igmp snooping tcn flood` interface configuration command to control this operation function.

### SUMMARY STEPS

1. `enable`
2. configure terminal  
3. interface interface-id  
4. no ip igmp snooping tcn flood  
5. end  
6. show ip igmp snooping  
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Switch> enable |
| **Step 2** configure terminal | Enters the global configuration mode.  
  Example:  
  Switch# configure terminal |
| **Step 3** interface interface-id | Specifies the interface to be configured, and enters interface configuration mode.  
  Example:  
  Switch(config)# interface gigabitethernet 1/0/1 |
| **Step 4** no ip igmp snooping tcn flood | Disables the flooding of multicast traffic during a spanning-tree TCN event.  
  By default, multicast flooding is enabled on an interface.  
  Note To re-enable multicast flooding on an interface, use the ip igmp snooping tcn flood interface configuration command.  
  Example:  
  Switch(config-if)# no ip igmp snooping tcn flood |
| **Step 5** end | Returns to privileged EXEC mode.  
  Example:  
  Switch(config)# end |
| **Step 6** show ip igmp snooping | Verifies the TCN settings.  
  Example:  
  Switch# show ip igmp snooping |
Configuring the IGMP Snooping Querier (CLI)

Follow these guidelines when configuring the IGMP snooping querier:

- Configure the VLAN in global configuration mode.
- Configure an IP address on the VLAN interface. When enabled, the IGMP snooping querier uses the IP address as the query source address.
- If there is no IP address configured on the VLAN interface, the IGMP snooping querier tries to use the configured global IP address for the IGMP querier. If there is no global IP address specified, the IGMP querier tries to use the VLAN switch virtual interface (SVI) IP address (if one exists). If there is no SVI IP address, the switch uses the first available IP address configured on the switch. The first IP address available appears in the output of the `show ip interface` privileged EXEC command. The IGMP snooping querier does not generate an IGMP general query if it cannot find an available IP address on the switch.
- The IGMP snooping querier supports IGMP Versions 1 and 2.
- When administratively enabled, the IGMP snooping querier moves to the nonquerier state if it detects the presence of a multicast router in the network.
- When it is administratively enabled, the IGMP snooping querier moves to the operationally disabled state under these conditions:
  - IGMP snooping is disabled in the VLAN.
  - PIM is enabled on the SVI of the corresponding VLAN.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp snooping querier
4. ip igmp snooping querier address ip_address
5. ip igmp snooping querier query-interval interval-count
6. ip igmp snooping querier tcn query [count count | interval interval]
7. ip igmp snooping querier timer expiry timeout
8. ip igmp snooping querier version version
9. end
10. show ip igmp snooping vlan vlan-id
11. copy running-config startup-config
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters the global configuration mode. |
| `configure terminal` | |
| **Example:**      | |
| `Switch# configure terminal` | |

| **Step 3**        | Enables the IGMP snooping querier. |
| `ip igmp snooping querier` | |
| **Example:**      | |
| `Switch(config)# ip igmp snooping querier` | |

| **Step 4**        | (Optional) Specifies an IP address for the IGMP snooping querier. If you do not specify an IP address, the querier tries to use the global IP address configured for the IGMP querier. |
| `ip igmp snooping querier address ip_address` | |
| **Example:**      | The IGMP snooping querier does not generate an IGMP general query if it cannot find an IP address on the switch. |
| `Switch(config)# ip igmp snooping querier address 172.16.24.1` | **Note** |

| **Step 5**        | (Optional) Sets the interval between IGMP queriers. The range is 1 to 18000 seconds. |
| `ip igmp snooping querier query-interval interval-count` | |
| **Example:**      | |
| `Switch(config)# ip igmp snooping querier query-interval 30` | |

| **Step 6**        | (Optional) Sets the time between Topology Change Notification (TCN) queries. The count range is 1 to 10. The interval range is 1 to 255 seconds. |
| `ip igmp snooping querier tcn query [count count | interval interval]` | |
| **Example:**      | |
| `Switch(config)# ip igmp snooping querier tcn query interval 20` | |

| **Step 7**        | (Optional) Sets the length of time until the IGMP querier expires. The range is 60 to 300 seconds. |
| `ip igmp snooping querier timer expiry timeout` | |
| **Example:**      | |
| `Switch(config)# ip igmp snooping querier timer expiry 180` | |
**Disabling IGMP Report Suppression (CLI)**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 8</strong></td>
<td>ip igmp snooping querier version <em>version</em></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# ip igmp snooping querier version 2</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>show ip igmp snooping vlan <em>vlan-id</em></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# show ip igmp snooping vlan 30</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>copy running-config startup-config</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

**Disabling IGMP Report Suppression (CLI)**

**Note**

IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

IGMP report suppression is enabled by default. When it is enabled, the switch forwards only one IGMP report per multicast router query. When report suppression is disabled, all IGMP reports are forwarded to the multicast routers.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no ip igmp snooping report-suppression
4. end
5. show ip igmp snooping
6. copy running-config startup-config

**Monitoring IGMP**

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

**Note**

This release does not support per-route statistics.
You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 27: Commands for Displaying System and Network Statistics**

## Displaying IGMP Filtering and Throttling Configuration

You can display IGMP profile characteristics, and you can display the IGMP profile and maximum group configuration for all interfaces on the switch or for a specified interface. You can also display the IGMP throttling configuration for all interfaces on the switch or for a specified interface.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `show ip igmp snooping groups [ count | [vlan vlan-id] [A.B.C.D | count ] ]` | Displays multicast table information for the switch or about a specific parameter:  
- `count`—Displays the total number of groups.  
- `vlan`—Displays group information by VLAN ID. |
| `show ip igmp snooping igmpv2-tracking` | Displays the IGMP snooping tracking.  
**Note** This command displays group and IP address entries only for wireless multicast IGMP joins and not for wired IGMP joins. Wireless IP multicast must be enabled for this command to display. |
| `show ip igmp snooping mrouter [vlan vlan-id]` | Displays information on dynamically learned and manually configured multicast router interfaces.  
**Note** When you enable IGMP snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces.  
(Optional) Enter `vlan vlan-id` to display information for a single VLAN. |
| `show ip igmp snooping querier [ detail | vlan vlan-id]` | Displays information about the IP address and receiving port for the most-recently received IGMP query messages in the VLAN.  
(Optional) Enter `detail` to display the detailed IGMP querier information in a VLAN.  
(Optional) Enter `vlan vlan-id` to display information for a single VLAN. |
| `show ip igmp snooping [vlan vlan-id [ detail ] ]` | Displays the snooping configuration information for all VLANs on the switch or for a specified VLAN.  
(Optional) Enter `vlan vlan-id` to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| `show ip igmp snooping wireless mgid` | Displays wireless-related events. |

### Configuration Examples for IGMP

#### Example: Configuring the Switch as a Member of a Multicast Group

This example shows how to enable the switch to join multicast group 255.2.2.2:

```
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ip igmp join-group 255.2.2.2
```

**Related Topics**
- Configuring the Switch as a Member of a Group (CLI), on page 176
- Joining a Multicast Group, on page 170
- IP Multicast Group Addresses, on page 168

#### Example: Controlling Access to Multicast Groups

To limit the number of joins on the interface, configure the port for filter which associates with the IGMP profile.

```
Switch# configure terminal
Switch(config)# ip igmp profile 10
Switch(config-igmp-profile)# ?
```

IGMP profile configuration commands:
- `deny` matching addresses are denied
- `exit` Exit from igmp profile configuration mode
- `no` Negate a command or set its defaults
- `permit` matching addresses are permitted
- `range` add a range to the set

```
Switch(config-igmp-profile)# range 172.16.5.1
Switch(config-igmp-profile)# exit
Switch(config)#
Switch(config)# interface gigabitEthernet 2/0/10
Switch(config-if)# ip igmp filter 10
```
**Examples: Configuring IGMP Snooping**

This example shows how to enable a static connection to a multicast router:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 mrouter interface gigabitethernet1/0/2
Switch(config)# end
```

This example shows how to statically configure a host on a port:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 105 static 224.2.4.12 interface gigabitethernet1/0/1
Switch(config)# end
```

This example shows how to enable IGMP Immediate Leave on VLAN 130:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 130 immediate-leave
Switch(config)# end
```

This example shows how to set the IGMP snooping querier source address to 10.0.0.64:

```
Switch# configure terminal
Switch(config)# ip igmp snooping querier 10.0.0.64
Switch(config)# end
```

This example shows how to set the IGMP snooping querier maximum response time to 25 seconds:

```
Switch# configure terminal
Switch(config)# ip igmp snooping querier query-interval 25
Switch(config)# end
```

This example shows how to set the IGMP snooping querier timeout to 60 seconds:

```
Switch# configure terminal
Switch(config)# ip igmp snooping querier timer expiry 60
Switch(config)# end
```

This example shows how to set the IGMP snooping querier feature to Version 2:

```
Switch# configure terminal
Switch(config)# no ip igmp snooping querier version 2
Switch(config)# end
```

Examples: Configuring Filtering and Throttling

This example shows how to create IGMP profile 4 allowing access to the single IP multicast address and how to verify the configuration. If the action was to deny (the default), it would not appear in the show ip igmp profile output display.

Switch(config)# ip igmp profile 4
Switch(config-igmp-profile)# permit
Switch(config-igmp-profile)# range 229.9.9.0
Switch(config-igmp-profile)# end
Switch# show ip igmp profile 4
IGMP Profile 4
    permit
    range 229.9.9.0 229.9.9.0

This example shows how to apply IGMP profile 4 to a port:

Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ip igmp filter 4
Switch(config-if)# end

This example shows how to limit to 25 the number of IGMP groups that a port can join:

Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ip igmp max-groups 25
Switch(config-if)# end

Example: Interface Configuration as a Routed Port

This example shows how to configure an interface on the switch as a routed port. This configuration is required on the interface for several IP multicast routing configuration procedures that require running the no switchport command.

Switch configure terminal
Switch(config)# interface GigabitEthernet1/0/9
Switch(config-if)# description interface to be use as routed port
Switch(config-if)# no switchport
Switch(config-if)# ip address 20.20.20.1 255.255.255.0
Switch(config-if)# ip pim sparse-dense-mode
Switch(config-if)# ip igmp join-group 224.1.2.3 source 15.15.15.2
Switch(config-if)# end
Switch# configure terminal
Switch# show run interface gigabitEthernet 1/0/9

Current configuration : 166 bytes
! interface GigabitEthernet1/0/9
no switchport
ip address 20.20.20.1 255.255.255.0
ip pim sparse-dense-mode
Example: Interface Configuration as an SVI

This example shows how to configure an interface on the switch as an SVI. This configuration is required on the interface for several IP multicast routing configuration procedures that require running the `no switchport` command.

```
Switch(config)# interface vlan 150
Switch(config-if)# ip address 20.20.20.1 255.255.255.0
Switch(config-if)# ip pim sparse-dense-mode
Switch(config-if)# ip igmp join-group 224.1.2.3 source 15.15.15.2
Switch(config-if)# end
Switch(config)# configure terminal
Switch(config)# ip igmp snooping vlan 20 static 224.1.2.3
interface gigabitEthernet 1/0/9
Switch(config)# show run interface vlan 150

Current configuration : 137 bytes
!
interface Vlan150
  ip address 20.20.20.1 255.255.255.0
  ip pim sparse-dense-mode
  ip igmp static-group 224.1.2.3 source 15.15.15.2
end
```

Where to Go Next for IGMP

You can configure the following:

- Wireless Multicast
- PIM
- SSM
- IP Multicast Routing
- Service Discovery Gateway

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Wireless Multicast

• The IP multicast routing must be enabled and the PIM version and PIM mode must be configured. The default routes should be available in the device. After performing these tasks, the device can then forward multicast packets and can populate its multicast routing table.

• To participate in IP multicasting, the multicast hosts, routers, and multilayer switches must have IGMP operating.

• When enabling multicast mode on the switch, a CAPWAP multicast group address should also be configured. Access points listen to the CAPWAP multicast group using IGMP.

Restrictions for Configuring Wireless Multicast

The following are the restrictions for configuring IP multicast routing:
Information About Wireless Multicast

If the network supports packet multicasting, the multicast method that the switch uses can be configured. The switch performs multicasting in two modes:

- **Unicast mode**—The switch unicasts every multicast packet to every access point associated to the switch. This mode is inefficient but might be required on networks that do not support multicasting.
- **Multicast mode**—The switch sends multicast packets to a CAPWAP multicast group. This method reduces overhead on the switch processor and shifts the work of packet replication to the network, which is much more efficient than the unicast method.

When the multicast mode is enabled and the switch receives a multicast packet from the wired LAN, the switch encapsulates the packet using CAPWAP and forwards the packet to the CAPWAP multicast group address. The switch always uses the management VLAN for sending multicast packets. Access points in the multicast group receive the packet and forward it to all the BSSIDs mapped to the VLAN on which clients receive multicast traffic.

The switch supports all the capabilities of v1 including Multicast Listener Discovery (MLD) v1 snooping but the v2 and v3 capabilities are limited. This feature keeps track of and delivers IPv6 multicast flows to the clients that request them. To support IPv6 multicast, global multicast mode should be enabled.

Internet Group Management Protocol (IGMP) snooping is introduced to better direct multicast packets. When this feature is enabled, the switch snooping gathers IGMP reports from the clients, processes them, creates unique multicast group IDs (MGIDs) based on the Layer 3 multicast address and the VLAN number, and sends the IGMP reports to the IGMP querier. The switch then updates the access point MGID table on the access point with the client MAC address. When the switch receives multicast traffic for a particular multicast group, it forwards it to all the access points, but only those access points that have active clients listening or subscribed to that multicast group send multicast traffic on that particular VLAN. IP packets are forwarded with an MGID that is unique for an ingress VLAN and the destination multicast group. Layer 2 multicast packets are forwarded with an MGID that is unique for the ingress VLAN.

MGID is a 14-bit value filled in the 16-bit reserved field of wireless information in CAPWAP header. The remaining 2 bits should be set to zero.

Information About Multicast Optimization

Multicast used to be based on the group of the multicast addresses and the VLAN as one entity, MGID. With the VLAN group, duplicate packets might increase. Using the VLAN group feature, every client listens to the multicast stream on a different VLAN. As a result, the switch creates different MGIDs for each multicast address and VLAN. Therefore, in a worst case situation, the upstream router sends one copy for each VLAN,
which results in as many copies as the number of VLANs in the group. Because the WLAN remains the same for all clients, multiple copies of the multicast packet are sent over the wireless network. To suppress the duplication of a multicast stream on the wireless medium between the switch and the access points, the multicast optimization feature can be used.

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the switch can be configured as a multicast VLAN where multicast groups are registered. The clients are allowed to listen to a multicast stream on the multicast VLAN. The MGID is generated using the multicast VLAN and multicast IP addresses. If multiple clients on different VLANs of the same WLAN are listening to a single multicast IP address, a single MGID is generated. The switch makes sure that all multicast streams from the clients on this VLAN group always go out on the multicast VLAN to ensure that the upstream router has one entry for all the VLANs of the VLAN group. Only one multicast stream hits the VLAN group even if the clients are on different VLANs. Therefore, the multicast packets that are sent out over the network is just one stream.

# How to Configure Wireless Multicast

## Configuring Wireless Multicast-MCMC Mode (CLI)

### SUMMARY STEPS

1. enable
2. configure terminal
3. wireless multicast
4. ap capwap multicast ipaddr
5. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>

<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

Command or Action | Purpose
---|---
Step 3 wireless multicast | Enables the multicast traffic for wireless clients. The default value is disable. Add `no` in the command to disable the multicast traffic for wireless clients.

**Example:**

```
Switch(config)# wireless multicast
Switch(config)# no wireless multicast
```

Step 4 ap capwap multicast ipaddr | Enables the forwarding mode in multicast. Add `no` in the command to disable the multicast mode.

**Example:**

```
Switch(config)# ap capwap multicast 231.1.1.1
Switch(config)# no ap capwap multicast 231.1.1.1
```

Step 5 end | Exits the configuration mode. Alternatively, press `Ctrl-Z` to exit the configuration mode.

**Example:**

```
Switch(config)# end
```

## Configuring IP Multicast VLAN for WLAN (CLI)

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `wlan wlan_name`
4. `shutdown`
5. `ip multicast vlan {vlan_name vlan_id}`
6. `no shutdown`
7. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | Enables privileged EXEC mode.  
  * Enter your password if prompted. |
| `enable` | Enters global command mode. |
| **Example:** | Switch> `enable` |
| **Step 2** | Enters the configuration mode to configure various parameters in the WLAN. |
| `configure terminal` | |
| **Example:** | Switch# `configure terminal` |
| **Step 3** | Disables WLAN. |
| `wlan wlan_name` | |
| **Example:** | Switch(config)# `wlan test 1` |
| **Step 4** | Configures multicast VLAN for WLAN. Add `no` in the command to disable the multicast VLAN for WLAN. |
| `shutdown` | |
| **Example:** | Switch(config-wlan)# `shutdown` |
| **Step 5** | Enables the disabled WLAN. |
| `ip multicast vlan {vlan_name vlan_id}` | |
| **Example:** | Switch(config-wlan)# `ip multicast vlan 5`  
Switch(config-wlan)# `no ip multicast vlan 5` |
| **Step 6** | Exits the configuration mode. Alternatively, press `Ctrl-Z` to exit the configuration mode. |
| `no shutdown` | |
| **Example:** | Switch(config-wlan)# `no shutdown` |
Monitoring Wireless Multicast

Table 30: Commands for Monitoring Wireless Multicast

<table>

<tbody>
<tr>
<td>show wireless multicast</td>
<td>Displays the multicast status and IP multicast mode, each VLAN's broadcast and non-IP multicast status. Also displays the mDNS bridging state.</td>
</tr>
<tr>
<td>show wireless multicast group summary</td>
<td>Displays all (Source, Group and VLAN) lists and the corresponding MGID value.</td>
</tr>
<tr>
<td>show wireless multicast [source source] group group vlan vlanid</td>
<td>Displays details of the given (S,G,V) and shows all of the clients associated with it and their MC2UC status.</td>
</tr>
<tr>
<td>show ip igmp snooping wireless mcast-spi-count</td>
<td>Displays statistics of the number of multicast SPIs per MGID sent between IOS and the Wireless Controller Module.</td>
</tr>
<tr>
<td>show ip igmp snooping wireless mgid</td>
<td>Displays the MGID mappings.</td>
</tr>
<tr>
<td>show ip igmp snooping igmpv2-tracking</td>
<td>Displays the client-to-SGV mappings and SGV-to-client mappings.</td>
</tr>
<tr>
<td>show ip igmp snooping querier vlan vlanid</td>
<td>Displays IGMP querier information for the specified VLAN.</td>
</tr>
<tr>
<td>show ip igmp snooping querier detail</td>
<td>Displays detailed IGMP querier information of all the VLANs.</td>
</tr>
<tr>
<td>show ipv6 mld snooping querier vlan vlanid</td>
<td>Displays MLD querier information for the specified VLAN.</td>
</tr>
<tr>
<td>show ipv6 mld snooping wireless mgid</td>
<td>Displays MGIDs for IPv6 multicast group.</td>
</tr>
</tbody>
</table>

Where to Go Next for Wireless Multicast

You can configure the following:

- IGMP
- PIM
- SSM
- IP Multicast Routing
• Service Discovery Gateway

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring PIM

The following are the prerequisites for configuring PIM and PIM stub routing:

- Before configuring PIM stub routing, you must have IP multicast routing configured on both the stub router and the central router. You must also have PIM mode (dense-mode, sparse-mode, or sparse-dense-mode) configured on the uplink interface of the stub router.

- Before configuring PIM stub routing, you must also configure either Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing or Open Shortest Path First (OSPF) stub routing on the switch. The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior.
Restrictions for Configuring PIM

The following are the restrictions for configuring PIM:

• PIM
  • PIM is not supported when running the LAN Base feature set.

• PIM stub routing
  • The IP Services image contains complete multicast routing.
  • In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a switch that is configured with PIM stub routing.
  • The redundant PIM stub router topology is not supported. Only the nonredundant access router topology is supported by the PIM stub feature.
  • Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
  • PIM stub routing is supported when running the IP Base and IP Services feature sets.

Restrictions for Configuring Auto-RP

The following are restrictions for configuring Auto-RP (if used in your network configuration):

• Auto-RP is not supported when running the LAN Base feature set.

• If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must manually configure an RP.

• If routed interfaces are configured in sparse mode, Auto-RP can still be used if all devices are configured with a manual RP address for the Auto-RP groups.

• If routed interfaces are configured in sparse mode and you enter the ip pim autorp listener global configuration command, Auto-RP can still be used even if all devices are not configured with a manual RP address for the Auto-RP groups.

Restrictions for Configuring Auto-RP and BSR

The following are restrictions for configuring Auto-RP and BSR (if used in your network configuration):

• If your network is all Cisco routers and multilayer switches, you can use either Auto-RP or BSR.
• If you have non-Cisco routers in your network, you must use BSR.

• If you have Cisco PIMv1 and PIMv2 routers and multilayer switches and non-Cisco routers, you must use both Auto-RP and BSR. If your network includes routers from other vendors, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 device. Ensure that no PIMv1 device is located in the path a between the BSR and a non-Cisco PIMv2 device.

Note: There are two approaches to using PIMv2. You can use Version 2 exclusively in your network or migrate to Version 2 by employing a mixed PIM version environment.

• Because bootstrap messages are sent hop-by-hop, a PIMv1 device prevents these messages from reaching all routers and multilayer switches in your network. Therefore, if your network has a PIMv1 device in it and only Cisco routers and multilayer switches, it is best to use Auto-RP.

• If you have a network that includes non-Cisco routers, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 router or multilayer switch. Ensure that no PIMv1 device is on the path between the BSR and a non-Cisco PIMv2 router.

• If you have non-Cisco PIMv2 routers that need to interoperate with Cisco PIMv1 routers and multilayer switches, both Auto-RP and a BSR are required. We recommend that a Cisco PIMv2 device be both the Auto-RP mapping agent and the BSR.

Information About PIM

Protocol-Independent Multicast (PIM) is called protocol-independent because regardless of the unicast routing protocols used to populate the unicast routing table, PIM uses this information to perform multicast forwarding instead of maintaining a separate multicast routing table.

PIM can leverage whichever unicast routing protocols are used to populate the unicast routing table, including EIGRP, OSPF, BGP, or static routes. PIM uses this unicast routing information to perform the multicast forwarding function, so it is IP protocol independent. Although PIM is called a multicast routing protocol, it actually uses the unicast routing table to perform the reverse path forwarding (RPF) check function instead of building up a completely independent multicast routing table. PIM does not send and receive multicast routing updates between routers as the other routing protocols do.

PIM is defined in RFC 4601, Protocol-Independent Multicast-Sparse Mode (PIM-SM): Protocol Specification. PIM is defined in these Internet Engineering Task Force (IETF) Internet drafts:

• Protocol Independent Multicast (PIM): Motivation and Architecture
• Protocol Independent Multicast (PIM), Dense Mode Protocol Specification
• Protocol Independent Multicast (PIM), Sparse Mode Protocol Specification
• draft-ietf-idmr-igmp-v2-06.txt, Internet Group Management Protocol, Version 2
• draft-ietf-pim-v2-dm-03.txt, PIM Version 2 Dense Mode
PIM Versions

PIMv2 includes these improvements over PIMv1:

- A single, active rendezvous point (RP) exists per multicast group, with multiple backup RPs. This single RP compares to multiple active RPs for the same group in PIMv1.

- A bootstrap router (BSR) provides a fault-tolerant, automated RP discovery and distribution function that enables routers and multilayer switches to dynamically learn the group-to-RP mappings.

- Sparse mode and dense mode are properties of a group, as opposed to an interface.

**Note**

We strongly recommend using sparse-dense mode as opposed to either sparse mode or dense mode only.

- PIM join and prune messages have more flexible encoding for multiple address families.

- A more flexible hello packet format replaces the query packet to encode current and future capability options.

- Register messages sent to an RP specify whether they are sent by a border router or a designated router.

- PIM packets are no longer inside IGMP packets; they are standalone packets.

PIMv1 and PIMv2 Interoperability

To avoid misconfiguring multicast routing on your switch, review the information in this section.

The Cisco PIMv2 implementation provides interoperability and transition between Version 1 and Version 2, although there might be some minor problems.

You can upgrade to PIMv2 incrementally. PIM Versions 1 and 2 can be configured on different routers and multilayer switches within one network. Internally, all routers and multilayer switches on a shared media network must run the same PIM version. Therefore, if a PIMv2 device detects a PIMv1 device, the Version 2 device downgrades itself to Version 1 until all Version 1 devices have been shut down or upgraded.

PIMv2 uses the BSR to discover and announce RP-set information for each group prefix to all the routers and multilayer switches in a PIM domain. PIMv1, together with the Auto-RP feature, can perform the same tasks as the PIMv2 BSR. However, Auto-RP is a standalone protocol, separate from PIMv1, and is a proprietary Cisco protocol. PIMv2 is a standards track protocol in the IETF.

**Note**

We recommend that you use PIMv2. The BSR function interoperates with Auto-RP on Cisco routers and multilayer switches.

When PIMv2 devices interoperate with PIMv1 devices, Auto-RP should have already been deployed. A PIMv2 BSR that is also an Auto-RP mapping agent automatically advertises the RP elected by Auto-RP. That is, Auto-RP sets its single RP on every router or multilayer switch in the group. Not all routers and switches in the domain use the PIMv2 hash function to select multiple RPs.

Dense-mode groups in a mixed PIMv1 and PIMv2 region need no special configuration; they automatically interoperate.
Sparse-mode groups in a mixed PIMv1 and PIMv2 region are possible because the Auto-RP feature in PIMv1 interoperates with the PIMv2 RP feature. Although all PIMv2 devices can also use PIMv1, we recommend that the RPs be upgraded to PIMv2. To ease the transition to PIMv2, we recommend:

- Using Auto-RP throughout the region.
- Configuring sparse-dense mode throughout the region.

If Auto-RP is not already configured in the PIMv1 regions, configure Auto-RP.

**PIM Modes**

PIM can operate in dense mode (DM), sparse mode (SM), or in sparse-dense mode (PIM DM-SM), which handles both sparse groups and dense groups at the same time.

**PIM DM**

PIM DM builds source-based multicast distribution trees. In dense mode, a PIM DM router or multilayer switch assumes that all other routers or multilayer switches forward multicast packets for a group. If a PIM DM device receives a multicast packet and has no directly connected members or PIM neighbors present, a prune message is sent back to the source to stop unwanted multicast traffic. Subsequent multicast packets are not flooded to this router or switch on this pruned branch because branches without receivers are pruned from the distribution tree, leaving only branches that contain receivers.

When a new receiver on a previously pruned branch of the tree joins a multicast group, the PIM DM device detects the new receiver and immediately sends a graft message up the distribution tree toward the source. When the upstream PIM DM device receives the graft message, it immediately puts the interface on which the graft was received into the forwarding state so that the multicast traffic begins flowing to the receiver.

**PIM-SM**

PIM-SM uses shared trees and shortest-path-trees (SPTs) to distribute multicast traffic to multicast receivers in the network. In PIM-SM, a router or multilayer switch assumes that other routers or switches do not forward multicast packets for a group, unless there is an explicit request for the traffic (join message). When a host joins a multicast group using IGMP, its directly connected PIM-SM device sends PIM join messages toward the root, also known as the rendezvous point (RP). This join message travels router-by-router toward the root, constructing a branch of the shared tree as it goes.

The RP keeps track of multicast receivers. It also registers sources through register messages received from the source’s first-hop router (designated router [DR]) to complete the shared tree path from the source to the receiver. When using a shared tree, sources must send their traffic to the RP so that the traffic reaches all receivers.

Prune messages are sent up the distribution tree to prune multicast group traffic. This action permits branches of the shared tree or SPT that were created with explicit join messages to be torn down when they are no longer needed.

When the number of PIM-enabled interfaces exceeds the hardware capacity and PIM-SM is enabled with the SPT threshold is set to infinity, the switch does not create (source, group (S, G)) entries in the multicast routing table for the some directly connected interfaces if they are not already in the table. The switch might not correctly forward traffic from these interfaces.
Multicast Source Discovery Protocol (MSDP)

Multicast Source Discovery Protocol (MSDP) is used for inter-domain source discovery when PIM SM is used. Each PIM administrative domain has its own RP. In order for the RP in one domain to signal new sources to the RP in the other domain, MSDP is used.

When RP in a domain receives a PIM register message for a new source, with MSDP configured it sends a new source-active (SA) message to all its MSDP peers in other domains. Each intermediate MSDP peer floods this SA message away from the originating RP. The MSDP peers install this SA message in their MSDP sa-cache. If the RPs in other domains have any join requests for the group in the SA message (indicated by the presence of a (*,G) entry with non empty outgoing interface list), the domain is interested in the group, and the RP triggers an (S,G) join toward the source.

PIM Stub Routing

The PIM stub routing feature, available in all of the switch software images, reduces resource usage by moving routed traffic closer to the end user.

The PIM stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces: uplink PIM interfaces and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards IGMP traffic.

In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a switch that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IP multicast routing and configure only the switch as a PIM stub router. The switch does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the switch. The switch uplink port cannot be used with SVIs. If you need PIM for an SVI uplink port, you should upgrade to the IP Services feature set.

You must also configure EIGRP stub routing when configuring PIM stub routing on the switch. For information about this procedure, refer to the Catalyst 3850 IP Routing Configuration Guide.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM asset and designated router election mechanisms are not supported on the PIM passive interfaces. Only the nonredundant access router topology is supported by the PIM stub feature. By using a nonredundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

Figure 8: PIM Stub Router Configuration

In the following figure, Switch A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts
IGMP Helper

PIM stub routing moves routed traffic closer to the end user and reduces network traffic. You can also reduce traffic by configuring a stub router (switch) with the IGMP helper feature.

You can configure a stub router (switch) with the `ip igmp helper help-address` interface configuration command to enable the switch to send reports to the next-hop interface. Hosts that are not directly connected to a downstream router can then join a multicast group sourced from an upstream network. The IGMP packets from a host wanting to join a multicast stream are forwarded upstream to the next-hop device when this feature is configured. When the upstream central router receives the helper IGMP reports or leaves, it adds or removes the interfaces from its outgoing interface list for that group.

For complete syntax and usage information for the `ip igmp helper-address` command, see the *IP Multicast Command Reference, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*.

Auto-RP

The PIM-SM protocols require the presence of a rendezvous point (RP) in the network. An RP acts as the meeting place for sources and receivers of multicast data. If a static RP configuration is used, then the configuration needs to be applied on all the routers in the multicast network. To automate this process, the Auto-RP protocol was devised.

This Cisco proprietary feature eliminates the need to manually configure the RP information in every router and multilayer switch in the network. For Auto-RP to work, you configure a Cisco router or multilayer switch as the mapping agent. It uses IP multicast to learn which routers or switches in the network are possible candidate RPs to receive candidate RP announcements. Candidate RPs periodically send multicast RP-announce messages to a particular group or group range to announce their availability.

Mapping agents listen to these candidate RP announcements and use the information to create entries in their group-to-RP mapping caches. Only one mapping cache entry is created for any group-to-RP range received, even if multiple candidate RPs are sending RP announcements for the same range. As the RP-announce messages arrive, the mapping agent selects the router or switch with the highest IP address as the active RP and stores this RP address in the group-to-RP mapping cache.
Mapping agents periodically multicast the contents of their group-to-RP mapping caches. Thus, all routers and switches automatically discover which RP to use for the groups that they support. If a router or switch fails to receive RP-discovery messages and the group-to-RP mapping information expires, it changes to a statically configured RP that was defined with the `ip pim rp-address` global configuration command. If no statically configured RP exists, the router or switch changes the group to dense-mode operation.

Multiple RPs serve different group ranges or serve as hot backups of each other.

**Related Topics**
- Setting Up Auto-RP in a New Internetwork (CLI), on page 251
- Example: Configuring Auto-RP, on page 274

### Auto-RP Benefits

Auto-RP uses IP multicast to automate the distribution of group-to-RP mappings to all Cisco routers and multilayer switches in a PIM network. Auto-RP has these benefits:

- Easy to use multiple RPs within a network to serve different group ranges.
- Provides load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Avoids inconsistent, manual RP configurations on every router and multilayer switch in a PIM network, which can cause connectivity problems.

### PIM v2 BSR

PIMv2 BSR (Bootstrap Router) is another method to distribute group-to-RP mapping information to all PIM routers and multilayer switches in the network. It eliminates the need to manually configure RP information in every router and switch in the network. However, instead of using IP multicast to distribute group-to-RP mapping information, BSR uses hop-by-hop flooding of special BSR messages to distribute the mapping information.

The BSR is elected from a set of candidate routers and switches in the domain that have been configured to function as BSRs. The election mechanism is similar to the root-bridge election mechanism used in bridged LANs. The BSR election is based on the BSR priority of the device contained in the BSR messages that are sent hop-by-hop through the network. Each BSR device examines the message and forwards out all interfaces only the message that has either a higher BSR priority than its BSR priority or the same BSR priority, but with a higher BSR IP address. Using this method, the BSR is elected.

The elected BSR sends BSR messages with a TTL of 1. Neighboring PIMv2 routers or multilayer switches receive the BSR message and multicast it out all other interfaces (except the one on which it was received) with a TTL of 1. In this way, BSR messages travel hop-by-hop throughout the PIM domain. Because BSR messages contain the IP address of the current BSR, the flooding mechanism enables candidate RPs to automatically learn which device is the elected BSR.

Candidate RPs send candidate RP advertisements showing the group range for which they are responsible to the BSR, which stores this information in its local candidate-RP cache. The BSR periodically advertises the contents of this cache in BSR messages to all other PIM devices in the domain. These messages travel hop-by-hop through the network to all routers and switches, which store the RP information in the BSR message in their local RP cache. The routers and switches select the same RP for a given group because they all use a common RP hashing algorithm.

Multicast Forwarding and Reverse Path Check

With unicast routing, routers and multilayer switches forward traffic through the network along a single path from the source to the destination host whose IP address appears in the destination address field of the IP packet. Each router and switch along the way makes a unicast forwarding decision, using the destination IP address in the packet, by looking up the destination address in the unicast routing table and forwarding the packet through the specified interface to the next hop toward the destination.

With multicasting, the source is sending traffic to an arbitrary group of hosts represented by a multicast group address in the destination address field of the IP packet. To decide whether to forward or drop an incoming multicast packet, the router or multilayer switch uses a reverse path forwarding (RPF) check on the packet as follows:

1. The router or multilayer switch examines the source address of the arriving multicast packet to decide whether the packet arrived on an interface that is on the reverse path back to the source.

2. If the packet arrives on the interface leading back to the source, the RPF check is successful and the packet is forwarded to all interfaces in the outgoing interface list (which might not be all interfaces on the router).

3. If the RPF check fails, the packet is discarded.

Some multicast routing protocols, such as DVMRP, maintain a separate multicast routing table and use it for the RPF check. However, PIM uses the unicast routing table to perform the RPF check.

Note

DVMRP is not supported on the switch.

Figure 9: RPF Check

The following figure shows port 2 receiving a multicast packet from source 151.10.3.21. The following table shows that the port on the reverse path to the source is port 1, not port 2. Because the RPF check fails, the multilayer switch discards the packet. Another multicast packet from source 151.10.3.21 is received on port 1, and the routing table shows this port is on the reverse path to the source. Because the RPF check passes, the switch forwards the packet to all port in the outgoing port list.

Consolidated Platform Configuration Guide, Cisco IOS XE 3.3SE (Catalyst 3650 Switches)
PIM Shared Tree and Source Tree

### Table 31: Routing Table Example for an RPF Check

<table>
<thead>
<tr>
<th>Network</th>
<th>Port</th>

<td>Gigabit Ethernet 1/0/3</td>
</tr>
<tr>
<td>204.1.16.0/24</td>
<td>Gigabit Ethernet 1/0/4</td>
</tr>
</tbody>
</table>

PIM uses both source trees and RP-rooted shared trees to forward datagrams. The RPF check is performed differently for each:

- If a PIM router or multilayer switch has a source-tree state (that is, an (S, G) entry is present in the multicast routing table), it performs the RPF check against the IP address of the source of the multicast packet.
- If a PIM router or multilayer switch has a shared-tree state (and no explicit source-tree state), it performs the RPF check on the RP address (which is known when members join the group).

Sparse-mode PIM uses the RPF lookup function to decide where it needs to send joins and prunes:

- (S, G) joins (which are source-tree states) are sent toward the source.
- (*,G) joins (which are shared-tree states) are sent toward the RP.

---

**Note**

DVMRP is not supported on the switch.

### PIM Shared Tree and Source Tree

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.
Figure 10: Shared Tree and Source Tree (Shortest-Path Tree)

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

![Diagram of Shared and Source Trees](https://example.com/shared-source-tree)

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software switches to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.
4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.
5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.
6. By default, reception of the first data packet prompts Router C to send a join message toward the source.
7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.
8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree.

You can configure the PIM device to stay on the shared tree. You can configure the PIM device to stay on the shared tree. For more information, see Delaying the Use of PIM Shortest-Path Tree (CLI), on page 268.

How to Configure PIM

Enabling PIM Stub Routing (CLI)

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip pim passive
5. end
6. show ip pim interface
7. show ip igmp groups detail
8. show ip mroute
9. show running-config
10. copy running-config startup-config
## Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
  **Example:**  
  `Switch> enable`  
  - Enter your password if prompted. |
| **Step 2** | `configure terminal` | Enters the global configuration mode.  
  **Example:**  
  `Switch> configure terminal` |
| **Step 3** | `interface interface-id`  
  **Example:**  
  `Switch(config)# interface gigabitethernet 1/0/1` | Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode.  
  The specified interface must be one of the following:  
  - A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217  
  - An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218  
  These interfaces must have IP addresses assigned to them. |
| **Step 4** | `ip pim passive`  
  **Example:**  
  `Switch(config-if)# ip pim passive` | Configures the PIM stub feature on the interface. |
| **Step 5** | `end`  
  **Example:**  
  `Switch(config-if)# end` | Returns to privileged EXEC mode. |
### Configuring a Rendezvous Point

You must have a rendezvous point (RP), if the interface is in sparse-dense mode and if you want to handle the group as a sparse group. You can use several methods, as described in these sections:

- Manual assignment
  
  For information about this procedure, see **Manually Assigning an RP to Multicast Groups (CLI)**, on page 249.

- As a standalone, Cisco-proprietary protocol separate from PIMv1
  
  For information about these procedures, see the following sections:
  
  - **Setting Up Auto-RP in a New Internetwork (CLI)**, on page 251
You can use Auto-RP, BSR, or a combination of both, depending on the PIM version that you are running and the types of routers in your network. For information about working with different PIM versions in your network, see PIMv1 and PIMv2 Interoperability, on page 238.

**Manually Assigning an RP to Multicast Groups (CLI)**

If the rendezvous point (RP) for a group is learned through a dynamic mechanism (such as Auto-RP or BSR), you need not perform this task for that RP.

Senders of multicast traffic announce their existence through register messages received from the source first-hop router (designated router) and forwarded to the RP. Receivers of multicast packets use RPs to join a multicast group by using explicit join messages.

Note

RPs are not members of the multicast group; they serve as a *meeting place* for multicast sources and group members.

You can configure a single RP for multiple groups defined by an access list. If there is no RP configured for a group, the multilayer switch responds to the group as dense and uses the dense-mode PIM techniques.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip pim rp-address ip-address [access-list-number] [override]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Switch&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**  
**configure terminal**  
**Example:**  
Switch# configure terminal

**Step 3**  
**ip pim rp-address ip-address [access-list-number] [override]**  
**Example:**  
Switch(config)# ip pim rp-address 10.1.1.1 20 override

**Step 4**  
**access-list access-list-number {deny | permit} source [source-wildcard]**  
**Example:**  
Switch(config)# access-list 25 permit 10.5.0.1 255.224.0.0

---

**Note**  
If there is no RP configured for a group, the switch treats the group as dense, using the dense-mode PIM techniques.

A PIM device can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain. The access list conditions specify for which groups the device is an RP.

- For `ip-address`, enter the unicast address of the RP in dotted-decimal notation.
- (Optional) For `access-list-number`, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.
- (Optional) The `override` keyword indicates that if there is a conflict between the RP configured with this command and one learned by Auto-RP or BSR, the RP configured with this command prevails.

**Purpose**  
Enters the global configuration mode.

**Purpose**  
Configures the address of a PIM RP.

By default, no PIM RP address is configured. You must configure the IP address of RPs on all routers and multilayer switches (including the RP).

**Note**  
A PIM device can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain.

**Purpose**  
Creates a standard access list, repeating the command as many times as necessary.

- For `access-list-number`, enter the access list number specified in Step 2.
- The `deny` keyword denies access if the conditions are matched.
- The `permit` keyword permits access if the conditions are matched.
- For `source`, enter the multicast group address for which the RP should be used.
- (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the
<table>

</tbody>
</table>

## Setting Up Auto-RP in a New Internetwork (CLI)

If you are setting up Auto-RP in a new internetwork, you do not need a default RP because you configure all the interfaces for sparse-dense mode.

**Note**

Omit Step 3 in the following procedure, if you want to configure a PIM router as the RP for the local group.

### SUMMARY STEPS

1. enable
2. show running-config
3. configure terminal
4. ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds
5. access-list access-list-number {deny | permit} source [source-wildcard]
6. ip pim send-rp-discovery scope ttl
7. end
8. show running-config
9. show ip pim rp mapping
10. show ip pim rp
11. copy running-config startup-config
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | Enables privileged EXEC mode.  

**Example:**

Switch> enable

- Enter your password if prompted.

| **Step 2** | Verifies that a default RP is already configured on all PIM devices and the RP in the sparse-mode network. It was previously configured with the `ip pim rp-address` global configuration command.  

**Example:**

Switch# show running-config

- This step is not required for spare-dense-mode environments.

**Note**

The selected RP should have good connectivity and be available across the network. Use this RP for the global groups (for example, 224.x.x.x and other global groups). Do not reconfigure the group address range that this RP serves. RPs dynamically discovered through Auto-RP take precedence over statically configured RPs. Assume that it is desirable to use a second RP for the local groups.

| **Step 3** | Enters the global configuration mode.  

**Example:**

Switch# configure terminal

| **Step 4** | Configures another PIM device to be the candidate RP for local groups.  

**Example:**

Switch(config)# ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds

- For `interface-id`, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs.

- For `scope ttl`, specify the time-to-live value in hops. Enter a hop count that is high enough so that the RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255.

- For `group-list access-list-number`, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.

- For `interval seconds`, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383.

### Adding Auto-RP to an Existing Sparse-Mode Cloud (CLI)

This section contains suggestions for the initial deployment of Auto-RP into an existing sparse-mode cloud to minimize disruption of the existing multicast infrastructure.

This procedure is optional.

#### SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds**
5. **access-list access-list-number {deny | permit} source [source wildcard]**
6. **ip pim send-rp-discovery scope ttl**
7. **end**
8. **show running-config**
9. **show ip pim rp mapping**
10. **show ip pim rp**
11. **copy running-config startup-config**

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch&gt; enable</td>
</tr>
</tbody>
</table>

Enables privileged EXEC mode.

- Enter your password if prompted.
<table>
<thead>
<tr>

<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td><code>ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds</code></td>
<td>Configures another PIM device to be the candidate RP for local groups.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Switch(config)# ip pim send-rp-announce gigabitethernet 1/0/5 scope 20 group-list 10 interval 120</code></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>`access-list access-list-number {deny</td>
<td>permit} source [source-wildcard]`</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Switch(config)# access-list 10 permit 224.0.0.0 15.255.255.255</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>• The <strong>permit</strong> keyword permits access if the conditions are matched.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• For <strong>source</strong> , enter the multicast group address range for which the RP should be used.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• (Optional) For <strong>source-wildcard</strong> , enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Recall that the access list is always terminated by an implicit deny statement for everything.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Step 6**  
```
ip pim send-rp-discovery scope ttl
```

**Example:**
```
Switch(config)## ip pim send-rp-discovery scope 50
```

Finds a switch whose connectivity is not likely to be interrupted, and assigns it the role of RP-mapping agent.

For **scope ttl**, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255.

**Note**  
To remove the switch as the RP-mapping agent, use the **no ip pim send-rp-discovery** global configuration command.

**Step 7**  
```
end
```

**Example:**
```
Switch(config)## end
```

Returns to privileged EXEC mode.

**Step 8**  
```
show running-config
```

**Example:**
```
Switch## show running-config
```

Verifies your entries.

**Step 9**  
```
show ip pim rp mapping
```

**Example:**
```
Switch## show ip pim rp mapping
```

Displays active RPs that are cached with associated multicast routing entries.

**Step 10**  
```
show ip pim rp
```

**Example:**
```
Switch##
```

Displays the information cached in the routing table.
Preventing Join Messages to False RPs (CLI)

Determine whether the `ip pim accept-rp` command was previously configured throughout the network by using the `show running-config` privileged EXEC command. If the `ip pim accept-rp` command is not configured on any device, this problem can be addressed later. In those routers or multilayer switches already configured with the `ip pim accept-rp` command, you must enter the command again to accept the newly advertised RP.

To accept all RPs advertised with Auto-RP and reject all other RPs by default, use the `ip pim accept-rp auto-rp` global configuration command.

This procedure is optional.

Related Topics

Example: Preventing Join Messages to False RPs, on page 275

Filtering Incoming RP Announcement Messages (CLI)

You can add configuration commands to the mapping agents to prevent a maliciously configured router from masquerading as a candidate RP and causing problems.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip pim rp-announce-filter rp-list access-list-number group-list access-list-number`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch# show ip pim rp</code></td>
<td></td>
</tr>
<tr>
<td><code>Step 11</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Switch# copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Step 2** configure terminal  
    Example: Switch# configure terminal | Enters the global configuration mode. |
| **Step 3** ip pim rp-announce-filter rp-list access-list-number  
    group-list access-list-number  
    Example: Switch(config)# ip pim rp-announce-filter rp-list 10 group-list 14 | Filters incoming RP announcement messages. Enter this command on each mapping agent in the network. Without this command, all incoming RP-announce messages are accepted by default. For **rp-list access-list-number**, configure an access list of candidate RP addresses that, if permitted, is accepted for the group ranges supplied in the **group-list access-list-number** variable. If this variable is omitted, the filter applies to all multicast groups. If more than one mapping agent is used, the filters must be consistent across all mapping agents to ensure that no conflicts occur in the group-to-RP mapping information. |
| **Step 4** access-list access-list-number {deny | permit} source  
    [source-wildcard]  
    Example: Switch(config)# access-list 10 permit 10.8.1.0 255.255.224.0 | Creates a standard access list, repeating the command as many times as necessary.  
    • For **access-list-number**, enter the access list number specified in Step 2.  
    • The **deny** keyword denies access if the conditions are matched.  
    • The **permit** keyword permits access if the conditions are matched.  
    • Create an access list that specifies from which routers and multilayer switches the mapping agent accepts candidate RP announcements (rp-list ACL).  
    • Create an access list that specifies the range of multicast groups from which to accept or deny (group-list ACL).  
    • For **source**, enter the multicast group address range for which the RP should be used.  
    • (Optional) For **source-wildcard**, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
    The access list is always terminated by an implicit deny statement for everything. |

### Configuring PIMv2 BSR

The process for configuring PIMv2 BSR may involve the following optional tasks:

- Defining the PIM domain border
- Defining the IP multicast boundary
- Configuring candidate BSRs
- Configuring candidate RPs

### Defining the PIM Domain Border (CLI)

As IP multicast becomes more widespread, the chance of one PIMv2 domain bordering another PIMv2 domain increases. Because two domains probably do not share the same set of RPs, BSR, candidate RPs, and candidate BSRs, you need to constrain PIMv2 BSR messages from flowing into or out of the domain. Allowing messages to leak across the domain borders could adversely affect the normal BSR election mechanism and elect a single BSR across all bordering domains and comingle candidate RP advertisements, resulting in the election of RPs in the wrong domain.
Figure 11: Constraining PIMv2 BSR Messages

This figure displays how you can configure the PIM domain border by using the `ip pim bsr-border` command.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip pim bsr-border`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>

<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the interface to be configured, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• A routed port—A physical port that has been configured as a Layer 3 port by entering the <code>no switchport</code> interface configuration command. You</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217  • An SVI—A VLAN interface created by using the <code>interface vlan vlan-id</code> global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218  These interfaces must have IP addresses assigned to them.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**  `ip pim bsr-border`  
Example:  
Switch(config-if)# ip pim bsr-border  
Defines a PIM bootstrap message boundary for the PIM domain.  
Enter this command on each interface that connects to other bordering PIM domains. This command instructs the switch to neither send nor receive PIMv2 BSR messages on this interface.  
**Note**  To remove the PIM border, use the no `ip pim bsr-border` interface configuration command.  

**Step 5**  `end`  
Example:  
Switch(config)# end  
Returns to privileged EXEC mode.  

**Step 6**  `show running-config`  
Example:  
Switch# show running-config  
Verifies your entries.  

**Step 7**  `copy running-config startup-config`  
Example:  
Switch# copy running-config startup-config  
(Optional) Saves your entries in the configuration file.
## Defining the IP Multicast Boundary (CLI)

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information. This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `access-list access-list-number deny source [source-wildcard]`
4. `interface interface-id`
5. `ip multicast boundary access-list-number`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

### Defining the IP Multicast Boundary (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td>Specifies the interface to be configured, and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>The specified interface must be one of the following:</td>
</tr>
<tr>
<td><code>Switch(config)# interface gigabitethernet 1/0/1</code></td>
<td>- A routed port—A physical port that has been configured as a Layer 3 port by entering the <code>no switchport</code> interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217</td>
</tr>
<tr>
<td></td>
<td>- An SVI—A VLAN interface created by using the <code>interface vlan vlan-id</code> global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218</td>
</tr>
</tbody>
</table>

These interfaces must have IP addresses assigned to them.

| **Step 5** | `ip multicast boundary access-list-number` | Configures the boundary, specifying the access list you created in Step 2. |
| **Example:** | | |
| `Switch(config-if)# ip multicast boundary 12` | | |

| **Step 6** | `end` | Returns to privileged EXEC mode. |
| **Example:** | | |
| `Switch(config-if)# end` | | |

| **Step 7** | `show running-config` | Verifies your entries. |
| **Example:** | | |
| `Switch# show running-config` | | |

| **Step 8** | `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
| **Example:** | | |
| `Switch# copy running-config startup-config` | | |
Configuring Candidate BSRs (CLI)

You can configure one or more candidate BSRs. The devices serving as candidate BSRs should have good connectivity to other devices and be in the backbone portion of the network.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim bsr-candidate interface-id hash-mask-length [priority]
4. end
5. show running-config
6. copy running-config startup-config

### Configuring the Candidate RPs (CLI)

You can configure one or more candidate RPs. Similar to BSRs, the RPs should also have good connectivity to other devices and be in the backbone portion of the network. An RP can serve the entire IP multicast address space or a portion of it. Candidate RPs send candidate RP advertisements to the BSR. When deciding which devices should be RPs, consider these options:

- In a network of Cisco routers and multilayer switches where only Auto-RP is used, any device can be configured as an RP.
- In a network that includes only Cisco PIMv2 routers and multilayer switches and with routers from other vendors, any device can be used as an RP.
- In a network of Cisco PIMv1 routers, Cisco PIMv2 routers, and routers from other vendors, configure only Cisco PIMv2 routers and multilayer switches as RPs.

This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim rp-candidate interface-id [group-list access-list-number]
4. access-list access-list-number {deny | permit} source [source-wildcard]
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable`  
Example:  
Switch> `enable` | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Step 2** | `configure terminal`  
Example:  
Switch# `configure terminal` | Enters the global configuration mode. |
| **Step 3** | `ip pim rp-candidate interface-id [group-list access-list-number]`  
Example:  
Switch(config)# `ip pim rp-candidate gigabitethernet 1/0/5 group-list 10` | Configures your switch to be a candidate RP.  
• For `interface-id`, specify the interface whose associated IP address is advertised as a candidate RP address. Valid interfaces include physical ports, port channels, and VLANs.  
• (Optional) For `group-list access-list-number`, enter an IP standard access list number from 1 to 99. If no group-list is specified, the switch is a candidate RP for all groups. |
| **Step 4** | `access-list access-list-number {deny | permit} source [source-wildcard]`  
Example:  
Switch(config)# `access-list 10 permit 239.0.0.0 0.255.255.255` | Creates a standard access list, repeating the command as many times as necessary.  
• For `access-list-number`, enter the access list number specified in Step 2.  
• The `deny` keyword denies access if the conditions are matched. The `permit` keyword permits access if the conditions are matched.  
• For `source`, enter the number of the network or host from which the packet is being sent.  
• (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
The access list is always terminated by an implicit deny statement for everything. |
| **Step 5** | `end` | Returns to privileged EXEC mode. |
### Configuring Auto-RP and BSR for the Network (CLI)

If there are only Cisco devices in your network (no routers from other vendors), there is no need to configure a BSR. Configure Auto-RP in a network that is running both PIMv1 and PIMv2.

If you have non-Cisco PIMv2 routers that need to interoperate with Cisco PIMv1 routers and multilayer switches, both Auto-RP and a BSR are required. We recommend that a Cisco PIMv2 router or multilayer switch be both the Auto-RP mapping agent and the BSR.

If you must have one or more BSRs, we have these recommendations:

- Configure the candidate BSRs as the RP-mapping agents for Auto-RP. For information about these procedures, see:
  - Configuring a Rendezvous Point, on page 248
  - Configuring Candidate BSRs (CLI), on page 264

- For group prefixes advertised through Auto-RP, the PIMv2 BSR mechanism should not advertise a subrange of these group prefixes served by a different set of RPs. In a mixed PIMv1 and PIMv2 domain, backup RPs should serve the same group prefixes. This prevents the PIMv2 DRs from selecting a different RP from those PIMv1 DRs, due to the longest match lookup in the RP-mapping database.

### Before you begin

Beginning in privileged EXEC mode, follow these steps to verify the consistency of group-to-RP mappings. This procedure is optional.

| `show ip pim rp-hash group`                            | On a PIMv2 router or multilayer switch, confirms that the same RP is the one that a PIMv1 system chooses. |
|                                                        | For **group**, enter the group address for which to display RP information. |
| Example:                                               |         |
| `Switch# show ip pim rp-hash 239.1.1.1`               |         |

Delaying the Use of PIM Shortest-Path Tree (CLI)

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change occurs because the `ip pim spt-threshold` global configuration command controls that timing.

The shortest-path tree requires more memory than the shared tree but reduces delay. You might want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

This procedure is optional.
SUMMARY STEPS

1. enable
2. configure terminal
3. access-list access-list-number {deny | permit} source [source-wildcard]
4. ip pim spt-threshold {kbps | infinity} [group-list access-list-number]
5. end
6. show running-config
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>

<tr>
<td></td>
<td>The access list is always terminated by an implicit deny statement for everything.</td>
</tr>
<tr>
<td><strong>Step 4</strong> ip pim spt-threshold {kbps</td>
<td>infinity} [group-list access-list-number]</td>
</tr>
<tr>
<td>Example:</td>
<td>• For kbps, specify the traffic rate in kilobits per second.</td>
</tr>
<tr>
<td>Switch(config)# ip pim spt-threshold</td>
<td>The default is 0 kbps.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

infinity group-list 16

**Purpose**

Because of switch hardware limitations, 0 kbps is the only valid entry even though the range is 0 to 4294967.

- Specify **infinity** if you want all sources for the specified group to use the shared tree, never switching to the source tree.
- (Optional) For **group-list access-list-number**, specify the access list created in Step 2. If the value is 0 or if the group list is not used, the threshold applies to all groups.

### Step 5

**end**

**Example:**

Switch(config)# end

Returns to privileged EXEC mode.

### Step 6

**show running-config**

**Example:**

Switch# show running-config

Verifies your entries.

### Step 7

**copy running-config startup-config**

**Example:**

Switch# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

### Modifying the PIM Router-Query Message Interval (CLI)

PIM routers and multilayer switches send PIM router-query messages to find which device will be the designated router (DR) for each LAN segment (subnet). The DR is responsible for sending IGMP host-query messages to all hosts on the directly connected LAN.

With PIM DM operation, the DR has meaning only if IGMPv1 is in use. IGMPv1 does not have an IGMP querier election process, so the elected DR functions as the IGMP querier. With PIM-SM operation, the DR is the device that is directly connected to the multicast source. It sends PIM register messages to notify the RP that multicast traffic from a source needs to be forwarded down the shared tree. In this case, the DR is the device with the highest IP address.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. configure terminal
3. interface interface-id
4. ip pim query-interval seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>

<tr>
<td><strong>Step 3</strong></td>
<td>Specifies the interface to be configured, and enters interface configuration mode.</td>
</tr>
<tr>
<td>interface interface-id</td>
<td></td>
</tr>
<tr>
<td>Example: Switch(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Configures the frequency at which the switch sends PIM router-query messages.</td>
</tr>
<tr>
<td>ip pim query-interval seconds</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

The specified interface must be one of the following:

- A routed port—A physical port that has been configured as a Layer 3 port by entering the **no switchport** interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see **Example: Interface Configuration as a Routed Port, on page 217**

- An SVI—A VLAN interface created by using the **interface vlan vlan-id** global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see **Example: Interface Configuration as an SVI, on page 218**

These interfaces must have IP addresses assigned to them.
Monitoring PIM

Use the privileged EXEC commands in the following table to monitor your PIM configurations.

Table 33: PIM Monitoring Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip pim all-vrfs tunnel [tunnel tunnel_number</td>
<td>verbose]`</td>
</tr>
<tr>
<td><code>show ip pim autorp</code></td>
<td>Displays global auto-RP information.</td>
</tr>
<tr>
<td><code>show ip pim boundary</code></td>
<td>Displays information about mroutes filtered by administratively scoped IPv4 multicast boundaries configured on an interface.</td>
</tr>
<tr>
<td><code>show ip pim interface</code></td>
<td>Displays information about interfaces configured for Protocol Independent Multicast (PIM).</td>
</tr>
<tr>
<td><code>show ip pim neighbor</code></td>
<td>Displays the PIM neighbor information.</td>
</tr>
<tr>
<td>`show ip pim tunnel [tunnel</td>
<td>verbose]`</td>
</tr>
</tbody>
</table>
PurposeCommand
DisplaystheVPNrouting/forwardinginstance.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip pim vrf \ { word \ { all-vrfs</td>
<td>autorp</td>
</tr>
</tbody>
</table>

**Monitoring RP Mapping**

Use the privileged EXEC commands in the following table to monitor RP mapping.

*Table 34: RP Mapping Monitoring Commands*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip pim bsr</td>
<td>Displays information about the elected BSR.</td>
</tr>
<tr>
<td>show ip pim bsr-router</td>
<td>Displays information about the BSRv2.</td>
</tr>
<tr>
<td>show ip pim rp [ hostname or IP address</td>
<td>mapping</td>
</tr>
<tr>
<td>show ip pim rp-hash hostname or IP group address</td>
<td>Displays the RP that was selected for the specified group.</td>
</tr>
</tbody>
</table>

**Troubleshooting PIMv1 and PIMv2 Interoperability Problems**

When debugging interoperability problems between PIMv1 and PIMv2, check these in the order shown:

1. Verify RP mapping with the `show ip pim rp-hash` privileged EXEC command, making sure that all systems agree on the same RP for the same group.
2. Verify interoperability between different versions of DRs and RPs. Make sure that the RPs are interacting with the DRs properly (by responding with register-stops and forwarding decapsulated data packets from registers).

**Configuration Examples for PIM**

**Example: Enabling PIM Stub Routing**

In this example, IP multicast routing is enabled, Switch A PIM uplink port 25 is configured as a routed uplink port with `spare-dense-mode` enabled. PIM stub routing is enabled on the VLAN 100 interfaces and on Gigabit Ethernet port 20.

```
Switch(config)# ip multicast-routing distributed
Switch(config)# interface GigabitEthernet3/0/25
```
Example: Verifying PIM Stub Routing

To verify that PIM stub is enabled for each interface, use the `show ip pim interface` privileged EXEC command:

```
Switch# show ip pim interface
Address  Interface  Ver/ Nbr  Query  DR    DR    Mode Count  Intvl  Prior
3.1.1.2   GigabitEthernet3/0/25  v2/SD  1  30  1  3.1.1.2
100.1.1.1  Vlan100  v2/P  0  30  1  100.1.1.1
10.1.1.1   GigabitEthernet3/0/20  v2/P  0  30  1  10.1.1.1
```

Example: Manually Assigning an RP to Multicast Groups

This example shows how to configure the address of the RP to 147.106.6.22 for multicast group 225.2.2.2 only:

```
Switch(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Switch(config)# ip pim rp-address 147.106.6.22 1
```

Example: Configuring Auto-RP

This example shows how to send RP announcements out all PIM-enabled interfaces for a maximum of 31 hops. The IP address of port 1 is the RP. Access list 5 describes the group for which this switch serves as RP:

```
Switch(config)# ip pim send-rp-announce gigabitethernet1/0/1 scope 31 group-list 5
Switch(config)# access-list 5 permit 224.0.0.0 15.255.255.255
Example: Defining the IP Multicast Boundary to Deny Auto-RP Information

This example shows a portion of an IP multicast boundary configuration that denies Auto-RP information:

Switch(config)# access-list 1 deny 224.0.1.39
Switch(config)# access-list 1 deny 224.0.1.40
Switch(config)# access-list 1 permit all
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ip multicast boundary 1

Example: Filtering Incoming RP Announcement Messages

This example shows a sample configuration on an Auto-RP mapping agent that is used to prevent candidate RP announcements from being accepted from unauthorized candidate RPs:

Switch(config)# ip pim rp-announce-filter rp-list 10 group-list 20
Switch(config)# access-list 10 permit host 172.16.5.1
Switch(config)# access-list 10 permit host 172.16.2.1
Switch(config)# access-list 20 deny 239.0.0.0 0.0.255.255
Switch(config)# access-list 20 permit 224.0.0.0 15.255.255.255

The mapping agent accepts candidate RP announcements from only two devices, 172.16.5.1 and 172.16.2.1. The mapping agent accepts candidate RP announcements from these two devices only for multicast groups that fall in the group range of 224.0.0.0 to 239.255.255.255. The mapping agent does not accept candidate RP announcements from any other devices in the network. Furthermore, the mapping agent does not accept candidate RP announcements from 172.16.5.1 or 172.16.2.1 if the announcements are for any groups in the 239.0.0.0 through 239.255.255.255 range. This range is the administratively scoped address range.

Example: Preventing Join Messages to False RPs

If all interfaces are in sparse mode, use a default-configured RP to support the two well-known groups 224.0.1.39 and 224.0.1.40. Auto-RP uses these two well-known groups to collect and distribute RP-mapping information. When this is the case and the `ip pim accept-rp auto-rp` command is configured, another `ip pim accept-rp` command accepting the RP must be configured as follows:

Switch(config)# ip pim accept-rp 172.10.20.1 1
Switch(config)# access-list 1 permit 224.0.1.39
Switch(config)# access-list 1 permit 224.0.1.40
Example: Configuring Candidate BSRs

This example shows how to configure a candidate BSR, which uses the IP address 172.21.24.18 on a port as the advertised BSR address, uses 30 bits as the hash-mask-length, and has a priority of 10.

```
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ip address 172.21.24.18 255.255.255.0
Switch(config-if)# ip pim sparse-dense-mode
Switch(config-if)# ip pim bsr-candidate gigabitethernet1/0/2 30 10
```

Example: Configuring Candidate RPs

This example shows how to configure the switch to advertise itself as a candidate RP to the BSR in its PIM domain. Standard access list number 4 specifies the group prefix associated with the RP that has the address identified by a port. That RP is responsible for the groups with the prefix 239.

```
Switch(config)# ip pim rp-candidate gigabitethernet1/0/2 group-list 4
Switch(config)# access-list 4 permit 239.0.0.0 0.255.255.255
```

Where to Go Next for PIM

You can configure the following:

- IGMP
- Wireless Multicast
- SSM
- IP Multicast Routing
- Service Discovery Gateway

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring SSM

The following are the prerequisites for configuring source-specific multicast (SSM) and SSM mapping:

- Before you configure SSM mapping, you must perform the following tasks:
  - Enable IP multicast routing. For information about this procedure, see Configuring Basic IP Multicast Routing (CLI), on page 301.
  - Enable PIM sparse mode. For information about this procedure, see How to Configure PIM, on page 246.
  - Configure SSM. For information about this procedure, see Configuring SSM (CLI), on page 286.

- Before you configure static SSM mapping, you must configure access control lists (ACLs) that define the group ranges to be mapped to source addresses.
• Before you can configure and use SSM mapping with DNS lookups, you must be able to add records to a running DNS server. If you do not already have a DNS server running, you need to install one.

---

**Note** You can use a product such as Cisco Network Registrar to add records to a running DNS server.

---

**Restrictions for Configuring SSM**

The following are the restrictions for configuring SSM:

• To run SSM with IGMPv3, SSM must be supported in the Cisco IOS router, the host where the application is running, and the application itself.

• The SSM mapping feature does not have all the benefits of full SSM. Because SSM mapping takes a group join from a host and identifies this group with an application associated with one or more sources, it can only support one such application per group. Full SSM applications can still share the same group as in SSM mapping.

• Enable IGMPv3 carefully on the last hop router when you rely solely on SSM mapping as a transition solution for full SSM. When you enable both SSM mapping and IGMPv3 and the hosts already support IGMPv3 (but not SSM), the hosts send IGMPv3 group reports. SSM mapping does not support these IGMPv3 group reports, and the router does not correctly associate sources with these reports.

• Existing applications in a network predating SSM do not work within the SSM range unless they are modified to support (S, G) channel subscriptions. Therefore, enabling SSM in a network can cause problems for existing applications if they use addresses within the designated SSM range.

• IGMPv3 uses new membership report messages that might not be correctly recognized by older IGMP snooping switches.

• Address management is still necessary to some degree when SSM is used with Layer 2 switching mechanisms. Cisco Group Management Protocol (CGMP), IGMP snooping, or Router-Port Group Management Protocol (RGMP) support only group-specific filtering, not (S, G) channel-specific filtering. If different receivers in a switched network request different (S, G) channels sharing the same group, they do not benefit from these existing mechanisms. Instead, both receivers receive all (S, G) channel traffic and filter out the unwanted traffic on input.

Because SSM can re-use the group addresses in the SSM range for many independent applications, this situation can lead to decreased traffic filtering in a switched network. For this reason, it is important to use random IP addresses from the SSM range for an application to minimize the chance for re-use of a single address within the SSM range between different applications. For example, an application service providing a set of television channels should, even with SSM, use a different group for each television (S, G) channel. This setup guarantees that multiple receivers to different channels within the same application service never experience traffic aliasing in networks that include Layer 2 switches.

• In PIM-SSM, the last hop router continues to periodically send (S, G) join messages if appropriate (S, G) subscriptions are on the interfaces. Therefore, as long as receivers send (S, G) subscriptions, the shortest path tree (SPT) state from the receivers to the source is maintained, even if the source does not send traffic for longer periods of time (or even never).
The opposite situation occurs with PIM-SM, where (S, G) state is maintained only if the source is sending traffic and receivers are joining the group. If a source stops sending traffic for more than 3 minutes in PIM-SM, the (S, G) state is deleted and only reestablished after packets from the source arrive again through the RPT (rendezvous point tree). Because no mechanism in PIM-SSM notifies a receiver that a source is active, the network must maintain the (S, G) state in PIM-SSM as long as receivers are requesting receipt of that channel.

**Information About SSM**

The source-specific multicast (SSM) feature is an extension of IP multicast in which datagram traffic is forwarded to receivers from only those multicast sources that the receivers have explicitly joined. For multicast groups configured for SSM, only SSM distribution trees (no shared trees) are created.

This section describes how to configure source-specific multicast (SSM). For a complete description of the SSM commands in this section, refer to the *IP Multicast Command Reference*. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

**SSM Components Overview**

SSM is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core networking technology for the Cisco implementation of IP multicast solutions targeted for audio and video broadcast application environments. The switch supports the following components that support SSM implementation:

- Protocol independent multicast source-specific mode (PIM-SSM)
  
  PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM sparse mode (PIM-SM).

- Internet Group Management Protocol version 3 (IGMPv3)

**SSM and Internet Standard Multicast (ISM)**

The current IP multicast infrastructure in the Internet and many enterprise intranets is based on the PIM-SM protocol and Multicast Source Discovery Protocol (MSDP). These protocols have the limitations of the Internet Standard Multicast (ISM) service model. For example, with ISM, the network must maintain knowledge about which hosts in the network are actively sending multicast traffic.

The ISM service consists of the delivery of IP datagrams from any source to a group of receivers called the multicast host group. The datagram traffic for the multicast host group consists of datagrams with an arbitrary IP unicast source address (S) and the multicast group address (G) as the IP destination address. Systems receive this traffic by becoming members of the host group. Membership in a host group simply requires signaling the host group through IGMP version 1, 2, or 3.

In SSM, delivery of datagrams is based on (S, G) channels. In both SSM and ISM, no signaling is required to become a source. However, in SSM, receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources. In other words, receivers can receive traffic only from (S, G) channels to which they are subscribed, whereas in ISM, receivers need not know the IP addresses of sources from which they receive their traffic. The proposed standard approach for channel subscription signaling uses IGMP and includes modes membership reports, which are supported only in IGMP version 3.
SSM IP Address Range

SSM can coexist with the ISM service by applying the SSM delivery model to a configured subset of the IP multicast group address range. Cisco IOS software allows SSM configuration for the IP multicast address range of 224.0.0.0 through 239.255.255.255. When an SSM range is defined, existing IP multicast receiver applications do not receive any traffic when they try to use an address in the SSM range (unless the application is modified to use an explicit (S, G) channel subscription).

SSM Operations

An established network, in which IP multicast service is based on PIM-SM, can support SSM services. SSM can also be deployed alone in a network without the full range of protocols required for interdomain PIM-SM (for example, MSDP, Auto-RP, or bootstrap router [BSR]) if only SSM service is needed.

If SSM is deployed in a network already configured for PIM-SM, only the last-hop routers support SSM. Routers that are not directly connected to receivers do not require support for SSM. In general, these not-last-hop routers must only run PIM-SM in the SSM range and might need additional access control configuration to suppress MSDP signalling, registering, or PIM-SM shared tree operations from occurring within the SSM range.

Use the `ip pim ssm` global configuration command to configure the SSM range and to enable SSM. This configuration has the following effects:

- For groups within the SSM range, (S, G) channel subscriptions are accepted through IGMPv3 include-mode membership reports.

- PIM operations within the SSM range of addresses change to PIM-SSM, a mode derived from PIM-SM. In this mode, only PIM (S, G) join and prune messages are generated by the router, and no (S, G) rendezvous point tree (RPT) or (*, G) RPT messages are generated. Incoming messages related to RPT operations are ignored or rejected, and incoming PIM register messages are immediately answered with register-stop messages. PIM-SSM is backward-compatible with PIM-SM unless a router is a last-hop router. Therefore, routers that are not last-hop routers can run PIM-SM for SSM groups (for example, if they do not yet support SSM).

- No MSDP source-active (SA) messages within the SSM range are accepted, generated, or forwarded.

SSM Mapping

In a typical set-top box (STB) deployment, each TV channel uses one separate IP multicast group and has one active server host sending the TV channel. A single server can send multiple TV channels, but each to a different group. In this network environment, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the report addresses the well-known TV server for the TV channel associated with the multicast group.

When SSM mapping is configured, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the router translates this report into one or more channel memberships for the well-known sources associated with this group.

When the router receives an IGMPv1 or IGMPv2 membership report for a group, the router uses SSM mapping to determine one or more source IP addresses for the group. SSM mapping then translates the membership report as an IGMPv3 report and continues as if it had received an IGMPv3 report. The router then sends PIM joins and continues to be joined to these groups as long as it continues to receive the IGMPv1 or IGMPv2 membership reports, and the SSM mapping for the group remains the same.
SSM mapping enables the last hop router to determine the source addresses either by a statically configured table on the router or through a DNS server. When the statically configured table or the DNS mapping changes, the router leaves the current sources associated with the joined groups.

**Static SSM Mapping**

With static SSM mapping, you can configure the last hop router to use a static map to determine the sources that are sending to groups. Static SSM mapping requires that you configure ACLs to define group ranges. After configuring the ACLs to define group ranges, you can then map the groups permitted by those ACLs to sources by using the `ip igmp ssm-map static` global configuration command.

You can configure static SSM mapping in smaller networks when a DNS is not needed or to locally override DNS mappings. When configured, static SSM mappings take precedence over DNS mappings.

**Related Topics**

- Configuring Static SSM Mapping (CLI), on page 288
- Configuring Static Traffic Forwarding with SSM Mapping (CLI), on page 291

**DNS-Based SSM Mapping**

You can use DNS-based SSM mapping to configure the last hop router to perform a reverse DNS lookup to determine sources sending to groups. When DNS-based SSM mapping is configured, the router constructs a domain name that includes the group address and performs a reverse lookup into the DNS. The router looks up IP address resource records and uses them as the source addresses associated with this group. SSM mapping supports up to 20 sources for each group. The router joins all sources configured for a group.

*Figure 12: DNS-Based SSM Mapping*

The following figure displays DNS-based SSM mapping:

![DNS-Based SSM Mapping Diagram](image)

The SSM mapping mechanism that enables the last hop router to join multiple sources for a group can provide source redundancy for a TV broadcast. In this context, the last hop router provides redundancy using SSM mapping to simultaneously join two video sources for the same TV channel. However, to prevent the last hop...
router from duplicating the video traffic, the video sources must use a server-side switchover mechanism. One video source is active, and the other backup video source is passive. The passive source waits until an active source failure is detected before sending the video traffic for the TV channel. Thus, the server-side switchover mechanism ensures that only one of the servers is actively sending video traffic for the TV channel.

To look up one or more source addresses for a group that includes G1, G2, G3, and G4, you must configure these DNS records on the DNS server:

\[
\text{G4.G3.G2.G1 [multicast-domain] [timeout] IN A source-address-1} \\
\text{IN A source-address-2} \\
\text{IN A source-address-n}
\]

See your DNS server documentation for more information about configuring DNS resource records.

Configuring Source Specific Multicast Mapping

The Source Specific Multicast (SSM) mapping feature supports SSM transition when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. You can use SSM mapping to leverage SSM for video delivery to legacy STBs that do not support IGMPv3 or for applications that do not use the IGMPv3 host stack.

Configuring Static SSM Mapping (CLI)

The following procedure describes how to configure static SSM mapping.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp ssm-map enable
4. no ip igmp ssm-map query dns
5. ip igmp ssm-map static access-list source-address
6. Repeat Step 4 to configure additional static SSM mappings, if required.
7. end
8. show running-config
9. copy running-config startup-config

| `Switch# copy running-config startup-config` | |

### Related Topics

- [Static SSM Mapping](#), on page 285

### Configuring DNS-Based SSM Mapping (CLI)

To configure DNS-based SSM mapping, you need to create a DNS server zone or add records to an existing zone. If the routers that are using DNS-based SSM mapping are also using DNS for other purposes, you should use a normally configured DNS server. If DNS-based SSM mapping is the only DNS implementation being used on the router, you can configure a false DNS setup with an empty root zone or a root zone that points back to itself.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip igmp ssm-map enable`
4. `ip igmp ssm-map query dns`
5. `ip domain multicast domain-prefix`
6. `ip name-server server-address1 [server-address2 ... server-address6]`
7. Repeat Step 5 to configure additional DNS servers for redundancy, if required.
8. `end`
9. `show running-config`
10. `copy running-config startup-config`

| **Step 2** | Enters the global configuration mode. |
| configure terminal | |
| **Example:** | |
| Switch# configure terminal | |

| **Step 3** | Selects an interface on which to statically forward traffic for a multicast group using SSM mapping, and enters interface configuration mode. |
| interface type number | |
| **Example:** | |
| Switch(config)# interface gigabitethernet 1/0/1 | |

- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218

These interfaces must have IP addresses assigned to them.

**Note** Static forwarding of traffic with SSM mapping works with either DNS-based SSM mapping or statically configured SSM mapping.

| **Step 4** | Configures SSM mapping to statically forward a (S, G) channel from the interface. |
| ip igmp static-group group-address source ssm-map | |
| **Example:** | Use this command if you want to statically forward SSM traffic for certain groups. Use DNS-based SSM mapping to determine the source addresses of the channels. |
| Switch(config-if)# ip igmp static-group 239.1.2.1 source | |
Use the privileged EXEC commands in the following table to monitor SSM.

**Table 35: Commands for Monitoring SSM**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip igmp groups detail</code></td>
<td>Displays the (S, G) channel subscription through IGMPv3.</td>
</tr>
<tr>
<td><code>show ip mroute</code></td>
<td>Displays whether a multicast group supports SSM service or whether a source-specific host report was received.</td>
</tr>
</tbody>
</table>
Monitoring SSM Mapping

Use the privileged EXEC commands in the following table to monitor SSM mapping.

**Table 36: SSM Mapping Monitoring Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip igmp ssm-mapping</code></td>
<td>Displays information about SSM mapping.</td>
</tr>
<tr>
<td><code>show ip igmp ssm-mapping group-address</code></td>
<td>Displays the sources that SSM mapping uses for a particular group.</td>
</tr>
<tr>
<td>`show ip igmp groups [group-name</td>
<td>group-address</td>
</tr>
<tr>
<td><code>show host</code></td>
<td>Displays the default domain name, the style of name lookup service, a list of name server hosts, and the cached list of hostnames and addresses.</td>
</tr>
<tr>
<td><code>debug ip igmp group-address</code></td>
<td>Displays the IGMP packets received and sent and IGMP host-related events.</td>
</tr>
</tbody>
</table>

Where to Go Next for SSM

You can configure the following:

- IGMP
- Wireless Multicast
- PIM
- IP Multicast Routing
- Service Discovery Gateway

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring IP Multicast Routing

The following are the prerequisites for configuring IP multicast routing:

- To use the IP multicast routing feature on the switch, the switch or active switch must be running the IP Services feature set.

- You must enable IP multicast routing and configure the PIM version and PIM mode on the switch. After performing these tasks, the switch can then forward multicast packets and can populate its multicast routing table.

- To participate in IP multicasting, the multicast hosts, routers, and multilayer switch must have IGMP operating.
Restrictions for Configuring IP Multicast Routing

The following are the restrictions for configuring IP multicast routing:

- IP multicast routing is not supported on switches running the LAN Base feature set.
- Layer 3 IPv6 multicast routing is not supported on the switch.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About IP Multicast Routing

IP multicasting is an efficient way to use network resources, especially for bandwidth-intensive services such as audio and video. IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address.

The sending host inserts the multicast group address into the IP destination address field of the packet, and IP multicast routers and multilayer switches forward incoming IP multicast packets out all interfaces that lead to members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

Cisco’s Implementation of IP Multicast Routing

Cisco IOS software supports the following protocols to implement IP multicast routing:

- Internet Group Management Protocol (IGMP) is used among hosts on a LAN and the routers (and multilayer switches) on that LAN to track the multicast groups of which hosts are members.
- Protocol-Independent Multicast (PIM) protocol is used among routers and multilayer switches to track which multicast packets to forward to each other and to their directly connected LANs.

Note

The switch does not support the Distance Vector Multicast Routing Protocol (DVMRP) nor the Cisco Group Management Protocol (CGMP).
The following figure shows where the Cisco-supported protocols for the switch operate within the IP multicast environment.

According to IPv4 multicast standards, the MAC destination multicast address begins with 0100:5e and is appended by the last 23 bits of the IP address. For example, if the IP destination address is 239.1.1.39, the MAC destination address is 0100:5e01:0127.

A multicast packet is unmatched when the destination IPv4 address does not match the destination MAC address. The switch forwards the unmatched packet in hardware based upon the MAC address table. If the destination MAC address is not in the MAC address table, the switch floods the packet to the all port in the same VLAN as the receiving port.

**Multicast Forwarding Information Base Overview**

The switch uses the Multicast Forwarding Information Base (MFIB) architecture and the Multicast Routing Information Base (MRIB) for IP multicast.

The MFIB architecture provides both modularity and separation between the multicast control plane (Protocol Independent Multicast [PIM] and Internet Group Management Protocol [IGMP]) and the multicast forwarding plane (MFIB). This architecture is used in Cisco IOS IPv6 multicast implementations.

MFIB itself is a multicast routing protocol independent forwarding engine; that is, it does not depend on PIM or any other multicast routing protocol. It is responsible for:

- Forwarding multicast packets
- Registering with the MRIB to learn the entry and interface flags set by the control plane
- Handling data-driven events that must be sent to the control plane
- Maintaining counts, rates, and bytes of received, dropped, and forwarded multicast packets

The MRIB is the communication channel between MRIB clients. Examples of MRIB clients are PIM, IGMP, the multicast routing (mroute) table, and the MFIB.
Multicast Group Concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries. The hosts can be located anywhere on the Internet. Hosts that are interested in receiving data flowing to a particular group must join the group using IGMP. Hosts must be a member of the group to receive the data stream.

Multicast Boundaries

Administratively-scoped boundaries can be used to limit the forwarding of multicast traffic outside of a domain or subdomain. This approach uses a special range of multicast addresses, called administratively-scoped addresses, as the boundary mechanism. If you configure an administratively-scoped boundary on a routed interface, multicast traffic whose multicast group addresses fall in this range cannot enter or exit this interface, which provides a firewall for multicast traffic in this address range.

Note

Multicast boundaries and TTL thresholds control the scoping of multicast domains; however, TTL thresholds are not supported by the switch. You should use multicast boundaries instead of TTL thresholds to limit the forwarding of multicast traffic outside of a domain or subdomain.

Figure 14: Administratively-Scoped Boundaries

The following figure shows that Company XYZ has an administratively-scoped boundary set for the multicast address range 239.0.0.0/8 on all routed interfaces at the perimeter of its network. This boundary prevents any multicast traffic in the range 239.0.0.0 through 239.255.255.255 from entering or leaving the network. Similarly, the engineering and marketing departments have an administratively-scoped boundary of 239.128.0.0/16 around the perimeter of their networks. This boundary prevents multicast traffic in the range of 239.128.0.0 through 239.128.255.255 from entering or leaving their respective networks.

You can define an administratively-scoped boundary on a routed interface for multicast group addresses. A standard access list defines the range of addresses affected. When a boundary is defined, no multicast data
packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The IANA has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively-scoped addresses. This range of addresses can then be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

### Multicast Routing and Switch Stacks

For all multicast routing protocols, the entire stack appears as a single router to the network and operates as a single multicast router.

In a switch stack, the active switch performs these functions:

- It is responsible for completing the IP multicast routing functions of the stack. It fully initializes and runs the IP multicast routing protocols.
- It builds and maintains the multicast routing table for the entire stack.
- It is responsible for distributing the multicast routing table to all stack members.

The stack members perform these functions:

- They act as multicast routing standby devices and are ready to take over if there is an active switch failure.
  
  If the active switch fails, all stack members delete their multicast routing tables. The newly elected active switch starts building the routing tables and distributes them to the stack members.
- They do not build multicast routing tables. Instead, they use the multicast routing table that is distributed by the active switch.

### Default Multicast Routing Configuration

This table describes the default multicast routing configuration for the switch.

**Table 37: Default Multicast Routing Configuration**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multicast routing</td>
<td>Disabled on all interfaces.</td>
</tr>
</tbody>
</table>

### How to Configure Basic IP Multicast Routing

#### Configuring Basic IP Multicast Routing (CLI)

You must enable IP multicast routing and configure the PIM version and mode. After performing these tasks, the software can then forward multicast packets, and the switch can populate its multicast routing table.
You can configure an interface to be in PIM dense mode, sparse mode, or sparse-dense mode. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting. You must enable PIM in one of these modes for an interface to perform IP multicast routing.

Enabling PIM on an interface also enables IGMP operation on that interface.

If you enable PIM on multiple interfaces, when most of these interfaces are not on the outgoing interface list, and IGMP snooping is disabled, the outgoing interface might not be able to sustain line rate for multicast traffic because of the extra replication.

In populating the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream devices or when there is a directly connected member on the interface.

When forwarding from a LAN, sparse-mode operation occurs if there is a rendezvous point (RP) known for the group. An RP acts as the meeting place for sources and receivers of multicast data. If an RP exists, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver’s first-hop router might send join messages toward the source to build a source-based distribution tree.

By default, multicast routing is disabled, and there is no default mode setting.

This procedure is required.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast-routing`
4. `interface interface-id`
5. `ip pim {dense-mode | sparse-mode | sparse-dense-mode}`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

### Configuring IP Multicast Forwarding (CLI)

You can use the following procedure to configure IPv4 Multicast Forwarding Information Base (MFIB) interrupt-level IP multicast forwarding of incoming packets or outgoing packets on the switch.

**Note**

After you have enabled IP multicast routing by using the `ip multicast-routing` command, IPv4 multicast forwarding is enabled. Because IPv4 multicast forwarding is enabled by default, you can use the `no` form of the `ip mfib` command to disable IPv4 multicast forwarding.

## Configuring a Static Multicast Route (mroute) (CLI)

You can use the following procedure to configure static mroutes. Static mroutes are similar to unicast static routes but differ in the following ways:

- Static mroutes are used to calculate RPF information, not to forward traffic.
- Static mroutes cannot be redistributed.

Static mroutes are strictly local to the switch on which they are defined. Because Protocol Independent Multicast (PIM) does not have its own routing protocol, there is no mechanism to distribute static mroutes throughout the network. Consequently, the administration of static mroutes tends to be more complicated than the administration of unicast static routes.

### Command or Action | Purpose
--- | ---
Switch> enable |  
**Step 2** configure terminal | Enters the global configuration mode.  
*Example:*  
Switch# configure terminal

**Step 3** ip mfib | Enables IP multicast forwarding.  
*Example:*  
Switch(config)# ip mfib

**Step 4** exit | Returns to privileged EXEC mode.  
*Example:*  
Switch(config)# exit

**Step 5** show running-config | Verifies your entries.  
*Example:*  
Switch# show running-config

**Step 6** copy running-config startup-config | (Optional) Saves your entries in the configuration file.  
*Example:*  
Switch# copy running-config startup-config

### Related Topics
- Multicast Forwarding Information Base Overview, on page 299
When static mroutes are configured, they are stored on the switch in a separate table referred to as the static mroute table. When configured, the `ip mroute` command enters a static mroute into the static mroute table for the source address or source address range specified for the source-address and mask arguments. Sources that match the source address or that fall in the source address range specified for the source-address argument will RPF to either the interface associated with the IP address specified for the `rpf-address` argument or the local interface on the switch specified for the `interface-type` and `interface-number` arguments. If an IP address is specified for the `rpf-address` argument, a recursive lookup is done from the unicast routing table on this address to find the directly connected neighbor.

If there are multiple static mroutes configured, the switch performs a longest-match lookup of the mroute table. When the mroute with the longest match (of the source-address) is found, the search terminates and the information in the matching static mroute is used. The order in which the static mroutes are configured is not important.

The administrative distance of an mroute may be specified for the optional distance argument. If a value is not specified for the distance argument, the distance of the mroute defaults to zero. If the static mroute has the same distance as another RPF source, the static mroute will take precedence. There are only two exceptions to this rule: directly connected routes and the default unicast route.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip mroute [vrf vrf-name] source-address mask { fallback-lookup {global | vrf vrf-name }[ protocol ] {rpf-address | interface-type interface-number} } [distance]`
4. exit
5. show running-config
6. copy running-config startup-config

### Configuring sdr Listener Support

The MBONE is the small subset of Internet routers and hosts that are interconnected and capable of forwarding IP multicast traffic. Other multimedia content is often broadcast over the MBONE. Before you can join a multimedia session, you need to know what multicast group address and port are being used for the session, when the session is going to be active, and what sort of applications (audio, video, and so forth) are required on your workstation. The MBONE Session Directory Version 2 (sdr) tool provides this information. This freeware application can be downloaded from several sites on the World Wide Web, one of which is http://www.video.ja.net/mice/index.html.

SDR is a multicast application that listens to a well-known multicast group address and port for Session Announcement Protocol (SAP) multicast packets from SAP clients, which announce their conference sessions. These SAP packets contain a session description, the time the session is active, its IP multicast group addresses, media format, contact person, and other information about the advertised multimedia session. The information in the SAP packet is displayed in the SDR Session Announcement window.

### Enabling sdr Listener Support (CLI)

By default, the switch does not listen to session directory advertisements.

This procedure is optional.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
### Enabling sdr Listener Support (CLI)

4. `ip sap listen`  
5. `end`  
6. `show running-config`  
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | Enables privileged EXEC mode.  
* Enter your password if prompted.  
Example:  
Switch> `enable` |
| **Step 2** | Enters the global configuration mode.  
Example:  
Switch# `configure terminal` |
| **Step 3** | Specifies the interface to be enabled for sdr, and enters interface configuration mode.  
The specified interface must be one of the following:  
- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 217  
- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 218  
The interfaces must have IP addresses assigned to them.  
Example:  
Switch(config)# `interface gigabitethernet 1/0/1` |
| **Step 4** | Enables the switch software to listen to session directory announcements.  
Example:  
Switch(config-if)# `ip sap listen` |
### Limiting How Long an sdr Cache Entry Exists (CLI)

By default, entries are never deleted from the sdr cache. You can limit how long the entry remains active so that if a source stops advertising SAP information, old advertisements are not unnecessarily kept.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip sap cache-timeout minutes
4. end
5. show running-config
6. show ip sap
7. copy running-config startup-config

| **Step 3** access-list {access-list-number 1-99 | access-list-number 100-199 | access-list-number 1300-1999 | access-list-number 2000-2699 | dynamic-extended | rate-limit} | Creates a standard access list, repeating the command as many times as necessary.  
**Example:**  
Switch(config)# access-list 99 permit any  
**For access-list-number,** the ranges are as follows:  
• access-list-number 1—99 (IP standard access list)  
• access-list-number 100—199 (IP extended access list)  
• access-list-number 1300—1999 (IP standard access list - expanded range)  
• access-list-number 2000—2699 (IP extended access list - expanded range)  
• The **dynamic-extended** keyword extends the dynamic ACL absolute timer.  
• The **rate-limit** keyword permits a simple rate-limit specific access list.  
The access list is always terminated by an implicit deny statement for everything. |
| **Step 4** interface interface-id | Specifies the interface to be configured, and enters interface configuration mode.  
**Example:**  
Switch(config)# interface gigabitEthernet1/0/1 |  
The specified interface must be one of the following:  
• A routed port—A physical port that has been configured as a Layer 3 port by entering the no switchport interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a
### Configuring an IP Multicast Boundary (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong> <code>ip multicast boundary access-list-number</code></td>
<td></td>
</tr>
</tbody>
</table>
| **Example:** Switch(config-if)# `ip multicast boundary 99`  | Configures the boundary, specifying the access list you created in Step 2. Additional command options include:  
  - For `access-list-number`, the ranges are as follows:  
    - `access-list-number 1—99` (IP standard access list)  
    - `access-list-number 100—199` (IP extended access list)  
    - `access-list-number 1300—1999` (IP standard access list - expanded range)  
    - `access-list-number 2000—2699` (IP extended access list - expanded range)  
  - `Word`—IP named access list.  
  - `filter-autor`—Filter AutoRP packet contents.  
  - `in`—Restrict (s,g) creation when this interface is the RPF.  
  - `out`—Restrict interface addition to outgoing list. |
| **Step 6** `end`  |
| **Example:** Switch(config-if)# `end`  | Returns to privileged EXEC mode. |
| **Step 7** `show running-config`  |
| **Example:** Switch# `show running-config`  | Verifies your entries. |
### Purpose
- **Command or Action**: `copy running-config startup-config`

**Example:**

Switch# `copy running-config startup-config`

### Purpose
- (Optional) Saves your entries in the configuration file.

### What to do next
Proceed to the other supported IP multicast routing procedures.

## Monitoring and Maintaining IP Multicast Routing

### Clearing Caches, Tables, and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure are or suspected to be invalid.

You can use any of the privileged EXEC commands in the following table to clear IP multicast caches, tables, and databases.

**Table 38: Commands for Clearing Caches, Tables, and Databases**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`clear ip igmp group [group [hostname</td>
<td>IP address]</td>
</tr>
<tr>
<td>`clear ip mfib {counters [group</td>
<td>source]</td>
</tr>
<tr>
<td><code>clear ip mrm {status-report [source]}</code></td>
<td>IP multicast routing clear commands.</td>
</tr>
<tr>
<td><code>clear ip mroutef [source]</code></td>
<td>Deletes entries from the IP multicast routing table.</td>
</tr>
<tr>
<td>`clear ip msdp [peer</td>
<td>sa-cache</td>
</tr>
<tr>
<td>`clear ip multicast [limit</td>
<td>redundancy statistics]`</td>
</tr>
<tr>
<td>`clear ip pim [df</td>
<td>int</td>
</tr>
</tbody>
</table>
Displaying System and Network Statistics

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

**Note**
This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 39: Commands for Displaying System and Network Statistics**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>

<tr>
<td><code>show ip pim vrf name</code></td>
<td>Displays VPN routing and forwarding instances.</td>
</tr>
</tbody>
</table>
Monitoring IP Multicast Routing

You can use the privileged EXEC commands in the following table to monitor IP multicast routers, packets, and paths.

Table 40: Commands for Monitoring IP Multicast Routing

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>mrinfo { [hostname</td>
<td>address]</td>
</tr>
<tr>
<td>mstat { [hostname</td>
<td>address]</td>
</tr>
<tr>
<td>mtrace { [hostname</td>
<td>address]</td>
</tr>
</tbody>
</table>

Configuration Examples for IP Multicast Routing

Example: Configuring an IP Multicast Boundary

This example shows how to set up a boundary for all administratively-scoped addresses:
Switch(config)# access-list 1 deny 239.0.0.0 0.255.255.255
Switch(config)# access-list 1 permit 224.0.0.0 15.255.255.255
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ip multicast boundary 1

Example: Responding to mrinfo Requests

The software answers mrinfo requests sent by mrouted systems and Cisco routers and multilayer switches. The software returns information about neighbors through DVMRP tunnels and all the routed interfaces. This information includes the metric (always set to 1), the configured TTL threshold, the status of the interface, and various flags. You can also use the `mrinfo` privileged EXEC command to query the router or switch itself, as in this example:

Switch# mrinfo
171.69.214.27 (mm1-7kd.cisco.com) [version cisco 11.1] [flags: PMS]:
171.69.214.27 -> 171.69.214.26 (mm1-r7kb.cisco.com) [1/0/pim/querier]
171.69.214.27 -> 171.69.214.25 (mm1-45a.cisco.com) [1/0/pim/querier]
171.69.214.33 -> 171.69.214.34 (mm1-45c.cisco.com) [1/0/pim]
171.69.214.137 -> 0.0.0.0 [1/0/pim/querier/down/leaf]
171.69.214.203 -> 0.0.0.0 [1/0/pim/querier/down/leaf]
171.69.214.18 -> 171.69.214.20 (mm1-45e.cisco.com) [1/0/pim]
171.69.214.18 -> 171.69.214.19 (mm1-45c.cisco.com) [1/0/pim]
171.69.214.18 -> 171.69.214.17 (mm1-45a.cisco.com) [1/0/pim]

Where to Go Next for IP Multicast

You can configure the following:

- IGMP
- Wireless Multicast
- PIM
- SSM
- Service Discovery Gateway

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring the Service Discovery Gateway

The following are restrictions for configuring the Service Discovery Gateway:

- The Service Discovery Gateway does not support topologies with multiple hops. All network segments must be connected directly to it. The Service Discovery Gateway can learn services from all connected segments to build its cache and respond to requests acting as a proxy.
Information about the Service Discovery Gateway and mDNS

mDNS

mDNS was defined to achieve zero configuration, with zero configuration being defined as providing the following features:

- Addressing—Allocating IP addresses to hosts
- Naming—Using names to refer to hosts instead of IP addresses
- Service discovery—Finding services automatically on the network

With mDNS, network users no longer have to assign IP addresses, assign host names, or type in names to access services on the network. Users only need to ask to see what network services are available, and choose from a list.

With mDNS, *addressing* is accomplished through the use of DHCP/DHCPv6 or IPv4 and IPv6 Link Local scoped addresses. The benefit of zero-configuration occurs when no infrastructure services such as DHCP or DNS are present and self-assigned link-local addressing can be used. The client can then select a random IPv4 address in the link-local range (169.254.0.0/24) or use its IPv6 link-local address (FE80::/10) for communication.

With mDNS, *naming* (name-to-address translation on a local network using mDNS) queries are sent over the local network using link-local scoped IP multicast. Because these DNS queries are sent to a multicast address (IPv4 address 224.0.0.251 or IPv6 address FF02::FB), no single DNS server with global knowledge is required to answer the queries. When a service or device sees a query for any service it is aware of, it provides a DNS response with the information from its cache.

With mDNS, *service discovery* is accomplished by browsing. An mDNS query is sent out for a given service type and domain, and any device that is aware of matching services replies with service information. The result is a list of available services for the user to choose from.

The mDNS protocol (mDNS-RFC), together with DNS Service Discovery (DNS-SD-RFC) achieves the zero-configuration addressing, naming, and service discovery.

mDNS-SD

Multicast DNS Service Discovery (mDNS-SD) uses DNS protocol semantics and multicast over well-known multicast addresses to achieve zero configuration service discovery. DNS packets are sent to and received on port 5353 using a multicast address of 224.0.0.251 and its IPv6 equivalent FF02::FB.

Because mDNS uses a link-local multicast address, its scope is limited to a single physical or logical LAN. If the networking reach needs to be extended to a distributed campus or to a wide-area environment consisting of many different networking technologies, mDNS gateway is implemented. An mDNS gateway provides a transport for mDNS packets across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain to another.

mDNS-SD Considerations for Wireless Clients

- mDNS packets can be sent out of Layer 3 interfaces that might not have an IP address.
- Packets with mDNS multicast IP and multicast MAC are sent on a multicast CAPWAP tunnel, if multicast-multicast mode is enabled. A multicast CAPWAP tunnel is a special CAPWAP tunnel used
for reducing the number of copies of multicast packet that are required to be generated for each AP CAPWAP tunnel. Sending packets on the multicast CAPWAP tunnel requires the outer IP header to be destined to the multicast CAPWAP tunnel’s address, which all APs are subscribed to.

- All mDNS packet handling is done at a foreign switch for roamed clients. A foreign switch is the new switch that a roamed wireless client is actually attached to, which is called the point of attachment.

## Service Discovery Gateway

The Service Discovery Gateway feature enables multicast Domain Name System (mDNS) to operate across Layer 3 boundaries (different subnets). An mDNS gateway provides transport for service discovery across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain (subnet) to another. Prior to implementation of this feature, mDNS was limited in scope to within a subnet because of the use of link-local scoped multicast addresses. This feature enhances Bring Your Own Device (BYOD).

- Example: Interface mDNS Configuration, on page 334

### mDNS Gateway and Subnets

You need to enable an mDNS gateway for service discovery to operate across subnets. You can enable mDNS gateway for a device or for an interface.

---

**Note**

You need to configure service routing globally before configuring at the interface level.

---

After the device or interface is enabled, you can redistribute service discovery information across subnets. You can create service policies and apply filters on either incoming service discovery information (called IN-bound filtering) or outgoing service discovery information (called OUT-bound filtering).

---

**Note**

If redistribution is enabled globally, global configuration is given higher priority than interface configuration.

---

**Figure 15: Sample Networking Scenario**

For example, if the mDNS gateway functionality is enabled on the router in this figure, then service information can be sent from one subnet to another and vice-versa. For example, the printer and fax service information being advertised in the network with IP address 192.0.2.6 are redistributed to the network with IP address 198.51.100.4. The printer and fax service information in the network with IP address 192.0.2.6 is learned by
Filtering

After configuring the mDNS gateway and subnets, you can filter services that you want to redistribute. While creating a service list, the `permit` or `deny` command options are used:

- The `permit` command option allows you to permit or transport specific service list information.
- The `deny` option allows you to deny service list information that is available to be transported to other subnets.

You need to include a sequence number when using the `permit` or `deny` command option. The same service list name can be associated with multiple sequence numbers and each sequence number will be mapped to a rule.

---

**Note**

If no filters are configured, then the default action is to deny service list information to be transported through the device or interface.

---

**Note**

Query is another option provided when creating service lists. You can create queries using a service list. If you want to browse for a service, then active queries can be used. This function is helpful to keep the records refreshed in the cache.

---

**Note**

Active queries can only be used globally and cannot be used at the interface level.

---

A service end-point (such as a printer or fax) sends unsolicited announcements when a service starts up. After that, it sends unsolicited announcements whenever a network change event occurs (such as an interface coming up or going down). The device always respond to queries.
After creating a service list and using the **permit** or **deny** command options, you can filter using match statements (commands) based on **service-instance**, **service-type**, or **message-type** (announcement or query).

## How to Configure the Service Discovery Gateway

### Configuring the Service List (CLI)

This procedure describes how to create a service list, apply a filter for the service list, and configure parameters for the service list name.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. service-list mDNS-sd service-list-name {deny sequence-number | permit sequence-number | query}
4. match message-type {announcement | any | query}
5. match service-instance {LINE}
6. match service-type {LINE}
7. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Switch&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
Purpose

Command or Action

Step 3  service-list mdns-sd service-list-name {deny sequence-number | permit sequence-number | query}

Example:

Switch(config)# service-list mdns-sd sl1 permit 3

Switch(config)# service-list mdns-sd sl4 query

Purpose

Enters mDNS service discovery service list mode. In this mode, you can:

• Create a service list and apply a filter on the service list according to the permit or deny option applied to the sequence number.

• Create a service list and associate a query for the service list name if the query option is used.

Note  The sequence number sets the priority of the rule. A rule with a lower sequence number is selected first and the service announcement or query is allowed or denied accordingly. You define the sequence number as per your network requirements.

Step 4  match message-type {announcement | any | query}

Example:

Switch(config-mdns-sd-sl) # match message-type announcement

(Optional) Sets the message type to match. You can match the following message types:

• announcement

• any

• query

These commands configure the parameters for the service list name that is created in step 2.

If the match message-type is an announcement, then the service list rule only allows service advertisements or announcements for the device. If the match message-type is a query, then only a query from the client for a certain service in the network is allowed.

Multiple service maps of the same name with different sequence numbers can be created and the evaluation of the filters will be ordered on the sequence number. Service lists are an ordered sequence of individual statements, each one has a permit or deny result. Evaluation of service list consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is stopped once the first statement match is found and an action permit/deny associated with the statement match is performed. The default action after scanning through the entire list is to deny.

Note  You cannot use the match command if you have used the query option in the previous step. The match command can be used only for the permit or deny option.
### Purpose

#### Command or Action

**Step 5**

match service-instance \{ \textit{LINE} \}  

**Example:**

Switch(config-mdns-sd-sl)# match service-instance servInst 1

- **Purpose:** (Optional) Sets the service instance to match. This command configures the parameters for the service list name that is created in step 2.

- **Note:** You cannot use the \texttt{match} command if you have used the \texttt{query} option in the previous step. The \texttt{match} command can be used only for the \texttt{permit} or \texttt{deny} option.

**Step 6**

match service-type \{ \textit{LINE} \}  

**Example:**

Switch(config-mdns-sd-sl)# match service-type _ipp._tcp

- **Purpose:** (Optional) Sets the value of the mDNS service type string to match. This command configures the parameters for the service list name that is created in step 2.

- **Note:** You cannot use the \texttt{match} command if you have used the \texttt{query} option in the previous step. The \texttt{match} command can be used only for the \texttt{permit} or \texttt{deny} option.

**Step 7**

\texttt{end}

**Example:**

Switch(config-mdns-sd-sl)# end

- **Purpose:** Returns to privileged EXEC mode.

### What to do next

Proceed to enable the mDNS gateway and redistribution of services.

### Configuring Service List (GUI)

#### SUMMARY STEPS

1. Choose **Configuration > Controller > mDNS > Service List.**
2. Click **Create Service.**
3. In the **Service List Name** text box, enter the service list name.
4. From the **Service rule** drop-down list, choose from the following options:
   - **permit**—permits the service list.
   - **deny**—denies the service list.
5. In the **Sequence number** text box, enter the priority of the rule.
6. From the **Message type** drop-down list, choose the message type to match from the following options:
• **announcement**—The service list rule allows only service advertisements or announcements for the device.
• **query**—The service list rule allows only a query from the client for a service in the network.
• **any**—The service list rule allows any type of message.

7. In the **Service instance** text box, enter the service instance to match.
8. In the **Custom** text box, enter the mDNS service type string to match.
9. Click **Apply**.
10. Click **Save Configuration**.

**DETAILED STEPS**

**Step 1**
Choose **Configuration > Controller > mDNS > Service List**.

**Step 2**
Click **Create Service**.
The **Service List > Create Service** page is displayed.

**Step 3**
In the **Service List Name** text box, enter the service list name.

**Step 4**
From the **Service rule** drop-down list, choose from the following options:
- **permit**—permits the service list.
- **deny**—denies the service list.

**Step 5**
In the **Sequence number** text box, enter the priority of the rule.
A rule with a lower sequence number is selected first and the service announcement or query is allowed or denied accordingly. You define the sequence number as per your network requirements.

**Step 6**
From the **Message type** drop-down list, choose the message type to match from the following options:
- **announcement**—The service list rule allows only service advertisements or announcements for the device.
- **query**—The service list rule allows only a query from the client for a service in the network.
- **any**—The service list rule allows any type of message.

Multiple service maps of the same name with different sequence numbers can be created and the evaluation of the filters will be ordered on the sequence number. Service lists are an ordered sequence of individual statements, each one has a permit or deny result. Evaluation of service list consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is stopped once the first statement match is found and an action permit/deny associated with the statement match is performed. The default action after scanning through the entire list is to deny.

**Step 7**
In the **Service instance** text box, enter the service instance to match.

**Step 8**
In the **Custom** text box, enter the mDNS service type string to match.
The **Learned Service** box shows the services that are added after enabling the learned service type configured by navigating to **Configuration > Controller > mDNS > Global**. For example, _roap._tcp.local.
The **Selected Service** box shows the learned service that you have selected for an mDNS service.

**Step 9**
Click **Apply**.

**Step 10**
Click **Save Configuration**.
What to do next
Proceed to enable the mDNS gateway and redistribution of services.

Enabling mDNS Gateway and Redistributing Services (CLI)

After enabling mDNS gateway for a device, you can apply filters (apply IN-bound filtering or OUT-bound filtering) and active queries by using `service-policy` and `service-policy-query` commands, respectively. You can redistribute services and service announcements using the `redistribute mdns-sd` command, and set some part of the system memory for cache using the `cache-memory-max` command.

Note
By default, mDNS gateway is disabled on all interfaces.

SUMMARY STEPS

1. enable
2. configure terminal
3. service-routing mdns-sd
4. service-policy `service-policy-name` {IN | OUT}
5. redistribute mdns-sd
6. cache-memory-max `cache-config-percentage`
7. service-policy-query `service-list-query-name` `service-list-query-periodicity`
8. exit
9. wireless multicast
10. no wireless mdns-bridging
11. end

### Enabling mDNS Gateway and Redistributing Services (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong></td>
<td>Enter the <code>service-routing mdns-sd source-interface if-name</code> command in either global-config or interface-config mode, to specify an alternate source interface for outgoing mDNS packets, so its IP address can be used when there is none configured on the outgoing interface.</td>
</tr>
</tbody>
</table>

**Step 4**

**service-policy service-policy-name {IN | OUT}**

*Example:*

Switch (config-mdns)# service-policy serv-pol1 IN

(Optional) For a service list, applies a filter on incoming service discovery information (IN-bound filtering) or outgoing service discovery information (OUT-bound filtering).

**Step 5**

**redistribute mdns-sd**

*Example:*

Switch (config-mdns)# redistribute mdns-sd

(Optional) Redistributes services or service announcements across subnets.

**Note** | If redistribution is enabled globally, global configuration is given higher priority than interface configuration.

**Step 6**

**cache-memory-max cache-config-percentage**

*Example:*

Switch (config-mdns)# cache-memory-max 20

(Optional) Sets some part of the system memory (in percentage) for cache.

**Note** | By default, 10 percent of the system memory is set aside for cache. You can override the default value by using this command.

**Step 7**

**service-policy-query service-list-query-name service-list-query-periodicity**

*Example:*

Switch (config-mdns)# service-policy-query sl-query1 100

(Optional) Configures service list-query periodicity.

**Step 8**

**exit**

*Example:*

Switch (config-mdns)#exit

(Optional) Returns to global configuration mode.

**Step 9**

**wireless multicast**

*Example:*

Switch (config)# wireless multicast

(Optional) Enables wireless Ethernet multicast support.

## Enabling Multicast DNS Gateway (GUI)

### SUMMARY STEPS

1. Choose **Configuration > Controller > mDNS > Global.**
2. Select the **mDNS gateway** check box.
3. From the **Learn Service** drop-down list, choose from the following options:
   - **Enable**— Allows the switch to learn all the announced services. It is used to learn services by enabling all announcement/queries by using Service Policy IN of type GUI-permit-all and in Service Policy OUT of type GUI-deny-all.
   - **Disable**— Denies all the traffics IN and OUT. It is used to deny services by disabling all announcement/queries by using Service Policy IN of type GUI-deny-all and in Service Policy OUT of type GUI-deny-all.
   - **Custom**— You can set your own IN and OUT policy. It allows you to define a custom service list.
4. Click **Apply**.
5. Click **Save Configuration**.

### DETAILED STEPS

**Step 1** Choose **Configuration > Controller > mDNS > Global.**
The Global Service Rules page is displayed.

**Step 2** Select the mDNS gateway check box.

**Step 3** From the Learn Service drop-down list, choose from the following options:

- **Enable**— Allows the switch to learn all the announced services. It is used to learn services by enabling all announcement/queries by using Service Policy IN of type GUI-permit-all and in Service Policy OUT of type GUI-deny-all.

- **Disable**— Denies all the traffics IN and OUT. It is used to deny services by disabling all announcement/queries by using Service Policy IN of type GUI-deny-all and in Service Policy OUT of type GUI-deny-all.

- **Custom**— You can set your own IN and OUT policy. It allows you to define a custom service list.

**Step 4** Click Apply.

**Step 5** Click Save Configuration.

</tbody>
</table>

### Configuration Examples

**Example: Specify Alternative Source Interface for Outgoing mDNS Packets**

The following example displays how to specify an alternate source interface for outgoing mDNS packets, so its IP address can be used when there is none configured on the outgoing interface.

```
Switch(config)# service-routing mdns
Switch(config-mdns)# source-interface if-name
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 MLD Snooping

You can use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP Version 6 (IPv6) multicast data to clients and routers in a switched network on the switch. Unless otherwise noted, the term switch refers to a standalone switch and to a switch stack.

---

**Note**

To use IPv6 on a Catalyst 2960-XR switch, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch.

---

**Note**

For complete syntax and usage information for the commands used in this chapter, see the command reference for this release or the Cisco IOS documentation referenced in the procedures.
Understanding MLD Snooping

In IP Version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on the links that are directly attached to the routers and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD Version 1 (MLDv1) is equivalent to IGMPv2, and MLD Version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol Version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.

- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

**Note**
The switch does not support MLDv2 enhanced snooping, which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

According to IPv6 multicast standards, the switch derives the MAC multicast address by performing a logical-OR of the four low-order octets of the switch MAC address with the MAC address of \( \text{FF02:DEAD:BEEF:1:3} \) maps to the Ethernet MAC address of \( \text{33:33:00:01:00:03} \). For example, the IPv6 MAC address of \( \text{FF02:DEAD:BEEF:1:3} \) maps to the Ethernet MAC address of \( \text{33:33:00:01:00:03} \).

A multicast packet is unmatched when the destination IPv6 address does not match the destination MAC address. The switch forwards the unmatched packet in hardware based the MAC address table. If the destination MAC address is not in the MAC address table, the switch floods the packet to all ports in the same VLAN as the receiving port.

**MLD Messages**

MLDv1 supports three types of messages:

- **Listener Queries** are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).

- **Multicast Listener Reports** are the equivalent of IGMPv2 reports.

- **Multicast Listener Done messages** are the equivalent of IGMPv2 leave messages.
MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages. Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

**MLD Queries**

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast group address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

**Note**

When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the Catalyst 2960, 2960-S, 2960-C, or 2960-X switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

**Multicast Client Aging Robustness**

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

**Multicast Router Discovery**

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.

Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether or not MLD snooping is enabled on the switch.

After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address is entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port. The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the `ipv6 mld snooping last-listener-query count` global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the `ipv6 mld snooping last-listener-query-interval` global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

When Immediate Leave is not enabled and a port receives an MLD Done message, the switch generates MASQs on the port and sends them to the IPv6 multicast address for which the Done message was sent. You can optionally configure the number of MASQs that are sent and the length of time the switch waits for a response before deleting the port from the multicast group.
When you enable MLDv1 Immediate Leave, the switch immediately removes a port from a multicast group when it detects an MLD Done message on that port. You should only use the Immediate-Leave feature when there is a single receiver present on every port in the VLAN. When there are multiple clients for a multicast group on the same port, you should not enable Immediate-Leave in a VLAN.

**Topology Change Notification Processing**

When topology change notification (TCN) solicitation is enabled by using the `ipv6 mld snooping tcn query solicit` global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the `ipv6 mld snooping tcn flood query count` global configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This is same as done in IGMP snooping.

**MLD Snooping in Switch Stacks**

The MLD IPv6 group address databases are maintained on all switches in the stack, regardless of which switch learns of an IPv6 multicast group. Report suppression and proxy reporting are done stack-wide. During the maximum response time, only one received report for a group is forwarded to the multicast routers, regardless of which switch the report arrives on.

The election of a new stack master does not affect the learning or bridging of IPv6 multicast data; bridging of IPv6 multicast data does not stop during a stack master re-election. When a new switch is added to the stack, it synchronizes the learned IPv6 multicast information from the stack master. Until the synchronization is complete, data ingress on the newly added switch is treated as unknown multicast data.

**How to Configure IPv6 MLD Snooping**

**Default MLD Snooping Configuration**

Table 42: Default MLD Snooping Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>MLD snooping (Global)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLD snooping (per VLAN)</td>
<td>Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place.</td>
</tr>
<tr>
<td>IPv6 Multicast addresses</td>
<td>None configured.</td>
</tr>
<tr>
<td>IPv6 Multicast router ports</td>
<td>None configured.</td>
</tr>
<tr>
<td>MLD snooping Immediate Leave</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLD snooping robustness variable</td>
<td>Global: 2; Per VLAN: 0.</td>
</tr>
</tbody>
</table>

**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.
### MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the `ipv6 mld snooping` global configuration command for the configuration to take effect.

- When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch.

- The maximum number of multicast entries allowed on the switch or switch stack is determined by the configured SDM template.

- The maximum number of address entries allowed for the switch or switch stack is 4000.

### Enabling or Disabling MLD Snooping on the Switch (CLI)

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis or for a range of VLANs, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

Beginning in privileged EXEC mode, follow these steps to globally enable MLD snooping on the switch:
### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>ipv6 mld snooping</code></td>
<td>Enables MLD snooping on the switch.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# <code>ipv6 mld snooping</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# <code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# <code>copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>reload</code></td>
<td>Reload the operating system.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# <code>reload</code></td>
<td></td>
</tr>
</tbody>
</table>

### Enabling or Disabling MLD Snooping on a VLAN (CLI)

Beginning in privileged EXEC mode, follow these steps to enable MLD snooping on a VLAN.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# <code>configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a Static Multicast Group (CLI)

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

Beginning in privileged EXEC mode, follow these steps to add a Layer 2 port as a member of a multicast group:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Configures a multicast group with a Layer 2 port as a member of a multicast group:</td>
</tr>
<tr>
<td><code>ipv6 mld snooping vlan vlan-id static</code></td>
<td></td>
</tr>
<tr>
<td><code>ipv6_multicast_address interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch(config)# ipv6 mld snooping vlan 1 static FF12::3 interface gigabitethernet 0/1</code></td>
<td></td>
</tr>
</tbody>
</table>

- `vlan-id` is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094.
- `ipv6_multicast_address` is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373.
- `interface-id` is the member port. It can be a physical interface or a port channel (1 to 48).
Static connections to multicast routers are supported only on switch ports.

Beginning in privileged EXEC mode, follow these steps to add a multicast router port to a VLAN:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Specifies the multicast router VLAN ID, and specify the interface to the multicast router.</td>
</tr>
<tr>
<td><code>ipv6 mld snooping vlan vlan-id mrouter interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# ipv6 mld snooping vlan 1 mrouter interface gigabitethernet 0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Enabling MLD Immediate Leave (CLI)

Beginning in privileged EXEC mode, follow these steps to enable MLDv1 Immediate Leave:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>ipv6 mld snooping vlan vlan-id immediate-leave</td>
<td>Enables MLD Immediate Leave on the VLAN interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# ipv6 mld snooping vlan 1 immediate-leave</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>show ipv6 mld snooping vlan vlan-id</td>
<td>Verifies that Immediate Leave is enabled on the VLAN interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# show ipv6 mld snooping vlan 1</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring MLD Snooping Queries (CLI)

Beginning in privileged EXEC mode, follow these steps to configure MLD snooping query characteristics for the switch or for a VLAN:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
<tr>
<td>2</td>
<td>ipv6 mld snooping robustness-variable <code>value</code></td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping robustness-variable 3</td>
</tr>
<tr>
<td>3</td>
<td>ipv6 mld snooping vlan <code>vlan-id</code> robustness-variable <code>value</code></td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping vlan 1 robustness-variable 3</td>
</tr>
<tr>
<td>4</td>
<td>ipv6 mld snooping last-listener-query-count <code>count</code></td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping last-listener-query-count 7</td>
</tr>
<tr>
<td>5</td>
<td>ipv6 mld snooping vlan <code>vlan-id</code> last-listener-query-count <code>count</code></td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping vlan 1 last-listener-query-count 7</td>
</tr>
<tr>
<td>6</td>
<td>ipv6 mld snooping last-listener-query-interval <code>interval</code></td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping last-listener-query-interval 2000</td>
</tr>
<tr>
<td>7</td>
<td>ipv6 mld snooping vlan <code>vlan-id</code> last-listener-query-interval <code>interval</code></td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping vlan 1 last-listener-query-interval 2000</td>
</tr>
<tr>
<td>8</td>
<td>ipv6 mld snooping tcn query solicit</td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ipv6 mld snooping tcn query solicit</td>
</tr>
</tbody>
</table>
### Disabling MLD Listener Message Suppression (CLI)

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

Beginning in privileged EXEC mode, follow these steps to disable MLD listener message suppression:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>no ipv6 mld snooping listener-message-suppression</td>
<td>Disable MLD message suppression.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# no ipv6 mld snooping listener-message-suppression</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>end</td>
<td>Return to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# end</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>show ipv6 mld snooping</td>
<td>Verify that IPv6 MLD snooping report suppression is disabled.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch# show ipv6 mld snooping</td>
<td></td>
</tr>
</tbody>
</table>
Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display IPv6 group address multicast entries for a VLAN configured for MLD snooping.

Table 43: Commands for Displaying MLD Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `show ipv6 mld snooping [ vlan vlan-id ]` | Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN.  
(Optional) Enter `vlan vlan-id` to display information for a single VLAN.  
The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| `show ipv6 mld snooping mrouter [ vlan vlan-id ]` | Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces.  
(Optional) Enters `vlan vlan-id` to display information for a single VLAN.  
The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| `show ipv6 mld snooping querier [ vlan vlan-id ]` | Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN.  
(Optional) Enters `vlan vlan-id` to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| `show ipv6 mld snooping address [ vlan vlan-id ] [ count | dynamic | user ]` | Displays all IPv6 multicast address information or specific IPv6 multicast address information for the switch or a VLAN.  
- Enters `count` to show the group count on the switch or in a VLAN.  
- Enters `dynamic` to display MLD snooping learned group information for the switch or for a VLAN.  
- Enters `user` to display MLD snooping user-configured group information for the switch or for a VLAN. |
| `show ipv6 mld snooping address vlan vlan-id [ ipv6-multicast-address ]` | Displays MLD snooping for the specified VLAN and IPv6 multicast address. |

Configuration Examples for Configuring MLD Snooping

Configuring a Static Multicast Group: Example

This example shows how to statically configure an IPv6 multicast group:
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 2 static FF12::3 interface gigabitethernet 1/0/1
Switch(config)# end

Configuring a Multicast Router Port: Example

This example shows how to add a multicast router port to VLAN 200:

Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet 0/2
Switch(config)# exit

Enabling MLD Immediate Leave: Example

This example shows how to enable MLD Immediate Leave on VLAN 130:

Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 130 immediate-leave
Switch(config)# exit

Configuring MLD Snooping Queries: Example

This example shows how to set the MLD snooping global robustness variable to 3:

Switch# configure terminal
Switch(config)# ipv6 mld snooping robustness-variable 3
Switch(config)# exit

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Switch(config)# exit

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

Switch# configure terminal
Switch(config)# ipv6 mld snooping last-listener-query-interval 2000
Switch(config)# exit
Configuring IPv6 Unicast Routing

• Configuring DHCP for IPv6 Address Assignment, on page 375
• Configuration Examples for IPv6 Unicast Routing, on page 379

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 Unicast Routing

This chapter describes how to configure IPv6 unicast routing on the switch.

Note

To use all IPv6 features in this chapter, the switch or stack master must be running the IP services feature set. Switches running the IP base feature set support IPv6 static routing, RIP for IPv6, and OSPF. Switches running the LAN base feature set support only IPv6 host functionality.

Understanding IPv6

IPv4 users can move to IPv6 and receive services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to:

For information about IPv6 and other features in this chapter
IPv6 Addresses

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses, or anycast addresses.

The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: n:n:n:n:n:n:n:n. This is an example of an IPv6 address:

2031:0000:130F:0000:0000:09C0:080F:130B

For easier implementation, leading zeros in each field are optional. This is the same address without leading zeros:

2031:0:130F:0:0:09C0:080F:130B

You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:

2031:0:130F::09C0:080F:130B

For more information about IPv6 address formats, address types, and the IPv6 packet header, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of Cisco IOS IPv6 Configuration Library on Cisco.com.

In the “Information About Implementing Basic Connectivity for IPv6” chapter, these sections apply to the switch:

- IPv6 Address Formats
- IPv6 Address Type: Unicast
- IPv6 Address Type: Multicast
- IPv6 Address Output Display
- Simplified IPv6 Packet Header

Supported IPv6 Unicast Routing Features

The switch supports hop-by-hop extension header packets, which are routed in software.

The switch provides IPv6 routing capability over Routing Information Protocol (RIP) for IPv6, and Open Shortest Path First (OSPF) Version 3 Protocol. It supports up to 16 equal-cost routes and can simultaneously forward IPv4 and IPv6 frames at line rate.

128-Bit Wide Unicast Addresses

The switch supports aggregatable global unicast addresses and link-local unicast addresses. It does not support site-local unicast addresses.

- Aggregatable global unicast addresses are IPv6 addresses from the aggregatable global unicast prefix. The address structure enables strict aggregation of routing prefixes and limits the number of routing table
entries in the global routing table. These addresses are used on links that are aggregated through organizations and eventually to the Internet service provider.

These addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). Addresses with a prefix of 2000::/3(001) through E000::/3(111) must have 64-bit interface identifiers in the extended unique identifier (EUI)-64 format.

• Link local unicast addresses can be automatically configured on any interface by using the link-local prefix FE80::/10(1111111010) and the interface identifier in the modified EUI format. Link-local addresses are used in the neighbor discovery protocol (NDP) and the stateless autoconfiguration process. Nodes on a local link use link-local addresses and do not require globally unique addresses to communicate. IPv6 routers do not forward packets with link-local source or destination addresses to other links.

For more information, see the section about IPv6 unicast addresses in the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

DNS for IPv6

IPv6 supports Domain Name System (DNS) record types in the DNS name-to-address and address-to-name lookup processes. The DNS AAAA resource record types support IPv6 addresses and are equivalent to an A address record in IPv4. The switch supports DNS resolution for IPv4 and IPv6.

Path MTU Discovery for IPv6 Unicast

The switch supports advertising the system maximum transmission unit (MTU) to IPv6 nodes and path MTU discovery. Path MTU discovery allows a host to dynamically discover and adjust to differences in the MTU size of every link along a given data path. In IPv6, if a link along the path is not large enough to accommodate the packet size, the source of the packet handles the fragmentation.

ICMPv6

The Internet Control Message Protocol (ICMP) in IPv6 generates error messages, such as ICMP destination unreachable messages, to report errors during processing and other diagnostic functions. In IPv6, ICMP packets are also used in the neighbor discovery protocol and path MTU discovery.

Neighbor Discovery

The switch supports NDP for IPv6, a protocol running on top of ICMPv6, and static neighbor entries for IPv6 stations that do not support NDP. The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), to verify the reachability of the neighbor, and to keep track of neighboring routers.

The switch supports ICMPv6 redirect for routes with mask lengths less than 64 bits. ICMP redirect is not supported for host routes or for summarized routes with mask lengths greater than 64 bits.

Neighbor discovery throttling ensures that the switch CPU is not unnecessarily burdened while it is in the process of obtaining the next hop forwarding information to route an IPv6 packet. The switch drops any additional IPv6 packets whose next hop is the same neighbor that the switch is actively trying to resolve. This drop avoids further load on the CPU.

Default Router Preference

The switch supports IPv6 default router preference (DRP), an extension in router advertisement messages. DRP improves the ability of a host to select an appropriate router, especially when the host is multihomed and the routers are on different links. The switch does not support the Route Information Option in RFC 4191.
An IPv6 host maintains a default router list from which it selects a router for traffic to offlink destinations. The selected router for a destination is then cached in the destination cache. NDP for IPv6 specifies that routers that are reachable or probably reachable are preferred over routers whose reachability is unknown or suspect. For reachable or probably reachable routers, NDP can either select the same router every time or cycle through the router list. By using DRP, you can configure an IPv6 host to prefer one router over another, provided both are reachable or probably reachable.

For more information about DRP for IPv6, see the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### IPv6 Stateless Autoconfiguration and Duplicate Address Detection

The switch uses stateless autoconfiguration to manage link, subnet, and site addressing changes, such as management of host and mobile IP addresses. A host autonomously configures its own link-local address, and booting nodes send router solicitations to request router advertisements for configuring interfaces.

For more information about autoconfiguration and duplicate address detection, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### IPv6 Applications

The switch has IPv6 support for these applications:

- Ping, traceroute, Telnet, and TFTP
- Secure Shell (SSH) over an IPv6 transport
- HTTP server access over IPv6 transport
- DNS resolver for AAAA over IPv4 transport
- Cisco Discovery Protocol (CDP) support for IPv6 addresses

For more information about managing these applications, see the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### DHCP for IPv6 Address Assignment

DHCPv6 enables DHCP servers to pass configuration parameters, such as IPv6 network addresses, to IPv6 clients. The address assignment feature manages non-duplicate address assignment in the correct prefix based on the network where the host is connected. Assigned addresses can be from one or multiple prefix pools. Additional options, such as default domain and DNS name-server address, can be passed back to the client. Address pools can be assigned for use on a specific interface, on multiple interfaces, or the server can automatically find the appropriate pool.

For more information and to configure these features, see the *Cisco IOS IPv6 Configuration Guide*.

This document describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### Static Routes for IPv6

Static routes are manually configured and define an explicit route between two networking devices. Static routes are useful for smaller networks with only one path to an outside network or to provide security for certain types of traffic in a larger network.

For more information about static routes, see the “Implementing Static Routes for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.
RIP for IPv6

Routing Information Protocol (RIP) for IPv6 is a distance-vector protocol that uses hop count as a routing metric. It includes support for IPv6 addresses and prefixes and the all-RIP-routers multicast group address FF02::9 as the destination address for RIP update messages.

For more information about RIP for IPv6, see the “Implementing RIP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

OSPF for IPv6

The switch running the IP Base feature set supports Open Shortest Path First (OSPF) for IPv6, a link-state protocol for IP. For more information, see *Cisco IOS IPv6 Configuration Library* on Cisco.com.

HSRP for IPv6

Switches running the IPServices and IPBase feature set support the Hot Standby Router Protocol (HSRP) for IPv6. HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.

An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address. Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

For more information about configuring HSRP for IPv6, see the "HSRP for IPv6" section.

For more information about configuring HSRP for IPv4, see the "Configuring HSRP" section.

EIGRP IPv6

Switches running the IP services feature set support the Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address.

---

**Note**

Switches running the IP base feature set do not support any IPv6 EIGRP features, including IPv6 EIGRP stub routing.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv4 address, so any IPv4 node always has an available router ID. However, EIGRP IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv4 router ID.

For more information about EIGRP for IPv6, see the “Implementing EIGRP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

SNMP and Syslog Over IPv6

To support both IPv4 and IPv6, IPv6 network management requires both IPv6 and IPv4 transports. Syslog over IPv6 supports address data types for these transports.

SNMP and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and to modify the SNMP agent to support traps for an IPv6 host
• SNMP- and syslog-related MIBs to support IPv6 addressing
• Configuration of IPv6 hosts as trap receivers

For support over IPv6, SNMP modifies the existing IP transport mapping to simultaneously support IPv4 and IPv6. These SNMP actions support IPv6 transport management:
• Opens User Datagram Protocol (UDP) SNMP socket with default settings
• Provides a new transport mechanism called SR_IPV6_TRANSPORT
• Sends SNMP notifications over IPv6 transport
• Supports SNMP-named access lists for IPv6 transport
• Supports SNMP proxy forwarding using IPv6 transport
• Verifies SNMP Manager feature works with IPv6 transport

For information on SNMP over IPv6, including configuration procedures, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

For information about syslog over IPv6, including configuration procedures, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**HTTP(S) Over IPv6**

The HTTP client sends requests to both IPv4 and IPv6 HTTP servers, which respond to requests from both IPv4 and IPv6 HTTP clients. URLs with literal IPv6 addresses must be specified in hexadecimal using 16-bit values between colons.

The accept socket call chooses an IPv4 or IPv6 address family. The accept socket is either an IPv4 or IPv6 socket. The listening socket continues to listen for both IPv4 and IPv6 signals that indicate a connection. The IPv6 listening socket is bound to an IPv6 wildcard address.

The underlying TCP/IP stack supports a dual-stack environment. HTTP relies on the TCP/IP stack and the sockets for processing network-layer interactions.

Basic network connectivity (ping) must exist between the client and the server hosts before HTTP connections can be made.

For more information, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**Unsupported IPv6 Unicast Routing Features**

The switch does not support these IPv6 features:

• IPv6 policy-based routing
• IPv6 virtual private network (VPN) routing and forwarding (VRF) table support
• Support for IPv6 routing protocols: multiprotocol Border Gateway Protocol (BGP) and Intermediate System-to-Intermediate System (IS-IS) routing
• IPv6 packets destined to site-local addresses
• Tunneling protocols, such as IPv4-to-IPv6 or IPv6-to-IPv4
• The switch as a tunnel endpoint supporting IPv4-to-IPv6 or IPv6-to-IPv4 tunneling protocols
IPv6 Feature Limitations

Because IPv6 is implemented in switch hardware, some limitations occur due to the IPv6 compressed addresses in the hardware memory. These hardware limitations result in some loss of functionality and limits some features.

These are feature limitations.

- The switch cannot forward SNAP-encapsulated IPv6 packets in hardware. They are forwarded in software.
- The switch cannot apply QoS classification on source-routed IPv6 packets in hardware.

IPv6 and Switch Stacks

The switch supports IPv6 forwarding across the stack and IPv6 host functionality on the stack master. The stack master runs the IPv6 unicast routing protocols and computes the routing tables. They receive the tables and create hardware IPv6 routes for forwarding. The stack master also runs all IPv6 applications.

Note

To route IPv6 packets in a stack, all switches in the stack should be running the IP Base feature set.

If a new switch becomes the stack master, it recomputes the IPv6 routing tables and distributes them to the member switches. While the new stack master is being elected and is resetting, the switch stack does not forward IPv6 packets. The stack MAC address changes, which also changes the IPv6 address. When you specify the stack IPv6 address with an extended unique identifier (EUI) by using the `ipv6 address ipv6-prefix/prefix length eui-64` interface configuration command, the address is based on the interface MAC address. See the Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI), on page 360.

If you configure the persistent MAC address feature on the stack and the stack master changes, the stack MAC address does not change for approximately 4 minutes.

These are the functions of IPv6 stack master and members:

- Stack master:
  - runs IPv6 routing protocols
  - generates routing tables
  - distributes routing tables to stack members that use dCEFv6
  - runs IPv6 host functionality and IPv6 applications

- Stack member (must be running the IP services feature set):
  - receives CEFv6 routing tables from the stack master
  - programs the routes into hardware
IPv6 packets are routed in hardware across the stack if the packet does not have exceptions (IPv6Options) and the switches in the stack have not run out of hardware resources.

- flushes the CEFv6 tables on master re-election

Default IPv6 Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>

Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI)

This section describes how to assign IPv6 addresses to individual Layer 3 interfaces and to globally forward IPv6 traffic on the switch.

Before configuring IPv6 on the switch, consider these guidelines:

- Not all features discussed in this chapter are supported by the switch. See the Unsupported IPv6 Unicast Routing Features, on page 358.

- In the `ipv6 address` interface configuration command, you must enter the `ipv6-address` and `ipv6-prefix` variables with the address specified in hexadecimal using 16-bit values between colons. The `prefix-length` variable (preceeded by a slash `/`) is a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address).

To forward IPv6 traffic on an interface, you must configure a global IPv6 address on that interface. Configuring an IPv6 address on an interface automatically configures a link-local address and activates IPv6 for the interface. The configured interface automatically joins these required multicast groups for that link:

- solicited-node multicast group FF02:0:0:0:1:ff00::/104 for each unicast address assigned to the interface (this address is used in the neighbor discovery process.)

- all-nodes link-local multicast group FF02::1

- all-routers link-local multicast group FF02::2
To remove an IPv6 address from an interface, use the `no ipv6 address ipv6-prefix/prefix length eui-64` or `no ipv6 address ipv6-address link-local` interface configuration command. To remove all manually configured IPv6 addresses from an interface, use the `no ipv6 address` interface configuration command without arguments. To disable IPv6 processing on an interface that has not been explicitly configured with an IPv6 address, use the `no ipv6 enable` interface configuration command. To globally disable IPv6 routing, use the `no ipv6 unicast-routing` global configuration command.

For more information about configuring IPv6 routing, see the “Implementing Addressing and Basic Connectivity for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to assign an IPv6 address to a Layer 3 interface and enable IPv6 routing:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Selects an SDM template that supports IPv4 and IPv6.</td>
</tr>
<tr>
<td>`sdm prefer dual-ipv4-and-ipv6 {advanced</td>
<td>vlan}`</td>
</tr>
<tr>
<td>Example: <code>Switch(config)# sdm prefer dual-ipv4-and-ipv6 default</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch(config)# end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Reloads the operating system.</td>
</tr>
<tr>
<td><code>reload</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch# reload</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Enters global configuration mode after the switch reloads.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 6**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>interface interface-id</code></td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure. The interface can be a physical interface, a switch virtual interface (SVI), or a Layer 3 EtherChannel.</td>
</tr>
</tbody>
</table>

**Example:**

```plaintext
Switch(config)# interface gigabitethernet 1/0/1
```

**Step 7**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>no switchport</code></td>
<td>Removes the interface from Layer 2 configuration mode (if it is a physical interface).</td>
</tr>
</tbody>
</table>

**Example:**

```plaintext
Switch(config-if)# no switchport
```

**Step 8**

Use one of the following:

- `ipv6 address ipv6-prefix/prefix length eui-64`
- `ipv6 address ipv6-address/prefix length`
- `ipv6 address ipv6-address link-local`
- `ipv6 enable`
- `ipv6 address WORD`
- `ipv6 address autoconfig`
- `ipv6 address dhcp`

**Example:**

```plaintext
Switch(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
```

**Example:**

```plaintext
Switch(config-if)# ipv6 address 2001:0DB8:c18:1::/64
```

**Example:**

```plaintext
Switch(config-if)# ipv6 address 2001:0DB8:c18:1:: link-local
```

**Example:**

```plaintext
Switch(config-if)# ipv6 enable
```

**Step 9**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exit</code></td>
<td>Returns to global configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

```plaintext
Switch(config-if)# exit
```

**Step 10**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip routing</code></td>
<td>Enables IP routing on the switch.</td>
</tr>
</tbody>
</table>

**Example:**

```plaintext
Switch(config)# ip routing
```

**Step 11**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ipv6 unicast-routing</code></td>
<td>Enables forwarding of IPv6 unicast data packets.</td>
</tr>
</tbody>
</table>

**Example:**

```plaintext

```
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ipv6 unicast-routing</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 12</td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

| Step 13 | show ipv6 interface interface-id |
| Example: | |
| Switch# show ipv6 interface gigabitethernet 1/0/1 | Verifies your entries. |

| Step 14 | copy running-config startup-config |
| Example: | |
| Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Configuring IPv4 and IPv6 Protocol Stacks (CLI)

Beginning in privileged EXEC mode, follow these steps to configure a Layer 3 interface to support both IPv4 and IPv6 and to enable IPv6 routing.

**Note**
To disable IPv6 processing on an interface that has not been configured with an IPv6 address, use the `no ipv6 enable` interface configuration command.

**SUMMARY STEPS**

1. configure terminal
2. ip routing
3. ipv6 unicast-routing
4. interface interface-id
5. no switchport
6. ip address ip-address mask [secondary]
7. Use one of the following:
   - ipv6 address ipv6-prefix/prefix length eui-64
   - ipv6 address ipv6-address/prefix length
   - ipv6 address ipv6-address link-local
   - ipv6 enable
   - ipv6 address WORD
   - ipv6 address autoconfig
### IPv6 Address Configuration

8. **End**

9. Use one of the following:
   - `show interface interface-id`
   - `show ip interface interface-id`
   - `show ipv6 interface interface-id`

10. `copy running-config startup-config`

### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ip address ip-address mask [secondary]</td>
<td>Specifies a primary or secondary IPv4 address for the interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch(config-if)# ip address 10.1.2.3 255.255.255</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Default Router Preference (CLI)

Router advertisement messages are sent with the default router preference (DRP) configured by the `ipv6 nd router-preference` interface configuration command. If no DRP is configured, RAs are sent with a medium preference.

A DRP is useful when two routers on a link might provide equivalent, but not equal-cost routing, and policy might dictate that hosts should prefer one of the routers.

For more information about configuring DRP for IPv6, see the “Implementing IPv6 Addresses and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to configure a DRP for a router on an interface.

<table>
<thead>
<tr>
<th>Step 7</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use one of the following:</td>
<td>• <code>ipv6 address ipv6-prefix/prefix length eui-64</code>&lt;br&gt;• <code>ipv6 address ipv6-address/prefix length</code>&lt;br&gt;• <code>ipv6 address ipv6-address link-local</code>&lt;br&gt;• <code>ipv6 enable</code>&lt;br&gt;• <code>ipv6 address WORD</code>&lt;br&gt;• <code>ipv6 address autoconfig</code>&lt;br&gt;• <code>ipv6 address dhcp</code></td>
<td>• Specifies a global IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address.&lt;br&gt;• Specifies a link-local address on the interface to be used instead of the automatically configured link-local address when IPv6 is enabled on the interface.&lt;br&gt;• Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link.</td>
</tr>
</tbody>
</table>

| Note | To remove all manually configured IPv6 addresses from an interface, use the `no ipv6 address` interface configuration command without arguments. |

<table>
<thead>
<tr>
<th>Step 8</th>
<th>end&lt;br&gt;Example:</th>
<th>Returns to privileged EXEC mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# <code>end</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 9</th>
<th>Use one of the following:</th>
<th>Verifies your entries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <code>show interface interface-id</code>&lt;br&gt;• <code>show ip interface interface-id</code>&lt;br&gt;• <code>show ipv6 interface interface-id</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 10</th>
<th>copy running-config startup-config&lt;br&gt;Example:</th>
<th>(Optional) Saves your entries in the configuration file.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>copy running-config startup-config</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring IPv6 ICMP Rate Limiting (CLI)

ICMP rate limiting is enabled by default with a default interval between error messages of 100 milliseconds and a bucket size (maximum number of tokens to be stored in a bucket) of 10.

Beginning in privileged EXEC mode, follow these steps to change the ICMP rate-limiting parameters:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | configure terminal  
Example: Switch# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface-id  
Example: Switch(config)# interface gigabitethernet 1/0/1 | Enters interface configuration mode and identifies the Layer 3 interface on which you want to specify the DRP. |
| Step 3 | ipv6 nd router-preference {high | medium | low}  
Example: Switch(config-if)# ipv6 nd router-preference medium | Specifies a DRP for the router on the switch interface. |
| Step 4 | end  
Example: Switch(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ipv6 interface  
Example: Switch# show ipv6 interface | Verifies the configuration. |
| Step 6 | copy running-config startup-config  
Example: Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
# Configuring CEF and dCEF for IPv6

Cisco Express Forwarding (CEF) is a Layer 3 IP switching technology to improve network performance. CEF implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. It is less CPU-intensive than fast-switching route-caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed CEF (dCEF) in the stack. IPv4 CEF and dCEF are enabled by default. IPv6 CEF and dCEF are disabled by default, but automatically enabled when you configure IPv6 routing.

IPv6 CEF and dCEF are automatically disabled when IPv6 routing is unconfigured. IPv6 CEF and dCEF cannot be disabled through configuration. You can verify the IPv6 state by entering the `show ipv6 cef` privileged EXEC command.

---

## Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>ipv6 icmp error-interval interval [bucketsize]</code></td>
<td>Configures the interval and bucket size for IPv6 ICMP error messages:</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch(config)# ipv6 icmp error-interval 50 20</code></td>
<td>• <em>interval</em>—The interval (in milliseconds) between tokens being added to the bucket. The range is from 0 to 2147483647 milliseconds.</td>
</tr>
<tr>
<td></td>
<td>• <em>bucketsize</em>—(Optional) The maximum number of tokens stored in the bucket. The range is from 1 to 200.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>

<td></td>
</tr>
<tr>
<td><code>Switch# show ipv6 interface gigabitethernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>
To route IPv6 unicast packets, you must first globally configure forwarding of IPv6 unicast packets by using the `ipv6 unicast-routing` global configuration command, and you must configure an IPv6 address and IPv6 processing on an interface by using the `ipv6 address` interface configuration command.

For more information about configuring CEF and dCEF, see Cisco IOS IPv6 Configuration Library on Cisco.com.

**Configuring Static Routing for IPv6 (CLI)**

Before configuring a static IPv6 route, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on at least one Layer 3 interface by configuring an IPv6 address on the interface.

For more information about configuring static IPv6 routing, see the “Implementing Static Routes for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  * configure terminal
  * Example:
    
    ```
    Switch# configure terminal
    ```
  | Enters global configuration mode. |
| **Step 2**
  * `ipv6 route ipv6-prefix/prefix-length {ipv6-address | interface-id [ipv6-address]} [administrative-distance]`
  * Example:
    
    ```
    Switch(config)# ipv6 route 2001:0DB8::/32
gigabitethernet2/0/1 130
    ```
  | Configures a static IPv6 route.
  |  * `ipv6-prefix`—The IPv6 network that is the destination of the static route. It can also be a hostname when static host routes are configured.
  |  * `/prefix length`—The length of the IPv6 prefix. A decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark must precede the decimal value.
  |  * `ipv6-address`—The IPv6 address of the next hop that can be used to reach the specified network. The IPv6 address of the next hop need not be directly connected; recursion is done to find the IPv6 address of the directly connected next hop. The address must be in the form documented in RFC 2373, specified in hexadecimal using 16-bit values between colons.
  |  * `interface-id`—Specifies direct static routes from point-to-point and broadcast interfaces. With point-to-point interfaces, there is no need to specify the IPv6 address of the next hop. With broadcast interfaces, you should always specify the IPv6 address of the next hop, or ensure that the specified prefix is assigned to the link, specifying a link-local address as
Command or Action | Purpose
--- | ---
 | You can optionally specify the IPv6 address of the next hop to which packets are sent.
 * **Note** You must specify an *interface-id* when using a link-local address as the next hop (the link-local next hop must also be an adjacent router).

- *administrative distance*—(Optional) An administrative distance. The range is 1 to 254; the default value is 1, which gives static routes precedence over any other type of route except connected routes. To configure a floating static route, use an administrative distance greater than that of the dynamic routing protocol.

---

**Step 3**

**Example:**

Switch(config)# end

Returns to privileged EXEC mode.

**Step 4**

Use one of the following:

- *show ipv6 static [ipv6-address | ipv6-prefix/prefix length] [interface interface-id] [detail] [recursive]*
- *show ipv6 route static [updated]*

**Example:**

Switch# show ipv6 static 2001:0DB8::/32 interface gigabitethernet2/0/1

or

Switch# show ipv6 route static

Verifies your entries by displaying the contents of the IPv6 routing table.

- *interface interface-id*—(Optional) Displays only those static routes with the specified interface as an egress interface.

- *recursive*—(Optional) Displays only recursive static routes. The *recursive* keyword is mutually exclusive with the *interface* keyword, but it can be used with or without the IPv6 prefix included in the command syntax.

- *detail*—(Optional) Displays this additional information:
  
  - For valid recursive routes, the output path set, and maximum resolution depth.
  
  - For invalid routes, the reason why the route is not valid.

**Step 5**

**Example:**

Switch# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
## Configuring RIP for IPv6 (CLI)

Before configuring the switch to run IPv6 RIP, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on any Layer 3 interfaces on which IPv6 RIP is to be enabled.

For more information about configuring RIP routing for IPv6, see the “Implementing RIP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ipv6 router rip name</td>
<td>Configures an IPv6 RIP routing process, and enters router configuration mode for the process.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# ipv6 router rip cisco</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> maximum-paths number-paths</td>
<td>(Optional) Define the maximum number of equal-cost routes that IPv6 RIP can support. The range is from 1 to 32, and the default is 16 routes.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config-router)# maximum-paths 6</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config-router)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> interface interface-id</td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ipv6 rip name enable</td>
<td>Enables the specified IPv6 RIP routing process on the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config-if)# ipv6 rip cisco enable</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 7**

ipv6 rip name default-information {only | originate}

**Example:**

Switch(config-if)# ipv6 rip cisco
default-information only

**Purpose**

(Optional) Originates the IPv6 default route (::/0) into the RIP routing process updates sent from the specified interface.

**Note**

To avoid routing loops after the IPv6 default route (::/0) is originated from any interface, the routing process ignores all default routes received on any interface.

- **only**—Select to originate the default route, but suppress all other routes in the updates sent on this interface.
- **originate**—Select to originate the default route in addition to all other routes in the updates sent on this interface.

**Step 8**

end

**Example:**

Switch(config)# end

**Purpose**

Returns to privileged EXEC mode.

**Step 9**

Use one of the following:

- show ipv6 rip [name] [ interface interface-id ] [ database ] [ next-hops ]
- show ipv6 rip

**Example:**

Switch# show ipv6 rip cisco interface
gigabitethernet2/0/1

or

Switch# show ipv6 rip

**Purpose**

- Displays information about current IPv6 RIP processes.
- Displays the current contents of the IPv6 routing table.

**Step 10**

**copy running-config startup-config**

**Example:**

Switch# copy running-config startup-config

**Purpose**

(Optional) Saves your entries in the configuration file.

---

**Configuring OSPF for IPv6 (CLI)**

You can customize OSPF for IPv6 for your network. However, the defaults for OSPF in IPv6 are set to meet the requirements of most customers and features.

Follow these guidelines:
• Be careful when changing the defaults for IPv6 commands. Changing the defaults might adversely affect OSPF for the IPv6 network.

• Before you enable IPv6 OSPF on an interface, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on Layer 3 interfaces on which you are enabling IPv6 OSPF.

For more information about configuring OSPF routing for IPv6, see the “Implementing OSPF for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enables OSPF router configuration mode for the process. The process ID is the number assigned administratively when enabling the OSPF for IPv6 routing process. It is locally assigned and can be a positive integer from 1 to 65535.</td>
</tr>
<tr>
<td><code>ipv6 router ospf process-id</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# ipv6 router ospf 21</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>(Optional) Consolidates and summarizes routes at an area boundary.</td>
</tr>
<tr>
<td>`area area-id range {ipv6-prefix/prefix length} [advertise</td>
<td>not-advertise] [cost cost]`</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# area .3 range 2001:0DB8::/32 not-advertise</td>
<td></td>
</tr>
</tbody>
</table>

- **area-id**—Identifier of the area about which routes are to be summarized. It can be specified as either a decimal value or as an IPv6 prefix.

- **ipv6-prefix/prefix length**—The destination IPv6 network and a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark (/) must precede the decimal value.

- **advertise**—(Optional) Sets the address range status to advertise and generate a Type 3 summary link-state advertisement (LSA).

- **not-advertise**—(Optional) Sets the address range status to DoNotAdvertise. The Type 3 summary LSA is suppressed, and component networks remain hidden from other networks.

- **cost cost**—(Optional) Sets the metric or cost for this summary route, which is used during OSPF SPF calculation to determine the shortest paths to the destination. The value can be 0 to 16777215.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 4** | **maximum paths** *number-paths*
| Example: | **Switch**(config)# **maximum paths** 16 |
| **Step 5** | **exit**
| Example: | **Switch**(config-if)# **exit** |
| **Step 6** | **interface** *interface-id*
| Example: | **Switch**(config)# **interface** gigabitethernet 1/0/1 |
| **Step 7** | **ipv6 ospf** *process-id* [*area* *area-id*] [*instance* *instance-id*]
| Example: | **Switch**(config-if)# **ipv6 ospf** 21 *area* .3 |
| **Step 8** | **end**
| Example: | **Switch**(config)# **end** |
| **Step 9** | Use one of the following:
  - **show ipv6 ospf** [*process-id*] [*area-id*] [*interface* [*interface-id*]]
  - **show ipv6 ospf** [*process-id*] [*area-id*]
| Example: | **Switch**# **show ipv6 ospf** 21 *interface* gigabitethernet2/0/1
| | or
| | **Switch**# **show ipv6 ospf** 21 |
| **Step 10** | **copy running-config startup-config**
| Example: | **Switch**# **copy running-config startup-config** |
Configuring EIGRP for IPv6

Before configuring the switch to run IPv6 EIGRP, enable routing by entering the `ip routing global configuration` command, enable the forwarding of IPv6 packets by entering the `ipv6 unicast-routing global configuration` command, and enable IPv6 on any Layer 3 interfaces on which you want to enable IPv6 EIGRP.

To set an explicit router ID, use the `show ipv6 eigrp` command to see the configured router IDs, and then use the `router-id` command.

As with EIGRP IPv4, you can use EIGRPv6 to specify your EIGRP IPv6 interfaces and to select a subset of those as passive interfaces. Use the `passive-interface` command to make an interface passive, and then use the `no passive-interface` command on selected interfaces to make them active. EIGRP IPv6 does not need to be configured on a passive interface.

For more configuration procedures, see the “Implementing EIGRP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

Displaying IPv6

Configuring DHCP for IPv6 Address Assignment

This section describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

Default DHCPv6 Address Assignment Configuration

By default, no DHCPv6 features are configured on the switch.

DHCPv6 Address Assignment Configuration Guidelines

When configuring DHCPv6 address assignment, consider these guidelines:

- In the procedures, the specified interface must be one of these Layer 3 interfaces:
  - DHCPv6 IPv6 routing must be enabled on a Layer 3 interface.
  - SVI: a VLAN interface created by using the `interface vlan vlan_id` command.
  - EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the `interface port-channel port-channel-number` command.

- The switch can act as a DHCPv6 client, server, or relay agent. The DHCPv6 client, server, and relay function are mutually exclusive on an interface.

- The DHCPv6 client, server, or relay agent runs only on the master switch. When there is a stack master re-election, the new master switch retains the DHCPv6 configuration. However, the local RAM copy of the DHCP server database lease information is not retained.
Enabling DHCPv6 Server Function (CLI)

Use the `no` form of the DHCP pool configuration mode commands to change the DHCPv6 pool characteristics. To disable the DHCPv6 server function on an interface, use the `no ipv6 dhcp server` interface configuration command.

Beginning in privileged EXEC mode, follow these steps to enable the DHCPv6 server function on an interface.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
 configure terminal  
 **Example:**  
 Switch# configure terminal | Enters global configuration mode. |
| **Step 2**  
 ipv6 dhcp pool poolname  
 **Example:**  
 Switch(config)# ipv6 dhcp pool 7 | Enters DHCP pool configuration mode, and define the name for the IPv6 DHCP pool. The pool name can be a symbolic string (such as Engineering) or an integer (such as 0). |
| **Step 3**  
 address prefix IPv6-prefix \{lifetime\} \{t1 t1 | infinite\}  
 **Example:**  
 Switch(config-dhcpv6)# address prefix  
 2001:1000::0/64 lifetime 3600 | (Optional) Specifies an address prefix for address assignment.  
 This address must be in hexadecimal, using 16-bit values between colons.  
 **lifetime t1 t1**—Specifies a time interval (in seconds) that an IPv6 address prefix remains in the valid state. The range is 5 to 4294967295 seconds. Specify **infinite** for no time interval. |
| **Step 4**  
 link-address IPv6-prefix  
 **Example:**  
 Switch(config-dhcpv6)# link-address  
 2001:1002::0/64 | (Optional) Specifies a link-address IPv6 prefix.  
 When an address on the incoming interface or a link-address in the packet matches the specified IPv6 prefix, the server uses the configuration information pool.  
 This address must be in hexadecimal, using 16-bit values between colons. |
| **Step 5**  
 vendor-specific vendor-id  
 **Example:**  
 Switch(config-dhcpv6)# vendor-specific 9 | (Optional) Enters vendor-specific configuration mode and specifies a vendor-specific identification number. This number is the vendor IANA Private Enterprise Number. The range is 1 to 4294967295. |
| **Step 6**  
 suboption number \{address IPv6-address | ascii ASCII-string | hex hex-string\}  
 **Example:** | (Optional) Enters a vendor-specific suboption number.  
 The range is 1 to 65535. Enter an IPv6 address, ASCII text, or a hex string as defined by the suboption parameters. |

### Configuration Examples for IPv6 Unicast Routing

#### Configuring IPv6 Addressing and Enabling IPv6 Routing: Example

This example shows how to enable IPv6 with both a link-local address and a global address based on the IPv6 prefix 2001:0DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the `show ipv6 interface` EXEC command is included to show how the interface ID (20B:46FF:FE2F:D940) is appended to the link-local prefix FE80::/64 of the interface.

```plaintext
Switch(config)# ipv6 unicast-routing
Switch(config)# interface gigabitethernet1/0/11
Switch(config-if)# no switchport
Switch(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Switch(config-if)# end
Switch# show ipv6 interface gigabitethernet1/0/11
GigabitEthernet1/0/11 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
Global unicast address(es):
  2001:0DB8:c18:1:20B:46FF:FE2F:D940, subnet is 2001:0DB8:c18:1::/64 [EUI]
Joined group address(es):
  FF02::1
  FF02::2
  FF02::1:FF2F:D940
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
Hosts use stateless autoconfig for addresses.
```

#### Configuring Default Router Preference: Example

This example shows how to configure a DRP of `high` for the router on an interface.

```plaintext
Switch(config)# ipv6 unicast-routing
Switch(config)# interface gigabitethernet1/0/11
Switch(config-if)# no switchport
Switch(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Switch(config-if)# end
```

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td></td>
</tr>
<tr>
<td><code>show ipv6 dhcp interface</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Switch# show ipv6 dhcp interface</td>
</tr>
</tbody>
</table>
Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ipv6 nd router-preference high
Switch(config-if)# end

Configuring IPv4 and IPv6 Protocol Stacks: Example

This example shows how to enable IPv4 and IPv6 routing on an interface.

Switch(config)# ip routing
Switch(config)# ipv6 unicast-routing
Switch(config)# interface fastethernet1/0/11
Switch(config-if)# no switchport
Switch(config-if)# ip address 192.168.99.1 255.255.255.0
Switch(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Switch(config-if)# end

Enabling DHCPv6 Server Function: Example

This example shows how to configure a pool called engineering with an IPv6 address prefix:

Switch# configure terminal
Switch(config)# ipv6 dhcp pool engineering
Switch(config-dhcpv6)# address prefix 2001:1000::0/64
Switch(config-dhcpv6)# end

This example shows how to configure a pool called testgroup with three link-addresses and an IPv6 address prefix:

Switch# configure terminal
Switch(config)# ipv6 dhcp pool testgroup
Switch(config-dhcpv6)# link-address 2001:1001::0/64
Switch(config-dhcpv6)# link-address 2001:1002::0/64
Switch(config-dhcpv6)# link-address 2001:2000::0/48
Switch(config-dhcpv6)# address prefix 2001:1003::0/64
Switch(config-dhcpv6)# end

This example shows how to configure a pool called 350 with vendor-specific options:

Switch# configure terminal
Switch(config)# ipv6 dhcp pool 350
Switch(config-dhcpv6)# address prefix 2001:1005::0/48
Switch(config-dhcpv6)# vendor-specific 9
Switch(config-dhcpv6-vs)# suboption 1 address 1000:235D::1
Switch(config-dhcpv6-vs)# suboption 2 ascii "IP-Phone"
Switch(config-dhcpv6-vs)# end
Enabling DHCPv6 Client Function: Example

This example shows how to acquire an IPv6 address and to enable the rapid-commit option:

```
Switch(config) # interface gigabitethernet2/0/1
Switch(config-if) # ipv6 address dhcp rapid-commit
```

Configuring IPv6 ICMP Rate Limiting: Example

This example shows how to configure an IPv6 ICMP error message interval of 50 milliseconds and a bucket size of 20 tokens.

```
Switch(config) # ipv6 icmp error-interval 50 20
```

Configuring Static Routing for IPv6: Example

This example shows how to configure a floating static route to an interface with an administrative distance of 130:

```
Switch(config) # ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130
```

Configuring RIP for IPv6: Example

This example shows how to enable the RIP routing process `cisco` with a maximum of eight equal-cost routes and to enable it on an interface:

```
Switch(config) # ipv6 router rip cisco
Switch(config-router) # maximum-paths 8
Switch(config) # exit
Switch(config) # interface gigabitethernet2/0/11
Switch(config-if) # ipv6 rip cisco enable
```

Displaying IPv6: Example

This is an example of the output from the `show ipv6 interface` privileged EXEC command:

```
Switch# show ipv6 interface
Vlan1 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
Global unicast address(es):
3FFE:CO00:0:1:20B:46FF:FE2F:D940, subnet is 3FFE:CO00:0:1::/64 [EUI]
Joined group address(es):
FF02::1
FF02::2
FF02::1:FF2F:D940
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
```
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
<output truncated>

Prerequisites for IPv6 Client Address Learning

Before configuring IPv6 client address learning, configure the wireless clients to support IPv6.

Related Topics
- Configuring RA Guard Policy (CLI), on page 389

Information About IPv6 Client Address Learning

Client Address Learning is configured on switch to learn the wireless client's IPv4 and IPv6 address and clients transition state maintained by the switch on an association, re-association, de-authentication and timeout.
There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLACC)
- Stateful DHCPv6
- Static Configuration

For all of these methods, the IPv6 client always sends neighbor solicitation DAD (Duplicate Address Detection) request to ensure there is no duplicate IP address on the network. The switch snoops the client's NDP and DHCPv6 packets to learn about its client IP addresses.

**SLAAC Address Assignment**

The most common method for IPv6 client address assignment is Stateless Address Auto-Configuration (SLAAC). SLAAC provides simple plug-and-play connectivity where clients self-assign an address based on the IPv6 prefix. This process is achieved

Stateless Address Auto-Configuration (SLAAC) is configured as follows:

- Host sends a router solicitation message.
- Hosts waits for a Router Advertisement message.
- Hosts take the first 64 bits of the IPv6 prefix from the Router Advertisement message and combines it with the 64 bit EUI-64 address (in the case of ethernet, this is created from the MAC Address) to create a global unicast message. The host also uses the source IP address, in the IP header, of the Router Advertisement message, as its default gateway.
- Duplicate Address Detection is performed by IPv6 clients in order to ensure that random addresses that are picked do not collide with other clients.
- The choice of algorithm is up to the client and is often configurable.

The last 64 bits of the IPv6 address can be learned based on the following 2 algorithms:

- EUI-64 which is based on the MAC address of the interface, or
- Private addresses that are randomly generated.

The following Cisco IOS configuration commands from a Cisco-capable IPv6 router are used to enable SLAAC addressing and router advertisements:

```
ipv6 unicast-routing
interface Vlan20
```
The use of DHCPv6 is not required for IPv6 client connectivity if SLAAC is already deployed. There are two modes of operation for DHCPv6 called Stateless and Stateful.

The DHCPv6 Stateless mode is used to provide clients with additional network information that is not available in the router advertisement, but not an IPv6 address as this is already provided by SLAAC. This information can include the DNS domain name, DNS server(s), and other DHCP vendor-specific options. This interface configuration is for a Cisco IOS IPv6 router implementing stateless DHCPv6 with SLAAC enabled:

```
ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPOOL
  address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPV6-DHCP-Stateless
  ip address 192.168.20.1 255.255.255.0
  ipv6 nd other-config-flag
  ipv6 dhcp server IPV6_DHCPPOOL
  ipv6 address 2001:DB8:0:20::1/64
end
```

The DHCPv6 Stateful option, also known as managed mode, operates similarly to DHCPv4 in that it assigns unique addresses to each client instead of the client generating the last 64 bits of the address as in SLAAC. This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on a local Switch:

```
ipv6 unicast-routing
ipv6 dhcp pool IPV6_DHCPPOOL
  address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
```
IPv6-DHCP-Stateful

This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on an external DHCP server:

```
description IPv6-DHCP-Stateful
ip address 192.168.20.1 255.255.255.0
ipv6 address 2001:DB8:0:20::1/64
ipv6 nd prefix 2001:DB8:0:20::/64 no-advertise
ipv6 nd managed-config-flag
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPPPOOL
end
```

Static IP Address Assignment

Statically configured address on a client.

Router Solicitation

A Router Solicitation message is issued by a host controller to facilitate local routers to transmit Router Advertisement from which it can obtain information about local routing or perform Stateless Auto-configuration. Router Advertisements are transmitted periodically and the host prompts with an immediate Router Advertisement using a Router Solicitation such as - when it boots or following a restart operation.

Related Topics

- Configuring IPv6 ND Suppress Policy (CLI), on page 394

Router Advertisement

A Router Advertisement message is issued periodically by a router or in response to a Router Solicitation message from a host. The information contained in these messages is used by hosts to perform Stateless Auto-configuration and to modify its routing table.

Related Topics

- Configuring IPv6 ND Suppress Policy (CLI), on page 394
Neighbor Discovery

IPv6 Neighbor Discovery is a set of messages and processes that determine relationships between neighboring nodes. Neighbor Discovery replaces ARP, ICMP Router Discovery, and ICMP Redirect used in IPv4.

IPv6 Neighbor Discovery inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery packets that do not comply are dropped. The neighbor binding table in the switch tracks each IPv6 address and its associated MAC address. Clients are expired from the table according to Neighbor Binding timers.

Related Topics

Configuring IPv6 ND Suppress Policy (CLI), on page 394

Neighbor Discovery Suppression

The IPv6 addresses of wireless clients are cached by the switch. When the switch receives an NS multicast looking for an IPv6 address, and if the target address is known to the switch and belongs to one of its clients, the switch will reply with an NA message on behalf of the client. The result of this process generates the equivalent of the Address Resolution Protocol (ARP) table of IPv4 but is more efficient - uses generally fewer messages.

Note

The switch acts like proxy and respond with NA, only when the `ipv6 nd suppress` command is configured

If the switch does not have the IPv6 address of a wireless client, the switch will not respond with NA and forward the NS packet to the wireless side. To resolve this, an NS Multicast Forwarding knob is provided. If this knob is enabled, the switch gets the NS packet for the IPv6 address that it does not have (cache miss) and forwards it to the wireless side. This packet reaches the intended wireless client and the client replies with NA.

This cache miss scenario occurs rarely, and only very few clients which do not implement complete IPv6 stack may not advertise their IPv6 address during NDP.

Related Topics

Configuring IPv6 ND Suppress Policy (CLI), on page 394

RA Guard

IPv6 clients configure IPv6 addresses and populate their router tables based on IPv6 router advertisement (RA) packets. The RA guard feature is similar to the RA guard feature of wired networks. RA guard increases the security of the IPv6 network by dropping the unwanted or rogue RA packets that come from wireless clients. If this feature is not configured, malicious IPv6 wireless clients announce themselves as the router for the network often with high priority, which would take higher precedence over legitimate IPv6 routers.

RA-Guard also examines the incoming RA’s and decides whether to switch or block them based solely on information found in the message or in the switch configuration. The information available in the frames received is useful for RA validation:

- Port on which the frame is received
- IPv6 source address
• Prefix list

The following configuration information created on the switch is available to RA-Guard to validate against the information found in the received RA frame:

• Trusted/Untrusted ports for receiving RA-guard messages
• Trusted/Untrusted IPv6 source addresses of RA-sender
• Trusted/Untrusted Prefix list and Prefix ranges
• Router Preference

RA guard occurs at the switch. You can configure the switch to drop RA messages at the switch. All IPv6 RA messages are dropped, which protects other wireless clients and upstream wired network from malicious IPv6 clients.

//Create a policy for RA Guard//
ipv6 nd raguard policy raguard-router
trusted-port
device-role router

//Applying the RA Guard Policy on port/interface//
interface tengigabitethernet1/0/1 (Katana)
interface gigabitethernet1/0/1 (Edison)

ipv6 nd raguard attach-policy raguard-router

Applying RA Guard Policy (CLI), on page 390
Configuring RA Throttle Policy (CLI), on page 391
Applying RA Throttle Policy on VLAN (CLI), on page 392

RA Throttling

RA throttling allows the controller to enforce limits to RA packets headed toward the wireless network. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will still maintain an IPv6 client connectivity. If a client sends an RS packet, an RA is sent back to the client. This RA is allowed through the controller and unicasted to the client. This process ensures that the new clients or roaming clients are not affected by the RA throttling.

Configuring IPv6 Unicast (CLI)

IPv6 uncasting must always be enabled on the switch and the controller. IPv6 unicast routing is disabled.
Before you begin

To enable the forwarding of IPv6 unicast datagrams, use the `ipv6 unicast-routing` command in global configuration mode. To disable the forwarding of IPv6 unicast datagrams, use the `no` form of this command.

**SUMMARY STEPS**

1. `configure terminal`
2. `ipv6 unicast routing`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>

<td></td>
</tr>
</tbody>
</table>

**Configuring RA Guard Policy (CLI)**

Configure RA Guard policy on the switch to add IPv6 client addresses and populate the router table based on IPv6 router advertisement packets.

**SUMMARY STEPS**

1. `configure terminal`
2. `ipv6 nd raguard policy raguard-router`
3. `trustedport`
4. `device-role router`
5. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
- `configure terminal`
- Example:
  
  Switch# configure terminal |
  | Enters the global configuration mode. |
| **Step 2**
- `ipv6 nd ra-throttler policy ra-throttler1`
- Example:
  
  Switch(config)# ipv6 nd ra-throttler policy ra-throttler1 |
  | Define the router advertisement (RA) throttle policy name and enter IPv6 RA throttle policy configuration mode. |
### Applying RA Throttle Policy on VLAN (CLI)

Applying the RA Throttle policy on a VLAN. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will still maintain an IPv6 client connectivity.

### SUMMARY STEPS

1. configure terminal
2. vlan configuration 1
3. ipv6 nd ra throttler attach-policy ra-throttler1

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>vlan configuration 1</td>
<td>Configures a VLAN or a collection of VLANs and enters VLAN configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# vlan configuration 1</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring IPv6 Snooping (CLI)

IPv6 snooping must always be enabled on the switch and the controller.

**Before you begin**
Enable IPv6 on the client machine.

**SUMMARY STEPS**
1. `vlan configuration 1`
2. `ipv6 snooping`
3. `ipv6 nd suppress`
4. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>vlan configuration 1</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;<code>Switch(config)# vlan configuration 1</code></td>
<td>Enters Vlan configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td><code>ipv6 snooping</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;<code>Switch(config-vlan)# ipv6 snooping</code></td>
<td>Enables IPv6 snooping on the Vlan.</td>
</tr>
<tr>
<td>3</td>
<td><code>ipv6 nd suppress</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;<code>Switch(config-vlan-config)# ipv6 nd suppress</code></td>
<td>Enables the IPv6 ND suppress on the Vlan.</td>
</tr>
</tbody>
</table>
Configuring IPv6 ND Suppress Policy (CLI)

The IPv6 neighbor discovery (ND) multicast suppress feature stops as many ND multicast neighbor solicit (NS) messages as possible by dropping them (and responding to solicitations on behalf of the targets) or converting them into unicast traffic. This feature runs on a layer 2 switch or a wireless controller and is used to reduce the amount of control traffic necessary for proper link operations.

When an address is inserted into the binding table, an address resolution request sent to a multicast address is intercepted, and the device either responds on behalf of the address owner or, at layer 2, converts the request into a unicast message and forwards it to its destination.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ipv6 nd suppress policy

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>

## Monitoring IPv6 Clients (GUI)

To view the IPv6 clients associated with the Switch

Select Monitor > Clients

The Clients page is displayed. The Clients page contains the following details:

- **Client MAC Address**—Displays the MAC address of the client.
- **AP Name**—Displays the access point name to which the client is connected to.
- **WLAN**—Displays the WLAN associated with the client.
- **State**—Displays the client authentication.
- **Protocol**—Displays the protocol used.

To view the client related general details, click the Client MAC Address parameter in the Clients page. The **Client > Detail** page displays IPv6 addresses of the client under the **General** tab.

## Verifying IPv6 Address Learning Configuration

This example displays the output of the `show ipv6 dhcp pool` command. This command displays the IPv6 service configuration on the switch. The vlan 21 configured pool detail displays 6 clients that are currently using addresses from the pool.

**SUMMARY STEPS**

1. `show ipv6 dhcp pool`

**DETAILED STEPS**

Prerequisites for IPv6 WLAN Security

A client VLAN must be mapped to the WLAN configured on the switch.

Restrictions for IPv6 WLAN Security

RADIUS Server Support

- If multiple RADIUS servers are configured for redundancy, the user database must be identical in all the servers for the backup to work properly.

Radius ACS Support

- You must configure RADIUS on both your Cisco Secure Access Control Server (ACS) and your switch.
- RADIUS is supported on Cisco Secure ACS version 3.2 and later releases.

Information About IPv6 WLAN Security

Information About RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a client/server protocol that provides centralized security for users attempting to gain management access to a network. It serves as a back-end database similar to Local EAP and provides authentication and accounting services.
• Authentication—The process of verifying users when they attempt to log into the switch

Users must enter a valid username and password for the switch to authenticate users to the RADIUS server. If multiple databases are configured, then specify the sequence in which the backend database must be tried.

• Accounting—The process of recording user actions and changes.

Whenever a user successfully executes an action, the RADIUS accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided. If the RADIUS accounting server is unreachable, the users can continue their sessions uninterrupted.

User Datagram Protocol—RADIUS uses User Datagram Protocol (UDP) for its transport. It maintains a database and listens on UDP port 1812 for incoming authentication requests and UDP port 1813 for incoming accounting requests. The switch, which requires access control, acts as the client and requests AAA services from the server. The traffic between the switch and the server is encrypted by an algorithm defined in the protocol and a shared secret key configured on both devices.

Configures multiple RADIUS accounting and authentication servers. For example, you can have one central RADIUS authentication server but several RADIUS accounting servers in different regions. If you configure multiple servers of the same type and the first one fails or becomes unreachable, the controller automatically tries the second one, then the third one if necessary, and so on.

When RADIUS method is configured for the WLAN, the switch will use the RADIUS method configured for the WLAN. When the WLAN is configured to use local EAP, the RADIUS method configured on the WLAN points to Local. The WLAN must also be configured with the name of the local EAP profile to use.

If no RADIUS method is configured in the WLAN, the switch will use the default RADIUS method defined in global mode.

Information About Local EAP

Local EAP is an authentication method that allows users and wireless clients to be authenticated locally. It is designed for use in remote offices that maintain connectivity to wireless clients when the back-end system is disrupted or the external authentication server goes down. When you enable local EAP, the switch serves as the authentication server and the local user database, which removes dependence on an external authentication server. Local EAP retrieves user credentials from the local user database or the LDAP back-end database to authenticate users. Local EAP supports LEAP, EAP-FAST, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC authentication between the controller and wireless clients.

Note
The LDAP back-end database supports these local EAP methods: EAP-TLS, EAP-FAST/GTC, and PEAPv1/GTC. LEAP, EAP-FAST/MSCHAPv2, and PEAPv0. MSCHAPv2 is supported only if the LDAP server is set up to return a clear-text password.

Note
Switch support Local EAP authentication against external LDAP databases such as Microsoft Active Directory and Novell’s eDirectory. For more information about configuring the controller for Local EAP authentication against Novell’s eDirectory, see the Configure Unified Wireless Network for Authentication Against Novell’s eDirectory Database whitepaper.

Configuring IPv6 ACL

- Prerequisites for IPv6 ACL, on page 429
- Restrictions for IPv6 ACL, on page 429
- Information About IPv6 ACL, on page 430
- Configuring IPv6 ACLs, on page 432
- How To Configure an IPv6 ACL, on page 433

- Configuration Examples for IPv6 ACL, on page 439
- Additional References, on page 444
- Feature Information for IPv6 ACLs, on page 444

Prerequisites for IPv6 ACL

You can filter IP Version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP Version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic when the switch is running the IP base feature set.

Related Topics
- Creating IPv6 ACL, on page 433

Restrictions for IPv6 ACL

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs.

The switch supports most of the Cisco IOS-supported IPv6 ACLs with some exceptions:

- The switch does not support matching on these keywords: flowlabel, routing header, and undetermined-transport.
- The switch does not support reflexive ACLs (the reflect keyword).
- The switch does not apply MAC-based ACLs on IPv6 frames.
- When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware
forwarding (physical ports or SVIs), the switch checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.

• If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the switch does not allow the ACE to be added to the ACL that is currently attached to the interface

### Information About IPv6 ACL

An access control list (ACL) is a set of rules used to limit access to a particular interface (for example, if you want to restrict a wireless client from pinging the management interface of the controller). ACLs are configured on the switch and applied to the management interface, the AP-manager interface, any of the dynamic interfaces, or a WLAN to control data traffic to and from wireless clients or to the controller central processing unit (CPU) to control all traffic destined for the CPU.

You can also create a preauthentication ACL for web authentication. Such an ACL is used to allow certain types of traffic before authentication is complete.

IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source and destination ports.

---

**Note**

You can enable only IPv4 traffic in your network by blocking IPv6 traffic. That is, you can configure an IPv6 ACL to deny all IPv6 traffic and apply it on specific or all WLANs.

---

### Understanding IPv6 ACLs

A switch supports two types of IPv6 ACLs:

• IPv6 router ACLs are supported on outbound or inbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. IPv6 router ACLs apply only to IPv6 packets that are routed.

• IPv6 port ACLs are supported on inbound traffic on Layer 2 interfaces only. IPv6 port ACLs are applied to all IPv6 packets entering the interface.

A switch running the IP base feature set supports only input router IPv6 ACLs. It does not support port ACLs or output IPv6 router ACLs.

---

**Note**

If you configure unsupported IPv6 ACLs, an error message appears and the configuration does not take affect.

The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.

You can apply both IPv4 and IPv6 ACLs to an interface. As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs:

• When an input router ACL and input port ACL exist in an SVI, packets received on ports to which a port ACL is applied are filtered by the port ACL. Routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.
• When an output router ACL and input port ACL exist in an SVI, packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IPv6 packets are filtered by the router ACL. Other packets are not filtered.

Note
If any port ACL (IPv4, IPv6, or MAC) is applied to an interface, that port ACL is used to filter packets, and any router ACLs attached to the SVI of the port VLAN are ignored.

Related Topics
  • Creating IPv6 ACL, on page 433
  • Applying an IPv6 to an Interface, on page 437
  • Creating WLAN IPv6 ACL, on page 438
  • Displaying IPv6 ACLs, on page 439

Types of ACL

Per User IPv6 ACL

For the per-user ACL, the full access control entries (ACE) as the text strings are configured on the ACS. The ACE is not configured on the Controller. The ACE is sent to the switch in the ACCESS-Accept attribute and applies it directly for the client. When a wireless client roams into an foreign switch, the ACEs are sent to the foreign switch as an AAA attribute in the mobility Handoff message.

Filter ID IPv6 ACL

For the filter-Id ACL, the full ACEs and the acl name(filter-id) is configured on the switch and only the filter-id is configured on the ACS. The filter-id is sent to the switch in the ACCESS-Accept attribute, and the switch looks up the filter-id for the ACEs, and then applies the ACEs to the client. When the client L2 roams to the foreign switch, only the filter-id is sent to the foreign switch in the mobility Handoff message. The foreign switch has to configure the filter-id and ACEs beforehand.

Downloadable IPv6 ACL

For the downloadable ACL(dACL), the full ACEs and the dacl name are all configured on the ACS only.

Note
The controller does not configure any ACL.

The ACS sends the dacl name to the switch in its ACCESS-Accept attribute, which takes the dacl name and sends the dACL name back to the ACS, for the ACEs, using the access-request attribute.

The ACS responds to the corresponding ACEs of the switch in the access-accept attribute. When the wireless client roams to an foreign switch, only the dacl name is sent to the foreign switch in the mobility Handoff message. The foreign switch contacts the ACS server with the dacl name to retrieve the ACEs.
IPv6 ACLs and Switch Stacks

The stack master supports IPv6 ACLs in hardware and distributes the IPv6 ACLs to the stack members.

For full IPv6 functionality in a switch stack, all stack members must be running the IP services feature set.

Note

If a new switch takes over as stack master, it distributes the ACL configuration to all stack members. The member switches sync up the configuration distributed by the new stack master and flush out entries that are not required.

When an ACL is modified, attached to, or detached from an interface, the stack master distributes the change to all stack members.

Configuring IPv6 ACLs

To filter IPv6 traffic, you perform these steps:

Before you begin

Before configuring IPv6 ACLs, you must select one of the dual IPv4 and IPv6 SDM templates.

SUMMARY STEPS

1. Create an IPv6 ACL, and enter IPv6 access list configuration mode.
2. Configure the IPv6 ACL to block (deny) or pass (permit) traffic.
3. Apply the IPv6 ACL to the interface where the traffic needs to be filtered.
4. Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Create an IPv6 ACL, and enter IPv6 access list configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Configure the IPv6 ACL to block (deny) or pass (permit) traffic.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Apply the IPv6 ACL to the interface where the traffic needs to be filtered.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.</td>
</tr>
</tbody>
</table>
Default IPv6 ACL Configuration

There are no IPv6 ACLs configured or applied.

Interaction with Other Features and Switches

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.
- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.
- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.
- If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.

Note: Only packets of the same type as the ACL that could not be added (ipv4, ipv6, MAC) will be dropped on the interface.

How To Configure an IPv6 ACL

Creating IPv6 ACL

Beginning in privileged EXEC mode, follow these steps to create an IPv6 ACL:

**SUMMARY STEPS**

1. `configure terminal`
2. `ipv6 access-list acl_name`
3. `{deny|permit} protocol`
4. `{deny|permit} tcp`
5. `{deny|permit} udp`
6. `{deny|permit} icmp`
7. `end`
8. `show ipv6 access-list`
9. `copy running-config startup-config`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** configure terminal
  **Example:** Switch# configure terminal | Enters global configuration mode. |
| **Step 2** ipv6 access-list *acl_name*
  **Example:** ipv6 access-list access-list-name | Use a name to define an IPv6 access list and enter IPv6 access-list configuration mode. |
| **Step 3** {deny|permit} protocol
  **Example:**
  {deny | permit} protocol
  {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dscp value] [fragments] [log] [log-input] [routing] [sequence value] [time-range name] | Enter deny or permit to specify whether to deny or permit the packet if conditions are matched. These are the conditions:
  - For **protocol**, enter the name or number of an Internet protocol: ahp, esp, icmp, ipv6, pcp, step, tcp, or udp, or an integer in the range 0 to 255 representing an IPv6 protocol number.
  - The source-ipv6-prefix/prefix-length or destination-ipv6-prefix/ prefix-length is the source or destination IPv6 network or class of networks for which to set deny or permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373).
  - Enter any as an abbreviation for the IPv6 prefix ::/0.
  - For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons.
  - (Optional) For **operator**, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range.
  - (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP.
  - (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Purpose</strong></td>
<td>in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63.</td>
</tr>
<tr>
<td>• (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter log to cause an logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter routing to specify that IPv6 packets be routed.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

{deny|permit} tcp

Example:

{deny | permit} tcp
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}
{operator [port-number]}{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}
{operator [port-number]}[ack] [dscp value][established] [fin] [log][log-input] [neq {port | protocol}] [psh]
{range{port | protocol}} [rst][routing] [sequence value] [syn] [time-range name][urg]

(Optional) Define a TCP access list and the access conditions.

Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:

- **ack**—Acknowledgment bit set.
- **established**—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set.
- **fin**—Finished bit set; no more data from sender.
- **neq {port | protocol}**—Matches only packets that are not on a given port number.
- **psh**—Push function bit set.
- **range {port | protocol}**—Matches only packets in the port number range.
- **rst**—Reset bit set.
- **syn**—Synchronize bit set.
- **urg**—Urgent pointer bit set.

**Step 5**

{deny|permit} udp

Example:

(Optional) Define a UDP access list and the access conditions.
**Purpose**

Command or Action

- `deny | permit` udp
- `{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}`
- `[operator [port-number]] [{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}]`
- `[operator [port-number]] [dscp value]`
- `[log] [log-input]`
- `[neq [port |protocol]] [range [port |protocol]]`
- `[routing] [sequence value] [time-range name]`

Enter `udp` for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the operator `[port]` port number or name must be a UDP port number or name, and the established parameter is not valid for UDP.

**Step 6**

```
{deny|permit} icmp
```

Example:

```
{deny|permit} icmp
{source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address}
[operator [port-number]]
{destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address}
[operator [port-number]] [icmp-type [icmp-code]]
[icmp-message] [dscp value] [log] [log-input]
[routing] [sequence value] [time-range name]
```

(Optional) Define an ICMP access list and the access conditions.

Enter `icmp` for Internet Control Message Protocol. The ICMP parameters are the same as those described for most IP protocols in Step 3a, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:

- `icmp-type`—Enter to filter by ICMP message type, a number from 0 to 255.
- `icmp-code`—Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255.
- `icmp-message`—Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name. To see a list of ICMP message type names and code names, use the `?` key or see command reference for this release.

**Step 7**

```
end
```

Example:

```
Switch(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

**Step 8**

```
show ipv6 access-list
```

Example:

```
show ipv6 access-list
```

Verify the access list configuration.

**Step 9**

```
copy running-config startup-config
```

Example:

```
copy running-config startup-config
```

(Optional) Save your entries in the configuration file.

Applying an IPv6 to an Interface

This section describes how to apply IPv6 ACLs to network interfaces. You can apply an IPv6 ACL to outbound or inbound traffic on layer 2 and Layer 3 interfaces. You can apply IPv6 ACLs only to inbound management traffic on Layer 3 interfaces.

Beginning in privileged EXEC mode, follow these steps to control access to an interface:

SUMMARY STEPS

1. configure terminal
2. interface interface_id
3. no switchport
4. ipv6 address ipv6_address
5. ipv6 traffic-filter acl_name
6. end
7. show running-config interface tenGigabitEthernet 1/0/3
8. copy running-config startup-config

Configuration Examples for IPv6 ACL

**Example: Creating IPv6 ACL**

This example configures the IPv6 access list named CISCO. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny -all condition is at the end of each IPv6 access list.
Example: Applying IPv6 ACLs

This example shows how to apply the access list Cisco to outbound traffic on a Layer 3 interface.

Switch(config)# interface TenGigabitEthernet 1/0/3
Switch(config-if)# no switchport
Switch(config-if)# ipv6 address 2001::/64 eui-64
Switch(config-if)# ipv6 traffic-filter CISCO out

Example: Displaying IPv6 ACLs

This is an example of the output from the `show access-lists` privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

Switch# show access-lists
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10

This is an example of the output from the `show ipv6 access-list` privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

Switch# show ipv6 access-list
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30

IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any sequence 20

Example: Configuring RA Throttling and NS Suppression

This task describes how to create an RA throttle policy in order to help the power-saving wireless clients from being disturbed by frequent unsolicited periodic RA’s. The unsolicited multicast RA is throttled by the controller.

Before you begin

Enable IPv6 on the client machine.

SUMMARY STEPS

1. configure terminal
**IPv6**

2. `ipv6 nd ra-throttler policy Mythrottle`
3. `throttle-period 20`
4. `max-through 5`
5. `allow at-least 3 at-most 5`
6. `switch (config)# vlan configuration 100`
7. `ipv6 nd suppress`
8. `ipv6 nd ra-th attach-policy attach-policy_name`
9. `end`

### Detailed Steps

Prerequisites for IPv6 Web Authentication

The following configurations must be in place before you start with IPv6 Web Authentication:

- IPv6 Device Tracking.
- IPv6 DHCP Snooping.
- Disable security of type 802.1x on the wlan.
- Each WLAN must have a vlan associated to it.
- Change the default wlan setting from shutdown to no shutdown.

Related Topics
- Enabling Security on the WLAN, on page 450

Restrictions for IPv6 Web Authentication

The following restrictions are implied when using IPv6 web authentication:

Related Topics
- Enabling Security on the WLAN, on page 450
Information About IPv6 Web Authentication

Web authentication is a Layer 3 security feature and the switch disallows IP traffic (except DHCP and DNS-related packets) from a particular client until it supplies a valid username and password. It is a simple authentication method without the need for a supplicant or client utility. Web authentication is typically used by customers who deploy a guest-access network. Traffic from both, HTTP and HTTPS, page is allowed to display the login page.

Note

Web authentication does not provide data encryption and is typically used as simple guest access for either a hot spot or campus atmosphere, where connectivity is always a factor.

A WLAN is configured as security webauth for web based authentication. The switch supports the following types of web based authentication:

- Web Authentication – The client enters the credentials in a web page which is then validated by the Wlan controller.
- Web Consent – The Wlan controller presents a policy page with Accept/Deny buttons. Click Accept button to access the network.

A Wlan is typically configured for open authentication, that is without Layer 2 authentication, when web-based authentication mechanism is used.

Web Authentication Process

The following events occur when a WLAN is configured for web authentication:

- The user opens a web browser and enters a URL address, for example, http://www.example.com. The client sends out a DNS request for this URL to get the IP address for the destination. The switch bypasses the DNS request to the DNS server, which in turn responds with a DNS reply that contains the IP address of the destination www.example.com. This, in turn, is forwarded to the wireless clients.

- The client then tries to open a TCP connection with the destination IP address. It sends out a TCP SYN packet destined to the IP address of www.example.com.

- The switch has rules configured for the client and cannot act as a proxy for www.example.com. It sends back a TCP SYN-ACK packet to the client with source as the IP address of www.example.com. The client sends back a TCP ACK packet in order to complete the three-way TCP handshake and the TCP connection is fully established.

- The client sends an HTTP GET packet destined to www.example.com. The switch intercepts this packet and sends it for redirection handling. The HTTP application gateway prepares an HTML body and sends it back as the reply to the HTTP GET requested by the client. This HTML makes the client go to the default web-page of the switch, for example, http://<Virtual-Server-IP>/login.html.

- The client closes the TCP connection with the IP address, for example, www.example.com.

- If the client wants to go to virtual IP, the client tries to open a TCP connection with the virtual IP address of the switch. It sends a TCP SYN packet for virtual IP to the switch.
The switch responds back with a TCP SYN-ACK and the client sends back a TCP ACK to the switch in order to complete the handshake.

The client sends an HTTP GET for /login.html destined to virtual IP in order to request for the login page.

This request is allowed to the web server of the switch, and the server responds with the default login page. The client receives the login page in the browser window where the user can log in.

How to Configure IPv6 Web Authentication

Disabling WPA

**Before you begin**
Disable 802.1x. A typical web authentication does not use Layer 2 security. Use this configuration to remove Layer 2 security.

**SUMMARY STEPS**

1. configure terminal
2. wlan test1 2 test1
3. no security wpa

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

### Configuring the WLAN

**Before you begin**

- The WLAN must have a Vlan associated with it. By default, a new Wlan is always associated with Vlan 1, which can be changed as per the configuration requirements.
- Configure and enable the WLAN to `no shutdown`. By default, the Wlan is configured with the `shutdown` parameter and is disabled.

**SUMMARY STEPS**

1. `wlan 1`
2. `client vlan interface ID`
3. `security web-auth authentication list webauthlistlocal`
4. `security web-auth parameter-map global`
5. `no security wpa`
6. `no shutdown`
7. `end`
### DETAILED STEPS

| Step 1 | wlan 1  
Example:  
Switch(config-wlan)# wlan 1 name vicweb ssid vicweb |
<table>

Prerequisites for IPv6 Client Mobility

To enable wireless IPv6 client connectivity, the underlying wired network must support IPv6 routing and an address assignment mechanism such as SLAAC or DHCPv6. The switch must have L2 adjacency to the IPv6 router, and the VLAN needs to be tagged when the packets enter the switch. APs do not require connectivity on an IPv6 network, as all traffic is encapsulated inside the IPv4 CAPWAP tunnel between the AP and switch.

Restrictions For IPv6 Client Mobility

- When using the IPv6 Client Mobility, clients must support IPv6 with either static stateless auto configuration (such as Windows XP clients) or stateful DHCPv6 IP addressing (such as Windows 7 clients).

- To allow smooth operation of stateful DHCPv6 IP addressing, you must have a switch or router that supports the DHCP for IPv6 feature (such as the switch) that is configured to act like a DHCPv6 server, or you need a dedicated server such as a Windows 2008 server with a built-in DHCPv6 server. Cisco Catalyst 3850 switch and Cisco Catalyst 5700 switch can act as (internal) a DHCPv6 server.

Note

To load the SDM IPv6 template in the Cisco Catalyst 3850 switch, enter the `sdm prefer dual-ipv4 and v6` default command and then reset the switch.
Information About IPv6 Client Mobility

The Switch supports IPv6 mobility for IPv6-only or dual-stack nodes. The IPv6 Client Mobility is divided into:

- Link Layer and
- Network Layer

The link layer is handled by the 802.11 protocol which enables the client to roam to any AP in the same BSS (basic service set) identified by the same SSID without losing the link layer connectivity.

However, link layer mobility is not enough to make wireless client Layer 3 applications continue to work seamlessly while roaming. Cisco IOSd’s wireless mobility module uses mobility tunneling to retain seamless connectivity for the client’s Layer 3 PoP (point of presence) when the client roams across different subnets on different switches.

IPv6 is the next-generation network layer Internet protocol intended to replace IPv4 in the TCP/IP suite of protocols. This new version increases the internet global address space to accommodate users and applications that require unique global IP addresses. IPv6 incorporates 128-bit source and destination addresses, which provide significantly more addresses than the 32-bit IPv4 addresses.

To support IPv6 clients across controllers, ICMPv6 messages must be dealt with specially to ensure the IPv6 client remains on the same Layer 3 network. The switch keep track of IPv6 clients by intercepting the ICMPv6 messages to provide seamless mobility and protect the network from network attacks. The NDP (neighbor discovery packets) packets are converted from multicast to unicast and delivered individually per client. This unique solution ensures that Neighbor Discovery and Router Advertisement packets are not leaked across Vlans. Clients can receive specific Neighbor Discovery and Router Advertisement packets ensuring correct IPv6 addressing and avoids unnecessary multicast traffic.

The configuration for IPv6 mobility is the same as IPv4 mobility and requires no separate software on the client side to achieve seamless roaming. The switch must be part of the same mobility group. Both IPv4 and IPv6 client mobility are enabled by default.

IPv6 client mobility is used for the following:

- Retaining the client IPv6 multiple addresses in Layer-2 and Layer-3 roaming.
- IPv6 Neighbor Discovery Protocol (NDP) packet management.
- Client IPv6 addresses learning.

Using Router Advertisement

The Neighbor Discovery Protocol(NDP) operates in the link-layer and is responsible for the discovery of other nodes on the link. It determines the link-layer addresses of other nodes, finds the available routers, and maintains reachability information about the paths to other active neighbor nodes.

Router Advertisement (RA) is one of the IPv6 Neighbor Discovery Protocol (NDP) packets that is used by the hosts to discover available routers, acquire the network prefix to generate the IPv6 addresses, link MTU, and so on. The routers send RA on a regular basis, or in response to hosts Router Solicitation messages.
IPv6 wireless client mobility manages the IPv6 RA packet. The converged access switch forwards the link-local all-nodes multicast RA packets to the local and roaming wireless nodes mapped on same VLAN the RA was received on.

Figure 1 illustrates the link-local all-nodes mcast RA forwarding issue in the wireless node mobility.

*Figure 19: Roaming Client Receiving Invalid RA from Router 2*

Figure 2 illustrates how a roaming client “MN” receives RA from VLAN 200 in a foreign switch and how it acquires a new IP address and breaks into L3 mobility’s point of presence.

*Figure 20: Roaming Client Receives Valid RA from Router 1*

**Related Topics**

**RA Throttling and NS suppression**

To safeguard the power-saving wireless clients from being disturbed by frequent unsolicited periodic RAs, the controller can throttle the unsolicited multicast RA.

**Related Topics**
- Verifying IPv6 Client Mobility, on page 463
- Monitoring IPv6 Client Mobility, on page 463
IPv6 Address Learning

There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static configuration

For these methods, the IPv6 client always sends NS DAD (duplicate address detection) to ensure that there is no duplicated IP address on the network. The switch snoops the clients NDP and DHCPv6 packets to learn about its client IP addresses and then updates the controllers database. The database then informs the controller for the clients new IP address.

Related Topics

- Verifying IPv6 Client Mobility, on page 463
- Monitoring IPv6 Client Mobility, on page 463

Handling Multiple IP Addresses

In the case when the new IP address is received after RUN state, whether an addition or removal, the controller updates the new IP addresses on its local database for display purposes. Essentially, the IPv6 uses the existing or same PEM state machine code flow as in IPv4. When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller will include all the available IP addresses, IPv4 and IPv6, in the API/SPI interface to the external entities.

An IPv6 client can acquire multiple IP addresses from stack for different purposes. For example, a link-local address for link local traffic, and a routable unique local or global address.

When the client is in the DHCP request state and the controller receives the first IP address notification from the database for either an IPv4 or IPv6 address, the PEM moves the client into the RUN state.

When a new IP address is received after the RUN state, either for addition or removal, the controller updates the new IP addresses on its local database for display purposes.

When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller provides the available IP addresses, both IPv4 and IPv6, to the external entities.

Related Topics

- Verifying IPv6 Client Mobility, on page 463

IPv6 Configuration

The switch supports IPv6 client as seamlessly as the IPv4 clients. The administrator must manually configure the Vlans to enable the IPV6, IPv6’s snooping and throttling functionality. This will enable the NDP packets to throttle between the switch and its various clients

Related Topics

- Verifying IPv6 Client Mobility, on page 463

High Availability

The switch will sync with the wireless clients when the clients IP address is hard to learn. When a switchover happens, the IPv6 neighbor binding table is synced to standby state. However, the wireless client will itself disassociate and reassociate to a new active state once the switchover is complete and the neighbor binding table is updated with latest information for that client.

If, during the reassociation, the client moves to another AP then the original entry in the binding table is marked as down for sometime and will be aged-out.

For the new entries joining the switch from another AP, the new IP address is learned and notified to the controller's database.

---

**Note**

This feature is available only for the Cisco Catalyst 3850 Switch.

Pre-requisites for IPv6 Mobility

The mobility and its related infrastructure must be configured and ready for use.

Information About IPv6 Mobility

Mobility, or roaming, is a wireless LAN client's ability to maintain its association seamlessly from one access point to another securely and with as little latency as possible. This section explains how mobility works when switches are included in a wireless network.

When a wireless client associates and authenticates to an access point, the access point's switch places an entry for that client in its client database. This entry includes the client's MAC and IP addresses, security context and associations, quality of service (QoS) contexts, the WLAN, and the associated access point. The switch uses this information to forward frames and manage traffic to and from the wireless client.

When the wireless client moves its association from one access point to another, the switch simply updates the client database with the newly associated access point. If necessary, new security context and associations are established as well. The process becomes more complicated, however, when a client roams from an access point joined to one switch to an access point joined to a different switch. It also varies based on whether the switches are operating on the same subnet.

Inter Controller Roaming

When the client associates to an access point joined to a new switch, the new switch exchanges mobility messages with the original switch, and the client database entry is moved to the new switch if sticky anchoring is disabled.
Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming

Inter-subnet roaming is similar to inter-controller roaming in that the switch exchange mobility messages on the client roam. However, instead of moving the client database entry to the new switch, the original switch marks the client with an "Anchor" entry in its own client database. The database entry is copied to the new switch client database and marked with a "Foreign" entry in the new switch. The roam remains transparent to the wireless client, and the client maintains its original IP address.

In inter-subnet roaming, WLANs on both anchor and foreign switch need to have the same network access privileges and no source-based routing or source-based firewalls in place. Otherwise, the clients may have network connectivity issues after the handoff.

For more information on configuring mobility see, the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE, Release 3.2SE.

How to Configure IPv6 Mobility

Monitoring IPv6 Mobility

This chapter displays the mobility related IPv6 configuration. To see the mobility related configurations refer to the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE 3.2SE.

SUMMARY STEPS

1. show ipv6 neighbors binding mac C0C1.C06B.C4E2

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 show ipv6 neighbors binding mac C0C1.C06B.C4E2</td>
<td>Displays the IPv6 related mobility configurations.</td>
</tr>
</tbody>
</table>

Example

Switch# show ipv6 neighbors binding mac C0C1.C06B.C4E2
Binding Table has 45 entries, 37 dynamic (limit 100)

Configuring IPv6 NetFlow

• Prerequisites For IPv6 Netflow, on page 473
• Restrictions For IPv6 Netflow, on page 473
• Information About IPv6 Netflow, on page 474
• How To Configure IPv6 Netflow, on page 475
• Verifying IPv6 Netflow, on page 486
• Monitoring IPv6 Netflow, on page 486
• Additional References, on page 486
• Feature Information for IPv6 NetFlow, on page 487

Prerequisites For IPv6 Netflow

The networking device must be running a Cisco IOSd release that supports Cisco IOS Flexible NetFlow.

IPv6 Traffic

• One of the following must be enabled on your router and on any interfaces on which you want to enable Flexible NetFlow:
  • Cisco Express Forwarding IPv6 or
  • Distributed Cisco Express Forwarding IPv6.

Restrictions For IPv6 Netflow

The following restrictions apply to IPv6 Netflow configurations:

• Locally generated traffic (traffic that is generated by the router, Cisco WLC 5760, on which the Flexible NetFlow Output Accounting feature is configured) is not counted as flow traffic for the Output Flexible NetFlow Accounting feature.
• The Flexible NetFlow Output Accounting feature counts CEF-switched packets only. Process switched transit packets are not counted.
Information About IPv6 Netflow

NetFlow is a monitoring feature used on customer applications for network monitoring, user monitoring and profiling, network planning, security analysis, billing and accounting, and data warehousing and mining. You can use Flexible NetFlow on uplink ports to monitor user-defined flows, collect flow statistics, and perform per-flow policing. It collects and exports flow statistics to a collector device.

Note

Flexible NetFlow is supported only on the Catalyst 3750-X and 3560-X switch running the IP base or IP services feature set and equipped with the network services module. It is not supported on switches running the NPE or the LAN base image.

Note

Not all of the Flexible NetFlow commands in the command reference are available on the switch. Unsupported commands are either not visible or generate an error message if entered.

Understanding Flexible Netflow

With Flexible NetFlow, traffic is processed and packets are classified into flows. New flows are inserted in the NetFlow table, and statistics are automatically updated. You must configure both ingress and egress NetFlow monitoring. The network services module supports one monitor per interface per direction.

Flexible NetFlow consists of the following components:

- **Records**— These are combinations of key and non-key fields assigned to monitor Flexible NetFlow monitors to define the cache used to store data.
- **Flow monitors**— These are applied to interfaces to perform network traffic monitoring. A flow monitor includes a user-defined record, an optional flow exporter, and a cache that is automatically created when the monitor is applied to the first interface. The switch supports normal caches that age out according to settings.
- **Flow exporters**— These export the data in the flow monitor cache to a remote system, such as a server running NetFlow collector.
- **Flow samplers**— These reduce the load that Flexible NetFlow puts on the networking device to monitor traffic by limiting the number of packets that are analyzed.

You can configure unidirectional flow (destination or source-address based flows), and flow aging. The following features are supported on the network services module:

- Configuring collection statistics for Layer 2-switched (non-routing) traffic, Layer 3 (CAPWAP) IPv4 and IPv6 traffic, and Layer 4 TCP, IGMP, and ICMP traffic.
- NetFlow counting, maintenance, troubleshooting (debugging commands).
- NetFlow analysis is performed on traffic crossing the physical interfaces on the network services module. The switch processes egress (outbound) traffic after forwarding decisions are performed. Locally switched or routed traffic is forced through service module ports by configuring private VLANs or protected ports.

The following NetFlow characteristics are not supported:
IPv6 Netflow

Flexible Netflow (FNF) allows the user to define a flow record (a particular set of key, non-key, counter and time-stamp fields of interest) that is optimal for a particular application by selecting the fields from a big collection of pre-defined fields, using CLI configuration commands.

The collection of the pre-defined fields includes the following fields:

- Data-link layer (L2) header fields
- IPv6 header fields
- Transport layer (L4) header fields
- Application layer (L5) header fields
- Routing attributes (generic, IPv4, IPv6)
- Interface fields
- Counter fields
- Timestamp fields

### How To Configure IPv6 Netflow

#### Configuring a Customized Flow Record

You can match the following fields for the flow record:

- IPv4 or IPv6 destination address
- Datalink fields, to identify Layer 2 source and destination address and VLAN for traffic entering or leaving the interfaces, providing the MAC address of the directly connected host. Class of Service (CoS) and Ethertype datalink header fields are also available.
- Transport field source and destination ports, to identify the type of application: ICMP, IGMP, or TCP traffic.

You can collect the following fields for the flow record:
• The total number of bytes, flows or packets sent by the exporter (exporter) or the number of bytes or packets in a 64-bit counter (long). The timestamp based on system uptime from the time the first packet was sent or from the time the most recent (last) packet was seen.

• The SNMP index of the input or output interface. The interface for traffic entering or leaving the service module is based on the switch forwarding cache. This field is typically used in conjunction with datalink, IPv4, and IPv6 addresses, and provides the actual first-hop interface for directly connected hosts.

  • A value of 0 means that interface information is not available in the cache.
  • Some NetFlow collectors require this information in the flow record.

The following steps configure the customized flow record:

### SUMMARY STEPS

1. configure terminal
2. flow record recordname
3. description description
4. match {ipv4 | ipv6} {destination | hop-limit | protocol | source | traffic-class | version} address
5. match datalink [dot1q | ethertype | mac | vlan]
6. match transport [destination-port | icmp | source-port]
7. match interface [input | output]
8. match flow direction
9. collect counter {bytes [layer2 | long] | packets [long]}
10. collect timestamp absolute [first | last]
11. collect interface [input | output]
12. collect transport tcp flags {ack | cwr | ece | fin | psh | rst | syn | urg}
13. end

Configuring the Flow Exporters

The following steps are used to configure the NetFlow exporter.

Note

The optional export-protocol flow exporter configuration command specifies the NetFlow export protocol used by the exporter. The switch supports only netflow-v9. Though visible in the CLI help, netflow-5 is not supported.

SUMMARY STEPS

1. configure terminal
2. flow exporter exporter-name
3. description description
4. destination {hostname | ip-address} vrf vrf-name
5. dscp <0-63>
6. source interface-id
7. option {exporter-stats | interface-table | sampler-table} timeout seconds
8. export-protocol netflow-v9
9. template data timeout seconds
10. transport udp udp-port
11. ttl seconds
12. end
<table>

</tbody>
</table>
### Configuring a Customized Flow Monitor

The following steps are used to configure a NetFlow monitor.

#### SUMMARY STEPS

1. configure terminal
2. flow monitor monitor -name
3. description description
4. record {TestNetFlowRecordName/TestRecord}
5. cache {timeout [active|inactive|update] (seconds) | type (normal)}
6. cache {timeout [active|inactive|update] (seconds) | type (normal)}
7. exporter TestNetFlowExporterName

---

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 10</strong> transport udp udp-port</td>
<td>Specifies the UDP port on which the destination system is listening for exported datagrams. The range for udp-port is from 1 to 65536.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch(config-flow-exporter)# transport udp 67</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong> ttl seconds</td>
<td>(Optional) Configures the time-to-live (TTL) value for datagrams sent by the exporter. The range is from 1 to 255 seconds. The default is 255.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch(config-flow-exporter)# ttl 100</td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong> end</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

---

### Example

```
Switch(config)# flow exporter QoS-Collector
Switch(config-flow-exporter)# description QoS Collector Bldg 19
Switch(config-flow-exporter)# destination 172.20.244.28
Switch(config-flow-exporter)# source vlan 1
Switch(config-flow-exporter)# dscp 3
Switch(config-flow-exporter)# transport udp 2055
Switch(config-flow-exporter)# end
```

---

### What to do next

Configuring a Customized Flow Monitor.

- Configuring and Enabling Flow Sampling, on page 484
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
|     |  **Example:**  
|     | `Switch# configure terminal` | |
| Step 2 | `flow monitor monitor -name` | Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode. You can also use this command to modify an existing flow monitor. |
|     |  **Example:**  
|     | `Switch(config)# flow monitor SampleMonitorName` | |
| Step 3 | `description description` | (Optional) Configures a description for the flow monitor. |
|     |  **Example:**  
|     | `Switch(config-flow-monitor)# Description SampleNetFlowMonitorName` | |
| Step 4 | `record {TestNetflowRecordName|TestRecord}` | Specifies the record for the flow monitor. |
|     |  **Example:**  
|     | `Switch(config-flow-monitor)#record TestNetflowRecordName` | |
| Step 5 | `cache {timeout [active|inactive|update] (seconds) | type (normal)}` | (Optional) Modifies the flow monitor cache parameters such as timeout values, number of cache entries, and the cache type. |
|     |  **Example:**  
|     | `Switch(config-flow-monitor)# cache type normal` | 
|     |   - **timeout active seconds**—Configures the active flow timeout. This defines the granularity of the traffic analysis. The range is from 1 to 604800 seconds. The default is 1800. Typical values are 60 or 300 seconds. See the Configuring Data Export for Cisco IOS Flexible NetFlow with Flow Exporters document for recommended values. |
|     |   - **type normal**—Configures normal flow removal from the flow cache. |
|     | **Note** Although visible in the command line help, the entries keyword and inactive and update timeouts are not supported. |
| Step 6 | `cache {timeout [active|inactive|update] (seconds) | type (normal)}` | Repeat step 5 to configure additional cache parameters for the flow monitor. |
|     |  **Example:**  
|     | `Switch(config-flow-monitor)# cache type normal` | |
| Step 7 | `exporter TestNetFlowExporterName` | (Optional) Specifies the name of an exporter that was created previously. |
|     |  **Example:**  
|     | |
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Switch(config-flow-monitor)# exporter</strong>&lt;br&gt;TestNetFlowExporterName</td>
</tr>
</tbody>
</table>

#### Step 8

- **cache** `{timeout [active|inactive|update] (seconds) | type (normal)}`
  
  **Example:**
  ```
  Switch(config-flow-monitor)# cache type normal
  ```

- **Repeat step 5 to configure additional cache parameters for the flow monitor.**

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 9**
  **end**
  
  **Example:**
  ```
  Switch(config)# end
  ```

- **Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.**

### Example

- Switch(config)# flow monitor FLOW-MONITOR-1
- Switch(config-flow-monitor)# Used for ipv6 traffic analysis
- Switch(config-flow-monitor)# record FLOW-RECORD-1
- Switch(config-flow-monitor)# cache timeout active 300
- Switch(config-flow-monitor)# cache type normal
- Switch(config-flow-monitor)# exporter EXPORTER-1
- Switch(config-flow-monitor)# exit

### What to do next

Apply a flow monitor to an interface

<td>Identifies an interface and enters interface configuration mode. Flexible Net Flow is supported only on the service module 1-Gigabit or 10-Gigabit Ethernet interfaces. <strong>Note</strong> You cannot attach a NetFlow monitor to a port channel interface. If both service module interfaces are part of an EtherChannel, you should attach the monitor to both physical interfaces.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>wlan ssid</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;<code>Switch (config)# wlan test 1 test</code></td>
<td>Configures the flow monitor on WLAN.</td>
</tr>
</tbody>
</table>
| **Step 4** | `[ ip | ipv6 | datalink] flow monitor [name sampler [sampler | input | output]]`<br>**Example:**<br>`Switch(config-if)# ipv6 flow monitor SampleMonitorName input` | Activates a previously created flow monitor by assigning it to the interface to analyze incoming or outgoing traffic.  
  - `ip`—Enters record matching IPv4 IP addresses.  
  - `ipv6`—Enters record matching IPv6 IP addresses.  
  **Note** This keyword is visible only when the dual IPv4 and IPv6 Switch Database Management (SDM) template is configured on the switch.  
  - `input`—Applies the flow monitor on input traffic.  
  - `output`—Applies the flow monitor on output traffic.  
  - `sampler`—(Optional) Applies the flow monitor sampler. |
| **Step 5** | `exit`<br>**Example:**<br>`Switch(config-if)# exit` | Returns to global configuration mode. |
| **Step 6** | Repeat steps 2 and 3<br>**Example:**<br>`Switch(config)#` | Configures additional cache parameters for the flow monitor. |
| **Step 7** | `end`<br>**Example:**<br>`Switch(config)# end` | Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode. |
### Example

```shell
Switch(config)# interface tengigabitethernet 1/0/1
Switch(config-if)# ip flow monitor FLOW-MONITOR-1 input
Switch(config-if)# ip flow monitor FLOW-MONITOR-2 output
Switch(config-if)# end
```

## Configuring and Enabling Flow Sampling

The following steps are used to configure and enable flow sampling.

### SUMMARY STEPS

1. `configure terminal`
2. `sampler sampler -name`
3. `description description`
4. `mode {deterministic|random} (<1-1>) out-of <2-1024>`
5. `end`
6. `interface interface-id`
7. `wlan ssid`
8. `{ip | ipv6 | datalink} flow monitor monitor-name sampler sampler-name {input | output}`
9. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Example: <code>Switch# configure terminal</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Creates a flow monitor and enters Flexible NetFlow sampler configuration mode. You can also use this command to modify an existing sampler.</td>
</tr>
<tr>
<td><code>sampler sampler -name</code></td>
<td>Example: <code>Switch(config)# sampler SampleNameForSAMPLER</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>(Optional) Configures a description for the sampler.</td>
</tr>
<tr>
<td><code>description description</code></td>
<td>Example: <code>Switch(config-sampler)#description SamplerName_1</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Specifies the mode and window size from which to select packets. The window size range is from 2 to 1024.</td>
</tr>
<tr>
<td>`mode {deterministic</td>
<td>random} (&lt;1-1&gt;) out-of &lt;2-1024&gt;`</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong> Switch(config-sampler)# mode random 1 out-of 2</td>
<td><strong>Note</strong> Although visible in the CLI help, the mode deterministic keyword is not supported.</td>
</tr>
</tbody>
</table>

### Step 5

**end**

**Example:** Switch(config-sampler)# end

Returns to global configuration mode.

### Step 6

**interface interface-id**

**Example:** Switch(config)# interface tengigabitethernet 1/0/1

Identifies an interface and enters interface configuration mode.

### Step 7

**wlan ssid**

**Example:** Switch(config)# wlan test 1 test

Configures to apply flow sampler on WLAN.

### Step 8

**{ip | ipv6 | datalink} flow monitor monitor-name sampler sampler-name {input | output}**

**Example:** Switch(config-if)# ip flow monitor FLOW-MONITOR-1 sampler SAMPLE-1 input

Activates a previously created IPv4 or IPv6 flow monitor by assigning it to the interface to analyze traffic.

### Step 9

**end**

**Example:** Switch(config)# end

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

---

**Example**

Switch(config)# sampler SAMPLER-1
Switch(config-sampler)# description Sample at 50
Switch(config-sampler)# mode random 1 out-of 2
Switch(config-sampler)# exit
Switch(config)# interface tengigabitethernet 1/0/1
Switch(config)# wlan test 1 test
Switch(config)# ip flow monitor FLOW-MONITOR-1 sampler SAMPLE-1 input

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for STP

• An attempt to configure a switch as the root switch fails if the value necessary to be the root switch is less than 1.

• If your network consists of switches that support and do not support the extended system ID, it is unlikely that the switch with the extended system ID support will become the root switch. The extended system ID increases the switch priority value every time the VLAN number is greater than the priority of the connected switches running older software.

• The root switch for each spanning-tree instance should be a backbone or distribution switch. Do not configure an access switch as the spanning-tree primary root.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About Spanning Tree Protocol

Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Switches might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

The STP uses a spanning-tree algorithm to select one switch of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

- Root—A forwarding port elected for the spanning-tree topology
- Designated—A forwarding port elected for every switched LAN segment
- Alternate—A blocked port providing an alternate path to the root bridge in the spanning tree
- Backup—A blocked port in a loopback configuration

The switch that has all of its ports as the designated role or as the backup role is the root switch. The switch that has at least one of its ports in the designated role is called the designated switch.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Switches send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The switches do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending switch and its ports, including switch and MAC addresses, switch priority, port priority, and path cost. Spanning tree uses this information to elect the root switch and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a switch are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

**Note**

By default, the switch sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the `no keepalive` interface configuration command with no keywords.

**Spanning-Tree Topology and BPDUs**

The stable, active spanning-tree topology of a switched network is controlled by these elements:
The unique bridge ID (switch priority and MAC address) associated with each VLAN on each switch. In a switch stack, all switches use the same bridge ID for a given spanning-tree instance.

The spanning-tree path cost to the root switch.

The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the switches in a network are powered up, each functions as the root switch. Each switch sends a configuration BPDU through all of its ports. The BPDU's communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the switch that the sending switch identifies as the root switch
- The spanning-tree path cost to the root
- The bridge ID of the sending switch
- Message age
- The identifier of the sending interface
- Values for the hello, forward delay, and max-age protocol timers

When a switch receives a configuration BPDU that contains superior information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the switch, the switch also forwards it with an updated message to all attached LANs for which it is the designated switch.

If a switch receives a configuration BPDU that contains inferior information to that currently stored for that port, it discards the BPDU. If the switch is a designated switch for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:

- One switch in the network is elected as the root switch (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.

For each VLAN, the switch with the highest switch priority (the lowest numerical priority value) is elected as the root switch. If all switches are configured with the default priority (32768), the switch with the lowest MAC address in the VLAN becomes the root switch. The switch priority value occupies the most significant bits of the bridge ID, as shown in the following figure.

- A root port is selected for each switch (except the root switch). This port provides the best path (lowest cost) when the switch forwards packets to the root switch.

When selecting the root port on a switch stack, spanning tree follows this sequence:

- Selects the lowest root bridge ID
- Selects the lowest path cost to the root switch
- Selects the lowest designated bridge ID
- Selects the lowest designated path cost
- Selects the lowest port ID
• Only one outgoing port on the stack root switch is selected as the root port. The remaining switches in the stack become its designated switches (Switch 2 and Switch 3) as shown in the following figure.

• The shortest distance to the root switch is calculated for each switch based on the path cost.

• A designated switch for each LAN segment is selected. The designated switch incurs the lowest path cost when forwarding packets from that LAN to the root switch. The port through which the designated switch is attached to the LAN is called the designated port.

Figure 21: Spanning-Tree Port States in a Switch Stack

One stack member is elected as the stack root switch. The stack root switch contains the outgoing root port

All paths that are not needed to reach the root switch from anywhere in the switched network are placed in the spanning-tree blocking mode.

Bridge ID, Device Priority, and Extended System ID

The IEEE 802.1D standard requires that each switch has an unique bridge identifier (bridge ID), which controls the selection of the root switch. Because each VLAN is considered as a different logical bridge with PVST+ and Rapid PVST+, the same switch must have a different bridge ID for each configured VLAN. Each VLAN on the switch has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the switch priority, and the remaining 6 bytes are derived from the switch MAC address.

The switch supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the switch priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for
the switch, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.

The 2 bytes previously used for the switch priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

Table 49: Device Priority Value and Extended System ID

<table>
<thead>
<tr>
<th>Priority Value</th>
<th>Extended System ID (Set Equal to the VLAN ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 16 Bit 15 Bit 14 Bit 13 Bit 12 Bit 11 Bit 10 Bit 9 Bit 8 Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 Bit 1</td>
<td></td>
</tr>
<tr>
<td>32768 16384 8192 4096 2048 1024 512 256 128 64 32 16 8 4 2 1</td>
<td></td>
</tr>
</tbody>
</table>

Spanning tree uses the extended system ID, the switch priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the switch stack appears as a single switch to the rest of the network, all switches in the stack use the same bridge ID for a given spanning tree. If the stack master fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack master.

Support for the extended system ID affects how you manually configure the root switch, the secondary root switch, and the switch priority of a VLAN. For example, when you change the switch priority value, you change the probability that the switch will be elected as the root switch. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root switch for the specified VLAN has a switch priority lower than 24576, the switch sets its own priority for the specified VLAN to 4096 less than the lowest switch priority. 4096 is the value of the least-significant bit of a 4-bit switch priority value as shown in the table.

Port Priority Versus Path Cost

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your switch is a member of a switch stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see Related Topics.
Spanning-Tree Interface States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

Each Layer 2 interface on a switch using spanning tree exists in one of these states:

- **Blocking**—The interface does not participate in frame forwarding.
- **Listening**—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.
- **Learning**—The interface prepares to participate in frame forwarding.
- **Forwarding**—The interface forwards frames.
- **Disabled**—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:

- From initialization to blocking
- From blocking to listening or to disabled
- From listening to learning or to disabled
- From learning to forwarding or to disabled
- From forwarding to disabled
An interface moves through the states.

When you power up the switch, spanning tree is enabled by default, and every interface in the switch, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:

1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.
2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.
3. In the learning state, the interface continues to block frame forwarding as the switch learns end-station location information for the forwarding database.
4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

### Blocking State

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each switch interface. A switch initially functions as the root until it exchanges BPDUs with other switches. This exchange establishes which switch in the network is the root or root switch. If there is only one switch in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after switch initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs
Listening State

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

Learning State

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs

Forwarding State

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface
- Forwards frames switched from another interface
- Learns addresses
- Receives BPDUs

Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Does not receive BPDUs
How a Switch or Port Becomes the Root Switch or Root Port

If all switches in a network are enabled with default spanning-tree settings, the switch with the lowest MAC address becomes the root switch.

*Figure 23: Spanning-Tree Topology*

Switch A is elected as the root switch because the switch priority of all the switches is set to the default (32768) and Switch A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Switch A might not be the ideal root switch. By increasing the priority (lowering the numerical value) of the ideal switch so that it becomes the root switch, you force a spanning-tree recalculation to form a new topology with the ideal switch as the root.

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.

For example, assume that one port on Switch B is a Gigabit Ethernet link and that another port on Switch B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.

**Related Topics**
- Configuring Port Priority (CLI), on page 508

**Spanning Tree and Redundant Connectivity**

*Figure 24: Spanning Tree and Redundant Connectivity*

You can create a redundant backbone with spanning tree by connecting two switch interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds
are the same, the port priority and port ID are added together, and spanning tree disables the link with the highest value.

You can also create redundant links between switches by using EtherChannel groups.

**Spanning-Tree Address Management**

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C2000000 to 0x0180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each switch in the stack receives but does not forward packets destined for addresses between 0x0180C2000000 and 0x0180C2000010.

If spanning tree is enabled, the CPU on the switch or on each switch in the stack receives packets destined for 0x0180C2000000 and 0x0180C2000010. If spanning tree is disabled, the switch or each switch in the stack forwards those packets as unknown multicast addresses.

**Accelerated Aging to Retain Connectivity**

The default for aging dynamic addresses is 5 minutes, the default setting of the `mac address-table aging-time` global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (`spanning-tree vlan vlan-id forward-time seconds` global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the switch accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the switch.

- Restrictions for STP, on page 491

**Spanning-Tree Modes and Protocols**

The switch supports these spanning-tree modes and protocols:

- **PVST+**—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. It is the default spanning-tree mode used on all Ethernet port-based VLANs. The PVST+ runs on each
VLAN on the switch up to the maximum supported, ensuring that each has a loop-free path through the network.

The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root switch. This root switch propagates the spanning-tree information associated with that VLAN to all other switches in the network. Because each switch has the same information about the network, this process ensures that the network topology is maintained.

- Rapid PVST+—This spanning-tree mode is the same as PVST+ except that it is uses a rapid convergence based on the IEEE 802.1w standard. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

  Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the switch needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to re-provision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

- MSTP—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a switch stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

- Changing the Spanning-Tree Mode (CLI), on page 504

**Supported Spanning-Tree Instances**

In PVST+ or Rapid PVST+ mode, the switch or switch stack supports up to 128 spanning-tree instances.

In MSTP mode, the switch or switch stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

**Spanning-Tree Interoperability and Backward Compatibility**

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ switch cannot connect to multiple MST regions.

When a network contains switches running Rapid PVST+ and switches running PVST+, we recommend that the Rapid PVST+ switches and PVST+ switches be configured for different spanning-tree instances. In the Rapid PVST+ spanning-tree instances, the root switch must be a Rapid PVST+ switch. In the PVST+ instances, the root switch must be a PVST+ switch. The PVST+ switches should be at the edge of the network.
All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

**STP and IEEE 802.1Q Trunks**

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for all VLANs allowed on the trunks. However, in a network of Cisco switches connected through IEEE 802.1Q trunks, the switches maintain one spanning-tree instance for each VLAN allowed on the trunks.

When you connect a Cisco switch to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco switch uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the switch uses it instead of PVST+. The switch combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q switch.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco switches separated by a cloud of non-Cisco IEEE 802.1Q switches. The non-Cisco IEEE 802.1Q cloud separating the Cisco switches is treated as a single trunk link between the switches.

PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

**VLAN-Bridge Spanning Tree**

Cisco VLAN-bridge spanning tree is used with the fallback bridging feature (bridge groups), which forwards non-IP protocols such as DECnet between two or more VLAN bridge domains or routed ports. The VLAN-bridge spanning tree allows the bridge groups to form a spanning tree on top of the individual VLAN spanning trees to prevent loops from forming if there are multiple connections among VLANs. It also prevents the individual spanning trees from the VLANs being bridged from collapsing into a single spanning tree.

To support VLAN-bridge spanning tree, some of the spanning-tree timers are increased. To use the fallback bridging feature, you must have the IP services feature set enabled on your switch.

**Spanning Tree and Switch Stacks**

When the switch stack is operating in PVST+ or Rapid PVST+ mode:

- A switch stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.
When a new switch joins the stack, it sets its bridge ID to the active switch bridge ID. If the newly added switch has the lowest ID and if the root path cost is the same among all stack members, the newly added switch becomes the stack root.

When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

If a neighboring switch external to the switch stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a switch in the active topology.

If a new switch external to the switch stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a switch in the network.

How to Configure Spanning-Tree Features

Changing the Spanning-Tree Mode (CLI)

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the switch runs the PVST+ protocol. If you want to enable a mode that is different from the default mode, this procedure is required.

Beginning in privileged EXEC mode, follow these steps to change the spanning-tree mode:

**SUMMARY STEPS**

1. `configure terminal`
2. `spanning-tree mode {pvst | mst | rapid-pvst}`
3. `interface interface-id`
4. `spanning-tree link-type point-to-point`
5. `end`
6. `clear spanning-tree detected-protocols`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Purpose:</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>spanning-tree mode {pvst</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# spanning-tree mode pvst</td>
</tr>
<tr>
<td>Purpose:</td>
<td>Configures a spanning-tree mode. All stack members run the same version of spanning tree.</td>
</tr>
<tr>
<td></td>
<td>• Select <strong>pvst</strong> to enable PVST+ (the default setting).</td>
</tr>
<tr>
<td></td>
<td>• Select <strong>mst</strong> to enable MSTP (and RSTP).</td>
</tr>
<tr>
<td></td>
<td>• Select <strong>rapid-pvst</strong> to enable rapid PVST+.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>interface interface-id</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# interface GigabitEthernet1/0/1</td>
</tr>
<tr>
<td>Purpose:</td>
<td>(Recommended for Rapid PVST+ mode only) Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port channels. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>spanning-tree link-type point-to-point</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config-if)# spanning-tree link-type point-to-point</td>
</tr>
<tr>
<td>Purpose:</td>
<td>(Recommended for Rapid PVST+ mode only) Specifies that the link type for this port is point-to-point.</td>
</tr>
<tr>
<td>Example:</td>
<td>If you connect this port (local port) to a remote port through a point-to-point link and the local port becomes a designated</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Step 5**
  end
  Example:
  Switch(config-if)# end | Returns to privileged EXEC mode. |
| **Step 6**
  clear spanning-tree detected-protocols
  Example:
  Switch# clear spanning-tree detected-protocols | (Recommended for Rapid PVST+ mode only) If any port on the switch is connected to a port on a legacy IEEE 802.1D switch, this command restarts the protocol migration process on the entire switch. This step is optional if the designated switch detects that this switch is running rapid PVST+. |

- Spanning-Tree Modes and Protocols, on page 500

**Disabling Spanning Tree (CLI)**

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

⚠️ **Caution**

When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to disable a spanning tree:

**SUMMARY STEPS**

1. configure terminal
2. no spanning-tree vlan vlan-id
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  configure terminal
  Example:
  Switch# configure terminal | Enters the global configuration mode. |
Purpose | Command or Action |
---|---|
Step 2 | no spanning-tree vlan vlan-id |
Example: |
Switch(config)# no spanning-tree vlan 300 |
Step 3 | end |
Example: |
Switch(config)# end |

### Configuring the Root Switch (CLI)

To configure a switch as the root for the specified VLAN, use the `spanning-tree vlan vlan-id root` global configuration command to modify the switch priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the switch priority of the root switches for each VLAN. Because of the extended system ID support, the switch sets its own priority for the specified VLAN to 24576 if this value will cause this switch to become the root for the specified VLAN.

Use the `diameter` keyword to specify the Layer 2 network diameter (that is, the maximum number of switch hops between any two end stations in the Layer 2 network). When you specify the network diameter, the switch automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the `hello` keyword to override the automatically calculated hello time.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure a switch to become the root for the specified VLAN:

**SUMMARY STEPS**

1. configure terminal
2. spanning-tree vlan vlan-id root primary [diameter net-diameter ]
3. end

**DETAILED STEPS**

| Command or Action | Purpose |
---|---|
Step 1 | configure terminal |
Example: |
Switch# configure terminal | Enters the global configuration mode. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Configures a switch to become the root for the specified VLAN.</td>
</tr>
</tbody>
</table>
| **spanning-tree vlan vlan-id root primary [diameter net-diameter]** | • For vlan-id, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.  
• (Optional) For diameter net-diameter, specify the maximum number of switches between any two end stations. The range is 2 to 7. |
| **Example:** | Switch(config)# spanning-tree vlan 20-24 root primary diameter 4 |
| Step 3 | Returns to privileged EXEC mode. |
| **end** | Switch(config)# end |

**What to do next**

After configuring the switch as the root switch, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the spanning-tree vlan vlan-id hello-time, spanning-tree vlan vlan-id forward-time, and the spanning-tree vlan vlan-id max-age global configuration commands.

- Accelerated Aging to Retain Connectivity, on page 500
- Restrictions for STP, on page 491

**Configuring a Secondary Root Device (CLI)**

When you configure a switch as the secondary root, the switch priority is modified from the default value (32768) to 28672. With this priority, the switch is likely to become the root switch for the specified VLAN if the primary root switch fails. This is assuming that the other network switches use the default switch priority of 32768, and therefore, are unlikely to become the root switch.

You can execute this command on more than one switch to configure multiple backup root switches. Use the same network diameter and hello-time values that you used when you configured the primary root switch with the spanning-tree vlan vlan-id root primary global configuration command.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure a switch to become a secondary root for the specified VLAN:

**SUMMARY STEPS**

1. configure terminal
2. `spanning-tree vlan vlan-id root secondary [diameter net-diameter]`

3. `end`

### DETAILED STEPS

<table>
<thead>
<tr>

<tr>
<td><code>Switch(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

### Configuring Port Priority (CLI)

**Note**
If your switch is a member of a switch stack, you must use the `spanning-tree [vlan vlan-id] cost cost` interface configuration command instead of the `spanning-tree [vlan vlan-id] port-priority priority` interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure port priority:

### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. spanning-tree port-priority priority
4. spanning-tree vlan vlan-id port-priority priority
5. end

- For `vlan-id`, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.
- For `cost`, the range is 1 to 200000000; the default value is derived from the media speed of the interface.
Configuring the Device Priority of a VLAN (CLI)

You can configure the switch priority and make it more likely that a standalone switch or a switch in the stack will be chosen as the root switch.

Note

Exercise care when using this command. For most situations, we recommend that you use the `spanning-tree vlan vlan-id root primary` and the `spanning-tree vlan vlan-id root secondary` global configuration commands to modify the switch priority.

This procedure is optional. Beginning in privileged EXEC mode, follow these steps to configure the switch priority of a VLAN:

**SUMMARY STEPS**

1. configure terminal
2. spanning-tree vlan vlan-id priority priority
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for MSTP

- For two or more switches to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

- For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

- For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a switch stack by manually configuring the path cost.

- For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the internal spanning tree (IST) master of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST regions must contain the CST root, and all of the other MST regions must have a better path to the root...
contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the switches in the clouds.

Restrictions for MSTP

- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
- The switch stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.
- PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)
- All stack members must run the same version of spanning tree (all PVST+, Rapid PVST+, or MSTP).
- VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each switch within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.
- Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.
- A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.
- After configuring a switch as the root switch, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the spanning-tree mst hello-time, spanning-tree mst forward-time, and the spanning-tree mst max-age global configuration commands.

Information About MSTP

MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing, and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

Note

The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment.

When the switch is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.

Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A switch stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same switch ID.

MSTP Configuration Guidelines

- When you enable MST by using the `spanning-tree mode mst` global configuration command, RSTP is automatically enabled.

- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.

- When the switch is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

<table>
<thead>
<tr>
<th>Speed</th>
<th>Path Cost Value</th>

### Root Switch

The switch maintains a spanning-tree instance for the group of VLANs mapped to it. A switch ID, consisting of the switch priority and the switch MAC address, is associated with each instance. For a group of VLANs, the switch with the lowest switch ID becomes the root switch.

When you configure a switch as the root, you modify the switch priority from the default value (32768) to a significantly lower value so that the switch becomes the root switch for the specified spanning-tree instance. When you enter this command, the switch checks the switch priorities of the root switches. Because of the extended system ID support, the switch sets its own priority for the specified instance to 24576 if this value will cause this switch to become the root for the specified spanning-tree instance.

If any root switch for the specified instance has a switch priority lower than 24576, the switch sets its own priority to 4096 less than the lowest switch priority. (4096 is the value of the least-significant bit of a 4-bit switch priority value. For more information, select "Bridge ID, Switch Priority, and Extended System ID" link in Related Topics.

If your network consists of switches that support and do not support the extended system ID, it is unlikely that the switch with the extended system ID support will become the root switch. The extended system ID increases the switch priority value every time the VLAN number is greater than the priority of the connected switches running older software.

The root switch for each spanning-tree instance should be a backbone or distribution switch. Do not configure an access switch as the spanning-tree primary root.

Use the `diameter` keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of switch hops between any two end stations in the Layer 2 network). When you specify the network diameter, the switch automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the `hello` keyword to override the automatically calculated hello time.

**Multiple Spanning-Tree Regions**

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each switch belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the switch for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the "Specifying the MST Region Configuration and Enabling MSTP" link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

**IST, CIST, and CST**

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- An internal spanning tree (IST), which is the spanning tree that runs in an MST region.

  Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

  The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because the MSTP BPDU carries information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

  All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root switch ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

  An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- A common and internal spanning tree (CIST), which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.
The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

Operations Within an MST Region

The IST connects all the MSTP switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the IST master before the implementation of the IEEE 802.1s standard). It is the switch within the region with the lowest switch ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MSTP switches at the boundary of the region is selected as the CIST regional root.

When an MSTP switch initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The switch also initializes all of its MST instances and claims to be the root for all of them. If the switch receives superior MST root information (lower switch ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

Related Topics

Illustration of MST Regions, on page 525

Operations Between MST Regions

If there are multiple regions or legacy IEEE 802.1D switches within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP switches in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP switches in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual switch to adjacent STP switches and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring switches and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, switch priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.

MSTP switches use Version 3 RSTP BPDUs or IEEE 802.1D STP BPDUs to communicate with legacy IEEE 802.1D switches. MSTP switches use MSTP BPDUs to communicate with MSTP switches.

Illustration of MST Regions, on page 525
IEEE 802.1s Terminology

Some MST naming conventions used in Cisco’s prestandard implementation have been changed to identify some internal or regional parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root switch for the unique instance that spans the whole network, the CIST.
- The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single switch for the CIST. The CIST external root path cost is the root path cost calculated between these virtual switches and switches that do not belong to any region.
- The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest switch to the CIST root in the region. The CIST regional root acts as a root switch for the IST.
- The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

**Illustration of MST Regions**

This figure displays three MST regions and a legacy IEEE 802.1D switch (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.
Hop Count

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the **spanning-tree mst max-hops** global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root switch of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a switch receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDDUs it generates. When the count reaches zero, the switch discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.
Boundary Ports

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated switch of which is either a single spanning-tree switch or a switch with a different MST configuration.

There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both switches and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

Note

If there is a legacy STP switch on the segment, messages are always considered external.

The other change from the Cisco prestandard implementation is that the CIST regional root switch ID field is now inserted where an RSTP or legacy IEEE 802.1Q switch has the sender switch ID. The whole region performs like a single virtual switch by sending a consistent sender switch ID to neighboring switches. In this example, switch C would receive a BPDU with the same consistent sender switch ID of root, whether or not A or B is designated for the segment.

IEEE 802.1s Implementation

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

Port Role Naming Change

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco’s implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special master role.
• The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the `show` commands identify a port as boundary in the `type` column of the output.

**Interoperation Between Legacy and Standard Switches**

Because automatic detection of prestandard switches can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard switch, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a switch receives a prestandard BPDU on a port that has not been configured for prestandard BPDU transmission.

*Figure 26: Standard and Prestandard Switch Interoperation*

Assume that A is a standard switch and B a prestandard switch, both configured to be in the same region. A is the root switch for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPU, AY cannot detect that a prestandard switch is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology changes.

![Diagram of standard and prestandard switch interoperation](image)

We recommend that you minimize the interaction between standard and prestandard MST implementations.

**Detecting Unidirectional Link Failure**

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.
Figure 27: Detecting Unidirectional Link Failure

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Switch A is the root switch, and its BPDUs are lost on the link leading to switch B. RSTP and MST BPDUss include the role and state of the sending port. With this information, switch A can detect that switch B does not react to the superior BPDUs it sends and that switch B is the designated, not root switch. As a result, switch A blocks (or keeps blocking) its port, which prevents the bridging loop.

MSTP and Switch Stacks

A switch stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

If a switch that does not support MSTP is added to a switch stack that does support MSTP or the reverse, the switch is put into a version mismatch state. If possible, the switch is automatically upgraded or downgraded to the same version of software that is running on the switch stack.

Interoperability with IEEE 802.1D STP

A switch running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D switches. If this switch receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUss on that port. An MSTP switch also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the switch does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUss because it cannot detect whether the legacy switch has been removed from the link unless the legacy switch is the designated switch. A switch might also continue to assign a boundary role to a port when the switch to which this switch is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring switches), use the **clear spanning-tree detected-protocols** privileged EXEC command.

If all the legacy switches on the link are RSTP switches, they can process MSTP BPDUss as if they are RSTP BPDUss. Therefore, MSTP switches send either a Version 0 configuration and TCN BPDUss or Version 3 MSTP BPDUss on a boundary port. A boundary port connects to a LAN, the designated switch of which is either a single spanning-tree switch or a switch with a different MST configuration.

RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).
Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the switch with the highest switch priority (lowest numerical priority value) as the root switch. The RSTP then assigns one of these port roles to individual ports:

- **Root port**—Provides the best path (lowest cost) when the switch forwards packets to the root switch.
- **Designated port**—Connects to the designated switch, which incurs the lowest path cost when forwarding packets from that LAN to the root switch. The port through which the designated switch is attached to the LAN is called the designated port.
- **Alternate port**—Offers an alternate path toward the root switch to that provided by the current root port.
- **Backup port**—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a switch has two or more connections to a shared LAN segment.
- **Disabled port**—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

### Table 55: Port State Comparison

<table>
<thead>
<tr>
<th>Operational Status</th>

</tbody>
</table>

To be consistent with Cisco STP implementations, this guide defines the port state as *blocking* instead of *discarding*. Designated ports start in the listening state.

**Rapid Convergence**

The RSTP provides for rapid recovery of connectivity following the failure of a switch, a switch port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

- **Edge ports**—If you configure a port as an edge port on an RSTP switch by using the `spanning-tree portfast` interface configuration command, the edge port immediately transitions to the forwarding state.
An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.

- **Root ports**—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.

- **Point-to-point links**—If you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

**Figure 28: Proposal and Agreement Handshaking for Rapid Convergence**

Switch A is connected to Switch B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Switch A is a smaller numerical value than the priority of Switch B. Switch A sends a proposal message (a configuration BPDU with the proposal flag set) to Switch B, proposing itself as the designated switch.

After receiving the proposal message, Switch B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Switch B’s agreement message, Switch A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Switch B blocked all of its nonedge ports and because there is a point-to-point link between Switches A and B.

When Switch C is connected to Switch B, a similar set of handshaking messages are exchanged. Switch C selects the port connected to Switch B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more switch joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a switch stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the switch is in MST mode.

The switch learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the `spanning-tree link-type` interface configuration command.
Synchronization of Port Roles

When the switch receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The switch is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the switch is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

*Figure 29: Sequence of Events During Rapid Convergence*

After ensuring that all of the ports are synchronized, the switch sends an agreement message to the designated switch corresponding to its root port. When the switches connected by a point-to-point link are in agreement about their port roles, the RSTP immediately transitions the port states to forwarding.
The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

</tbody>
</table>

The sending switch sets the proposal flag in the RSTP BPDU to propose itself as the designated switch on that LAN. The port role in the proposal message is always set to the designated port.
The sending switch sets the agreement flag in the RSTP BPDU to accept the previous proposal. The port role in the agreement message is always set to the root port.

The RSTP does not have a separate topology change notification (TCN) BPDU. It uses the topology change (TC) flag to show the topology changes. However, for interoperability with IEEE 802.1D switches, the RSTP switch processes and generates TCN BPDUs.

The learning and forwarding flags are set according to the state of the sending port.

**Processing Superior BPDU Information**

If a port receives superior root information (lower switch ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDU received is an RSTP BPDU with the proposal flag set, the switch sends an agreement message after all of the other ports are synchronized. If the BPDU is an IEEE 802.1D BPDU, the switch does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

**Processing Inferior BPDU Information**

If a designated port receives an inferior BPDU (such as a higher switch ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.

**Topology Changes**

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- **Detection**—Unlike IEEE 802.1D in which any transition between the blocking and the forwarding state causes a topology change, only transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP switch detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.

- **Notification**—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP switch processes and generates TCN BPDUs.

- **Acknowledgement**—When an RSTP switch receives a TCN message on a designated port from an IEEE 802.1D switch, it replies with an IEEE 802.1D configuration BPDU with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D switch and a configuration BPDU with the TCA bit set is received, the TC-while timer is reset.

This behavior is only required to support IEEE 802.1D switches. The RSTP BPDUs never have the TCA bit set.

- **Propagation**—When an RSTP switch receives a TC message from another switch through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding
Protocol Migration Process

A switch running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D switches. If this switch receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDU s on that port. An MSTP switch also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the switch does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDU s because it cannot detect whether the legacy switch has been removed from the link unless the legacy switch is the designated switch. A switch also might continue to assign a boundary role to a port when the switch to which it is connected has joined the region.

<td></td>
</tr>
<tr>
<td>Switch(config)# spanning-tree mst configuration</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> instance instance-id vlan vlan-range</td>
<td>Maps VLANs to an MST instance.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config-mst)# instance 1 vlan 10-20</td>
<td>* For instance-id, the range is 0 to 4094.</td>
</tr>
<tr>
<td></td>
<td>* For vlan vlan-range, the range is 1 to 4094.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>When you map VLANs to an MST instance, the mapping is incremental, and the VLANs specified in the command are added to or removed from the VLANs that were previously mapped. To specify a VLAN range, use a hyphen; for example, <code>instance 1 vlan 1-63</code> maps VLANs 1 through 63 to MST instance 1. To specify a VLAN series, use a comma; for example, <code>instance 1 vlan 10, 20, 30</code> maps VLANs 10, 20, and 30 to MST instance 1.</td>
<td></td>
</tr>
</tbody>
</table>

| Step 4 | `name name` |
| Example: | Switch(config-mst)# name region1 |
| Specifies the configuration name. The `name` string has a maximum length of 32 characters and is case sensitive. |

| Step 5 | `revision version` |
| Example: | Switch(config-mst)# revision 1 |
| Specifies the configuration revision number. The range is 0 to 65535. |

| Step 6 | `show pending` |
| Example: | Switch(config-mst)# show pending |
| Verifies your configuration by displaying the pending configuration. |

| Step 7 | `exit` |
| Example: | Switch(config-mst)# exit |
| Applies all changes, and returns to global configuration mode. |

| Step 8 | `spanning-tree mode mst` |
| Example: | Switch(config)# spanning-tree mode mst |
| Enables MSTP. RSTP is also enabled. Changing spanning-tree modes can disrupt traffic because all spanning-tree instances are stopped for the previous mode and restarted in the new mode. You cannot run both MSTP and PVST+ or both MSTP and Rapid PVST+ at the same time. |

| Step 9 | `end` |
| Example: | Switch(config)# end |
| Returns to privileged EXEC mode. |

### Configuring a Secondary Root Switch (CLI)

When you configure a switch with the extended system ID support as the secondary root, the switch priority is modified from the default value (32768) to 28672. The switch is then likely to become the root switch for the specified instance if the primary root switch fails. This is assuming that the other network switches use the default switch priority of 32768 and therefore are unlikely to become the root switch.

You can execute this command on more than one switch to configure multiple backup root switches. Use the same network diameter and hello-time values that you used when you configured the primary root switch with the `spanning-tree mst instance-id root primary` global configuration command.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure a secondary root switch.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. configure terminal
2. spanning-tree mst instance-id root secondary
3. end

## Configuring Port Priority (CLI)

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

### Note
If the switch is a member of a switch stack, you must use the `spanning-tree mst [instance-id] cost cost` interface configuration command instead of the `spanning-tree mst [instance-id] port-priority priority` interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure a different port priority for the switch.

### Before you begin
A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.
You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `spanning-tree mst instance-id port-priority priority`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal&lt;br&gt;Example: Switch# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id&lt;br&gt;Example: Switch(config)# interface GigabitEthernet1/0/1</td>
<td>Specifies an interface to configure, and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst instance-id port-priority priority&lt;br&gt;Example: Switch(config-if)# spanning-tree mst 0 port-priority 64</td>
<td>Configures port priority.</td>
</tr>
<tr>
<td><strong>Step 4</strong> end&lt;br&gt;Example: Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

The `show spanning-tree mst interface interface-id` privileged EXEC command displays information only if the port is in a link-up operative state. Otherwise, you can use the `show running-config interface` privileged EXEC command to confirm the configuration.

**Related Topics**

- Specifying the MST Region Configuration and Enabling MSTP (CLI), on page 536
Configuring Path Cost (CLI)

The MSTP path cost default value is derived from the media speed of an interface. If a loop occurs, the MSTP uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure a different path cost for the switch.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. spanning-tree mst instance-id cost cost
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces. The port-channel range is 1 to 48.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch(config)# interface gigabitethernet1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree mst instance-id cost cost</td>
<td>Configures the cost.</td>
</tr>
<tr>
<td><strong>Example:</strong> Switch(config-if)# spanning-tree mst 0 cost 17031970</td>
<td>If a loop occurs, the MSTP uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.</td>
</tr>
<tr>
<td>• For instance-id, you can specify a single instance, a range of instances separated by a hyphen, or a series</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

- Define the priority of instances separated by a comma. The range is 0 to 4094.
  - For `cost`, the range is 1 to 200000000; the default value is derived from the media speed of the interface.

### Step 4

**Example:**

```bash
Switch(config-if)# end
```

The `show spanning-tree mst interface interface-id` privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the `show running-config` privileged EXEC command to confirm the configuration.

### Configuring the Switch Priority (CLI)

Changing the priority of a switch makes it more likely to be chosen as the root switch whether it is a standalone switch or a switch in the stack.

**Note**

Exercise care when using this command. For normal network configurations, we recommend that you use the `spanning-tree mst instance-id root primary` and the `spanning-tree mst instance-id root secondary` global configuration commands to specify a switch as the root or secondary root switch. You should modify the switch priority only in circumstances where these commands do not work.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to configure a different switch priority for the switch.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.

You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

Specifying the Link Type to Ensure Rapid Transitions (CLI)

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote switch running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

Beginning in privileged EXEC mode, follow these steps to override the default link-type setting. This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. spanning-tree link-type point-to-point
4. end

**DETAILED STEPS**

Designating the Neighbor Type (CLI)
A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.

You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the show commands, even if the port is in STP compatibility mode.

Beginning in privileged EXEC mode, follow these steps to override the default link-type setting. This procedure is optional.

**Before you begin**
A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.

**SUMMARY STEPS**
1.  configure terminal
2.  interface interface-id
3.  spanning-tree mst pre-standard

### Restarting the Protocol Migration Process (CLI)

This procedure restarts the protocol migration process and forces renegotiation with neighboring switches. It reverts the switch to MST mode. It is needed when the switch no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Beginning in privileged EXEC mode, follow these steps to restart the protocol migration process (force the renegotiation with neighboring switches) on the switch.

#### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the switch. For instructions, see Related Topics.

If you want to use the interface version of the command, you must also know the MST interface used. This example uses GigabitEthernet1/0/1 as the interface because that was the interface set up by the instructions listed under Related Topics.

#### SUMMARY STEPS

1. Enter one of the following commands:
   - `clear spanning-tree detected-protocols`
   - `clear spanning-tree detected-protocols interface interface-id`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | Enter one of the following commands:  
- `clear spanning-tree detected-protocols`
- `clear spanning-tree detected-protocols interface interface-id`
| | | The switch reverts to the MSTP mode, and the protocol migration process restarts. |

---

**Example:**

```
Switch# clear spanning-tree detected-protocols
```

---

• Additional References for Optional Spanning Tree Features, on page 575
• Feature Information for Optional Spanning-Tree Features, on page 576

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restriction for Optional Spanning-Tree Features

• PortFast minimizes the time that interfaces must wait for spanning tree to converge, so it is effective only when used on interfaces connected to end stations. If you enable PortFast on an interface connecting to another switch, you risk creating a spanning-tree loop.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Related Topics
Enabling PortFast (CLI), on page 564
PortFast, on page 554
Information About Optional Spanning-Tree Features

PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to converge. Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.

Related Topics
- Enabling PortFast (CLI), on page 564
- Restriction for Optional Spanning-Tree Features, on page 553

BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast-enabled ports, spanning tree shuts down ports that are in a PortFast-operational state if any BPDU is received on them. In a valid configuration, PortFast-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast feature, and the port receives a BPDU, it is put in the error-disabled state.
The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.

Related Topics

- Enabling BPDU Guard (CLI), on page 565

**BPDU Filtering**

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast-enabled interfaces at the global level keeps those interfaces that are in a PortFast-operational state from sending or receiving BPDUss. The interfaces still send a few BPDUss at link-up before the switch begins to filter outbound BPDUss. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDUss. If a BPDU is received on a PortFast-enabled interface, the interface loses its PortFast-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast feature keeps the interface from sending or receiving BPDUss.

---

**Caution**

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature for the entire switch or for an interface.

Related Topics

- Enabling BPDU Filtering (CLI), on page 566

**UplinkFast**

*Figure 31: Switches in a Hierarchical Network*

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one
If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.

When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

---

**Note**

UplinkFast is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.
This topology has no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in a blocking state.

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked interface on Switch C and transitions it to the forwarding state without going through the listening and learning states. This change takes approximately 1 to 5 seconds.

- Events That Cause Fast Convergence, on page 559

**Cross-Stack UplinkFast**

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see Related Topics.
How Cross-Stack Uplink Fast Works

Cross-Stack Uplink Fast (CSUF) ensures that one link in the stack is elected as the path to the root.

*Figure 34: Cross-Stack Uplink Fast Topology*

The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.

When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.
Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate (2 * forward-delay time + max-age time).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

**Related Topics**
- Enabling UplinkFast for Use with Redundant Links (CLI), on page 568
- Events That Cause Fast Convergence, on page 559

### Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur.

Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.
  
  If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.

- The failed link, which connects the stack root to the spanning-tree root, recovers.

- A network reconfiguration causes a new stack-root switch to be selected.

- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

**Note**

The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.

- The stack-root switch, which was powered off or failed, is powered on.

- A new switch, which might become the stack root, is added to the stack.

BackboneFast

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches. BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDUs from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDUs for the maximum aging time (default is 20 seconds).

The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.
This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B is in the blocking state.

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDU to Switch C, identifying itself as the root. When Switch C receives the inferior BPDU from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is set. BackboneFast reconfigures the topology to account for the failure of link L1.

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDU did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDU that indicate it is the root switch. However, the other switches ignore these inferior
BPDUs, and the new switch learns that Switch B is the designated switch to Switch A, the root switch.

**EtherChannel Guard**

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel, but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.

Related Topics
- Enabling EtherChannel Guard (CLI), on page 571

**Root Guard**

*Figure 38: Root Guard in a Service-Provider Network*

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer’s network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer’s switch from becoming the root switch or being in the path to the root.
If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer’s switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

⚠️ 

Caution

Misuse of the root guard feature can cause a loss of connectivity.

Related Topics

Enabling Root Guard (CLI), on page 572

Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in MST mode, BPDUs are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.
How to Configure Optional Spanning-Tree Features

Enabling PortFast (CLI)

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

⚠️ Caution

Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to enable PortFast on the switch.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. spanning-tree portfast [trunk]
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  configure terminal
  Example: Switch# configure terminal |
| **Step 2**
  interface interface-id
  Example: Switch(config)# interface gigabitethernet1/0/2 |

Enters the global configuration mode.

Specifies an interface to configure, and enters interface configuration mode.
### Enabling BPDU Guard (CLI)

You can enable the BPDU guard feature if your switch is running PVST+, Rapid PVST+, or MSTP.

**Caution**

Configure PortFast only on ports that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to enable BPDU guard on the switch.

**SUMMARY STEPS**

1. configure terminal
2. spanning-tree portfast bpduguard default
3. interface interface-id
4. spanning-tree portfast
5. end
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 spanning-tree portfast bpduguard default | Globally enables BPDU guard. |
| Example: Switch(config)# spanning-tree portfast bpduguard default | By default, BPDU guard is disabled. |

| Step 3 interface interface-id | Specifies the interface connected to an end station, and enters interface configuration mode. |
| Example: Switch(config)# interface gigabitethernet1/0/2 | |

| Step 4 spanning-tree portfast | Enables the PortFast feature. |
| Example: Switch(config-if)# spanning-tree portfast | |

| Step 5 end | Returns to privileged EXEC mode. |
| Example: Switch(config-if)# end | |

What to do next
To prevent the port from shutting down, you can use the **errdisable detect cause bpduguard shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

You also can use the **spanning-tree bpduguard enable** interface configuration command to enable BPDU guard on any port without also enabling the PortFast feature. When the port receives a BPDU, it is put it in the error-disabled state.

**Related Topics**

- **BPDU Guard**, on page 554

## Enabling BPDU Filtering (CLI)

You can also use the **spanning-tree bpdufilter enable** interface configuration command to enable BPDU filtering on any interface without also enabling the PortFast feature. This command prevents the interface from sending or receiving BPDUs.
Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution

Configure PortFast only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to enable BPDU filtering on the switch.

**SUMMARY STEPS**

1. `configure terminal`
2. `spanning-tree portfast bpdufilter default`
3. `interface interface-id`
4. `spanning-tree portfast`
5. `end`

**DETAILED STEPS**

<table>

BPDU Filtering, on page 555

### Enabling UplinkFast for Use with Redundant Links (CLI)

**Note**
When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Beginning in privileged EXEC mode, follow these steps to enable UplinkFast and CSUF.

**Before you begin**
UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the `no spanning-tree vlan vlan-id priority` global configuration command.

### SUMMARY STEPS

1. configure terminal
2. spanning-tree uplinkfast [max-update-rate pkts-per-second]
3. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
Example: |  
Switch# configure terminal |  
| **Step 2** | Enables UplinkFast. |
| spanning-tree uplinkfast [max-update-rate pkts-per-second] | (Optional) For `pkts-per-second`, the range is 0 to 32000 packets per second; the default is 150. |  
| Example: |  

### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config)# spanning-tree uplinkfast max-update-rate 200</code></td>
<td>If you set the rate to 0, station-learning frames are not generated, and the spanning-tree topology converges more slowly after a loss of connectivity. When you enter this command, CSUF also is enabled on all nonstack port interfaces.</td>
</tr>
</tbody>
</table>

**Step 3**

**Example:**

Switch(config)# end

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

When UplinkFast is enabled, the switch priority of all VLANs is set to 49152. If you change the path cost to a value less than 3000 and you enable UplinkFast or UplinkFast is already enabled, the path cost of all interfaces and VLAN trunks is increased by 3000 (if you change the path cost to 3000 or above, the path cost is not altered). The changes to the switch priority and the path cost reduce the chance that a switch will become the root switch.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you enable the UplinkFast feature using these instructions, CSUF is automatically globally enabled on nonstack port interfaces.

#### Disabling UplinkFast (CLI)

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

**Before you begin**

UplinkFast must be enabled.

**SUMMARY STEPS**

1. `configure terminal`
2. `no spanning-tree uplinkfast`
3. `end`
### Enabling BackboneFast (CLI)

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Beginning in privileged EXEC mode, follow these steps to enable BackboneFast on the switch.

**Before you begin**

If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

### SUMMARY STEPS

1. configure terminal
2. spanning-tree backbonefast
3. end
Enabling EtherChannel Guard (CLI)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your switch is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Beginning in privileged EXEC mode, follow these steps to enable EtherChannel Guard on the switch.

**SUMMARY STEPS**

1.  configure terminal
2.  spanning-tree etherchannel guard misconfig
3.  end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Enables EtherChannel guard.</td>
</tr>
<tr>
<td>spanning-tree etherchannel guard misconfig</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# spanning-tree etherchannel guard misconfig</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
Enabling Root Guard (CLI)

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.

What to do next

You can use the `show interfaces status err-disabled` privileged EXEC command to show which switch ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the `show etherchannel summary` privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the `shutdown` and `no shutdown` interface configuration commands on the port-channel interfaces that were misconfigured.

Enabling Loop Guard (CLI)

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

Note
You cannot enable both loop guard and root guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional. Beginning in privileged EXEC mode, follow these steps to enable loop guard on the switch.

SUMMARY STEPS

1. Enter one of the following commands:
   • show spanning-tree active
   • show spanning-tree mst
2. configure terminal
3. spanning-tree loopguard default
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for EtherChannels

The following are restrictions for EtherChannels:

- All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.
- Layer 3 EtherChannels are not supported if running the LAN Base license feature set.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
Information About EtherChannels

EtherChannel Overview

An EtherChannel consists of individual Ethernet links bundled into a single logical link.

The EtherChannel provides full-duplex bandwidth up to 8 Gb/s (Gigabit EtherChannel) or 80 Gb/s (10-Gigabit EtherChannel) between your switch and another switch or host.

Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The number of EtherChannels is limited to 128.

The LAN Base feature set supports up to 24 EtherChannels.

All ports in each EtherChannel must be configured as either Layer 2 or Layer 3 ports. The EtherChannel Layer 3 ports are made up of routed ports. Routed ports are physical ports configured to be in Layer 3 mode by using the no switchport interface configuration command.

Related Topics

- EtherChannel Configuration Guidelines, on page 590
- Default EtherChannel Configuration, on page 589
- Layer 2 EtherChannel Configuration Guidelines, on page 591
EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as if it were any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.

- When you configure an EtherChannel in the on mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the on mode; otherwise, packet loss can occur.

  - EtherChannel Configuration Guidelines, on page 590
  - Default EtherChannel Configuration, on page 589
  - Layer 2 EtherChannel Configuration Guidelines, on page 591

EtherChannel on Switches

You can create an EtherChannel on a switch, on a single switch in the stack, or on multiple switches in the stack (known as cross-stack EtherChannel).

Figure 40: Single-Switch EtherChannel
Figure 41: Cross-Stack EtherChannel

Figure 42: Relationship of Physical Ports, Channel Group and Port-Channel Interface

- Default EtherChannel Configuration, on page 589
- Layer 2 EtherChannel Configuration Guidelines, on page 591

EtherChannel Link Failover

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

Channel Groups and Port-Channel Interfaces

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.

The channel-group command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 128. This port-channel interface number corresponds to the one specified with the channel-group interface configuration command.
• With Layer 2 ports, use the `channel-group` interface configuration command to dynamically create the port-channel interface.

  You also can use the `interface port-channel port-channel-number` global configuration command to manually create the port-channel interface, but then you must use the `channel-group channel-group-number` command to bind the logical interface to a physical port. The `channel-group-number` can be the same as the `port-channel-number`, or you can use a new number. If you use a new number, the `channel-group` command dynamically creates a new port channel.

• With Layer 3 ports, you should manually create the logical interface by using the `interface port-channel` global configuration command followed by the `no switchport` interface configuration command. You then manually assign an interface to the EtherChannel by using the `channel-group` interface configuration command.

• With Layer 3 ports, use the `no switchport` interface command to configure the interface as a Layer 3 interface, and then use the `channel-group` interface configuration command to dynamically create the port-channel interface.

**Port Aggregation Protocol**

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco switches and on those switches licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP can be enabled on cross-stack EtherChannels.
By using PAgP, the switch or switch stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single switch in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single switch port.

**PAgP Modes**

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

**Table 60: EtherChannel PAgP Modes**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets.</td>
</tr>
<tr>
<td>desirable</td>
<td>Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel).</td>
</tr>
</tbody>
</table>

Switch ports exchange PAgP packets only with partner ports configured in the auto or desirable modes. Ports configured in the on mode do not exchange PAgP packets.

Both the auto and desirable modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed. and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the desirable mode can form an EtherChannel with another port that is in the desirable or auto mode.

- A port in the auto mode can form an EtherChannel with another port in the desirable mode.

A port in the auto mode cannot form an EtherChannel with another port that is also in the auto mode because neither port starts PAgP negotiation.

- Creating Port-Channel Logical Interfaces (CLI)
- Configuring the Physical Interfaces (CLI)

**Silent Mode**

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the non-silent keyword. If you do not specify non-silent with the auto or desirable mode, silent mode is assumed.
Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

**PAgP Learn Method and Priority**

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.

When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.

PAgP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the `pagp port-priority` interface configuration command. The higher the priority, the more likely that the port will be selected.

The switch supports address learning only on aggregate ports even though the `physical-port` keyword is provided in the CLI. The `pagp learn-method` command and the `pagp port-priority` command have no effect on the switch hardware, but they are required for PAgP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the switch is a physical learner, we recommend that you configure the switch as a physical-port learner by using the `pagp learn-method physical-port` interface configuration command. Set the load-distribution method based on the source MAC address by using the `port-channel load-balance src-mac` global configuration command. The switch then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the `pagp learn-method` command in this situation.

Related Topics
- Configuring the PAgP Learn Method and Priority (CLI), on page 599
- EtherChannel Configuration Guidelines, on page 590
PAgP Interaction with Other Features

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAgP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active switch as soon as the interface is created (through the `interface port-channel` global configuration command).

PAgP sends and receives PAgP PDUs only from ports that are up and have PAgP enabled for the auto or desirable mode.

Link Aggregation Control Protocol

The LACP is defined in IEEE 802.3ad and enables Cisco switches to manage Ethernet channels between switches that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the switch or switch stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single switch port.

LACP Modes

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.</td>
</tr>
<tr>
<td>passive</td>
<td>Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets.</td>
</tr>
</tbody>
</table>

Both the active and passive LACP modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the active mode can form an EtherChannel with another port that is in the active or passive mode.
A port in the **passive** mode cannot form an EtherChannel with another port that is also in the **passive** mode because neither port starts LACP negotiation.

## LACP and Link Redundancy

LACP port-channel operation, bandwidth availability, and link redundancy can be further refined with the LACP port-channel min-links and the LACP max-bundle features.

The LACP port-channel min-links feature:
- Configures the minimum number of ports that must be linked up and bundled in the LACP port channel.
- Prevents a low-bandwidth LACP port channel from becoming active.
- Causes an LACP port channel to become inactive if there are too few active members ports to supply the required minimum bandwidth.

The LACP max-bundle feature:
- Defines an upper limit on the number of bundled ports in an LACP port channel.
- Allows hot-standby ports with fewer bundled ports. For example, in an LACP port channel with five ports, you can specify a max-bundle of three, and the two remaining ports are designated as hot-standby ports.

## LACP Interaction with Other Features

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active switch as soon as the interface is created through the `interface port-channel` global configuration command.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

## EtherChannel On Mode

EtherChannel **on** mode can be used to manually configure an EtherChannel. The **on** mode forces a port to join an EtherChannel without negotiations. The **on** mode can be useful if the remote device does not support
PAgP or LACP. In the on mode, a usable EtherChannel exists only when the switches at both ends of the link are configured in the on mode.

Ports that are configured in the on mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the on mode.

Caution

You should use care when using the on mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

Load-Balancing and Forwarding Methods

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the switch.

You configure the load-balancing and forwarding method by using the `port-channel load-balance` and the `port-channel load-balance extended` global configuration commands.

MAC Address Forwarding

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host’s MAC address of the incoming packet. Therefore, packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular switch. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

Related Topics

- Configuring EtherChannel Load-Balancing (CLI), on page 596
- EtherChannel Configuration Guidelines, on page 590
IP Address Forwarding

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel. Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular switch. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

Load-Balancing Advantages

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the switch in the network and the kind of traffic that needs to be load-distributed.

Figure 43: Load Distribution and Forwarding Methods

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the switch EtherChannel ensures that the switch uses all available bandwidth to the router. The router is configured for destination-based forwarding because
the large number of workstations ensures that the traffic is evenly distributed from the router

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

**EtherChannel and Switch Stacks**

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active switch removes the failed stack member switch ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a switch is added to an existing stack, the new switch receives the running configuration from the active switch and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAgP or LACP configuration on a winning switch stack is not affected, but the PAgP or LACP configuration on the losing switch stack is lost after the stack reboots.
Switch Stack and PAgP

With PAgP, if the active switch fails or leaves the stack, the standby switch becomes the new active switch. A spanning-tree reconvergence is not triggered unless there is a change in the EtherChannel bandwidth. The new active switch synchronizes the configuration of the stack members to that of the active switch. The PAgP configuration is not affected after an active switch change unless the EtherChannel has ports residing on the old active switch.

Switch Stacks and LACP

With LACP, the system ID uses the stack MAC address from the active switch. When an active switch fails or leaves the stack and the standby switch becomes the new active switch change, the LACP system ID is unchanged. By default, the LACP configuration is not affected after the active switch changes.

Default EtherChannel Configuration

The default EtherChannel configuration is described in this table.

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

- Do not try to configure more than 128 EtherChannels on the switch or switch stack.
- Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
- Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
- Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
- Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the `shutdown` interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.
- When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:
  - Allowed-VLAN list
  - Spanning-tree path cost for each VLAN
  - Spanning-tree port priority for each VLAN
  - Spanning-tree Port Fast setting
- Do not configure a port to be a member of more than one EtherChannel group.
- Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same switch or on different switches in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.
- Do not configure a secure port as part of an EtherChannel or the reverse.
• Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.

• If EtherChannels are configured on switch interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a switch by using the `dot1x system-auth-control` global configuration command.

• If cross-stack EtherChannel is configured and the switch stack partitions, loops and forwarding issues can occur.

**Layer 2 EtherChannel Configuration Guidelines**

When configuring Layer 2 EtherChannels, follow these guidelines:

• Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.

• An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAgP is set to the `auto` or `desirable` mode.

• Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

Configuring Layer 2 EtherChannels (CLI)

You configure Layer 2 EtherChannels by assigning ports to a channel group with the `channel-group` interface configuration command. This command automatically creates the port-channel logical interface.

SUMMARY STEPS

1. configure terminal
2. `interface interface-id`
3. `switchport mode {access | trunk}`
4. `switchport access vlan vlan-id`
5. `channel-group channel-group-number mode {auto [non-silent] | desirable [non-silent] | on } | { active | passive}`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Specifies a physical port, and enters interface configuration mode. Valid interfaces are physical ports. For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group. For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch(config)# interface gigabitethernet2/0/1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Assigns all ports as static-access ports in the same VLAN, or configure them as trunks. If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.</td>
</tr>
<tr>
<td>`switchport mode {access</td>
<td>trunk}`</td>
</tr>
<tr>
<td>Example: <code>Switch(config-if)# switchport mode access</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>(Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.</td>
</tr>
<tr>
<td><code>switchport access vlan vlan-id</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Switch(config-if)# switchport access vlan 22</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Assigns the port to a channel group, and specifies the PAgP or the LACP mode. For mode, select one of these keywords:</td>
</tr>
<tr>
<td>`channel-group channel-group-number mode {auto [non-silent]</td>
<td>desirable [non-silent]</td>
</tr>
<tr>
<td>Example: <code>Switch(config-if)# channel-group 5 mode auto</code></td>
<td></td>
</tr>
</tbody>
</table>

- **auto** – Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different switches in the switch stack.
<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
<tr>
<td></td>
<td>Example:</td>
<td>For mode, select one of these keywords:</td>
</tr>
<tr>
<td></td>
<td>Switch(config-if)# channel-group 1 mode auto</td>
<td></td>
</tr>
</tbody>
</table>
Purpose

Command or Action

Example:

```
Switch(config-if)# channel-group 5 mode auto
```

- **auto**—Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different switches in the switch stack.

- **desirable**—Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different switches in the switch stack.

- **on**—Forces the port to channel without PAgP or LACP. In the `on` mode, an EtherChannel exists only when a port group in the `on` mode is connected to another port group in the `on` mode.

- **non-silent**—(Optional) If your switch is connected to a partner that is PAgP capable, configures the switch port for nonsilent operation when the port is in the `auto` or `desirable` mode. If you do not specify `non-silent`, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

- **active**—Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.

- **passive**—Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.

### Configuring EtherChannel Load-Balancing (CLI)

You can configure EtherChannel load-balancing to use one of several different forwarding methods.

This task is optional.
SUMMARY STEPS

1. configure terminal
2. port-channel load-balance { dst-ip | dst-mac | dst-mixed-ip-port | dst-port | extended 
   [ dst-ip | dst-mac | dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port 
   src-mixed-ip-port | src-port }
3. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
| Step 2 | port-channel load-balance { dst-ip | dst-mac | dst-mixed-ip-port | dst-port | extended [ dst-ip | dst-mac | dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port 
   src-mixed-ip-port | src-port } | Configures an EtherChannel load-balancing method. The default is src-mac. Select one of these load-distribution methods: |
|      | Example: Switch(config)# port-channel load-balance src-mac | • dst-ip—Specifies destination-host IP address. |
|      | | • dst-mac—Specifies the destination-host MAC address of the incoming packet. |
|      | | • dst-mixed-ip-port—Specifies the host IP address and TCP/UDP port. |
|      | | • dst-port—Specifies the destination TCP/UDP port. |
|      | | • extended—Specifies extended load balance methods—combinations of source and destination methods beyond those available with the standard command. |
|      | | • ipv6-label—Specifies the IPv6 flow label. |
|      | | • l3-proto—Specifies the Layer 3 protocol. |
|      | | • src-dst-ip—Specifies the source and destination host IP address. |
|      | | • src-dst-mac—Specifies the source and destination host MAC address. |
|      | | • src-dst-mixed-ip-port—Specifies the source and destination host IP address and TCP/UDP port. |
|      | | • src-dst-port—Specifies the source and destination TCP/UDP port. |
|      | | • src-ip—Specifies the source host IP address. |
### Configuring EtherChannel Extended Load-Balancing (CLI)

Configure EtherChannel extended load-balancing when you want to use a combination of load-balancing methods.

This task is optional.

**Configuring LACP Hot-Standby Ports**

When LACP is enabled, the software, by default, tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time; the remaining eight links are placed in hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.
You can override the default behavior by specifying the maximum number of active ports in a channel, in which case, the remaining ports become hot-standby ports. For example, if you specify a maximum of five ports in a channel, up to 11 ports become hot-standby ports.

If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the switch MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

### Configuring the LACP Max Bundle Feature (CLI)

When you specify the maximum number of bundled LACP ports allowed in a port channel, the remaining ports in the port channel are designated as hot-standby ports.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of LACP ports in a port channel. This procedure is optional.

### SUMMARY STEPS

1. `configure terminal`
2. `interface port-channel channel-number`
3. `lacp max-bundle max-bundle-number`
4. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

- `configure terminal`

  **Example:**  
  `Switch# configure terminal`

| **Step 2**

- `interface port-channel channel-number`

  **Example:**  
  Enters interface configuration mode for a port channel.  
  The range is 1 to 128.
### Configuring the Port Channel Min-Links Feature (CLI)

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state.

Beginning in privileged EXEC mode, follow these steps to configure the minimum number of links that are required for a port channel. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface port-channel channel-number`
3. `port-channel min-links min-links-number`
4. `end`

Configuring the LACP System Priority (CLI)

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the `lacp system-priority` global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Beginning in privileged EXEC mode, follow these steps to configure the LACP system priority. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `lacp system-priority priority`
3. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>lacp system-priority priority</code></td>
<td>Configures the LACP system priority.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch(config)# lacp system-priority 32000</code></td>
<td>The range is 1 to 65535. The default is 32768. The lower the value, the higher the system priority.</td>
</tr>
</tbody>
</table>
Configuring the LACP Port Priority (CLI)

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Note

If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Beginning in privileged EXEC mode, follow these steps to configure the LACP port priority. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `lacp port-priority priority`
4. `end`

| show etherchannel [ channel-group-number { detail | port | port-channel | protocol | summary }] [ detail | load-balance | port | port-channel | protocol | summary ] | Displays EtherChannel information in a brief, detailed, and one-line summary form. Also displays the load-balance or frame-distribution scheme, port, port-channel, and protocol information. |
| show pAgP [ channel-group-number ] { counters | internal | neighbor } | Displays PAgP information such as traffic information, the internal PAgP configuration, and neighbor information. |
### Configuration Examples for Configuring EtherChannels

#### Configuring Layer 2 EtherChannels: Examples

This example shows how to configure an EtherChannel on a single switch in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAgP mode `desirable`:

```
Switch# configure terminal
Switch(config)# interface range gigabitethernet2/0/1 -2
Switch(config-if-range)# switchport mode access
Switch(config-if-range)# switchport access vlan 10
Switch(config-if-range)# channel-group 5 mode desirable non-silent
Switch(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single switch in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode `active`:

```
Switch# configure terminal
Switch(config)# interface range gigabitethernet2/0/1 -2
Switch(config-if-range)# switchport mode access
Switch(config-if-range)# switchport access vlan 10
Switch(config-if-range)# channel-group 5 mode active
Switch(config-if-range)# end
```

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

```
Switch# configure terminal
```
Switch(config)# interface range gigabitethernet2/0/4 -5
Switch(config-if-range)# switchport mode access
Switch(config-if-range)# switchport access vlan 10
Switch(config-if-range)# channel-group 5 mode passive
Switch(config-if-range)# exit
Switch(config)# interface gigabitethernet3/0/3
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 10
Switch(config-if)# channel-group 5 mode passive
Switch(config-if)# exit

Configuring Layer 3 EtherChannels: Examples

This example shows how to configure a Layer 3 EtherChannel. It assigns two ports to channel 5 with the LACP mode active:

Switch# configure terminal
Switch(config)# interface range gigabitethernet2/0/1 -2
Switch(config-if-range)# no ip address
Switch(config-if-range)# no switchport
Switch(config-if-range)# channel-group 5 mode active
Switch(config-if-range)# end

This example shows how to configure a cross-stack Layer 3 EtherChannel. It assigns two ports on stack member 2 and one port on stack member 3 to channel 7 using LACP active mode:

Switch# configure terminal
Switch(config)# interface range gigabitethernet2/0/4 -5
Switch(config-if-range)# no ip address
Switch(config-if-range)# no switchport
Switch(config-if-range)# channel-group 7 mode active
Switch(config-if-range)# exit
Switch(config)# interface gigabitethernet3/0/3
Switch(config-if)# no ip address
Switch(config-if)# no switchport
Switch(config-if)# channel-group 7 mode active
Switch(config-if)# exit

Configuring LACP Hot-Standby Ports: Example

This example shows how to configure an EtherChannel (port channel 2) that will be active when there are at least three active ports, will comprise up to seven active ports and the remaining ports (up to nine) as hot-standby ports:

Switch# configure terminal
Switch(config)# interface port-channel 2
Switch(config-if)# port-channel min-links 3
Switch(config-if)# lACP max-bundle 7

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring Flex Links and MAC Address-Table Move Update

- Flex Links are supported only on Layer 2 ports and port channels.
- You can configure up to 16 backup links.
- You can configure only one Flex Links backup link for any active link, and it must be a different interface from the active interface.
- An interface can belong to only one Flex Links pair. An interface can be a backup link for only one active link. An active link cannot belong to another Flex Links pair.
Information About Flex Links and MAC Address-Table Move Update

Flex Links

Flex Links are a pair of a Layer 2 interfaces (switch ports or port channels) where one interface is configured to act as a backup to the other. The feature provides an alternative solution to the Spanning Tree Protocol (STP). Users can disable STP and still retain basic link redundancy. Flex Links are typically configured in service provider or enterprise networks where customers do not want to run STP on the switch. If the switch is running STP, Flex Links are not necessary because STP already provides link-level redundancy or backup.

You configure Flex Links on one Layer 2 interface (the active link) by assigning another Layer 2 interface as the Flex Links or backup link. On switches, the Flex Links can be on the same switch or on another switch in the stack. When one of the links is up and forwarding traffic, the other link is in standby mode, ready to begin forwarding traffic if the other link shuts down. At any given time, only one of the interfaces is in the linkup state and forwarding traffic. If the primary link shuts down, the standby link starts forwarding traffic. When the active link comes back up, it goes into standby mode and does not forward traffic. STP is disabled on Flex Links interfaces.

Flex Links Configuration

In the following figure, ports 1 and 2 on switch A are connected to uplink switches B and C. Because they are configured as Flex Links, only one of the interfaces is forwarding traffic; the other is in standby mode. If port 1 is the active link, it begins forwarding traffic between port 1 and switch B; the link between port 2 (the backup link) and switch C is not forwarding traffic. If port 1 goes down, port 2 comes up and starts forwarding traffic to switch C. When port 1 comes back up, it goes into standby mode and does not forward traffic; port 2 continues forwarding traffic.

You can also configure a preemption function, specifying the preferred port for forwarding traffic. For example, you can configure the Flex Links pair with preemption mode. In the scenario shown, when port 1 comes back up and has more bandwidth than port 2, port 1 begins forwarding traffic after 60 seconds. Port 2 becomes the standby port. You do this by entering the `switchport backup interface preemption mode bandwidth` and `switchport backup interface preemption delay` interface configuration commands.
If a primary (forwarding) link goes down, a trap notifies the network management stations. If the standby link goes down, a trap notifies the users.

Flex Links are supported only on Layer 2 ports and port channels, not on VLANs or on Layer 3 ports.

**VLAN Flex Links Load Balancing and Support**

VLAN Flex Links load balancing allows users to configure a Flex Links pair so that both ports simultaneously forward the traffic for some mutually exclusive VLANs. For example, if Flex Links ports are configured for 1 to 100 VLANs, the traffic of the first 50 VLANs can be forwarded on one port and the rest on the other port. If one of the ports fail, the other active port forwards all the traffic. When the failed port comes back up, it resumes forwarding traffic in the preferred VLANs. In addition to providing the redundancy, this Flex Links pair can be used for load balancing. Flex Links VLAN load balancing does not impose any restrictions on uplink switches.

**Multicast Fast Convergence with Flex Links Failover**

Multicast fast convergence reduces the multicast traffic convergence time after a Flex Links failure. Multicast fast convergence is implemented by a combination of learning the backup link as an mrouter port, generating IGMP reports, and leaking IGMP reports.

**Learning the Other Flex Links Port as the mrouter Port**

In a typical multicast network, there is a querier for each VLAN. A switch deployed at the edge of a network has one of its Flex Links ports receiving queries. Flex Links ports are also always forwarding at any given time.

A port that receives queries is added as an mrouter port on the switch. An mrouter port is part of all the multicast groups learned by the switch. After a changeover, queries are received by the other Flex Links port.
The other Flex Links port is then learned as the mrouter port. After changeover, multicast traffic then flows through the other Flex Links port. To achieve faster convergence of traffic, both Flex Links ports are learned as mrouter ports whenever either Flex Links port is learned as the mrouter port. Both Flex Links ports are always part of multicast groups. Although both Flex Links ports are part of the groups in normal operation mode, all traffic on the backup port is blocked. The normal multicast data flow is not affected by the addition of the backup port as an mrouter port. When the changeover happens, the backup port is unblocked, allowing the traffic to flow. In this case, the upstream multicast data flows as soon as the backup port is unblocked.

Generating IGMP Reports

When the backup link comes up after the changeover, the upstream new distribution switch does not start forwarding multicast data, because the port on the upstream router, which is connected to the blocked Flex Links port, is not part of any multicast group. The reports for the multicast groups were not forwarded by the downstream switch because the backup link is blocked. The data does not flow on this port, until it learns the multicast groups, which occurs only after it receives reports.

The reports are sent by hosts when a general query is received, and a general query is sent within 60 seconds in normal scenarios. When the backup link starts forwarding, to achieve faster convergence of multicast data, the downstream switch immediately sends proxy reports for all the learned groups on this port without waiting for a general query.

Leaking IGMP Reports

To achieve multicast traffic convergence with minimal loss, a redundant data path must be set up before the Flex Links active link goes down. This can be achieved by leaking only IGMP report packets on the Flex Links backup link. These leaked IGMP report messages are processed by upstream distribution routers, so multicast data traffic gets forwarded to the backup interface. Because all incoming traffic on the backup interface is dropped at the ingress of the access switch, no duplicate multicast traffic is received by the host. When the Flex Links active link fails, the access switch starts accepting traffic from the backup link immediately. The only disadvantage of this scheme is that it consumes bandwidth on the link between the distribution switches and on the backup link between the distribution and access switches. This feature is disabled by default and can be configured by using the `switchport backup interface interface-id multicast fast-convergence` command.

When this feature has been enabled at changeover, the switch does not generate the proxy reports on the backup port, which became the forwarding port.

MAC Address-Table Move Update

The MAC address-table move update feature allows the switch to provide rapid bidirectional convergence when a primary (forwarding) link goes down and the standby link begins forwarding traffic.

**Figure 46: MAC Address-Table Move Update Example**

In the following figure, switch A is an access switch, and ports 1 and 2 on switch A are connected to uplink switches B and D through a Flex Links pair. Port 1 is forwarding traffic, and port 2 is in the backup state. Traffic from the PC to the server is forwarded from port 1 to port 3. The MAC address of the PC has been
learned on port 3 of switch C. Traffic from the server to the PC is forwarded from port 3 to port 1.

If the MAC address-table move update feature is not configured and port 1 goes down, port 2 starts forwarding traffic. However, for a short time, switch C keeps forwarding traffic from the server to the PC through port 3, and the PC does not get the traffic because port 1 is down. If switch C removes the MAC address of the PC on port 3 and relearns it on port 4, traffic can then be forwarded from the server to the PC through port 2.

If the MAC address-table move update feature is configured and enabled on the switches, and port 1 goes down, port 2 starts forwarding traffic from the PC to the server. The switch sends a MAC address-table move update packet from port 2. Switch C gets this packet on port 4 and immediately learns the MAC address of the PC on port 4, which reduces the reconvergence time.

You can configure the access switch, switch A, to send MAC address-table move update messages. You can also configure the uplink switches B, C, and D to get and process the MAC address-table move update messages. When switch C gets a MAC address-table move update message from switch A, switch C learns the MAC address of the PC on port 4. Switch C updates the MAC address table, including the forwarding table entry for the PC.

Switch A does not need to wait for the MAC address-table update. The switch detects a failure on port 1 and immediately starts forwarding server traffic from port 2, the new forwarding port. This change occurs in less than 100 milliseconds (ms). The PC is directly connected to switch A, and the connection status does not change. Switch A does not need to update the PC entry in the MAC address table.
Flex Links VLAN Load Balancing Configuration Guidelines

- For Flex Links VLAN load balancing, you must choose the preferred VLANs on the backup interface.
- You cannot configure a preemption mechanism and VLAN load balancing for the same Flex Links pair.

MAC Address-Table Move Update Configuration Guidelines

- You can enable and configure this feature on the access switch to send the MAC address-table move updates.
- You can enable and configure this feature on the uplink switches to get the MAC address-table move updates.

Default Flex Links and MAC Address-Table Move Update Configuration

- Flex Links is not configured, and there are no backup interfaces defined.
- The preemption mode is off.
- The preemption delay is 35 seconds.
- The MAC address-table move update feature is not configured on the switch.

How to Configure Flex Links and the MAC Address-Table Move Update Feature

Configuring Flex Links (CLI)

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. switchport backup interface interface-id
4. end

Configuration Examples for Flex Links

Configuring Flex Links: Examples

This example shows how to verify the configuration after you configure an interface with a backup interface:

Switch# show interface switchport backup

Switch Backup Interface Pairs:
Active Interface Backup Interface State
-------------------------------------------------------------------------------
GigabitEthernet1/0/1 GigabitEthernet1/0/2 Active Up/Backup Standby

This example shows how to verify the configuration after you configure the preemption mode as forced for a backup interface pair:

Switch# show interface switchport backup detail

Switch Backup Interface Pairs:
Active Interface Backup Interface Interface Pair Preemption Mode Preemption Delay Bandwidth Mac Address Move Update Vlan
-------------------------------------------------------------------------------
GigabitEthernet1/0/211 GigabitEthernet1/0/2 Active Up/Backup Standby Gi1/0/1, Gi1/0/2 forced 50 seconds 100000 Kbit 100000 Kbit auto

Configuring VLAN Load Balancing on Flex Links: Examples

In the following example, VLANs 1 to 50, 60, and 100 to 120 are configured on the switch:

Switch(config)# interface gigabitethernet 2/0/6
Switch(config-if)# switchport backup interface gigabitethernet 2/0/8 prefer vlan 60,100-120

When both interfaces are up, Gi2/0/8 forwards traffic for VLANs 60 and 100 to 120 and Gi2/0/6 forwards traffic for VLANs 1 to 50.

Switch# show interfaces switchport backup

Switch Backup Interface Pairs:
Active Interface Backup Interface State
-------------------------------------------------------------------------------
GigabitEthernet2/0/6 GigabitEthernet2/0/8 Active Up/Backup Standby
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
When a Flex Links interface goes down (LINK_DOWN), VLANs preferred on this interface are moved to the peer interface of the Flex Links pair. In this example, if interface Gi2/0/6 goes down, Gi2/0/8 carries all VLANs of the Flex Links pair.

Switch# show interfaces switchport backup

Switch Backup Interface Pairs:

<table>
<thead>
<tr>
<th>Active Interface</th>
<th>Backup Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>GigabitEthernet2/0/6</td>
<td>GigabitEthernet2/0/8</td>
<td>Active Down/Backup Up</td>
</tr>
</tbody>
</table>

Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120

When a Flex Links interface comes up, VLANs preferred on this interface are blocked on the peer interface and moved to the forwarding state on the interface that has just come up. In this example, if interface Gi2/0/6 comes up, VLANs preferred on this interface are blocked on the peer interface Gi2/0/8 and forwarded on Gi2/0/6.

Switch# show interfaces switchport backup

Switch Backup Interface Pairs:

<table>
<thead>
<tr>
<th>Active Interface</th>
<th>Backup Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>GigabitEthernet2/0/6</td>
<td>GigabitEthernet2/0/8</td>
<td>Active Up/Backup Standby</td>
</tr>
</tbody>
</table>

Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120

Switch# show interfaces switchport backup detail

Switch Backup Interface Pairs:

<table>
<thead>
<tr>
<th>Active Interface</th>
<th>Backup Interface</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>FastEthernet1/0/3</td>
<td>FastEthernet1/0/4</td>
<td>Active Down/Backup Up</td>
</tr>
</tbody>
</table>

Vlans Preferred on Active Interface: 1-2, 5-4094
Vlans Preferred on Backup Interface: 3-4
Preemption Mode : off
Bandwidth : 10000 Kbit (Fa1/0/3), 100000 Kbit (Fa1/0/4)
Mac Address Move Update Vlan : auto

Configuring the MAC Address-Table Move Update: Examples

This example shows how to verify the configuration after you configure an access switch to send MAC address-table move updates:

Switch# show mac address-table move update

Switch-ID : 010b.4630.1780
Dst mac-address : 0180.c200.0010
Vlans/Macs supported : 1023/8320
Default/Current settings: Rcv Off/On, Xmt Off/On
Max packets per min : Rcv 40, Xmt 60
Rcv packet count : 5
Rcv conforming packet count : 5
Rcv invalid packet count : 0
Rcv packet count this min : 0
Rcv threshold exceed count : 0
Rcv last sequence# this min : 0
Rcv last interface : Po2
Rcv last src-mac-address : 000b.462d.c502
Rcv last switch-ID : 0403.fd6a.8700
Xmt packet count : 0
Xmt packet count this min : 0
Xmt threshold exceed count : 0
Xmt pak buf unavail cnt : 0
Xmt last interface : None

Configuring Multicast Fast Convergence with Flex Links Failover: Examples

These are configuration examples for learning the other Flex Links port as the mrouter port when Flex Links is configured on GigabitEthernet1/0/11 and GigabitEthernet1/0/12, and output for the show interfaces switchport backup command:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet1/0/11
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# switchport backup interface GigabitEthernet1/0/12
Switch(config-if)# exit
Switch(config)# interface GigabitEthernet1/0/12
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# exit
Switch(config)# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface Backup Interface State
GigabitEthernet1/0/11 GigabitEthernet1/0/12 Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : Off
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)
Mac Address Move Update Vlan : auto

This output shows a querier for VLANs 1 and 401, with their queries reaching the switch through GigabitEthernet1/0/11:

Switch# show ip igmp snooping querier
Vlan  IP Address  IGMP Version  Port
-----------------------------------------
 1   1.1.1.1    v2    Gi1/0/11
401  41.41.41.1 v2    Gi1/0/11

This example is output for the show ip igmp snooping mrouter command for VLANs 1 and 401:

Switch# show ip igmp snooping mrouter
Vlan  ports
----  ----
Similarly, both Flex Links ports are part of learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Switch# show ip igmp snooping groups
Vlan  Group  Type Version Port List
1     228.1.5.1 igmp v2 Gi1/0/11, Gi1/0/12, Gi2/0/11
1     228.1.5.2 igmp v2 Gi1/0/11, Gi1/0/12, Gi2/0/11
```

When a host responds to the general query, the switch forwards this report on all the mrouter ports. In this example, when a host sends a report for the group 228.1.5.1, it is forwarded only on GigabitEthernet1/0/11, because the backup port GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding.

As soon as this port starts forwarding, the switch sends proxy reports for the groups 228.1.5.1 and 228.1.5.2 on behalf of the host. The upstream router learns the groups and starts forwarding multicast data. This is the default behavior of Flex Links. This behavior changes when the user configures fast convergence using the `switchport backup interface gigabitEthernet1/0/12 multicast fast-convergence` command. This example shows turning on this feature:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitEthernet 1/0/11
Switch(config-if)# switchport backup interface gigabitEthernet 1/0/12 multicast fast-convergence
Switch(config-if)# exit
Switch# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active  Interface  Backup Interface  State
-----------------------------------------------
GigabitEthernet1/0/11  GigabitEthernet1/0/12  Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : On
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLAN 1 and 401 with their queries reaching the switch through GigabitEthernet1/0/11:

```
Switch# show ip igmp snooping querier
Vlan  IP Address  IGMP Version  Port
----------------------------------------
1     1.1.1.1     v2            Gi1/0/11
401   41.41.41.1  v2            Gi1/0/11
```

This is output for the `show ip igmp snooping mrouter` command for VLAN 1 and 401:

```
Switch# show ip igmp snooping mrouter
Vlan  ports
```
Similarly, both the Flex Links ports are a part of the learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Switch# show ip igmp snooping groups
Vlan  Group  Type  Version  Port List
-----------------------------------------------
 1  228.1.5.1  igmp  v2  Gi1/0/11, Gi1/0/12, Gi2/0/11
 1  228.1.5.2  igmp  v2  Gi1/0/11, Gi1/0/12, Gi2/0/11
```

Whenever a host responds to the general query, the switch forwards this report on all the mrouter ports. When you turn on this feature through the command-line port, and when a report is forwarded by the switch on GigabitEthernet1/0/11, it is also leaked to the backup port GigabitEthernet1/0/12. The upstream router learns the groups and starts forwarding multicast data, which is dropped at the ingress because GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding. You do not need to send any proxy reports as the multicast data is already being forwarded by the upstream router. By leaking reports to the backup port, a redundant multicast path has been set up, and the time taken for the multicast traffic convergence is very minimal.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [http://www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another switch.

- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

⚠️ Caution

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.
Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

Modes of Operation

UDLD supports two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

Related Topics

- Enabling UDLD Globally (CLI), on page 632
- Enabling UDLD on an Interface (CLI), on page 634

Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
- One of the fiber strands in the cable is disconnected.
In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heartbeat whose presence guarantees the health of the link. Conversely, the loss of the heartbeat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

- Enabling UDLD Globally (CLI), on page 632
- Enabling UDLD on an Interface (CLI), on page 634

### Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

**Related Topics**

- Enabling UDLD Globally (CLI), on page 632
- Enabling UDLD on an Interface (CLI), on page 634

### Neighbor Database Maintenance

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the switch receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the switch receives a new hello message before an older cache entry ages, the switch replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the switch is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

### Event-Driven Detection and Echoing

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

**Related Topics**

UDLD Reset Options

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The `udld reset` interface configuration command.
- The `shutdown` interface configuration command followed by the `no shutdown` interface configuration command restarts the disabled port.
- The `no udld {aggressive | enable}` global configuration command followed by the `udld {aggressive | enable}` global configuration command reenables the disabled ports.
- The `no udld port` interface configuration command followed by the `udld port [aggressive]` interface configuration command reenables the disabled fiber-optic port.
- The `errdisable recovery cause udld` global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the `errdisable recovery interval interval` global configuration command specifies the time to recover from the UDLD error-disabled state.

How to Configure UDLD

**Enabling UDLD Globally (CLI)**

Follow these steps to enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic ports on the switch.
SUMMARY STEPS

1. configure terminal
2. udld {aggressive | enable | message time message-timer-interval}
3. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** configure terminal
   Example:
   Switch# configure terminal | Enters global configuration mode. |
| **Step 2** udld {aggressive | enable | message time message-timer-interval}
   Example:
   Switch(config)# udld enable message time 10 | Specifies the UDLD mode of operation:
   • aggressive—Enables UDLD in aggressive mode on all fiber-optic ports.
   • enable—Enables UDLD in normal mode on all fiber-optic ports on the switch. UDLD is disabled by default.
   An individual interface configuration overrides the setting of the udld enable global configuration command.
   • message time message-timer-interval—Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are detected to be bidirectional. The range is from 1 to 90 seconds; the default value is 15.
   Note: This command affects fiber-optic ports only. Use the udld interface configuration command to enable UDLD on other port types.
   Use the no form of this command, to disable UDLD. |
| **Step 3** end
   Example:
   Switch(config)# end | Returns to privileged EXEC mode. |

• Configuring Power over Ethernet, on page 711
Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Switch for Access Point Discovery

- Ensure that the Control and Provisioning of Wireless Access Points (CAPWAP) UDP ports 5246 and 5247 (similar to the Lightweight Access Point Protocol (LWAPP) UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the switch.

- If access control lists (ACLs) are in the control path between the switch and its access points, you must open new protocol ports to prevent access points from being stranded.

- If an access point is in the UP state and its IP address changes, the access point tears down the existing CAPWAP tunnel and rejoins the switch.

- Access points must be discovered by a switch before they can become an active part of the network. The lightweight access points support the following switch discovery processes:
• Layer 3 CAPWAP discovery—You can enable this feature on different subnets from the access point. This feature uses IP addresses and UDP packets rather than the MAC addresses used by Layer 2 discovery.

• Locally stored switch IP address discovery—If the access point was previously associated to a switch, the IP addresses of the primary, secondary, and tertiary switches are stored in the access point’s nonvolatile memory. This process of storing switch IP addresses on an access point for later deployment is called **priming the access point**.

• DHCP server discovery—This feature uses DHCP option 43 to provide switch IP addresses to the access points. Cisco switches support a DHCP server option that is typically used for this capability.

• DNS discovery—The access point can discover switches through your domain name server (DNS). You must configure your DNS to return switch IP addresses in response to CISCO-CAPWAP-CONTROLLER.localdomain, where localdomain is the access point domain name. When an access point receives an IP address and DNS information from a DHCP server, it contacts the DNS to resolve CISCO-CAPWAP-CONTROLLER.localdomain. When the DNS sends a list of switch IP addresses, the access point sends discovery requests to the switches.

### Restrictions for Configuring the Switch for Access Point Discovery

• Ensure that the switches are configured with the correct date and time. If the date and time configured on the switch precedes the creation and installation date of certificates on the access points, the access point fails to join the switch.

• During the discovery process, access points that are supported by the Cisco switch, such as the 1140, 1260, 3500, 1040, 1600, 2600, or 3600 query only for Cisco switches.

### Information About Configuring the Switch for Access Point Discovery

In a CAPWAP environment, a lightweight access point discovers a switch by using CAPWAP discovery mechanisms and then sends a CAPWAP join request to the switch. The switch sends a CAPWAP join response to the access point that allows the access point to join the switch. When the access point joins the switch, the switch manages its configuration, firmware, control transactions, and data transactions.

### Access Point Communication Protocols

Cisco lightweight access points use the IETF standard CAPWAP to communicate with the switch and other lightweight access points on the network.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a switch to manage a collection of wireless access points. CAPWAP is implemented in switch for these reasons:

• To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP
• To manage RFID readers and similar devices
• To enable switches to interoperate with third-party access points in the future

**Viewing Access Point Join Information**

Join statistics for an access point that sends a CAPWAP discovery request to the switch at least once are maintained on the switch even if the access point is rebooted or disconnected. These statistics are removed only when the switch is rebooted or when you choose to clear the statistics.

**Troubleshooting the Access Point Join Process**

Access points can fail to join a switch for many reasons such as a RADIUS authorization is pending, self-signed certificates are not enabled on the switch, the access point and switch’s regulatory domains do not match, and so on.

You can configure the access points to send all CAPWAP-related errors to a syslog server. You do not need to enable any debug commands on the switch because all of the CAPWAP error messages can be viewed from the syslog server itself.

The state of the access point is not maintained on the switch until it receives a CAPWAP join request from the access point, so it can be difficult to determine why the CAPWAP discovery request from a certain access point was rejected. In order to troubleshoot such joining issues without enabling CAPWAP debug commands on the switch, the switch collects information for all access points that send a discovery message to this switch and maintains information for any access points that have successfully joined this switch.

The switch collects all join-related information for each access point that sends a CAPWAP discovery request to the switch. Collection begins when the first discovery message is received from the access point and ends when the last configuration payload is sent from the switch to the access point.

When the switch is maintaining join-related information for the maximum number of access points, it does not collect information for any more access points.

You can also configure a DHCP server to return a syslog server IP address to the access point using option 7 on the server. The access point then starts sending all syslog messages to this IP address.

You can configure the syslog server IP address through the access point CLI, if the access point is not connected to the switch by entering the `capwap ap log-server syslog_server_IP_address` command.

When the access point joins a switch for the first time, the switch pushes the global syslog server IP address (the default is 255.255.255.255) to the access point. After that, the access point sends all syslog messages to this IP address, until it is overridden by one of the following scenarios:

- The access point is still connected to the same switch, and you changed the global syslog server IP address configuration on the switch by using the `ap syslog host Syslog_Server_IP_Address` command. In this case, the switch pushes the new global syslog server IP address to the access point.

- The access point is still connected to the same switch, and you configured a specific syslog server IP address for the access point on the switch by using the `ap name Cisco_AP syslog host Syslog_Host_IP_Address` command. In this case, the switch pushes the new specific syslog server IP address to the access point.

- The access point gets disconnected from the switch, and you configured the syslog server IP address from the access point CLI by using the `capwap ap log-server syslog_server_IP_address` command. This command works only if the access point is not connected to any switch.
• The access point gets disconnected from the switch and joins another switch. In this case, the new switch pushes its global syslog server IP address to the access point.

Whenever a new syslog server IP address overrides the existing syslog server IP address, the old address is erased from persistent storage, and the new address is stored in its place. The access point also starts sending all syslog messages to the new IP address, if the access point can reach the syslog server IP address.

How to Configure Access Point Discovery

Configuring the Syslog Server for Access Points (CLI)

SUMMARY STEPS

1. enable
2. configure terminal
3. ap syslog host host_ip_address
4. end
5. show ap config global
6. show ap name Cisco_AP config general

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters global configuration mode. |
| configure terminal|         |
| Example:          |         |
| Switch# configure terminal |         |

| **Step 3**        | Configures the global syslog server for all access points that join this switch. |
| ap syslog host host_ip_address |         |
| Example:          |         |
| Switch(config)# ap syslog host 10.9.9.16 |         |

**Note**

By default, the global syslog server IP address for all access points is 255.255.255.255. Make sure that the access points can reach the subnet on which the syslog server resides before configuring the syslog server on the switch. If the access points cannot reach this subnet, the access points are unable to send out syslog messages.

| **Step 4**        | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |
| end               |         |
| Example:          |         |
| Switch(config)# end |         |
### Monitoring Access Point Join Information (CLI)

#### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong> show ap config global</td>
<td>Displays the global syslog server settings for all access points that join the switch.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show ap config global</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> show ap name <em>Cisco_AP</em> config general</td>
<td>Displays the syslog server settings for a specific access point.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show ap name AP03 config general</td>
<td></td>
</tr>
</tbody>
</table>

#### Monitoring Access Point Join Information (CLI)

The procedure to perform this task using the switch GUI is not currently available.

#### SUMMARY STEPS

1. `enable`
2. `show ap join stats summary`
3. `show ap mac-address mac_address join stats summary`
4. `show ap mac-address mac_address join stats detailed`
5. `clear ap join statistics`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> show ap join stats summary</td>
<td>Displays the MAC addresses of all the access points that are joined to the switch or that have tried to join.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show ap join stats summary</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> show ap mac-address mac_address join stats summary</td>
<td>Displays all the statistics for the AP including the last join error detail.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show ap mac-address 000.2000.0400 join stats summary</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> show ap mac-address mac_address join stats detailed</td>
<td>Displays all join-related statistics collected for a specific access point.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show ap mac-address 000.2000.0400 join stats detailed</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------------------------------------</td>
</tr>
<tr>
<td>clear ap join statistics</td>
<td>Clears the join statistics for all access points.</td>
</tr>
</tbody>
</table>

**Example:**

```
Switch# clear ap join statistics
```

**Note**

To clear the join statistics that correspond to specific access points, enter the `clear ap mac-address mac_address join statistics` command.

---

---

### Searching for Access Point Radios (GUI)

**Step 1**

Choose **Monitor > Wireless > Access Points** and click **802.11a/n/ac Statistics** or **802.11b/g/n Statistics**.

The 802.11 Radio pages are displayed. These pages show all of the 802.11a/n/ac or 802.11b/g/n access point radios that are associated with the switch and their current settings.

**Note**

In a Cisco converged access environment, the 802.11a/n/ac and 802.11b/g/n radios should not be differentiated based on their Base Radio MAC addresses, because they might have the same addresses. Instead, the radios should be differentiated based on their physical addresses.

**Step 2**

From the **Show** drop-down list, choose **Quick Filter**.

The filter options (text boxes) appear in each of the column header in the table.

**Step 3**

Enter a keyword in the corresponding text boxes to specify the filter criteria based on which you want to search, and click the **Filter** icon.

---

### Monitoring the Interface Details (GUI)

**Step 1**

Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed showing a list of access points that are associated with the switch.

**Step 2**

Click the access point name.

The **AP > Edit** page is displayed.

**Step 3**

Click the **Interface** tab.

The interface details are displayed.
Configuration Examples for Configuring the Switch for Access Point Discovery

Displaying the MAC Addresses of all Access Points: Example

This example shows how to display MAC addresses of all the access points that are joined to the switch:

```bash
Switch# show ap join stats summary
Number of APs........................................... 4

<table>
<thead>
<tr>
<th>Base Mac</th>
<th>EthernetMac</th>
<th>AP Name</th>
<th>IP Address</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>00:0b:85:57:bc:c0</td>
<td>00:0b:85:57:bc:c0</td>
<td>AP1130</td>
<td>10.10.163.217</td>
<td>Joined</td>
</tr>
<tr>
<td>00:1c:0f:81:db:80</td>
<td>00:1c:63:23:ac:a0</td>
<td>AP1140</td>
<td>10.10.163.216</td>
<td>Not joined</td>
</tr>
<tr>
<td>00:1c:0f:81:fc:20</td>
<td>00:1b:d5:9f:7d:b2</td>
<td>AP1</td>
<td>10.10.163.215</td>
<td>Joined</td>
</tr>
<tr>
<td>00:21:1b:e4:36:60</td>
<td>00:0c:d4:8a:6b:01</td>
<td>AP2</td>
<td>10.10.163.214</td>
<td>Not joined</td>
</tr>
</tbody>
</table>
```

This example shows how to display the last join error details for a specific access point:

```bash
Switch# show ap mac-address 000.2000.0400 join stats summary
Is the AP currently connected to controller............... Yes
Time at which the AP joined this controller last time........ Aug 21 12:50:36.061
Type of error that occurred last.......................... AP got or has been disconnected
Reason for error that occurred last....................... The AP has been reset by the controller
Time at which the last join error occurred........ Aug 21 12:50:34.374
```

This example shows how to display all join-related statistics collected for a specific access point:

```bash
Switch# show ap mac-address 000.2000.0400 join stats detailed
Discovery phase statistics
- Discovery requests received............................. 2
- Successful discovery responses sent.................... 2
- Unsuccessful discovery request processing............. 0
- Reason for last unsuccessful discovery attempt...... Not applicable
- Time at last successful discovery attempt............. Aug 21 12:50:23.335
- Time at last unsuccessful discovery attempt......... Aug 21 12:50:34.374

Join phase statistics
- Join requests received................................. 1
- Successful join responses sent......................... 1
- Unsuccessful join request processing.................. 1
- Reason for last unsuccessful join attempt...... RADIUS authorization is pending for the AP
- Time at last successful join attempt............... Aug 21 12:50:34.481
- Time at last unsuccessful join attempt............. Aug 21 12:50:34.374

Configuration phase statistics
- Configuration requests received....................... 1
- Successful configuration responses sent.............. 1
- Unsuccessful configuration request processing....... 0
- Reason for last unsuccessful configuration attempt.. Not applicable
- Time at last successful configuration attempt....... Aug 21 12:50:34.374
- Time at last unsuccessful configuration attempt.... Not applicable

Last AP message decryption failure details
- Reason for last message decryption failure.......... Not applicable

Last AP disconnect details
- Reason for last AP connection failure.............. The AP has been reset by the controller

Last join error summary
- Type of error that occurred last.................... AP got or has been disconnected
- Reason for error that occurred last............... The AP has been reset by the controller
- Time at which the last join error occurred......... Aug 21 12:50:34.374

DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example

Configuring Data Encryption

- Finding Feature Information, on page 647
- Prerequisites for Configuring Data Encryption, on page 647
- Restrictions for Configuring Data Encryption, on page 647
- Information About Data Encryption, on page 648
- How to Configure Data Encryption, on page 648
- Configuration Examples for Configuring Data Encryption, on page 649

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Data Encryption

- Cisco 1260, 3500, 3600, 801, 1140, 1310, and 1520 series access points support Datagram Transport Layer Security (DTLS) data encryption.
- You can use the switch to enable or disable DTLS data encryption for a specific access point or for all access points.
- Non-Russian customers who use the Cisco switch do not need a data DTLS license.

Restrictions for Configuring Data Encryption

- Encryption limits throughput at both the switch and the access point, and maximum throughput is desired for most enterprise networks.
- If your switch does not have a data DTLS license and if the access point associated with the switch has DTLS enabled, the data path will be unencrypted.
• In images that do not have a DTLS license, the DTLS commands are not available.

Information About Data Encryption

The switch enables you to encrypt Control and Provisioning of Wireless Access Points (CAPWAP) control packets (and optionally, CAPWAP data packets) that are sent between the access point and the switch using DTLS. DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS. CAPWAP control packets are management packets exchanged between a switch and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data). If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

How to Configure Data Encryption

Configuring Data Encryption (CLI)

SUMMARY STEPS

1. configure terminal
2. ap link-encryption
3. end
4. show ap link-encryption
5. show wireless dtls connections

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# configure terminal</td>

<tr>
<td><strong>Step 3</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>show ap link-encryption</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Displays the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity errors.</td>
</tr>
</tbody>
</table>
### Command or Action

Switch# show ap link-encryption

### Purpose
check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet.

### Step 5

**show wireless dtls connections**

**Example:**
Switch# show wireless dtls connections

### Related Topics
Displaying Data Encryption States for all Access Points: Examples, on page 649

### Configuring Data Encryption (GUI)

#### Step 1
Choose Configuration > Wireless > Access Points > All APs.

The All APs page is displayed.

#### Step 2
Click the name of the access point for which you want to enable data encryption.

The AP > Edit page is displayed.

#### Step 3
Click the Advanced tab.

#### Step 4
Select or unselect the Data Encryption check box.

**Note** Changing the data encryption mode requires the access points to reassociate with the switch.

#### Step 5
Click Apply.

#### Step 6
Click Save Configuration.

### Configuration Examples for Configuring Data Encryption

### Displaying Data Encryption States for all Access Points: Examples

This example shows how to display the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet:

Switch# show ap link-encryption

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count

• You can configure the retransmission intervals and retry count both at a global and a specific access point level. A global configuration applies these configuration parameters to all the access points. Alternatively, when you configure the retransmission level and retry count at a specific access point level, the values are applied to that particular access point. The access point specific configuration has a higher precedence than the global configuration.
Information About Retransmission Interval and Retry Count

The switch and the access points exchange packets using the Control and Provisioning of Wireless Access Points (CAPWAP) reliable transport protocol. For each request, a response is defined. This response is used to acknowledge the receipt of the request message. Response messages are not explicitly acknowledged; therefore, if a response message is not received, the original request message is retransmitted after the retransmit interval. If the request is not acknowledged after a maximum number of retransmissions, the session is closed and the access points reassociate with another switch.

How to Configure Access Point Retransmission Interval and Retry Count

Configuring the Access Point Retransmission Interval and Retry Count (CLI)

SUMMARY STEPS

1. enable
2. configure terminal
3. ap capwap retransmit interval interval_time
4. ap capwap retransmit count count_value
5. end
6. ap name Cisco_AP capwap retransmit interval interval_time
7. ap name Cisco_AP capwap retransmit count count_value
8. show ap capwap retransmit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

### Configuring the Access Point Retransmission Interval and Retry Count (GUI)

**Procedure**

- Global configuration applicable to all APs:
  a) Choose **Configuration > Wireless > Access Points > Global AP Configuration**.
     The **Global Configuration** page is displayed.
  b) In the **AP Retransmit Config Parameters** area, enter the values for the following parameters:
    - **AP Retransmit Count**—Number of times you want the access point to retransmit the request to the switch. The valid range is between 3 and 8.
    - **AP Retransmit Interval**—Duration between the retransmission of requests. The valid range is between 2 and 5.

  c) Click **Apply**.
  d) Click **Save Configuration**.

- Configuration that is applicable to a specific AP:
  a) Choose **Configuration > Wireless > Access Points > All APs**.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>ap capwap retransmit count <em>count_value</em></td>
<td>Configures the control packet retry count for all access points globally.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>end</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press <strong>Ctrl-Z</strong> to exit global configuration mode.</td>
</tr>
</tbody>
</table>

- **Step 6** | ap name *Cisco_AP* capwap retransmit interval *interval_time* | Configures the control packet retransmit interval for the individual access point that you specify. | Switch# ap name AP02 capwap retransmit interval 2 |
  | **Example:** | Note: The range for the interval is from 2 to 5. | |
  | **Example:** | Note: You must be in privileged EXEC mode to use the **ap name** commands. |

- **Step 7** | ap name *Cisco_AP* capwap retransmit count *count_value* | Configures the control packet retry count for the individual access point that you specify. | Switch# ap name AP02 capwap retransmit count 3 |
  | **Example:** | Note: The range for the retry count is from 3 to 8. |

- **Step 8** | show ap capwap retransmit | Displays the CAPWAP retransmit details. | Switch# show ap capwap retransmit |
The All APs page is displayed with a list of access points.

b) Click the access point name.

The AP > Edit page is displayed.

c) Click the Advanced tab.

d) In the AP Retransmit Config Parameters area, enter the values for the following AP Retransmit Count and AP Retransmit Interval parameters:

- **AP Retransmit Count**—Number of times you want the access point to retransmit the request to the switch. The valid range is between 3 and 8.

- **AP Retransmit Interval**—Duration between the retransmission of requests. The valid range is between 2 and 5.

e) Click Apply.

f) Click Save Configuration.

### Viewing CAPWAP Maximum Transmission Unit Information (CLI)

#### SUMMARY STEPS

1. **enable**
2. **show ap name Cisco_AP config general**

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enters privileged EXEC mode.</td>

Configuring Adaptive Wireless Intrusion Prevention System

- Finding Feature Information, on page 657
- Prerequisites for Configuring wIPS, on page 657
- How to Configure wIPS on Access Points, on page 657
- Monitoring wIPS Information, on page 659
- Configuration Examples for Configuring wIPS on Access Points, on page 660

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring wIPS

- The regular local mode access point has been extended with a subset of Wireless Intrusion Prevention System (wIPS) capabilities. This feature enables you to deploy your access points to provide protection without needing a separate overlay network.

How to Configure wIPS on Access Points

Configuring wIPS on an Access Point (CLI)

SUMMARY STEPS

1. ap name Cisco_AP mode local
2. ap name Cisco_AP dot11 5ghz shutdown
3. `ap name Cisco_AP dot11 24ghz shutdown`
4. `ap name Cisco_AP mode monitor submode wips`
5. `ap name Cisco_AP monitor-mode wips-optimized`
6. `show ap dot11 24ghz monitor`
7. `ap name Cisco_AP no dot11 5ghz shutdown`
8. `ap name Cisco_AP no dot11 24ghz shutdown`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**        | Configures an access point for monitor mode.  
<p>| <code>ap name Cisco_AP mode local</code> | A message appears that indicates that changing the AP’s mode causes the access point to reboot. This message also displays a prompt that enables you to specify whether or not you want to continue with changing the AP mode. Enter <code>y</code> at the prompt to continue. |
| <strong>Example:</strong>      |         |
| Switch# ap name AP01 mode local |         |
| <strong>Step 2</strong>        | Disables the 802.11a radio on the access point. |
| <code>ap name Cisco_AP dot11 5ghz shutdown</code> | |
| <strong>Example:</strong>      |         |
| Switch# ap name AP01 dot11 5ghz shutdown | |
| <strong>Step 3</strong>        | Disables the 802.11b radio on the access point. |
| <code>ap name Cisco_AP dot11 24ghz shutdown</code> | |
| <strong>Example:</strong>      |         |
| Switch# ap name AP02 dot11 24ghz shutdown |         |
| <strong>Step 4</strong>        | Configures the wIPS submode on the access point. |
| <code>ap name Cisco_AP mode monitor submode wips</code> | To disable wIPS on the access point, enter the <code>ap name Cisco_AP modemonitor submode none</code> command. |
| <strong>Example:</strong>      |         |
| Switch# ap name AP01 mode monitor submode wips | |
| <strong>Step 5</strong>        | Enables wIPS optimized channel scanning for the access point. |
| <code>ap name Cisco_AP monitor-mode wips-optimized</code> | The access point scans each channel for 250 milliseconds. It derives the list of channels to be scanned from the monitor configuration. You can choose the following options: |
| <strong>Example:</strong>      |         |
| Switch# ap name AP01 monitor-mode wips-optimized | |
| <strong>Note</strong> | • <strong>All</strong>—All channels supported by the access point’s radio. |
| | • <strong>Country</strong>—Only the channels supported by the access point’s country of operation. |
| | • <strong>DCA</strong>—Only the channel set used by the dynamic channel assignment (DCA) algorithm, which by default includes all of the nonoverlapping channels allowed in the access point’s country of operation. |</p>
<table>

**Configuring wIPS on an Access Point (GUI)**

**Step 1** Choose Configuration > Wireless > Access Points > All APs

The All APs page is displayed.

**Step 2** Click the access point name.

The AP > Edit page is displayed.

**Step 3** From the AP Mode drop-down list, choose one of the following options to configure the AP mode parameters:

- Local
- Monitor

**Step 4** From the AP Sub Mode drop-down list, choose WIPS.

**Step 5** Click Apply.

**Step 6** Click Save Configuration.

**Monitoring wIPS Information**

**Note**

The procedure to perform this task using the switch GUI is not currently available.

**SUMMARY STEPS**

1. `show ap name Cisco_AP config general`
2. show ap monitor-mode summary
3. show wireless wps wips summary
4. show wireless wps wips statistics
5. clear wireless wips statistics

Configuring Authentication for Access Points

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Authentication for Access Points

• You can set a global username, password, and enable password for all access points that are currently joined to the switch and any that join in the future inherit as they join the switch. If desired, you can override the global credentials and assign a unique username, password, and enable password for a specific access point.

• After an access point joins the switch, the access point enables console port security, and you are prompted for your username and password whenever you log into the access point’s console port. When you log in, you are in nonprivileged mode, and you must enter the enable password in order to use the privileged mode.

• The global credentials that you configure on the switch are retained across switch and access point reboots. They are overwritten only if the access point joins a new switch that is configured with a global username and password. If the new switch is not configured with global credentials, the access point retains the global username and password configured for the first switch.

• You must track the credentials used by the access points. Otherwise, you might not be able to log into an access point’s console port. If you need to return the access points to the default Cisco/Cisco username
and password, you must clear the switch’s configuration and the access point’s configuration to return
them to factory-default settings. To reset the default access point configuration, enter the `ap name
Cisco_AP mgmtuser username Cisco password Cisco` command. Entering the command does not
clear the static IP address of the access point. Once the access point rejoins a switch, it adopts the default
Cisco/Cisco username and password.

- You can configure global authentication settings for all access points that are currently joined to the
switch and any that join in the future. If desired, you can override the global authentication settings and
assign unique authentication settings for a specific access point.

- This feature is supported on the following hardware:
  - All Cisco switches that support authentication.
  - Cisco Aironet 1140, 1260, 1310, 1520, 1600, 2600, 3500, and 3600 access points

**Restrictions for Configuring Authentication for Access Points**

- The switch name in the AP configuration is case sensitive. Therefore, make sure to configure the exact
  system name on the AP configuration. Failure to do this results in the AP fallback not working.

**Information about Configuring Authentication for Access Points**

Cisco IOS access points are shipped from the factory with *Cisco* as the default enable password. This password
allows users to log into the nonprivileged mode and enter the `show` and `debug` commands that pose a security
threat to your network. You must change the default enable password to prevent unauthorized access and to
enable users to enter configuration commands from the access point’s console port.

You can configure 802.1X authentication between a lightweight access point and a Cisco switch. The access
point acts as an 802.1X supplicant and is authenticated by the switch where it uses EAP-FAST with anonymous
PAC provisioning.

**How to Configure Authentication for Access Points**

**Configuring Global Credentials for Access Points (CLI)**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ap mgmtuser username user_name password 0 password secret 0 secret_value`
4. `end`
5. `ap name Cisco_AP mgmtuser username user_name password password secret secret`
6. `show ap summary`
7. `show ap name Cisco_AP config general`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>

<td>If this access point is configured for global credentials, the AP User Mode text boxes shows “Automatic.” If the global credentials have been overwritten for this access point, the AP User Mode text box shows “Customized.”</td>
</tr>
</tbody>
</table>
Configuring Global Credentials for Access Points (GUI)

Step 1  Choose Configuration > Wireless > Access Points > Global AP Configuration.
The Global Configuration page is displayed.

Step 2  In the Login Credentials area, enter the following parameters:
  • User Name
  • Password
  • Confirm Password
  • Secret Password
  • Confirm Secret Password

The password should contain characters from at least three of the following classes: lowercase letters, uppercase letters, digits, and special characters. No character in the password can be repeated more than three times consecutively. The password should not contain the management username or the reverse of the username. The password should not contain words like Cisco, oscic, admin, nimda or any variant obtained by changing the capitalization of letters by substituting 1, |, or ! or substituting 0 for o or substituting $ for s.

Step 3  Click Apply.  
The global username and password are applied to all the access points that are associated with the switches

Step 4  Click Save Configuration.

Step 5  (Optional) You can override the global credentials for a specific access point and assign a unique username and password by following these steps:
  a) Choose Configuration > Wireless > Access Points > All APs.
     The All APs page is displayed.
  b) Click the name of an access point.
     The AP > Edit page is displayed.
  c) Click the Credentials tab.
  d) In the Login Credentials area, select the Over-ride Global Credentials check box.
  e) Enter the values for the following parameters:
     • Username
     • Password
     • Enable Password
  f) Click Apply.
  g) Click Save Configuration.
# Configuring Authentication for Access Points (CLI)

## SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap dot1x username user_name_value password 0 password_value`
4. `end`
5. `ap name Cisco_AP dot1x-user username_value password password_value`
6. `configure terminal`
7. `no ap dot1x username user_name_value password 0 password_value`
8. `end`
9. `show ap summary`
10. `show ap name Cisco_AP config general`

- Displaying the Authentication Settings for Access Points: Examples, on page 672

**Configuring Authentication for Access Points (GUI)**

**Step 1** Choose **Configuration > Wireless > Access Points > Global AP Configuration**. The **Global Configuration** page is displayed.

**Step 2** In the **802.1x Supplicant Credentials** area, select the **Credentials Required** check box.

**Step 3** Enter the username and password details.

**Note** You must enter a strong password in these text boxes. Strong passwords have the following characteristics:

- They are at least eight characters long
- They contain a combination of uppercase and lowercase letters, numbers, and symbols
- They are not a word in any language

**Step 4** Click **Apply**.

**Step 5** Click **Save Configuration**.

**Step 6** *(Optional)* You can override the global configuration and assign a unique username and password to a specific access point by following these steps:

a) Choose **Configuration > Wireless > Access Points > All APs**. The **All APs** page is displayed.
Step 7  Click the name of an access point.
The AP > Edit is displayed.

Step 8  Click the Credentials tab.

Step 9  In the 802.1x Supplicant Credentials area, select the Over-ride Global Credentials check box.

Step 10 Enter the username and password details.

Step 11 Click Apply.

Step 12 Click Save Configuration.

---

Configuring the Switch for Authentication (CLI)

Note  The procedure to perform this task using the switch GUI is not currently available.

SUMMARY STEPS

1.  enable
2.  configure terminal
3.  dot1x system-auth-control
4.  aaa new-model
5.  aaa authentication dot1x default group radius
6.  radius-server host host_ip_address acct-port port_number auth-port port_number key 0 unencrypted_server_key
7.  interface TenGigabitEthernet1/0/1
8.  switch mode access
9.  dot1x pae authenticator
10. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  | **enable**  | Enters privileged EXEC mode.  
| Example: Switch# enable | |
| **Step 2**  | **configure terminal**  | Enters global configuration mode.  
| Example: Switch# configure terminal | |
| **Step 3**  | **dot1x system-auth-control**  | Enables system authentication control.  
<p>| Example: Switch(config)# dot1x system-auth-control | |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 4** aaa new-model  
Example: Switch(config)# aaa new-model | Enables new access control commands and functions. |
| **Step 5** aaa authentication dot1x default group radius  
Example: Switch(config)# aaa authentication dot1x default group radius | Sets the default authentications lists for IEEE 802.1X by using all the radius hosts in a server group. |
| **Step 6** radius-server host host_ip_address acct-port port_number auth-port port_number key 0 unencrypted_server_key  
Example: Switch(config)# radius-server host 10.1.1.1 acct-port 1813 auth-port 6225 key 0 encryptkey | Sets a clear text encryption key for the RADIUS authentication server. |
| **Step 7** interface TenGigabitEthernet1/0/1  
Example: Switch(config)# interface TenGigabitEthernet1/0/1 | Sets the 10-Gigbit Ethernet interface.  
The command prompt changes from Controller(config)# to Controller(config-if)#. |
| **Step 8** switch mode access  
Example: Switch(config-if)# switch mode access | Sets the unconditional truncking mode access to the interface. |
| **Step 9** dot1x pae authenticator  
Example: Switch(config-if)# dot1x pae authenticator | Sets the 802.1X interface PAE type as the authenticator. |
| **Step 10** end  
Example: Switch(config)# end | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |

Configuration Examples for Configuring Authentication for Access Points

Displaying the Authentication Settings for Access Points: Examples

This example shows how to display the authentication settings for all access points that join the switch:

```
Switch# show ap summary
Number of APs................................. 1
Global AP User Name.......................... globalap
Global AP Dot1x User Name.................. globalDot1x
```

This example shows how to display the authentication settings for a specific access point:

```
Switch# show ap name AP02 config dot11 24ghz general
Cisco AP Identifier.......................... 0
Cisco AP Name.................................. TSIM_AP2
...
AP Dot1x User Mode........................... AUTOMATIC
AP Dot1x User Name........................... globalDot1x
```
Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Converting Autonomous Access Points to Lightweight Mode

• Access points that are converted to lightweight mode do not support Wireless Domain Services (WDS). Converted access points communicate only with Cisco wireless LAN switches and cannot communicate with WDS devices. However, the switch provides functionality that is equivalent to WDS when the access point associates to it.
• All Cisco lightweight access points support 16 Basic Service Set Identifiers (BSSIDs) per radio and a total of 16 wireless LANs per access point. When a converted access point associates to a switch, only wireless LANs with IDs 1 through 16 are pushed to the access point unless the access point is a member of an access point group.

• Access points that are converted to lightweight mode must get an IP address and discover the switch using DHCP, DNS, or IP subnet broadcast.

Information About Autonomous Access Points Converted to Lightweight Mode

You can convert autonomous Cisco Aironet access points to lightweight mode. When you upgrade the access points to lightweight mode, the access point communicates with the switch and receives a configuration and software image from the switch.

See the Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode document for instructions to upgrade an autonomous access point to lightweight mode:

Reverting from Lightweight Mode to Autonomous Mode

After you convert an autonomous access point to lightweight mode, you can convert the access point from a lightweight unit back to an autonomous unit by loading a Cisco IOS release that supports autonomous mode (Cisco IOS Release 12.3(7)JA or earlier releases). If the access point is associated with a switch, you can use the switch to load the Cisco IOS release. If the access point is not associated to a switch, you can load the Cisco IOS release using TFTP. In either method, the access point must be able to access a TFTP server that contains the Cisco IOS release to be loaded.

Using DHCP Option 43 and DHCP Option 60

Cisco Aironet access points use the type-length-value (TLV) format for DHCP option 43. You must program the DHCP servers to return the option based on the access point’s DHCP Vendor Class Identifier (VCI) string (DHCP option 60).

For more information about DHCP VCI strings of access points, see http://www.cisco.com/en/US/tech/tk722/tk809/technologies_configuration_example09186a00808714fe.shtml.

See the product documentation for your DHCP server for instructions on configuring DHCP option 43. The Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode document contains example steps for configuring option 43 on a DHCP server.

If the access point is ordered with the Service Provider Option - AIR-OPT60-DHCP selected, the VCI string for that access point will be different than those strings listed in the previous table. The VCI string has the following suffix: ServiceProvider. For example, a 1260 with this option returns this VCI string: Cisco AP c1260-ServiceProvider.
The switch IP address that you obtain from the DHCP server should be a unicast IP address. Do not configure the switch IP address as a multicast address when configuring DHCP option 43.

How Converted Access Points Send Crash Information to the Switch

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the switch. If the unit rebooted because of a crash, the switch pulls up the crash file using existing CAPWAP messages and stores it in the switch flash memory. The crash information copy is removed from the access point flash memory when the switch pulls it from the access point.

Uploading Memory Core Dumps from Converted Access Points

By default, access points converted to lightweight mode do not send memory core dumps to the switch. This section provides instructions to upload access point core dumps using the switch GUI or CLI.

Displaying MAC Addresses for Converted Access Points

There are some differences in the way that controllers display the MAC addresses of converted access points on information pages in the controller GUI:

- On the AP Summary page, the controller lists the Ethernet MAC addresses of converted access points.
- On the AP Detail page, the controller lists the BSS MAC addresses and Ethernet MAC addresses of converted access points.
- On the Radio Summary page, the switch lists converted access points by the radio MAC address.

Configuring a Static IP Address for a Lightweight Access Point

If you want to specify an IP address for an access point rather than having one assigned automatically by a DHCP server, you can use the controller GUI or CLI to configure a static IP address for the access point. Static IP addresses are generally used only for deployments with a limited number of users.

An access point cannot discover the switch using domain name system (DNS) resolution if a static IP address is configured for the access point, unless you specify a DNS server and the domain to which the access point belongs. You can configure these parameters using either the switch CLI or the GUI.

If you configure an access point to use a static IP address that is not on the same subnet on which the access point’s previous DHCP address was, the access point falls back to a DHCP address after the access point reboots. If the access point falls back to a DHCP address, enter the `show ap config general Cisco_AP` CLI command to show that the access point is using a fallback IP address. However, the GUI shows both the static IP address and the DHCP address, but it does not identify the DHCP address as a fallback address.
How to Convert a Lightweight Access Point Back to an Autonomous Access Point

Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)

SUMMARY STEPS

1. enable
2. ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename

Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)

**Step 1** Configure the PC on which your TFTP server software runs with a static IP address in the range of 10.0.0.2 to 10.0.0.30.

**Step 2** Make sure that the PC contains the access point image file (such as c1140-k9w7-tar.123-7.JA.tar for a 1140 series access point) in the TFTP server folder and that the TFTP server is activated.

**Step 3** Rename the access point image file in the TFTP server folder to c1140-k9w7-tar.default for a 1140 series access point.

**Step 4** Connect the PC to the access point using a Category 5 (CAT5) Ethernet cable.

**Step 5** Disconnect power from the access point.

**Step 6** Press and hold the MODE button while you reconnect power to the access point.  

**Note** The MODE button on the access point must be enabled.

**Step 7** Hold the MODE button until the status LED turns red (approximately 20 to 30 seconds), and release the MODE button.

**Step 8** Wait until the access point reboots as indicated by all LEDs turning green followed by the Status LED blinking green.
Step 9 After the access point reboots, reconfigure the access point using the GUI or the CLI.

## Authorizing Access Points (CLI)

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap auth-list ap-policy authorize-ap`
4. `username user_name mac aaa attribute list list_name`
5. `aaa new-model`
6. `aaa authorization credential-download auth_list local`
7. `aaa attribute list list`
8. `aaa session-id common`
9. `aaa local authentication default authorization default`
10. `show ap name Cisco_AP config general`

### Authorizing Access Points (GUI)

**Step 1**   Choose **Configuration > Security > AAA > AP Policy**.

The AP Policy page is displayed.

**Step 2**   In the Policy Configuration area, enable or disable the following parameters:

- Authorize LSC APs against Auth-List
- AP with Self-Signed Certificate
- Authorize MIC APs against AAA
- AP with Manufacturing Installed Certificate

**Step 3**   Click **Apply**.

**Step 4**   Click **Save Configuration**.
Disabling the Reset Button on Converted Access Points (CLI)

You can enable or disable the Reset button on access points that are converted to lightweight mode. The Reset button is labeled MODE on the outside of the access point.

**Note**
The procedure to perform this task using the controller GUI is not currently available.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no ap reset-button
4. end
5. ap name Cisco_AP reset-button

**DETAILED STEPS**

<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>enable</strong></td>
<td>Enters privileged EXEC mode.</td>
</tr>
</tbody>
</table>
|      | **Example:**
|      | Switch# enable                                                                  |                                                                         |
| Step 2 | **ap name Cisco_AP static-ip ip-address**
|      | **static_ap_address netmask static_ip_netmask gateway**                        | Configures a static IP address on the access point. This command contains the following keywords and arguments:
|      | **Example:**
|      | Switch# ap name AP03 static-ip ip-address 9.9.9.16 netmask 255.255.0.0 gateway 9.9.9.2 | • **ip-address** — Specifies the Cisco access point static IP address.
|      |                                                                             | • **ip-address** — Cisco access point static IP address.              |
|      |                                                                             | • **netmask** — Specifies the Cisco access point static IP netmask.   |
|      |                                                                             | • **netmask** — Cisco access point static IP netmask.                 |
|      |                                                                             | • **gateway** — Specifies the Cisco access point gateway.             |
|      |                                                                             | • **gateway** — IP address of the Cisco access point gateway.         |
|      |                                                                             |                                                                         |
|      |                                                                             | The access point reboots and rejoins the switch, and the static IP address that you specify is pushed to the access point. After the static IP address has been sent to the access point, you can configure the DNS server IP address and domain name. You must perform Steps 3 and 4 after the access points reboot. |
| Step 3 | **enable**                                                                     | Enters privileged EXEC mode.                                             |
|      | **Example:**
|      | Switch# enable                                                                  |                                                                         |
| Step 4 | **configure terminal**                                                          | Enters global configuration mode.                                       |
|      | **Example:**
|      | Switch# configure terminal                                                      |                                                                         |
| Step 5 | **ap static-ip name-server nameserver_ip_address**                             | Configures a DNS server so that a specific access point or all access points can discover the switch using DNS resolution. |
|      | **Example:**
|      | Switch(config)# ap static-ip name-server 10.10.10.205                           | **Note** To undo the DNS server configuration, enter the **no ap static-ip name-server nameserver_ip_address** command. |
| Step 6 | **ap static-ip domain static_ip_domain**                                       | Configures the domain to which a specific access point or all access points belong. |
|      | **Example:**
|      |                                                                         |                                                                         |
Configuring a Static IP Address on an Access Point (GUI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ap static-ip domain domain1</td>
<td>To undo the domain name configuration, enter the <code>no ap static-ip domain static_ip_domain</code> command.</td>
</tr>
<tr>
<td>End</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Step 7 end</td>
<td>Example: Switch(config)# end</td>
</tr>
<tr>
<td>Step 8 show ap name Cisco_AP config general</td>
<td>Displays the IP address configuration for the access point.</td>
</tr>
<tr>
<td>Example: Switch# show ap name AP03 config general</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring a Static IP Address on an Access Point (GUI)**

**Step 1** Choose Configuration > Wireless > Access Points > All APs.

The All APs page is displayed.

**Step 2** Click the name of the access point.

The AP > Edit page is displayed.

**Step 3** In the General tab, in the IP Config area, select the Static IP check box if you want to assign a static IP address to the access point.

**Step 4** Enter the following details:

- Static IP
- Netmask
- Gateway

**Step 5** Click Apply.

The access point reboots and rejoins the switch, and the static IP address that you specified is sent to the access point.

**Step 6** After the static IP address has been sent to the access point, configure the DNS IP Address and Domain Name.

**Step 7** Click Apply.

**Step 8** Click Save Configuration.
Recovering the Access Point Using the TFTP Recovery Procedure

**Step 1**  Download the required recovery image from Cisco.com (ap3g2-k9w8-tar.152-2.JA.tar) and install it in the root directory of your TFTP server.

**Step 2**  Connect the TFTP server to the same subnet as the target access point and power-cycle the access point. The access point boots from the TFTP image and then joins the switch to download the oversized access point image and complete the upgrade procedure.

**Step 3**  After the access point has been recovered, you can remove the TFTP server.

Configuration Examples for Converting Autonomous Access Points to Lightweight Mode

**Displaying the IP Address Configuration for Access Points: Example**

This example shows how to display the IP address configuration for the access point:

```
Switch# show ap name AP03 dot11 24ghz config general
Cisco AP Identifier.............. 4
Cisco AP Name............................. AP6
IP Address Configuration............... Static IP assigned
IP Address................................. 10.10.10.118
IP NetMask................................. 255.255.255.0
Gateway IP Addr........................... 10.10.10.1
Domain.................................... Domain1
Name Server............................... 10.10.10.205
...  
```

**Displaying Access Point Crash File Information: Example**

This example shows how to display access point crash file information. Using this command, you can verify whether the file is downloaded to the switch:

```
Switch# show ap crash-file
Local Core Files:
lrad_AP1130.rdump0 (156)
```

The number in parentheses indicates the size of the file. The size should be greater than zero if a core dump file is available.
Displaying Access Point Crash File Information: Example
Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges

A WGB is a mode that can be configured on an autonomous Cisco IOS access point to provide wireless connectivity to a lightweight access point on behalf of clients that are connected by Ethernet to the WGB access point. A WGB connects a wired network over a single wireless segment by learning the MAC addresses of its wired clients on the Ethernet interface and reporting them to the lightweight access point using Internet Access Point Protocol (IAPP) messaging. The WGB provides wireless access connectivity to wired clients by establishing a single wireless connection to the lightweight access point.

When a Cisco WGB is used, the WGB informs the access points of all the clients that it is associated with. The switch is aware of the clients that are associated with the access point. When non-Cisco WGBs are used, the switch has no information about the IP address of the clients on the wired segment behind the WGB. Without this information, the switch drops the following types of messages:

- ARP REQ from the distribution system for the WGB client.
- ARP RPLY from the WGB client.
- DHCP REQ from the WGB client.
Monitoring the Status of Workgroup Bridges

The procedure to perform this task using the switch GUI is not currently available.

SUMMARY STEPS

1. enable
2. show wireless wgb summary
3. show wireless wgb mac-address wgb_mac_address detail

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enters privileged EXEC mode.</td>

Debugging WGB Issues (CLI)

The procedure to perform this task using the switch GUI is not currently available.

SUMMARY STEPS

1. enable
2. debug iapp all
3. debug iapp error
4. debug iapp packet
### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enters privileged EXEC mode.</td>
</tr>
</tbody>
</table>
  **Example:**
  ```
  Switch# enable
  ``` |
| Step 2 | `debug iapp all`  | Enables debugging for IAPP messages. |
  **Example:**
  ```
  Switch# debug iapp all
  ``` |
| Step 3 | `debug iapp error` | Enables debugging for IAPP error events. |
  **Example:**
  ```
  Switch# debug iapp error
  ``` |
| Step 4 | `debug iapp packet` | Enables debugging for IAPP packets. |
  **Example:**
  ```
  Switch# debug iapp packet
  ``` |
| Step 5 | `debug mobility handoff [switch switch_number]` | Enables debugging for any roaming issues. |
  **Example:**
  ```
  Switch# debug mobility handoff
  ``` |
| Step 6 | `debug dhcp`      | Debug an IP assignment issue when DHCP is used. |
  **Example:**
  ```
  Switch# debug dhcp
  ``` |
| Step 7 | `debug dot11 mobile` | Enables dot11/mobile debugging. Debug an IP assignment issue when static IP is used. |
  **Example:**
  ```
  Switch# debug dot11 mobile
  ``` |
| Step 8 | `debug dot11 state` | Enables dot11/state debugging. Debug an IP assignment issue when static IP is used. |
  **Example:**
  ```
  Switch# debug dot11 state
  ``` |
Configuration Examples for Configuring Workgroup Bridges

WGB Configuration: Example

This example shows how to configure a WGB access point using static WEP with a 40-bit WEP key:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# dot11 ssid WGB_with_static_WEP
Switch(config-ssid)# authentication open
Switch(config-ssid)# guest-mode
Switch(config-ssid)# exit
Switch(config)# interface dot11Radio 0
Switch(config)# station-role workgroup-bridge
Switch(config-if)# encry mode wep 40
Switch(config-if)# encry key 1 size 40 0 1234567890
Switch(config-if)# ssid WGB_with_static_WEP
Switch(config-if)# end
```

Verify that the WGB is associated to an access point by entering this command on the WGB:

```
show dot11 association
```

Information similar to the following appears:

```
Switch# show dot11 associations
802.11 Client Stations on Dot11Radio0:SSID [PCVTESTING] :
MAC Address   IP address   Device   Name   Parent   State
000b.8581.6ae2 10.11.12.1   WGB-client  map1   -       Assoc
ap#          
```
Configuring Probe Request Forwarding

• Finding Feature Information, on page 689
• Information About Configuring Probe Request Forwarding, on page 689
• How to Configure Probe Request Forwarding (CLI), on page 689

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Probe Request Forwarding

Probe requests are 802.11 management frames that are sent by clients to request information about the capabilities of Service Set Identifiers (SSIDs). By default, access points forward acknowledged probe requests to the switch for processing. Acknowledged probe requests are probe requests for SSIDs that are supported by the access point. If desired, you can configure access points to forward both acknowledged and unacknowledged probe requests to the switch. The switch can use the information from unacknowledged probe requests to improve the location accuracy.

How to Configure Probe Request Forwarding (CLI)

Note

The procedure to perform this task using the switch GUI is not currently available.

SUMMARY STEPS

1. configure terminal
2. wireless probe filter
3. wireless probe filter num_probes interval
### How to Configure Probe Request Forwarding (CLI)

1. **Step 1**: Enters global configuration mode.
   ```
   configure terminal
   Switch# configure terminal
   ```

2. **Step 2**: Enables or disables the filtering of probe requests forwarded from an access point to the switch.
   ```
   wireless probe filter
   Switch(config)# wireless probe filter
   ```
   **Note**: If you enable probe filtering, the default filter setting, the access point forwards only acknowledged probe requests to the switch. If you disable probe filtering, the access point forwards both acknowledged and unacknowledged probe requests to the switch.

3. **Step 3**: Limits the number of probe requests sent to the switch per client per access point radio in a given interval. You must specify the following arguments with this command:
   - `num_probes` — Number of probe requests forwarded to the switch per client per access point radio in a given interval. The range is from 1 to 100.
   - `interval` — Probe limit interval in milliseconds. The range is from 100 to 10000.
   ```
   wireless probe filter num_probes interval
   Switch(config)# wireless probe filter 5 5
   ```

4. **Step 4**: Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.
   ```
   end
   Switch(config)# end
   ```

5. **Step 5**: Displays the advanced probe request configuration.
   ```
   show wireless probe
   Switch# show wireless probe
   ```

---

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Optimizing RFID Tracking on Access Points

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

How to Optimize RFID Tracking on Access Points

• Prerequisites for Configuring Country Codes, on page 695
• Information About Configuring Country Codes, on page 696
• How to Configure Country Codes (CLI), on page 696
• Configuration Examples for Configuring Country Codes, on page 699

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Country Codes

• Generally, you configure one country code per switch; you configure one code that matches the physical location of the switch and its access points. You can configure up to 20 country codes per switch. This multiple-country support enables you to manage access points in various countries from a single switch.

• When the multiple-country feature is used, all switches that are going to join the same RF group must be configured with the same set of countries, configured in the same order.

• Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.

• The country list configured on the RF group leader determines which channels the members would operate on. This list is independent of which countries have been configured on the RF group members.

• For switches in the Japan regulatory domain, you must have had one or more Japan country codes (JP, J2, or J3) configured on your switch at the time you last booted your switch.

• For switches in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your switch.
Information About Configuring Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio’s broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- JP—Allows only -J radios to join the controller
- J2—Allows only -P radios to join the controller
- J3—Uses the -U frequencies but allows -U, -P and -Q (other than 1550/1600/2600/3600) radios to join the controller
- J4—Allows 2.4G JPQU and 5G PQU to join the controller.

Note
The 1550, 1600, 2600, and 3600 APs require J4.

See the Channels and Maximum Power Settings for Cisco Aironet Lightweight Access Points document for the list of channels and power levels supported by access points in the Japanese regulatory domains.

How to Configure Country Codes (CLI)

Note
The procedure to perform this task using the switch GUI is not currently available.

SUMMARY STEPS

1. enable
2. show wireless country supported
3. configure terminal
4. ap dot11 24ghz shutdown
5. ap dot11 5ghz shutdown
6. ap country country_code
7. end
8. show wireless country channels
9. configure terminal
10. no ap dot11 5ghz shutdown
11. `no ap dot11 24ghz shutdown`
12. `end`
13. `ap name Cisco_AP shutdown`
14. `configure terminal`
15. `ap country country_code`
16. `end`

- How to Configure Link Latency, on page 703
- How to Configure TCP MSS, on page 706
- Performing a Link Test (CLI), on page 707
- Configuration Examples for Configuring Link Latency, on page 708

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Link Latency

- The switch displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the switch is up or can be cleared and allowed to restart.

- You can configure link latency for a specific access point using the switch GUI or CLI or for all access points joined to the switch using the CLI.

Restrictions for Configuring Link Latency

- Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the switch. It does not measure network latency or ping responses.
Information About Configuring Link Latency

You can configure link latency on the switch to measure the link between an access point and the switch. You can use this feature with all access points that are joined to the switch where the link can be a slow or unreliable WAN connection.

TCP MSS

If the client’s maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the switch or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the ping link test, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the CCX link test, the switch can also test the link quality in the access point-to-client direction. The switch issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and switch. Not only can the access point or switch initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or switch.

The switch shows the link-quality metrics for CCX link tests in both directions (out— the access point to the client; in— the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)
- Total number of packets that are retried
- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet
The controller shows this metric regardless of direction:

- Link test request/reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCXv4 or v5, the controller performs a ping link test on the client. If a client supports CCXv4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

# How to Configure Link Latency

## Configuring Link Latency (CLI)

### SUMMARY STEPS

1. enable
2. configure terminal
3. ap link-latency
4. ap tcp-adjust-mss size size
5. show ap name Cisco_AP config general
6. ap name Cisco_AP link-latency [reset]
7. show ap name Cisco_AP config general

<td></td>
</tr>
</tbody>
</table>

**Configuring Link Latency (GUI)**

**Step 1** Choose **Configuration > Wireless > Access Points > All APs**.

The *All APs* page appears with a list of access points.

**Step 2** Click the name of the access point.

The *AP > Edit* page appears.

**Step 3** Click the *Advanced* tab.

**Step 4** In the **Link Latency** area, select or unselect the **Enable Link Latency** check box.

**Note** You can select the **Enable Link Latency** check box to enable link latency for this access point or unselect it to prevent the access point from sending the round-trip time to the switch after every echo response is received. The default state is unselected.

**Step 5** Click **Apply**.

**Step 6** When a message box appears that indicates that AP Parameters are modified successfully, click **OK**.

**Step 7** When the *All APs* page is displayed, click the access point that you have modified earlier.

The *AP > Edit* page appears.

**Step 8** Click the *Advanced* tab.

In the **Link Latency** area, the following link latency and data latency results are displayed:

- **Current(mSec)** — The current round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the switch and back.

- **Minimum(mSec)** — Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the switch and back.

- **Maximum(mSec)** — Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the switch and back.

**Step 9** Click **Reset Link Latency** to clear the current, minimum, and maximum link latency and data latency statistics on the switch for this access point.

**Note** After the page refreshes and the *All APs* page is displayed again, click the *Advanced* tab. The updated statistics appear in the **Minimum** and **Maximum** text boxes.
How to Configure TCP MSS

Configuring TCP MSS (CLI)

SUMMARY STEPS

1. configure terminal
2. ap tcp-adjust-mss size size_value
3. reload
4. show ap tcp-adjust-mss

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>ap tcp-adjust-mss size size_value</td>
<td>Enables the TCP MSS on the particular access point that you specify.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# ap tcp-adjust-mss size 537</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Note To enable TCP MSS on all the access points that are associated with the switch, enter the ap tcp-adjust-mss size size_value command, where the size parameter is from 536 to 1363 bytes. The default value varies for different clients.</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>reload</td>
<td>Reboots the switch in order for your change to take effect.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# reload</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>show ap tcp-adjust-mss</td>
<td>Displays the current TCP MSS setting for all the access points that are associated with the switch.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# show ap tcp-adjust-mss</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Note To display the TCP MSS settings that correspond to a specific access point, enter the show ap name Cisco_AP tcp-adjust-mss command.</td>
<td></td>
</tr>
</tbody>
</table>

Configuring TCP MSS (GUI)

Step 1 Choose Configuration > Wireless > Access Points > Global AP Configuration.

The Global Configuration page is displayed.
Step 2  In the TCP MSS area, select the **Global TCP Adjust MSS** check box and set the MSS for all access points that are associated with the switch. The valid range is from 536 to 1363 bytes.

Step 3  Click **Apply**.

Step 4  Click **Save Configuration**.

---

## Performing a Link Test (CLI)

**Note**

The procedure to perform this task using the switch GUI is not currently available.

### SUMMARY STEPS

1. test wireless linktest *mac_address*
2. configure terminal
3. wireless linktest frame-size *frame_size*
4. wireless linktest number-of-frames *number_of_frames*
5. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  test wireless linktest <em>mac_address</em></td>
<td>Runs a link test.</td>
</tr>
</tbody>
</table>
| Example:  
Switch# test wireless linktest  
00:0d:88:c5:8a:d1 | |
| Step 2  configure terminal | Enters global configuration mode. |
| Example:  
Switch# configure terminal | |
| Step 3  wireless linktest frame-size *frame_size* | Configures the link test frame size for each packet. |
| Example:  
Switch(config)# wireless linktest  
frame-size 41 | |
| Step 4  wireless linktest number-of-frames *number_of_frames* | Configures the number of frames to send for the link test. |
| Example:  
Switch(config)# wireless linktest  
number-of-frames 50 | |
| Step 5  end | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |
| Example:  
Switch(config)# end | |
Configuration Examples for Configuring Link Latency

Running a Link Test: Example

This example shows how to run a link test:

Switch# test wireless linktest 00:0d:88:c5:8a:d1

When CCX v4 or later releases is enabled on both the controller and the client being tested, information similar to the following appears:

CCX Link Test to 00:0d:88:c5:8a:d1.
Link Test Packets Sent ................................. 20
Link Test Packets Received ............................. 10
Link Test Packets Lost (Total/AP to Client/Client to AP) .... 10/5/5
Link Test Packets round trip time (min/max/average) .... 5ms/20ms/15ms
RSSI at AP (min/max/average) ............................. -60dBm/-50dBm/-55dBm
RSSI at Client (min/max/average) ......................... -50dBm/-40dBm/-45dBm
SNR at AP (min/max/average) ............................. 40dB/30dB/35dB
SNR at Client (min/max/average) ......................... 40dB/30dB/35dB
Transmit Retries at AP (Total/Maximum) ................. 5/3
Transmit Retries at Client (Total/Maximum) ............ 4/2
Transmit rate: 1M 2M 5.5M 6M 9M 11M 12M 18M 24M 36M 48M 54M 108M
Packet Count: 0 0 0 0 0 0 0 0 0 2 0 18 0
Transmit rate: 1M 2M 5.5M 6M 9M 11M 12M 18M 24M 36M 48M 54M 108M
Packet Count: 0 0 0 0 0 0 0 0 0 2 0 8 0

When CCX v4 or later releases is not enabled on either the controller or the client being tested, fewer details appear:

Ping Link Test to 00:0d:88:c5:8a:d1.
Link Test Packets Sent ................................. 20
Link Test Packets Received ............................. 20
Local Signal Strength .................................... -49dBm
Local Signal to Noise Ratio ......................... 39dB

Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

Switch# show ap name AP01 config general

Configuring Power over Ethernet

- Finding Feature Information, on page 711
- Information About Configuring Power over Ethernet, on page 711
- How to Configure Power over Ethernet, on page 711
- Configuration Examples for Configuring Power over Ethernet, on page 714

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Power over Ethernet

When an access point that has been converted to lightweight mode (such as an AP1262) access point is powered by a power injector that is connected to a Cisco pre-Intelligent Power Management (pre-IPM) switch, you must configure Power over Ethernet (PoE), which is also known as inline power.

How to Configure Power over Ethernet

Configuring Power over Ethernet (CLI)

SUMMARY STEPS

1. ap name Cisco_AP power injector installed
2. ap name Cisco_AP power injector override
3. ap name Cisco_AP power injector switch-mac-address switch_mac_address
4. show ap name Cisco_AP config general
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td>ap name Cisco_AP power injector installed</td>
<td>Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# ap name AP02 power injector installed</td>
</tr>
</tbody>
</table>

**Note**

Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail.

| **Step 2**        | Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified. |
| ap name Cisco_AP power injector override | Removes the safety checks and allows the access point to be connected to any switch port. You can use this command if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The access point assumes that a power injector is always connected. If you relocate the access point, it continues to assume that a power injector is present. |
| **Example:**      | Switch# ap name AP02 power injector override |

**Note**

Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail.

| **Step 3**        | Sets the MAC address of the switch port that has a power injector. |
| ap name Cisco_AP power injector switch-mac-address switch_mac_address | Sets the MAC address of the switch port that has a power injector. |
| **Example:**      | Switch# ap name AP02 power injector switch-mac-address 10a.2d.5c.3d |

**Note**

Enter this command if you know the MAC address of the connected switch port and do not want to automatically detect it using the installed option.

| **Step 4**        | Displays common information that includes the PoE settings for a specific access point. |
| show ap name Cisco_AP config general | Displays common information that includes the PoE settings for a specific access point. |
| **Example:**      | Switch# show ap name AP02 config general |

**Configuring Power over Ethernet (GUI)**

**Step 1**
Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page appears with a list of access points that are associated with the switch.

**Step 2**
Click the name of the access point.

The **AP > Edit** page appears.

**Step 3**
Click the **Advanced** tab.
**Step 4**  
In the **Power Over Ethernet Settings** area, select the **Pre-Standard 802.3af Switches** check box.

Select this check box if the access point is being powered by a high-power 802.3af Cisco switch. This switch provides more than the traditional 6 Watts of power but does not support the intelligent power management (IPM) feature.

**Note**  
Unselect the **Pre-standard 802.3af Switches** check box if power is being provided by a power injector. This is the default value.

**Step 5**  
Select the **Power Injector State** check box.

Select this check box if the attached switch does not support IPM and a power injector is being used. If the attached switch supports IPM, you do not need to select this check box.

The **Power Injector Selection** drop-down list is displayed that contains parameters that enable you to protect your switch port from an accidental overload if the power injector is inadvertently bypassed.

**Step 6**  
From the **Power Injector Selection** drop-down list, choose an option to specify the desired level of protection.

You can choose any one of the following three options:

- **Installed**—Examines and remembers the MAC address of the currently connected switch port and assumes that a power injector is connected. Choose this option if your network contains older Cisco 6-Watt switches and you want to avoid possible overloads by forcing a double-check of any relocated access points.

  If you want to configure the switch MAC address, enter the MAC address in the **Injector Switch MAC Address** text box. If you want the access point to find the switch MAC address, leave the **Injector Switch MAC Address** text box blank.

  **Note**  
  Each time that an access point is relocated, the MAC address of the new switch port fails to match the remembered MAC address, and the access point remains in low-power mode. You must then physically verify the existence of a power injector and reselect this option to cause the new MAC address to be remembered.

- **Override**—Allows the access point to operate in high-power mode without first verifying a matching MAC address. You can use this option if your network does not contain any older Cisco 6-W access points that could be overloaded if connected directly to a 12-W access point. The advantage of this option is that if you relocate the access point, it continues to operate in high-power mode without any further configuration. The disadvantage of this option is that if the access point is connected directly to a 6-W switch, an overload occurs.

**Step 7**  
Click **Apply**.

**Step 8**  
Click **Save Configuration**.

---

**What to do next**

Manually reset the access point in order for the change to take effect.
Configuration Examples for Configuring Power over Ethernet

Displaying Power over Ethernet Information: Example

This example shows how to display common information that includes the PoE settings for a specific access point:

```
Switch# show ap name AP01 config general
Cisco AP Identifier............ 1
Cisco AP Name.................. AP1
...
Poe Pre-Standard Switch........ Enabled
Poe Power Injector MAC Addr.... Disabled
Power Type/Mode................ PoE/Low Power (degraded mode)
...
```

- Platform Specific Scale Requirement for the Mobility Controller, on page 720

Overview

The switch delivers more services at access layer other than merely providing increased speeds and feeds. Wireless services is now integrated with the switch, which ensures that the access layer switch terminates the wireless users data plane, thereby delivering on the promise of Cisco's unified architecture. Unification implies that mobility services are provided to both wireless and wired stations.

The switch provides seamless roaming, which requires transparency of the network configuration and deployment options to the client.

From the end user's perspective, any mobility event must not change its IP address, its default router or DHCP server. This means that as stations roam, they must be able to

- Send an ARP to their default router, or
- Transmit a DHCP request to the server that had previously assigned their address.

From the infrastructure's perspective, as mobility events occur, the station's traffic must follow its current point of attachment, which can either be a mobility agent (MA) or mobility controller (MC). This must be true regardless of whether the station has moved to a network that is configured for a different subnet. The period from which the station is not receiving traffic following its mobility event must be as short as possible, even below 40 ms whenever possible, which includes any authentication procedures that are required.

From the infrastructure's perspective, the mobility management solution must have four main components, and all of these functions must be performed within the constraints of roaming:

- Initial Association—This function is used to identify the user's new point of attachment in the network.
- Context Transfer—This function is used to transfer state information associated with the station. This ensures that the station's static and real-time policies, including security and application ACLs, and services, remain the same across handoffs.
• Handoff—This function is used to signal that the station's point of attachment has changed, and control of the station should be relinquished by the previous access switch.

• Data Plane—This function is typically tied to the handoff process, and ensures that the station's traffic continues to be delivered and received from the station without any noticeable performance degradation.

Wired and Wireless Mobility

One of the key features of the Converged access solution (applicable to both the Cisco Catalyst 3850 Switch and Cisco WLC 5700 Series Controller) is its ability to provide a device with an IP address and maintain its session persistence, across mobility events from ethernet connections to wireless and vice-versa. This feature allows users to remain on an ethernet network when possible, and make use of the freedom of mobility associated with wireless when necessary.

This feature leverages support from both the client and the infrastructure and uses the two factor authentication-device and user. The device authentication credentials is cached in the mobility controller (MC). When a device transitions across link layers, the device credentials is validated, and if a match is found, the MC ensures that the same IP address is assigned to the new interface.

Features of Mobility

• Mobility Controller (MC)—The controller provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and policy based control protocols, such as RADIUS. This eliminates the need for the infrastructure servers to maintain a user's location as it transitions throughout the network. The MC sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members. A sub-domain is synonymous to the MC that forms it. Each sub-domain consists of an MC and zero or more access switches that have AP's associated to them.

• Mobility Agents (MA)— A mobility agent is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. A mobility agent is the wireless component that maintains client mobility state machine for a mobile client that is connected via an AP to the device that the MA is running on.

• Mobility Sub Domain— It is an autonomous portion of the mobility domain network. A mobility sub-domain comprises of a single mobility controller and its associated mobility agents (MAs).

**Note**

Even when more than one mobility controller is present, only one MC can be active at any given time.

A mobility sub-domain is the set of devices managed by the active mobility controller. A mobility sub-domain comprises of a set of mobility agents and associated access points.

• Mobility Group— A collection of mobility controllers (MCs) across which fast roaming is supported. The concept of mobility group is the same as a collection of buildings in a campus across which frequent roaming is expected.
• Mobility Domain—A collection of mobility sub-domains across which mobility is supported. The term mobility domain may be the same as a campus network.

• Mobility Oracle (MO)—The mobility oracle acts as the point of contact for mobility events that occur across mobility sub-domains. It also maintains a local database of each station in the entire mobility domain, their home and current sub-domain. A mobility domain includes one or more mobility oracle, though only one would be active at any given time.

• Mobility Tunnel Endpoint (MTE)—The mobility tunnel endpoint (MTE) provides data plane services for mobile devices through the use of tunneling. This minimizes the impact of roaming events on the network by keeping the user's point of presence on the network a constant.

• Point of Attachment—A station's point of attachment is where its data path is initially processed upon entry in the network. This could either be the access switch that is currently providing it service, or the wireless LAN controller.

• Point of Presence—A station's point of presence is the place in the network where the station is being advertised. For instance, if an access switch is advertising reachability to the station via a routing protocol, the interface on which the route is being advertised is considered the station's point of presence.

• Switch Peer Group (SPG)—A peer group is a statically created list of neighboring access switches between which fast mobility services is provided. A peer group limits the scope of interactions between switches during handoffs to only those that are geographically proximate.

• Station—A user's device that connects to and requests service from the network. The device may have a wired, wireless or both interfaces.

• Switch in the same SPG—A peer switch that is part of the peer group of the local switch.

• Switch outside the SPG—A peer access switch that is not part of the local switch's peer group.

• Foreign Mobility Controller—The mobility controller providing mobility management service for the station in a foreign mobility sub-domain. The foreign mobility controller acts as a liaison between access switches in the foreign sub-domain and the mobility controller in the home domain.

• Foreign Mobility Sub-Domain—The mobility sub-domain, controlled by a mobility controller, supporting a station which is anchored in another mobility sub-domain

• Foreign Switch—The access switch in the foreign mobility sub-domain currently providing service to the station.

• Anchor Mobility Controller—The mobility controller providing a single point of control and mobility management service for stations in their home mobility sub-domain.

• Anchor Mobility Sub-Domain—The mobility sub-domain, controlled by a mobility controller, for a station where its IP address was assigned.

• Anchor Switch—The switch in the home mobility sub-domain that last provided service to a station.

**Sticky Anchoring for Low Latency Roaming**

Sticky Anchoring ensures low roaming latency from the client's point of presence is maintained at the switch where the client initially joins the network. It is expensive to apply client policies at a switch for a roaming client. There can be considerable delay as it involves contacting the AAA server for downloadable ACLs which is not acceptable for restoring time sensitive client traffic.
Bridge Domain ID and L2/L3 Roaming

Bridge domain ID provides the mobility nodes with information to decide on specific roam type, either as L2 or L3 roam. It also allows the network administrators to reuse the VLAN IDs across network distribution. When the VLAN IDs do not have the associated subnet configurations, they may require additional parameter to use in conjunction with VLAN ID. The network administrator ensures that the given VLAN under the same bridge domain ID are associated with the unique subnet. The mobility nodes will first check for the bridge domain ID for the given node and the VLAN ID associated with the client to identify the roam type. The bridge domain ID and the VLAN ID must be same to treat a roam as L2 roam.

The bridge domain ID is configured for each SPG when creating a SPG and later on the MC. The bridge domain ID could be same for more than one SPG and all the MAs under the SPG will share the same bridge domain ID. This information is pushed to the MAs as part of the configuration download when MA comes up initially. If the bridge domain ID is modified when the system is up, it will be pushed to all the MAs in the modified SPG and will take immediate effect for the future roams.

Note

The MC can also have a bridge domain ID for it self, as the MC can also be part of a SPG.

Platform Specific Scale Requirement for the Mobility Controller

The Mobility Controller (MC) role is supported on a number of different platforms like, the Cisco WLC 5700 Series, CUWN and Catalyst 3850 Switches. The scale requirements on these three platforms are summarized in the table below:

<table>
<thead>
<tr>
<th>Scalability</th>

- Mobility Controller, on page 724
- Mobility Oracle, on page 725
- Guest Controller, on page 725

Mobility Agent

A Mobility Controller resides on the switch. It is both, control path and data path entity and is responsible for:

- Handling the mobility events on the switch
- Configuring the datapath elements on the switch for mobility, and
- Communicating with the mobility controller

As MA, the switch performs the datapath functions by terminating the CAPWAP tunnels that encapsulate 802.11 traffic sourced by wireless stations.

This allows the switch to apply features to wired and wireless traffic in a uniform fashion. As far as switch is concerned, 802.11 is just another access medium.

The MA performs the following functions:

- Support the mobility protocol – The MA is responsible for responding in a timely manner, ensuring the switch is capable of achieving its roaming budget.
- Point of presence – If the wireless subnets are not available at the MC, the MA assumes the point of presence if the wireless client VLAN is not available at the new point of attachment and tunnel the client traffic accordingly.
- ARP Server – When the network is configured in a layer 2 mode, the MA is responsible for advertising reachability for the stations connected to it. If tunneling is employed, the ARP request is transmitted on behalf of the station through the tunnel, which the point of presence (anchor switch) would bridge onto its uplink interface.
- Proxy IGMP – The MA on the switch is responsible for subscribing to multicast groups on behalf of a station after a roaming event has occurred. This information is passed as part of the context to the new switch. This ensures the multicast flows follow the user as it roams.
- Routing – When the switch is connected to a layer 3 access network, the MA is responsible for injecting routes for the stations that are associated with it for which tunneling is not provided.
• 802.1X Authenticator – The authenticator function is included in the MA, and handles both wired and wireless stations.
• Secure PMK Sharing – When a station successfully authenticates to the network, the MA forwards the PMK to the MC. The MC is responsible for flooding the PMK to all the MAs under its sub-domain and to the peer MCs in the mobility group.

The MA also performs the following datapath functions:
• Mobility tunnel – If tunneling is used, the MA encapsulates and decapsulates packets from the mobility tunnel to the MC, and to other MA in the peer group, if the access switches are serving as points of presence. The MA supports the tunneling of client data traffic between the point of attachment and the point of attachment. The packet format used for other switches is CAPWAP with an 802.3 payload. The MA also supports reassembly and fragmentation for mobility tunnels.
• Encryption – The mobility control traffic between the mobility nodes is DTLS encrypted. The MA also encrypts the CAPWAP control and data (optional) at the point of attachment.
• CAPWAP – The switch supports the CAPWAP control and data planes. The switch forwarding logic is responsible for terminating the CAPWAP tunnels with 802.11 as well as 802.3 payloads. Since support for large frames (greater than 1500 bytes) is not universally available, the switch supports CAPWAP fragmentation and reassembly.

**Mobility Controller**

The main function of mobility controller is to coordinate the client roaming beyond a switch peer group. The other features of the mobility controller are:

• Station Database—The Mobility Controller maintains a database of all the clients that are connected within the local mobility sub-domain.
• Mobility Protocol—The MC supports the mobility protocol which ensures the target roaming point responds in a timely manner and achieves the 150ms roaming budget
• Interface to Mobility Oracle—The Mobility Controller acts as a gateway between the switch and the Mobility Oracle. When the Mobility Controller does not find a match in its local database, it suggests a match for a wireless client entry (in its database) and forwards the request to the Mobility Oracle, which manages the Mobility Domain.

---

**Note**  
Mobility Oracle function can be enabled on an MC only if it is supported by the platform.

• ARP Server—When tunneling is employed for a station, its point of presence on the network is the Mobility Tunnel Endpoint (MTE). The Mobility Controller responds to any ARP requests received for the stations it is responsible for.
• Routing—When the Mobility Controller is connected to a layer three network, the Mobility Controller is responsible for injecting routes for the stations it supports into the network.
• Configures MTE—The Mobility Controller is the control point for the switch for all mobility management related requests. When a change in a station’s point of attachment occurs, the Mobility Controller is responsible for configuring the forwarding policy on the MTE.
• NTP Server—The Mobility Controller acts as an NTP server to the switch and supports all the nodes to have their clocks synchronized with it.
Mobility Oracle

The Mobility Oracle coordinates the client roams beyond the subdomain on a need basis and consists of the following features:

• Station Database—The Mobility Oracle maintains a database of all stations that are serviced within the mobility domain. This database is populated during the Mobility Oracle's interactions with all the Mobility Controllers, in all of the mobility sub-domains it supports.

• Interface to Mobility Controller—When the Mobility Oracle receives a request from a Mobility Controller, it performs a station lookup, and forwards, whenever needed, the request to the proper Mobility Controller.

• NTP Server—The Mobility Oracle acts as an NTP server to the Mobility Controllers and synchronizes all the switch clocks within the mobility domain.

Guest Controller

The guest access feature provides guest access to wireless clients. The guest tunnels use the same format as the mobility tunnels. Using the guest access feature, there is no need to configure guest VLANs on the access switch. Traffic from the wired and wireless clients terminates on Guest Controller. Since the guest VLAN is not present on the access switch, the traffic is tunneled to the MTE over the existing mobility tunnel, and then via a guest tunnel to the Guest Controller.

The advantage of this approach is that all guest traffic passes through the MTE before it is tunneled to the Guest Controller. The Guest Controller only needs to support tunnels between itself and all the MTEs.

The disadvantage is that the traffic from the guest client is tunneled twice - once to the MTE and then again to the Guest Controller.
Mobility Control Protocols

• About Mobility Control Protocols, on page 727
• Initial Association and Roaming, on page 727
• Initial Association, on page 728
• Intra Switch Handoff, on page 729
• Intra Switch Peer Group Handoff, on page 729
• Inter Switch Peer Group Handoff, on page 730
• Inter Sub Domain Handoff, on page 731
• Inter Mobility Group Handoff, on page 733

About Mobility Control Protocols

The mobility control protocol is used regardless of whether tunneled or routed. The mobility control protocol is used for mobility events between the MO, MC and MA.

The mobility architecture uses both,

• Distributed approach, using the direct communication with the switches in their respective SPG, as well as
• Centralized approach, using the MC and MO.

The goal is to reduce the overhead on the centralized MC, while limiting the interactions between switches to help scale the overall system.

Initial Association and Roaming

The following scenarios are applicable to the mobility management protocol:

• Initial Association
• Intra Switch Roam
• Intra Switch Peer Group Roam
• Inter Switch Peer Group Roam
• Inter Sub-Domain Roam
• Inter Group Roam
Initial Association

The illustration below explains the initial association process followed by the switch:

Figure 47: Initial Association

1. When a station initially associates with a mobility agent, the MA performs a lookup to determine whether keying information for key caching is locally available in the MA. If no keying information is available, which is the case when the station first appears in the network, the switch prompts the device to authenticate itself to generate the Pairwise Master Key (PMK). The PMK is generated on the client and the RADIUS server side, and the RADIUS sever forwards the PMK to the authenticator, the MA.

2. The MA sends the PMK to the MC.

3. After receiving the PMK from the MA, the MC transmits the PMK to all the MAs in its sub-domain, and to all the other MCs in its mobility group.

4. The mobility group is a single key domain. This ensures that 802.11r compliant stations recognize the key domain, and attempts to utilize the fast transition procedures defined in 802.11r.
The 802.11r protocol defines a key domain, which is a collection of access points that share keying information.

5. (Refer to step 2B in the illustration). Since the station is new to the mobility sub-domain, as indicated by the fact that the PMK is not in the MA local key cache, the MA transmits a mobile announce message to the MC.

6. The MC checks if the client exists in its database. As the client cannot be found, the MC in turn forwards it to the MO, if available.

7. (Refer to step 5 in the illustration). As the station is new to the network, the MO returns a negative response (NACK), which is forwarded by the MC to the switch. If the Mobility Oracle is not available then the MC is responsible for not responding to the Mobile Announce.

8. The MA on the switch informs the MC about the station's new point of attachment via the Handoff Complete message.

9. The MA then informs the other MAs in its switch peer group (SPG) about the station's new point of attachment via the Handoff Notification message. It is necessary to transmit this notification to the MAs in its SPG to allow local handoff without interacting with the MC. The Handoff Notification message sent to MAs in SPG need not carry all the information in Handoff Complete message sent to the MC.

10. (Refer to step 7B in the illustration). The MC updates its database and forwards the Handoff Complete message to the Mobility Oracle. This ensures that the Mobility Oracle's database is updated to record the station's current home mobility sub-domain.

To eliminate race conditions that could occur with devices moving quickly across switch, regardless of whether they are within a mobility sub-domain or not, the messages between MA and MC/MO are time synchronized. This would allow the MC and MO to properly process requests, if they are received out of order.

The Handoff Notification sent to MAs in the SPG are not acknowledged.

**Intra Switch Handoff**

Mobility events within an MA are completely transparent to the SPG and the MC. When a station moves across APs on the same MA and attempts to perform a fast handoff, the PMK is present on the MA. The MA will complete the fast handoff without invoking any additional signal.

**Intra Switch Peer Group Handoff**

The switch peer group (SPG) is a group of MAs between which users may roam, and expect fast roaming services. Allowing the MA to handoff directly within a SPG reduces the overhead on the MC as it requires fewer messages to be exchanged.

After the initial association is complete the station moves to another MA belonging to its SPG. In an intra switch peer group roam, the initial association, the stations PMK was forwarded to all MAs in the mobility sub-domain.
The following process explains the intra switch peer group handoff:

1. In the initial association example, the Handoff Notification message is sent to all MAs in its SPG to know the station's current point of attachment.
2. The new MA sends a unicast Mobile Announce message to the previous MA to which the client is associated.
3. After the handoff completion, the new MA transmits a Handoff Complete message to the MC.
4. The new switch sends a Handoff Notification to all MA in its own SPG to inform them about the clients new point of presence.

**Inter Switch Peer Group Handoff**

The Intra SPG roam does not cover all possible scenarios and there can be cases where it is possible for mobility events to occur between two MAs that are not in the same SPG.

When a MA does not have any information about a station's current point of attachment, because of the Handoff Notification message getting lost in the network, or because of the the station roaming to an MA that is not in the new SPG, the MA consults the MC. The MC provides information about the clients point of presence within the mobility sub-domain. This eliminates the need to consult all other MCs within the mobility sub-domain.
The image above illustrates an example of a mobility event that occurs across MAs that are not in the same SPG, but within the same mobility sub-domain.

**Note**

1. The new MA will have the PMK for the station, which was forwarded to each MA in the mobility sub-domain upon client initial authentication.
2. Since the MA had not been previously notified of the station's presence on a neighboring MA inside a different SPG transmits the mobile announce to the sub-domain's MC.
3. (Refer to step 2 in the illustration) On receiving the mobile announce message, the MC performs a lookup in its database, and forwards the request to the MA that was previously providing service to the station. This information is known to the MC through a previously received Handoff Complete message sent in a reliable fashion from the old MA.
4. (Refer to step 3 in the illustration) The old MA, shown in green above, transmits a Handoff message directly to the new MA.
5. The old MA needs to notify other MAs within its SPG of the fact that the station has left the group using a Station Left message. This ensures that if the station were to come back to one of the MA, they would be aware of the fact that the station is no longer being serviced by the old MA.
6. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the MC.
7. The new MA then transmits the Handoff Notification to the other MAs within its SPG.

**Inter Sub Domain Handoff**

A sub-domain is an ensemble formed by a mobility controller and the mobility agents it directly manages. An inter sub-domain mobility event implies communication between two mobility controllers. These 2 mobility controllers can be configured with the same mobility group value and recognize each other. They will appear in each other's mobility list, or they can be configured with different mobility group values, and still recognize each other.
When the roaming event occurs across sub-domains between MCs in the same mobility group, the 802.11r key domain advertised by the new APs are the same. Additionally, the client PMK is also transmitted to all MCs upon the client's initial authentication. The new MC does not need to force the client to reauthenticate, and the new MC also knows which previous MC was managing the wireless client mobility.

**Figure 50: Inter Sub Domain Handoff**

The following steps are involved in the inter sub domain handoff, when mobility controllers belong to the same mobility group:

1. When a clients PMK was sent by the initial MA to all the MCs in the mobility group, the new MA already had already received the client PMK from its MC, and re-authentication is not required.
2. The new MA was not notified previously of the station's presence on a neighboring MA inside a different SPG it transmits the mobile announce to the sub-domain's MC.
3. On receiving the mobile announce message, the MC forwards the mobile announce to the MO, which performs a lookup in its database, and forwards the request to the MC that was previously providing service to the station.
4. The previous MC, in turn, forwards the request to the MA that was previously providing service to the station.
5. The old MA, shown in yellow color above, transmits a Handoff message directly to the new MA.
6. The old MA must notify the other MAs within its SPG of the fact that the station has left the SPG using a Station Left message. This ensures that if the station comes back to one of the MA, the MA is aware of the fact that the station is no longer serviced by the old MA.
7. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the new Mobility Controller.
8. The new MA then transmits the Handoff Notification to all other MAs.
9. The new MC then transmits the Handoff Complete to the old MC.
Inter Mobility Group Handoff

A mobility group is formed by MCs sharing the same mobility group name, and knowing each other.

Since the roaming event occurs across mobility groups, the 802.11r key domain advertised by the new APs differ. This forces the client to re-authenticate. They are propagated only within a mobility group, and roaming across mobility groups requires the stations to re-authenticate when they cross mobility group boundaries. When the authentication is complete, the PMK that is generated is pushed to the MAs and MCs within the same mobility group. The stations cache the PMK from the previous sub-domain because each PMK is associated to a given sub-domain (802.11y key domain). This ensures that you do not have to re-authenticate when the PMK roams back to the previous sub-domain within the pmk cache timeout interval. The remaining procedure follows the inter-sub-domain handoff steps, except that these steps relate to inter mobility group roaming.
Configuring Mobility

• Configuring Mobility Controller, on page 735
• Configuring Mobility Agent, on page 743

Configuring Mobility Controller

Configuring Converged Access Controllers

Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)

Before you begin

• On the mobility agent, you can only configure the IP address of the mobility controller.
• On the mobility controller, you can define the peer group and the IP address of each peer group member.

SUMMARY STEPS

1. wireless mobility controller
2. wireless mobility controller peer-group SPG1
3. wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr
4. wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr
5. wireless mobility controller peer-group SPG2
6. wireless mobility controller peer-group SPG2 member ip member-ip-addr public-ip public-ip-addr
7. wireless mobility controller peer-group SPG1 bridge-domain-id id

<tr>
<td><code>Switch(config)# wireless mobility controller peer-group SPG1 bridge-domain-id 54</code></td>
<td></td>
</tr>
</tbody>
</table>

**Example**

This example shows how to create peer group and add members to it:

```
Switch(config)# wireless mobility controller
Switch(config)# wireless mobility controller peer-group SPG1
Switch(config)# wireless mobility controller peer-group SPG1
Switch(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip
```
Creating Peer Groups, Peer Group Member, and Bridge Domain ID (GUI)

Before you begin

- Ensure that the device is in mobility controller state.
- On the mobility agent, you can only configure the IP address of the mobility controller.
- On the mobility controller, you can define the peer group and the IP address of each peer group member.

Step 1 Choose Controller > Mobility Management > Switch Peer Group.

The Mobility Switch Peer Groups page is displayed.

Step 2 Click New.

Step 3 Enter the following details:
   a) Switch Peer Group Name
   b) Bridge Domain ID
   c) Multicast IP Address

Step 4 Click Apply.

Step 5 Click Save Configuration.

Configuring Local Mobility Group (CLI)

Configuration for wireless mobility groups and mobility group members where the mobility group is a group of MCs.

Before you begin

MCs can belong only to one mobility group, and can know MCs in several mobility groups.

SUMMARY STEPS

1. wireless mobility group name group-name
2. wireless mobility group member ip member-ip-addr public-ip public-ip-addr
3. wireless mobility group keepalive interval time-in-seconds
4. wireless mobility group keepalive count count
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> wireless mobility group member ip <em>member-ip-addr</em> public-ip <em>public-ip-addr</em></td>
<td>Adds a mobility controller to the Mygroup mobility group.</td>
</tr>
<tr>
<td>Example: Switch(config)# wireless mobility group member ip 10.10.34.10 public-ip 10.10.34.28</td>
<td>Note When NAT is used, use the optional public IP address to enter the NATed IP address of the mobility controller.</td>
</tr>
<tr>
<td><strong>Step 3</strong> wireless mobility group keepalive interval <em>time-in-seconds</em></td>
<td>Configures the interval between two keepalives sent to a mobility member.</td>
</tr>
<tr>
<td>Example: Switch(config)# wireless mobility group keepalive interval 5</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> wireless mobility group keepalive count <em>count</em></td>
<td>Configures the keep alive retries before a member status is termed DOWN.</td>
</tr>
<tr>
<td>Example: Switch(config)# wireless mobility group keepalive count 3</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring Local Mobility Group (GUI)**

**Before you begin**

Mobility controllers can belong to only one mobility group and can know mobility controllers in several mobility groups.

**Step 1** Choose Controller > Mobility Management > Mobility Global Config.

The Mobility Controller Configuration page is displayed.

**Step 2** Enter the following details:

a) Mobility Group Name
b) Mobility Keepalive Interval
c) Mobility Keepalive Count
d) **Multicast IP Address** if you want to enable multicast mode to send mobile announce messages to the mobility members.

**Note** If you do not enable multicast IP address, the device uses unicast mode to send mobile announce messages.

**Step 3** Click **Apply**.

**Step 4** Click **Save Configuration**.

---

### Adding a Peer Mobility Group (CLI)

**Before you begin**

MCs belong to only one group, and can know MCs in several groups.

**SUMMARY STEPS**

1. `wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Adds the member as a peer MC in a different group than the Mygroup.</td>
</tr>
<tr>
<td><code>wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# wireless mobility group member ip 10.10.10.24 public-ip 10.10.10.25 group Group2</td>
<td></td>
</tr>
</tbody>
</table>

### Adding a Peer Mobility Group (GUI)

**Before you begin**

Mobility controllers belong to only one group, and can know several mobility groups.

**Step 1** Choose **Controller > Mobility Management > Mobility Peer**.

The **Mobility Peer** page is displayed.

**Step 2** Click **New**.

**Step 3** Enter the following details:

a) **Mobility Member IP**

b) **Mobility Member Public IP**

c) **Mobility Member Group Name**

d) **Multicast IP Address**

**Step 4** Click **Apply**.

**Step 5** Click **Save Configuration**.
Configuring Optional Parameters for Roaming Behavior

Use this configuration to disable the sticky anchor. This command can also be used, if required, between all MA's and MC's where roaming is expected for the target SSID.

SUMMARY STEPS

1. `wlan open21`
2. `no mobility anchor sticky`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>wlan open21</code></td>
<td>Configures a WLAN.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch(config)# wlan open20</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>no mobility anchor sticky</code></td>
<td>Disables the default sticky mobility anchor.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch(config-wlan)# no mobility anchor sticky</code></td>
<td></td>
</tr>
</tbody>
</table>

Example

```
Switch(config)# wlan open20
Switch(config-wlan)# no mobility anchor sticky
```

Pointing the Mobility Controller to a Mobility Oracle (CLI)

**Before you begin**

You can configure a mobility oracle on a known mobility controller.

SUMMARY STEPS

1. `wireless mobility group member ip member-ip-addr group group-name`
2. `wireless mobility oracle ip oracle-ip-addr`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>wireless mobility group member ip member-ip-addr group group-name</code></td>
<td>Creates and adds a MC to a mobility group.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch(config)# wireless mobility group member ip 10.10.10.10 group Group3</code></td>
<td></td>
</tr>
</tbody>
</table>
Pointing the Mobility Controller to a Mobility Oracle (GUI)

Before you begin
You can configure a mobility oracle on a known mobility controller.

Step 1
Choose Controller > Mobility Management > Mobility Global Config.
The Mobility Controller Configuration page is displayed.

Step 2
Enter the Mobility Oracle IP Address.
Note To make the mobility controller itself a mobility oracle, select the Mobility Oracle Enabled check box.

Step 3
Click Apply.
Step 4
Click Save Configuration.

Configuring Guest Controller

A guest controller is used when the client traffic is tunneled to a guest anchor controller in the demilitarized zone (DMZ). The guest client goes through a web authentication process. The web authentication process is optional, and the guest is allowed to pass traffic without authentication too.

Enable the WLAN on the mobility agent on which the guest client connects with the mobility anchor address of the guest controller.

On the guest controller WLAN, which can be Cisco 5500 Series WLC, Cisco WiSM2, or Cisco 5700 Series WLC, configure the IP address of the mobility anchor as its own IP address. This allows the traffic to be tunneled to the guest controller from the mobility agent.

SUMMARY STEPS

1. wlan wlan-id
2. mobility anchor guest-anchor-ip-addr
3. client vlan vlan-name
4. security open

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>wireless mobility oracle ip oracle-ip-addr</td>
<td>Configures the mobility controller as mobility oracle.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config)# wireless mobility oracle ip 10.10.10</td>
<td></td>
</tr>
</tbody>
</table>

Example

Switch(config)# wireless mobility group member ip 10.10.10.10 group Group3
Switch(config)# wireless mobility oracle ip 10.10.10.10
## DETAILED STEPS

<table>

<tr>
<td></td>
<td>Example: Switch(config-wlan)# client vlan gc_ga_vlan1</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td><code>security open</code></td>
<td>Assigns a security type to the WLAN.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config-wlan)# security open</td>
<td></td>
</tr>
</tbody>
</table>

### Example

```plaintext
Switch(config)# wlan Mywlan1
Switch(config-wlan)# mobility anchor 10.10.10.2
Switch(config-wlan)# client vlan gc_ga_vlan1
Switch(config-wlan)# security open
```

## Configuring Guest Anchor

### SUMMARY STEPS

1. `wlan wlan1`
2. `mobility anchor <guest-anchors-own-ip-address>`
3. `client vlan<vlan-name>`
4. `security open`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>wlan Mywlan1</code></td>
<td>Creates a wlan for the client.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch(config)# wlan Mywlan1</td>
<td></td>
</tr>
</tbody>
</table>
Purpose

Command or Action

Step 2
mobility anchor  
<guest-anchors-own-ip-address>

Example:
Switch(config-wlan)# mobility anchor 10.10.10.2

Enables the guest anchors IP address on the guest anchor (GA). The GA assigns its own address on itself.

Step 3
client vlan<vlan-name>

Example:
Switch(config-wlan)# client vlan gc_ga_vlan1

Assigns a vlan to the clients wlan.

Step 4
security open

Example:
Switch(config-wlan)# security open

Assigns a security type to the wlan.

Example

Switch(config)# wlan Mywlan1
Switch(config-wlan)# mobility anchor 10.10.10.2
Switch(config-wlan)# client vlan gc_ga_vlan1
Switch(config-wlan)# security open

Configuring Mobility Agent

Configuring Mobility Agent by Pointing to Mobility Controller (CLI)

Before you begin

- By default, the switches are configured as mobility agents.
- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.
- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

SUMMARY STEPS

1. configure terminal
2. wireless management interface vlan 21
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> wireless management interface vlan 21</td>
<td>Enables the wireless functionality on the device and activates the mobility agent function. This ensures the APs have a place to terminate the CAPWAP tunnel.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch (config)# wireless management interface vlan 21</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

This example shows how to add a mobility agent into the mobility group by pointing it to a mobility controller:

```
Switch(config)# wireless management interface vlan 21
```

### Configuring Mobility Agent by Pointing to Mobility Controller (GUI)

#### Before you begin

- By default, the switches are configured as mobility agents.
- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.
- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

#### Step 1

Choose **Configuration > Controller > Mobility Management > Mobility Global Config**

The Mobility Controller Configuration page is displayed.

#### Step 2

From the **Mobility Role** drop-down list, choose **Mobility Agent**.

#### Step 3

In the **Mobility Controller IP Address**, enter the IP address of the mobility controller.

#### Step 4

Click **Apply**.

#### Step 5

Click **Save Configuration**.

#### Step 6

Reboot the device.
Configuring the Mobility Controller for the Mobility Agent (CLI)

SUMMARY STEPS

1. wireless mobility controller
2. wireless mobility controller ip ip-addr

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>wireless mobility controller</td>
<td>Enables the mobility function on the switch.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch (config)# wireless mobility controller Mobility role changed to Mobility Controller. Please save config and reboot the whole stack.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>wireless mobility controller ip ip-addr</td>
<td>Specifies the mobility controller to which the mobility agent relates.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch (config)# wireless mobility controller ip 10.10.21.3</td>
<td>If a mobility agent is configured and the mobility controller exists on a different device, configure the SPG on the mobility controller to ensure the mobility agent functions properly.</td>
</tr>
</tbody>
</table>

What to do next

After you add a mobility controller role to the mobility agent, you can configure optional parameters on the mobility agent.

Adding a Mobility Controller Role to the Mobility Agent

SUMMARY STEPS

1. wireless mobility controller ip 10.10.21.3

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>wireless mobility controller ip 10.10.21.3</td>
<td>Converts the mobility agent to a mobility controller.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# wireless mobility controller ip 10.10.21.3</td>
<td></td>
</tr>
</tbody>
</table>

Example

This example shows how to add the mobility controller role to a mobility agent:
Switch(config)# wireless mobility controller ip 10.10.21.3
Mobility role changed to Mobility Controller.
Please save config and reboot the whole stack.

Configuring Optional Parameters on a Mobility Agent (CLI)

This section shows how to configure load-balancing on a switch.

• By default, the load-balancing is enabled and it cannot be disabled.
• The switch supports a maximum of 2000 clients and the default threshold value is fifty percent of client max load.
• When the switch reaches its threshold, it redistributes the new clients load to other mobility agents in the same SPG, if their client load is lower.

SUMMARY STEPS

1. wireless mobility load-balance threshold threshold-value

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 wireless mobility load-balance threshold threshold-value</td>
<td>Configures the threshold that triggers load-balancing.</td>
</tr>
</tbody>
</table>
| Example:
Switch(config)# wireless mobility load-balance threshold 150 |       |

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Configuration Engine

• Obtain the name of the configuration engine instance to which you are connecting.

• Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured switch.

• All switches configured with the `cns config partial` global configuration command must access the event bus. The DeviceID, as originated on the switch, must match the DeviceID of the corresponding switch definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

Related Topics

Cisco Networking Services IDs and Device Hostnames, on page 752
DeviceID, on page 752
Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured switches can share the same value for ConfigID.

- Within the scope of a single instance of the event bus, no two configured switches can share the same value for DeviceID.

Cisco Networking Services IDs and Device Hostnames, on page 752

Information About Configuring the Configuration Engine

Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (switches and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
  - Web server
  - File manager
  - Namespace mapping server

- Event service (event gateway)
  - Data service directory (data models and schema)

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.
Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the switch. The Configuration Service delivers device and service configurations to the switch for initial configuration and mass reconfiguration by logical groups. Switches receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the switch and facilitates the communication between the switch and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.
**NameSpace Mapper**

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, cisco.cns.config.load. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

**Cisco Networking Services IDs and Device Hostnames**

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured switch. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term ConfigID is the unique identifier for a device. Within the scope of the event bus namespace, the term DeviceID is the CNS unique identifier for a device.

**ConfigID**

Each configured switch has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of switch CLI attributes. The ConfigID defined on the switch must match the ConfigID for the corresponding switch definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the switch hostname is reconfigured.

**DeviceID**

Each configured switch participating on the event bus has a unique DeviceID, which is analogous to the switch source address so that the switch can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the switch. However, the DeviceID variable and its usage reside within the event gateway adjacent to the switch.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the switch. The event gateway represents the switch and its corresponding DeviceID to the event bus.
The switch declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the switch.

**Related Topics**

- [Prerequisites for Configuring the Configuration Engine](#), on page 749

## Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the switch hostname is reconfigured.

When changing the switch hostname on the switch, the only way to refresh the DeviceID is to break the connection between the switch and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the switch sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

**Caution**

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the switch acquires after, not before, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

**Related Topics**

- [Refreshing DeviceIDs](#), on page 763

## Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a switch, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the cn=<value> of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the switch.

These and other associated attributes (tag value pairs) are set when you run **Setup** on the Cisco Configuration Engine.

## Cisco IOS CNS Agents

The CNS event agent feature allows the switch to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the switch Cisco IOS software, allow the switch to be connected and automatically configured.

## Initial Configuration

When the switch first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution switch acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new switch and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default
gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the switch.

The switch automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the switch loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the switch.

The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

![Figure 52: Initial Configuration](image)

**Related Topics**

Automated CNS Configuration, on page 755

### Incremental (Partial) Configuration

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the switch. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the switch to initiate a pull operation.

The switch can check the syntax of the configuration before applying it. If the syntax is correct, the switch applies the incremental configuration and publishes an event that signals success to the configuration server. If the switch does not apply the incremental configuration, it publishes an event showing an error status. When the switch has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

### Synchronized Configuration

When the switch receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the switch not to save the updated configuration into its NVRAM. The switch uses the updated configuration as its running configuration. This ensures that the switch configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.
Automated CNS Configuration

To enable automated CNS configuration of the switch, you must first complete the prerequisites listed in this topic. When you complete them, power on the switch. At the `setup` prompt, do nothing; the switch begins the initial configuration. When the full configuration file is loaded on your switch, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

How to Configure the Configuration Engine

Enabling the CNS Event Agent

You must enable the CNS event agent on the switch before you enable the CNS configuration agent.

Beginning in privileged EXEC mode, follow these steps to enable the CNS event agent on the switch.

**SUMMARY STEPS**

1. `configure terminal`
2. `cns event {hostname | ip-address} [port-number] [[keepalive seconds] [retry-count] [failover-time seconds] [reconnect-time time] [backup]]`
3. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enables the event agent, and enters the gateway parameters.</td>
</tr>
<tr>
<td>cns event {hostname</td>
<td>ip-address} [port-number] [keepalive seconds] [retry-count] [failover-time seconds] [reconnect-time time] [backup]</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# cns event 10.180.1.27 keepalive 120 10</td>
<td></td>
</tr>
</tbody>
</table>

- For `{hostname | ip-address}`, enter either the hostname or the IP address of the event gateway.
  - (Optional) For `port number`, enter the port number for the event gateway. The default port number is 11011.
  - (Optional) For `keepalive seconds`, enter how often the switch sends keepalive messages. For `retry-count`, enter the number of unanswered keepalive messages that the switch sends before the connection is terminated. The default for each is 0.
  - (Optional) For `failover-time seconds`, enter how long the switch waits for the primary gateway route after the route to the backup gateway is established.
  - (Optional) For `reconnect-time time`, enter the maximum time interval that the switch waits before trying to reconnect to the event gateway.
Purpose

Command or Action | Purpose
--- | ---
• (Optional) Enter backup to show that this is the backup gateway. (If omitted, this is the primary gateway.)

Note: Though visible in the command-line help string, the encrypt and the clock-timeout time keywords are not supported.

Step 3 | end | Returns to privileged EXEC mode.

Example:

Switch(config)# end

Example

This example shows how to enable the CNS event agent, set the IP address gateway to 10.180.1.27, set 120 seconds as the keepalive interval, and set 10 as the retry count.

Switch(config)# cns event 10.180.1.27 keepalive 120 10

What to do next

To verify information about the event agent, use the show cns event connections command in privileged EXEC mode.

To disable the CNS event agent, use the no cns event { ip-address | hostname } global configuration command.

Related Topics

Event Service, on page 751

Enabling the Cisco IOS CNS Agent

Beginning in privileged EXEC mode, follow these steps to enable the Cisco IOS CNS agent on the switch.

Before you begin

You must enable the CNS event agent on the switch before you enable this agent.

SUMMARY STEPS

1. configure terminal
2. cns config initial {hostname | ip-address} [port-number]
3. cns config partial {hostname | ip-address} [port-number]
4. end
5. Start the Cisco IOS CNS agent on the switch.
## Enabling an Initial Configuration for Cisco IOS CNS Agent

Beginning in privileged EXEC mode, follow these steps to enable the CNS configuration agent and initiate an initial configuration on the switch.

### DETAILED STEPS

<td></td>
</tr>
<tr>
<td><strong>Step 16</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>RemoteSwitch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

This example shows how to configure an initial configuration on a remote switch when the switch configuration is unknown (the CNS Zero Touch feature).
This example shows how to configure an initial configuration on a remote switch when the switch IP address is known. The Configuration Engine IP address is 172.28.129.22.

What to do next
To verify information about the configuration agent, use the `show cns config connections` command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the `no cns config initial { ip-address | hostname }` global configuration command.

### Refreshing DeviceIDs

Beginning in privileged EXEC mode, follow these steps to refresh a DeviceID when changing the hostname on the switch.

**SUMMARY STEPS**

1. `show cns config connections`
2. Make sure that the CNS event agent is properly connected to the event gateway.
3. `show cns event connections`
4. Record from the output of Step 3 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.
5. `configure terminal`
6. `no cns event ip-address port-number`
7. \texttt{cns event ip-address port-number} \\
8. \texttt{end} \\
9. Make sure that you have reestablished the connection between the switch and the event connection by examining the output from \texttt{show cns event connections}.

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | \texttt{show cns config connections}  \\
Example:  \\
\texttt{Switch\# show cns config connections} | Displays whether the CNS event agent is connecting to the gateway, connected, or active, and the gateway used by the event agent, its IP address and port number. |
| Step 2 | Make sure that the CNS event agent is properly connected to the event gateway. | Examine the output of \texttt{show cns config connections} for the following:  
- Connection is active.  
- Connection is using the currently configured switch hostname. The DeviceID will be refreshed to correspond to the new hostname configuration using these instructions. |
| Step 3 | \texttt{show cns event connections}  \\
Example:  \\
\texttt{Switch\# show cns event connections} | Displays the event connection information for your switch. |
| Step 4 | Record from the output of Step 3 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions. |  |
| Step 5 | \texttt{configure terminal}  \\
Example:  \\
\texttt{Switch\# configure terminal} | Enters global configuration mode. |
| Step 6 | \texttt{no cns event ip-address port-number}  \\
Example:  \\
\texttt{Switch(config)\# no cns event 172.28.129.22 2012} | Specifies the IP address and port number that you recorded in Step 4 in this command.  
This command breaks the connection between the switch and the event gateway. It is necessary to first break, then reestablish, this connection to refresh the DeviceID. |
| Step 7 | \texttt{cns event ip-address port-number}  \\
Example:  \\
\texttt{Switch(config)\# cns event 172.28.129.22 2012} | Specifies the IP address and port number that you recorded in Step 4 in this command.  
This command reestablishes the connection between the switch and the event gateway. |
Enabling a Partial Configuration for Cisco IOS CNS Agent

Beginning in privileged EXEC mode, follow these steps to enable the Cisco IOS CNS agent and to initiate a partial configuration on the switch.

SUMMARY STEPS

1. configure terminal
2. cns config partial {ip-address | hostname} [port-number] [source ip-address]
3. end

DETAILLED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 cns config partial {ip-address</td>
<td>hostname} [port-number] [source ip-address]</td>
</tr>
<tr>
<td>Example: Switch(config)# cns config partial 172.28.129.22 2013</td>
<td>• For {ip-address</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For port-number, enter the port number of the configuration server. The default port number is 80.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Enter source ip-address to use for the source IP address.</td>
</tr>
<tr>
<td><strong>Note</strong> Though visible in the command-line help string, the encrypt keyword is not supported.</td>
<td></td>
</tr>
</tbody>
</table>
What to do next

To verify information about the configuration agent, use either the `show cns config stats` or the `show cns config outstanding` command in privileged EXEC mode.

To disable the Cisco IOS agent, use the `no cns config partial { ip-address | hostname }` global configuration command. To cancel a partial configuration, use the `cns config cancel` global configuration command.

## Monitoring CNS Configurations

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About CDP

CDP Overview

CDP is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With CDP, network management applications can learn the device type and the Simple Network Management Protocol (SNMP) agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

CDP runs on all media that support Subnetwork Access Protocol (SNAP). Because CDP runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each CDP-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information, which is the length of time a receiving device holds CDP information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.
On the switch, CDP enables Network Assistant to display a graphical view of the network. The switch uses CDP to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command switch by default.

**CDP and Stacks**

A switch stack appears as a single switch in the network. Therefore, CDP discovers the switch stack, not the individual stack members. The switch stack sends CDP messages to neighboring network devices when there are changes to the switch stack membership, such as stack members being added or removed.

**Default CDP Configuration**

This table shows the default CDP configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDP global state</td>
<td>Enabled</td>
</tr>
<tr>
<td>CDP interface state</td>
<td>Enabled</td>
</tr>
<tr>
<td>CDP timer (packet update frequency)</td>
<td>60 seconds</td>
</tr>
<tr>
<td>CDP holdtime (before discarding)</td>
<td>180 seconds</td>
</tr>
<tr>
<td>CDP Version-2 advertisements</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

**How to Configure CDP**

**Configuring CDP Characteristics**

You can configure these CDP characteristics:

- Frequency of CDP updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version-2 advertisements

---

**Note**

Steps 2 through 4 are all optional and can be performed in any order.

Beginning in privileged EXEC mode, follow these steps to configure these characteristics.

**SUMMARY STEPS**

1. `configure terminal`
2. `cdp timer seconds`
3. `cdp holdtime seconds`
4. `cdp advertise-v2`
5. \textit{end}

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> cdp timer \textit{seconds}</td>
<td>(Optional) Sets the transmission frequency of CDP updates in seconds.</td>
</tr>
<tr>
<td>Example: Switch(config)# cdp timer 20</td>
<td>The range is 5 to 254; the default is 60 seconds.</td>
</tr>
<tr>
<td><strong>Step 3</strong> cdp holdtime \textit{seconds}</td>
<td>(Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it.</td>
</tr>
<tr>
<td>Example: Switch(config)# cdp holdtime 60</td>
<td>The range is 10 to 255 seconds; the default is 180 seconds.</td>
</tr>
<tr>
<td><strong>Step 4</strong> cdp advertise-v2</td>
<td>(Optional) Configures CDP to send Version-2 advertisements.</td>
</tr>
<tr>
<td>Example: Switch(config)# cdp advertise-v2</td>
<td>This is the default state.</td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

### Example

The following example shows how to configure CDP characteristics:

Switch# configure terminal
Switch(config)# cdp timer 50
Switch(config)# cdp holdtime 120
Switch(config)# cdp advertise-v2
Switch(config)# end

### What to do next

Use the \textit{no} form of the CDP commands to return to the default settings.

### Related Topics

Disabling CDP

CDP is enabled by default.

---

**Note**

Switch clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Beginning in privileged EXEC mode, follow these steps to disable the CDP device discovery capability.

**SUMMARY STEPS**

1. configure terminal
2. no cdp run
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>no cdp run</td>
<td>Disables CDP.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# no cdp run</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

You must reenable CDP to use it.

**Related Topics**

[Enabling CDP](#), on page 772

---

**Enabling CDP**

CDP is enabled by default.
Switch clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Beginning in privileged EXEC mode, follow these steps to enable CDP when it has been disabled.

**Before you begin**

CDP must be disabled, or it cannot be enabled.

**SUMMARY STEPS**

1. configure terminal
2. cdp run
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> cdp run</td>
<td>Enables CDP if it has been disabled.</td>
</tr>
<tr>
<td>Example: Switch(config)# cdp run</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

The following example shows how to enable CDP if it has been disabled:

Switch# configure terminal
Switch(config)# cdp run
Switch(config)# end

**What to do next**

Use the `show run all` command to show that CDP has been enabled. If you enter only `show run`, the enabling of CDP may not be displayed.
Disabling CDP on an Interface

CDP is enabled by default on all supported interfaces to send and to receive CDP information.

**Note**
Switch clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Beginning in privileged EXEC mode, follow these steps to disable CDP on a port.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `no cdp enable`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>

**Related Topics**
**Enabling CDP on an Interface, on page 775**
Enabling CDP on an Interface

CDP is enabled by default on all supported interfaces to send and to receive CDP information.

> Note
> Switch clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Beginning in privileged EXEC mode, follow these steps to enable CDP on a port on which it has been disabled.

**Before you begin**

CDP must be disabled on the port that you are trying to CDP enable on, or it cannot be enabled.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `cdp enable`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
configure terminal  
Example:  
Switch# configure terminal | Enters the global configuration mode. |
| **Step 2**  
interface interface-id  
Example:  
Switch(config)# interface gigabitethernet1/0/1 | Specifies the interface on which you are enabling CDP, and enters interface configuration mode. |
| **Step 3**  
`cdp enable`  
Example:  
Switch(config-if)# cdp enable | Enables CDP on a disabled interface. |
| **Step 4**  
`end`  
Example:  
Switch(config-if)# end | Returns to privileged EXEC mode. |

**Example**

The following example shows how to enable CDP on a disabled port:

Switch# configure terminal  
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# cdp enable
Switch(config-if)# end

Configuring Simple Network Management Protocol

• Finding Feature Information, on page 779
• Prerequisites for SNMP, on page 779
• Restrictions for SNMP, on page 781
• Information About SNMP, on page 781
• How to Configure SNMP, on page 786
• Monitoring SNMP Status, on page 800
• SNMP Examples, on page 800

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SNMP

Supported SNMP Versions

This software release supports the following SNMP versions:

• SNMPv1—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.

• SNMPv2C replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:
  
  • SNMPv2—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.

  • SNMPv2C—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
SNMPv3—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:

- Message integrity—Ensures that a packet was not tampered with in transit.
- Authentication—Determines that the message is from a valid source.
- Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

To select encryption, enter the `priv` keyword.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent’s MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

<table>
<thead>
<tr>
<th>Model</th>
<th>Level</th>
<th>Authentication</th>
<th>Encryption</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMPv1</td>
<td>noAuthNoPriv</td>
<td>Community string</td>
<td>No</td>
<td>Uses a community string match for authentication.</td>
</tr>
<tr>
<td>SNMPv2C</td>
<td>noAuthNoPriv</td>

</tr>
</tbody>
</table>
Result Encryption Authentication Level Model

Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms. Allows specifying the User-based Security Model (USM) with these encryption algorithms:

- DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard.
- 3DES 168-bit encryption
- AES 128-bit, 192-bit, or 256-bit encryption

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.

**Information About SNMP**

**SNMP Overview**

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime.
Infrastructure. The agent and MIB reside on the switch. To configure SNMP on the switch, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager’s requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

The active switch handles the SNMP requests and traps for the whole switch stack. The active switch transparently manages any requests or traps that are related to all stack members. When a new active switch is elected, the new active switch continues to handle SNMP requests and traps as configured on the previous active switch, assuming that IP connectivity to the SNMP management stations is still in place after the new active switch has taken control.

### SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

#### Table 69: SNMP Operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get-request</td>
<td>Retrieves a value from a specific variable.</td>
</tr>
<tr>
<td>get-next-request</td>
<td>Retrieves a value from a variable within a table.</td>
</tr>
<tr>
<td>get-bulk-request</td>
<td>Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data.</td>
</tr>
<tr>
<td>get-response</td>
<td>Replies to a get-request, get-next-request, and set-request sent by an NMS.</td>
</tr>
<tr>
<td>set-request</td>
<td>Stores a value in a specific variable.</td>
</tr>
<tr>
<td>trap</td>
<td>An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.</td>
</tr>
</tbody>
</table>

1 With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.
2 The get-bulk command only works with SNMPv2 or later.

### SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- **Get a MIB variable**—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.
- **Set a MIB variable**—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.
The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

**SNMP Community Strings**

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the switch, the community string definitions on the NMS must match at least one of the three community string definitions on the switch.

A community string can have one of the following attributes:

- **Read-only (RO)** — Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.

- **Read-write (RW)** — Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.

- When a cluster is created, the command switch manages the exchange of messages among member switches and the SNMP application. The Network Assistant software appends the member switch number (@esN, where N is the switch number) to the first configured RW and RO community strings on the command switch and propagates them to the member switches.

**SNMP MIB Variables Access**

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure 2.0 software uses the switch MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in get-request, get-next-request, and set-request format.

![Figure 53: SNMP Network](image)

**SNMP Notifications**

SNMP allows the switch to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps or informs, or both. Use the `snmp-server host` command to specify whether to send SNMP notifications as traps or informs.
SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the switch and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receives every notification, use inform requests. If traffic on the network or memory in the switch is a concern and notification is not required, use traps.

SNMP ifIndex MIB Object Values

In an NMS, the IF-MIB generates and assigns an interface index (ifIndex) object value that is a unique number greater than zero to identify a physical or a logical interface. When the switch reboots or the switch software is upgraded, the switch uses this same value for the interface. For example, if the switch assigns a port 2 an ifIndex value of 10003, this value is the same after the switch reboots.

The switch uses one of the values in the following table to assign an ifIndex value to an interface:

<table>
<thead>
<tr>
<th>Interface Type</th>
<th>ifIndex Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVI&lt;sup&gt;5&lt;/sup&gt;</td>
<td>1–4999</td>
</tr>
<tr>
<td>EtherChannel</td>
<td>5000–5012</td>
</tr>
<tr>
<td>Loopback</td>
<td>5013–5077</td>
</tr>
<tr>
<td>Tunnel</td>
<td>5078–5142</td>
</tr>
<tr>
<td>Physical (such as Gigabit Ethernet or SFP&lt;sup&gt;6&lt;/sup&gt;-module interfaces)</td>
<td>10000–14500</td>
</tr>
<tr>
<td>Null</td>
<td>14501</td>
</tr>
</tbody>
</table>

<sup>5</sup> SVI = switch virtual interface  
<sup>6</sup> SFP = small form-factor pluggable

Default SNMP Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMP agent</td>
<td>Disabled&lt;sup&gt;2&lt;/sup&gt;.</td>
</tr>
<tr>
<td>SNMP trap receiver</td>
<td>None configured.</td>
</tr>
<tr>
<td>SNMP traps</td>
<td>None enabled except the trap for TCP connections (tty).</td>
</tr>
<tr>
<td>Feature</td>
<td>Default Setting</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SNMP version</td>
<td>If no version keyword is present, the default is Version 1.</td>
</tr>
<tr>
<td>SNMPv3 authentication</td>
<td>If no keyword is entered, the default is the noauth (noAuthNoPriv) security level.</td>
</tr>
<tr>
<td>SNMP notification type</td>
<td>If no type is specified, all notifications are sent.</td>
</tr>
</tbody>
</table>

This is the default when the switch starts and the startup configuration does not have any `snmp-server` global configuration commands.

### SNMP Configuration Guidelines

If the switch starts and the switch startup configuration has at least one `snmp-server` global configuration command, the SNMP agent is enabled.

An SNMP group is a table that maps SNMP users to SNMP views. An SNMP user is a member of an SNMP group. An SNMP host is the recipient of an SNMP trap operation. An SNMP engine ID is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The `snmp-server host` global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.

- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.

- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the `snmp-server engineID` global configuration command with the `remote` option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.

- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.

- If a local user is not associated with a remote host, the switch does not send informs for the auth (authNoPriv) and the priv (authPriv) authentication levels.

- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the `snmp-server user username` global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.
How to Configure SNMP

Disabling the SNMP Agent

The `no snmp-server` global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenable all versions of the SNMP agent by the first `snmp-server` global configuration command that you enter. There is no Cisco IOS command specifically designated for enabling SNMP.

Beginning in privileged EXEC mode, follow these steps to disable the SNMP agent.

**Before you begin**

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first `snmp-server` global configuration command entered on the device.

**SUMMARY STEPS**

1. configure terminal
2. no snmp-server
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>

<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>no snmp-server</td>
<td>Disables the SNMP agent operation.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# no snmp-server</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the switch. Optionally, you can specify one or more of these characteristics associated with the string:
• An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent

• A MIB view, which defines the subset of all MIB objects accessible to the given community

• Read and write or read-only permission for the MIB objects accessible to the community

Beginning in privileged EXEC mode, follow these steps to configure a community string on the switch.

**SUMMARY STEPS**

1. `configure terminal`
2. `snmp-server community string [view view-name] [ro | rw] [access-list-number]`
3. `access-list access-list-number {deny | permit} source [source-wildcard]`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>**snmp-server community string [view view-name] [ro</td>
</tr>
</tbody>
</table>
| | Configures the community string. **Note** The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.

• For `string`, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings of any length.

• (Optional) For `view-name`, specify the view record accessible to the community.

• (Optional) Specify either read-only (`ro`) if you want authorized management stations to retrieve MIB objects, or specify read-write (`rw`) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects.

• (Optional) For `access-list-number`, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.
### Command or Action

| Step 3 | access-list access-list-number {deny | permit} source [source-wildcard] |
|---------|--------------------------------------------------------------------------------|
| **Example:** | Switch(config)# access-list 4 deny any |

### Purpose

(Optional) If you specified an IP standard access list number in Step 2, then create the list, repeating the command as many times as necessary.

- For *access-list-number*, enter the access list number specified in Step 2.
- The *deny* keyword denies access if the conditions are matched. The *permit* keyword permits access if the conditions are matched.
- For *source*, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent.
- (Optional) For *source-wildcard*, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

Recall that the access list is always terminated by an implicit deny statement for everything.

<table>
<thead>
<tr>
<th>Step 4</th>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>

This example shows how to assign the comaccess string to SNMP, to allow read-only access, and to specify that IP access list 4 can use the community string to gain access to the switch SNMP agent:

Switch(config)# snmp-server community comaccess ro 4

### What to do next

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the no `snmp-server community` community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the switch. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.
## Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the switch. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Beginning in privileged EXEC mode, follow these steps to configure SNMP groups and users on the switch.

### SUMMARY STEPS

1. `configure terminal`
2. `snmp-server engineID {local engineid-string | remote ip-address [udp-port port-number] engineid-string}`
3. `snmp-server group group-name {v1 | v2c | v3 {auth | noauth | priv}} [read readview] [write writeview] [notify notifyview] [access access-list]`
4. `snmp-server user username group-name {remote host [udp-port port] } {v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password] } [priv {des | 3des | aes {128 | 192 | 256} } priv-password]`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Switch# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>`snmp-server engineID {local engineid-string</td>
<td>remote ip-address [udp-port port-number] engineid-string}`</td>
</tr>
</tbody>
</table>
|      | Example: Switch(config)# `snmp-server engineID local 1234` | • The `engineid-string` is a 24-character ID string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. The Step Example configures an engine ID of 12340000000000000000000.  
  • If you select remote, specify the `ip-address` of the device that contains the remote copy of SNMP and the optional User Datagram Protocol (UDP) port on the remote device. The default is 162. |
| 3    | `snmp-server group group-name {v1 | v2c | v3 {auth | noauth | priv}} [read readview] [write writeview] [notify notifyview] [access access-list]` | Configures a new SNMP group on the remote device. |
|      | Example: | For `group-name`, specify the name of the group.  
Specify one of the following security models: 
• `v1` is the least secure of the possible security models. |
### Command or Action

```
Switch(config)# snmp-server group public v2c access
```

### Purpose

- **v2c** is the second least secure model. It allows transmission of informs and integers twice the normal width.

- **v3**, the most secure, requires you to select one of the following authentication levels:
  - **auth**—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.
  - **noauth**—Enables the noAuthNoPriv security level. This is the default if no keyword is specified.
  - **priv**—Enables Data Encryption Standard (DES) packet encryption (also called privacy).

(Optional) Enter **read** **readview** with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.

(Optional) Enter **write** **writeview** with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.

(Optional) Enter **notify** **notifyview** with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.

(Optional) Enter **access** **access-list** with a string (not to exceed 64 characters) that is the name of the access list.

---

### Step 4

```
snmp-server user username group-name { remote host [udp-port port] } { v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password] } { priv {des | 3des | aes {128 | 192 | 256}} priv-password }
```

Adds a new user for an SNMP group.

The **username** is the name of the user on the host that connects to the agent.

The **group-name** is the name of the group to which the user is associated.

Enter **remote** to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.

Enter the SNMP version number (**v1**, **v2c**, or **v3**). If you enter **v3**, you have these additional options:

- **encrypted** specifies that the password appears in encrypted format. This keyword is available only when the **v3** keyword is specified.

- **auth** is an authentication level setting session that can be either the HMAC-MD5-96 (**md5**) or the HMAC-SHA-96 (**sha**) authentication level and requires a password string **auth-password** (not to exceed 64 characters).
Purpose

If you enter v3 you can also configure a private (priv) encryption algorithm and password string `priv-password` using the following keywords (not to exceed 64 characters):

- **priv** specifies the User-based Security Model (USM).
- **des** specifies the use of the 56-bit DES algorithm.
- **3des** specifies the use of the 168-bit DES algorithm.
- **aes** specifies the use of the DES algorithm. You must select either 128-bit, 192-bit, or 256-bit encryption.

(Optional) Enter `access access-list` with a string (not to exceed 64 characters) that is the name of the access list.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

### Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the switch generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Switches running this Cisco IOS release can have an unlimited number of trap managers.

**Note**

Many commands use the word `traps` in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword `traps` refers to traps, informs, or both. Use the `snmp-server host` global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the `snmp-server host` global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

#### Table 71: Device Notification Types

<table>
<thead>
<tr>
<th>Notification Type Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bridge</td>
<td>Generates STP bridge MIB traps.</td>
</tr>
<tr>
<td>cluster</td>
<td>Generates a trap when the cluster configuration changes.</td>
</tr>
<tr>
<td>config</td>
<td>Generates a trap for SNMP configuration changes.</td>
</tr>
<tr>
<td>copy-config</td>
<td>Generates a trap for SNMP copy configuration changes.</td>
</tr>
<tr>
<td>cpu threshold</td>
<td>Allow CPU-related traps.</td>
</tr>
<tr>
<td>entity</td>
<td>Generates a trap for SNMP entity changes.</td>
</tr>
<tr>
<td>Notification Type Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>envmon</td>
<td>Generates environmental monitor traps. You can enable any or all of these environmental traps: fan, shutdown, status, supply, temperature.</td>
</tr>
<tr>
<td>flash</td>
<td>Generates SNMP FLASH notifications. In a switch stack, you can optionally enable notification for flash insertion or removal, which would cause a trap to be issued whenever a switch in the stack is removed or inserted (physical removal, power cycle, or reload).</td>
</tr>
<tr>
<td>fru-ctrl</td>
<td>Generates entity field-replaceable unit (FRU) control traps. In the switch stack, this trap refers to the insertion or removal of a switch in the stack.</td>
</tr>
<tr>
<td>hsrp</td>
<td>Generates a trap for Hot Standby Router Protocol (HSRP) changes.</td>
</tr>
<tr>
<td>ipmulticast</td>
<td>Generates a trap for IP multicast routing changes.</td>
</tr>
<tr>
<td>mac-notification</td>
<td>Generates a trap for MAC address notifications.</td>
</tr>
<tr>
<td>ospf</td>
<td>Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes.</td>
</tr>
<tr>
<td>pim</td>
<td>Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes.</td>
</tr>
</tbody>
</table>
| port-security             | Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit. 

**Note** When you configure a trap by using the notification type `port-security`, configure the port security trap first, and then configure the port security trap rate:

1. `snmp-server enable traps port-security`
2. `snmp-server enable traps port-security trap-rate rate` |
| snmp                      | Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down. |
| storm-control             | Generates a trap for SNMP storm-control. You can also set a maximum trap rate per minute. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence). |
| stpx                      | Generates SNMP STP Extended MIB traps. |
| syslog                    | Generates SNMP syslog traps. |
| tty                       | Generates a trap for TCP connections. This trap is enabled by default. |
| vlan-membership           | Generates a trap for SNMP VLAN membership changes. |
| vlancreate                | Generates SNMP VLAN created traps. |
| vlandelete                | Generates SNMP VLAN deleted traps. |
### Notification Type Keyword | Description
--- | ---
vt | Generates a trap for VLAN Trunking Protocol (VTP) changes.

Beginning in privileged EXEC mode, follow these steps to configure the switch to send traps or informs to a host.

#### SUMMARY STEPS

1. **configure terminal**
2. **snmp-server engineID remote** `ip-address engineid-string`
3. **snmp-server user** `username group-name {remote host [udp-port port] [v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password]}
4. **snmp-server group** `group-name {v1 | v2c | v3 {auth | noauth | priv} [read readview] [write writeview] [notify notifyview] [access access-list]}`
5. **snmp-server host** `host-addr [informs | traps] [version {1 | 2c | 3 {auth | noauth | priv} | community-string [notification-type]}
6. **snmp-server enable traps** `notification-types`
7. **snmp-server trap-source** `interface-id`
8. **snmp-server queue-length** `length`
9. **snmp-server trap-timeout** `seconds`
10. **end**

</table>
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) Establishes the message queue length for each trap host. The range is 1 to 1000; the default is 10.</td>
</tr>
<tr>
<td>(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.</td>
</tr>
<tr>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

#### Step 8

`snmp-server queue-length length`

**Example:**

```
Switch(config)# snmp-server queue-length 20
```

#### Step 9

`snmp-server trap-timeout seconds`

**Example:**

```
Switch(config)# snmp-server trap-timeout 60
```

#### Step 10

`end`

**Example:**

```
Switch(config)# end
```

---

### What to do next

The `snmp-server host` command specifies which hosts receive the notifications. The `snmp-server enable trap` command globally enables the method for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an `snmp-server host informs` command for the host and globally enable informs by using the `snmp-server enable traps` command.

To remove the specified host from receiving traps, use the `no snmp-server host host` global configuration command. The `no snmp-server host` command with no keywords disables traps, but not informs, to the host. To disable informs, use the `no snmp-server host informs` global configuration command. To disable a specific trap type, use the `no snmp-server enable traps notification-types` global configuration command.

### Setting the Agent Contact and Location Information

Beginning in privileged EXEC mode, follow these steps to set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file.

#### SUMMARY STEPS

1. `configure terminal`
2. `snmp-server contact text`
3. `snmp-server location text`
4. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Enter the global configuration mode.</strong></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
Limiting TFTP Servers Used Through SNMP

Beginning in privileged EXEC mode, follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

**SUMMARY STEPS**

1. `configure terminal`
2. `snmp-server tftp-server-list access-list-number`
3. `access-list access-list-number {deny | permit} source [source-wildcard]`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> snmp-server tftp-server-list access-list-number</td>
<td>Limits the TFTP servers used for configuration file copies through SNMP to the servers in the access list.</td>
</tr>
<tr>
<td>Example: Switch(config)# snmp-server tftp-server-list 44</td>
<td>For <code>access-list-number</code>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.</td>
</tr>
<tr>
<td><strong>Step 3</strong> access-list access-list-number {deny</td>
<td>permit} source [source-wildcard]</td>
</tr>
<tr>
<td>Example: Switch(config)# access-list 44 permit 10.1.1.2</td>
<td>For <code>access-list-number</code>, enter the access list number specified in Step 2.</td>
</tr>
</tbody>
</table>
### Purpose

The **deny** keyword denies access if the conditions are matched. The **permit** keyword permits access if the conditions are matched.

For **source**, enter the IP address of the TFTP servers that can access the switch.

(Optional) For **source-wildcard**, enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore.

The access list is always terminated by an implicit deny statement for everything.

### Step 4

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

### Example:

Switch(config)# end

---

## Configuring Trap Flags for SNMP

### SUMMARY STEPS

1. **configure terminal**
2. **trapflags ap { interfaceup | register }**
3. **trapflags client { dot11 | excluded }**
4. **trapflags dot11-security { ids-sig-attack | wep-decrypt-error }**
5. **trapflags mesh**
6. **trapflags rogueap**
7. **trapflags rrm-params { channels | tx-power }**
8. **trapflags rrm-profile { coverage | interference | load | noise }**
9. **end**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>configure terminal</strong></td>
<td>Enters the global configuration mode.</td>

</tr>
<tr>
<td></td>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>**trapflags ap { interfaceup</td>
<td>register }**</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch(config)# trapflags ap interfaceup</td>
<td></td>
</tr>
</tbody>
</table>

- **interfaceup**– Enables trap when a Cisco AP interface (A or B) comes up.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>register</td>
<td>Enables trap when a Cisco AP registers with a Cisco switch.</td>
</tr>
</tbody>
</table>

**Step 3** trapflags client \{dot11 | excluded\}

**Example:**

```plaintext
Switch(config)# trapflags client excluded
```

Enables sending client-related dot11 traps. Use the **no** form of the command to disable the trap flags.

- **dot11** – Enables Dot11 traps for clients.
- **excluded** – Enables excluded traps for clients.

**Step 4** trapflags dot11-security \{ids-sig-attack | wep-decrypt-error\}

**Example:**

```plaintext
Switch(config)# trapflags dot11-security wep-decrypt-error
```

Enables sending 802.11 security-related traps. Use the **no** form of the command to disable the trap flags.

- **ids-sig-attack** – Enables IDS signature attack traps.
- **wep-decrypt-error** – Enables traps for WEP decrypt error for clients.

**Step 5** trapflags mesh

**Example:**

```plaintext
Switch(config)# trapflags mesh
```

Enables trap for the mesh. Use the **no** form of the command to disable the trap flags.

**Step 6** trapflags rogueap

**Example:**

```plaintext
Switch(config)# trapflags rogueap
```

Enables trap for rogue AP detection. Use the **no** form of the command to disable the trap flags.

**Step 7** trapflags rrm-params \{channels | tx-power\}

**Example:**

```plaintext
Switch(config)# trapflags rrm-params tx-power
```

Enables sending RRM-parameter update-related traps. Use the **no** form of the command to disable the trap flags.

- **channels** – Enables trap when RF Manager automatically changes a channel number for the Cisco AP interface.
- **tx-power** – Enables the trap when RF Manager automatically changes Tx-Power level for the Cisco AP interface.

**Step 8** trapflags rrm-profile \{coverage | interference | load | noise\}

**Example:**

```plaintext
Switch(config)# trapflags rrm-profile interference
```

Enables sending RRM-profile-related traps. Use the **no** form of the command to disable the trap flags.

- **coverage** – Enables the trap when the coverage profile maintained by RF Manager fails.
- **interference** – Enables the trap when the interference profile maintained by RF Manager fails.
- **load** – Enables trap when the load profile maintained by RF Manager fails.
### Summary Steps

1. `configure terminal`
2. `snmp-server enable traps wireless [AP | RRM | bsn80211SecurityTrap | bsnAPParamUpdate | bsnAPProfile | bsnAccessPoint | bsnMobileStation | bsnRogue | client | mfp | rogue]`
3. `end`

### Detailed Steps

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>

<tbody>
<tr>
<td></td>
<td>Example: <code>Switch(config)# snmp-server enable traps wireless AP</code></td>
<td></td>
</tr>
</tbody>
</table>

- **AP**– Enables access point traps.
- **RRM**– Enables RRM traps.
- **bsn80211SecurityTrap**– Enables the security-related trap.
- **bsnAPParamUpdate**– Enables the trap for AP parameters that get updated.
- **bsnAPProfile**– Enables BSN AP profile traps.
- **bsnAccessPoint**– Enables BSN access point traps.
- **bsnMobileStation**– Controls wireless client traps.
- **bsnRogue**– Enables BSN rogue-related traps.
- **client**– Enables client traps.
- **mfp**– Enables MFP traps.
Monitoring SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the `show snmp` privileged EXEC command. You also can use the other privileged EXEC commands listed in the table to display SNMP information.

### Table 72: Commands for Displaying SNMP Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show snmp</code></td>
<td>Displays SNMP statistics.</td>
</tr>
<tr>
<td><code>show snmp engineID</code></td>
<td>Displays information on the local SNMP engine and all remote engines that have been configured on the device.</td>
</tr>
<tr>
<td><code>show snmp group</code></td>
<td>Displays information on each SNMP group on the network.</td>
</tr>
<tr>
<td><code>show snmp pending</code></td>
<td>Displays information on pending SNMP requests.</td>
</tr>
<tr>
<td><code>show snmp sessions</code></td>
<td>Displays information on the current SNMP sessions.</td>
</tr>
<tr>
<td><code>show snmp user</code></td>
<td>Displays information on each SNMP user name in the SNMP users table.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>You must use this command to display SNMPv3 configuration information for auth</td>
</tr>
</tbody>
</table>

### SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string `public`. This configuration does not cause the switch to send any traps.

```
Switch(config)# snmp-server community public
```
This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string *public*. The switch also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33 using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string *public* is sent with the traps.

```
Switch(config)# snmp-server community public
Switch(config)# snmp-server enable traps vtp
Switch(config)# snmp-server host 192.180.1.27 version 2c public
Switch(config)# snmp-server host 192.180.1.111 version 1 public
Switch(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the *comaccess* community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host *cisco.com* using the community string *public*.

```
Switch(config)# snmp-server community comaccess ro 4
Switch(config)# snmp-server enable traps snmp authentication
Switch(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host *cisco.com*. The community string is restricted. The first line enables the switch to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous `snmp-server host` commands for the host *cisco.com*.

```
Switch(config)# snmp-server enable traps entity
Switch(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the switch to send all traps to the host *myhost.cisco.com* using the community string *public*:

```
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send *auth* (authNoPriv) authentication-level informs when the user enters global configuration mode:

```
Switch(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Switch(config)# snmp-server group authgroup v3 auth
Switch(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Switch(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Switch(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server inform retries 0
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions on SLAs

This section lists the restrictions on SLAs.

The following are restrictions on IP SLAs network performance measurement:

• The switch does not support VoIP service levels using the gatekeeper registration delay operations measurements.

• Only a Cisco IOS device can be a source for a destination IP SLAs responder.

• You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

Information About SLAs

Cisco IOS IP Service Level Agreements (SLAs)

Cisco IOS IP SLAs send data across the network to measure performance between multiple network locations or across multiple network paths. They simulate network data and IP services and collect network performance information in real time. Cisco IOS IP SLAs generate and analyze traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLA operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLA operations, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLA packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs are Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collect a unique subset of the following performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like Cisco Prime Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products.

Using IP SLAs can provide the following benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring
  - Measurement of jitter, latency, or packet loss in the network.
  - Continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
Network operation troubleshooting by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.

- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the switch supports MPLS).

Network Performance Measurement with Cisco IOS IP SLAs

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices.

Figure 54: Cisco IOS IP SLAs Operation

The following figure shows how IP SLAs begin when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

Related Topics

- Restrictions on SLAs, on page 803

IP SLA Responder and IP SLA Control Protocol

The IP SLA responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLA request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLA Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond.

Note

The IP SLA responder can be a Cisco IOS Layer 2, responder-configurable switch. The responder does not need to support full IP SLA functionality.
The following figure shows where the Cisco IOS IP SLA responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLA operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLA packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

You do not need to enable the responder on the destination device for all IP SLA operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP).

**Related Topics**

Restrictions on SLAs, on page 803

---

**Response Time Computation for IP SLAs**

Switches, controllers, and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimize these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLA test packets use time stamping to minimize the processing delays.

When the IP SLA responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

**Figure 55: Cisco IOS IP SLA Responder Time Stamping**

The following figure demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt level to allow for greater accuracy. 

\[ \text{RTT (Round-trip time)} = T4 \times (\text{Time stamp } 4) - T1 \times (\text{Time stamp } 1) - \Delta \]

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

---

**IP SLAs Operation Scheduling**

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the `pending` option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an
operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLA operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLA multi-operations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the [Cisco IOS IP SLAs Configuration Guide](#).

**IP SLA Operation Threshold Monitoring**

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as the following:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold
- One-way packet loss
- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency

An IP SLA threshold violation can also trigger another IP SLA operation for further analysis. For example, the frequency could be increased or an Internet Control Message Protocol (ICMP) path echo or ICMP path jitter operation could be initiated for troubleshooting.

**ICMP Echo**

The ICMP echo operation measures the end-to-end response time between a Cisco device and any other device that uses IP. The response time is computed by measuring the time it takes to send an ICMP echo request message to a destination and receive an ICMP echo reply. Many customers use IP SLA ICMP-based operations, in-house ping testing, or ping-based dedicated probes to measure this response time. The IP SLA ICMP echo operation conforms to the same specifications as ICMP ping testing, and both methods result in the same response times.

**Related Topics**

Analyzing IP Service Levels by Using the ICMP Echo Operation, on page 817

**UDP Jitter**

Jitter is a simple term that describes interpacket delay variance. When multiple packets are sent consecutively at an interval of 10 ms from source to destination, the destination should receive them 10 ms apart (if the network is behaving correctly). However, if there are delays in the network (such as queuing, arriving through alternate routes, and so on), the time interval between packet arrivals might be more or less than 10 ms. A
A positive jitter value indicates that the packets arrived more than 10 ms apart. A negative jitter value indicates that the packets arrived less than 10 ms apart. If the packets arrive 12 ms apart, the positive jitter is 2 ms; if the packets arrive 8 ms apart, the negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLA UDP jitter operation can be used as a multipurpose data gathering operation. The packets generated by IP SLAs carry sequence information and time stamps from the source and operational target that include packet sending and receiving data. Based on this data, UDP jitter operations measure the following:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), you can use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

To provide accurate one-way delay (latency) measurements, time synchronization (as provided by NTP) is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

**Related Topics**

Analyzing IP Service Levels by Using the UDP Jitter Operation, on page 814

**Configuration Guidelines**

For information on the IP SLA commands, see the *Cisco IOS IP SLAs Command Reference, Release 12.4T* command reference.

For detailed descriptions and configuration procedures, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4TL*.

Not all of the IP SLA commands or operations described in the referenced guide are supported on the switch. The switch supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the `show ip sla application` privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

```
Switch# show ip sla application
```
How to Configure IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the Cisco IOS IP SLAs Configuration Guide. It does include several operations as examples, including configuring the responder, configuring a UDP jitter operation, which requires a responder, and configuring an ICMP echo operation, which does not require a responder. For details about configuring other operations, see the Cisco IOS IP SLAs Configuration Guide.

Configuring the IP SLA Responder

The IP SLA responder is available only on Cisco IOS software-based devices, including some Layer 2 switches that do not support full IP SLA functionality.

Beginning in privileged EXEC mode, follow these steps to configure the IP SLA responder on the target device (the operational target):

### SUMMARY STEPS

1. `configure terminal`
2. `ip sla responder { tcp-connect | udp-echo } ipaddress ip-address port port-number`
3. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| `configure terminal` | Enters the global configuration mode. |
| **Example:**
| `Switch# configure terminal` | |
Purpose
Command or Action | Purpose
---|---
**Step 2** | Configure the switch as an IP SLA responder.
`ip sla responder {tcp-connect | udp-echo} ip-address port port-number`
**Example:**
```
Switch(config)# ip sla responder udp-echo 172.29.139.134 5000
```

The keywords have these meanings:
- **tcp-connect**—Enables the responder for TCP connect operations.
- **udp-echo**—Enables the responder for User Datagram Protocol (UDP) echo or jitter operations.
- **ipaddress** *ip-address*—Enter the destination IP address.
- **port** *port-number*—Enter the destination port number.

**Note**
The IP address and port number must match those configured on the source device for the IP SLA operation.

**Step 3** | Returns to privileged EXEC mode.
```
end
```

**UDP Jitter Example**
This example shows how to configure the device as a responder for the UDP jitter IP SLA operation in the next procedure:
```
Switch(config)# ip sla responder udp-echo 172.29.139.134 5000
```

**Implementing IP SLA Network Performance Measurement**

Beginning in privileged EXEC mode, follow these steps to implement IP SLA network performance measurement on your switch:

**Before you begin**
Use the `show ip sla application` privileged EXEC command to verify that the desired operation type is supported on your software image.

**SUMMARY STEPS**
1. `configure terminal`
2. `ip sla operation-number`
3. `udp-jitter` {destination-ip-address | destination-hostname} destination-port [source-ip {ip-address | hostname}] [source-port port-number] [control {enable | disable}] [num-packets number-of-packets] [interval interpacket-interval]

4. frequency seconds

5. threshold milliseconds

6. exit

7. `ip sla schedule` operation-number [life {forever | seconds}] [start-time {hh:mm:ss} [month day | day month] | pending | now | after hh:mm:ss] [ageout seconds] [recurring]

8. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ip sla operation-number</td>
<td>Creates an IP SLA operation, and enters IP SLA configuration mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# ip sla 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> udp-jitter {destination-ip-address</td>
<td>destination-hostname} destination-port [source-ip {ip-address</td>
</tr>
<tr>
<td>Example: Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>destination device to establish a connection with the IP SLA responder</strong></td>
<td></td>
</tr>
<tr>
<td><strong>num-packets number-of-packets</strong>—Enters the number of packets to be generated. The range is 1 to 6000; the default is 10.</td>
<td></td>
</tr>
<tr>
<td><strong>interval inter-packet-interval</strong>—Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

**frequency seconds**

*Example:*

```
Switch(config-ip-sla-jitter)# frequency 45
```

(Optional) Configures options for the SLA operation. This example sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.

**Step 5**

**threshold milliseconds**

*Example:*

```
Switch(config-ip-sla-jitter)# threshold 200
```

(Optional) Configures threshold conditions. This example sets the threshold of the specified IP SLA operation to 200. The range is from 0 to 60000 milliseconds.

**Step 6**

**exit**

*Example:*

```
Switch(config-ip-sla-jitter)# exit
```

Exits the SLA operation configuration mode (UDP jitter configuration mode in this example), and returns to global configuration mode.

**Step 7**

```
ip sla schedule operation-number [life {forever | seconds}] [start-time {hh:mm [:ss] | month day | day month} | pending | now | after hh:mm:ss] [ageout seconds] [recurring]
```

*Example:*

```
Switch(config)# ip sla schedule 10 start-time now life forever
```

Configures the scheduling parameters for an individual IP SLA operation.

- **operation-number**—Enter the RTR entry number.

- **(Optional) life**—Sets the operation to run indefinitely (forever) or for a specific number of seconds. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour).

- **(Optional) start-time**—Enters the time for the operation to begin collecting information:
  
  To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.

  Enter **pending** to select no information collection until a start time is selected.

  Enter **now** to start the operation immediately.

  Enter **after hh:mm:ss** to show that the operation should start after the entered time has elapsed.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ageout seconds</td>
<td>(Optional) Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out).</td>
</tr>
<tr>
<td>recurring</td>
<td>(Optional) Set the operation to automatically run every day.</td>
</tr>
</tbody>
</table>

Step 8 end Example:
Switch(config)# end

UDP Jitter Configuration
This example shows how to configure a UDP jitter IP SLA operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 10
```

IP SLAs, Infrastructure Engine-II.

Analyzing IP Service Levels by Using the UDP Jitter Operation

Beginning in privileged EXEC mode, follow these steps to configure a UDP jitter operation on the source device:

**Before you begin**
You must enable the IP SLA responder on the target device (the operational target) to configure a UDP jitter operation on the source device.

**SUMMARY STEPS**

1. **configure terminal**
2. **ip sla operation-number**
3. **udp-jitter {destination-ip-address | destination-hostname} destination-port [source-ip {ip-address | hostname}] [source-port port-number] [control {enable | disable}] [num-packets number-of-packets] [interval interpacket-interval]
4. **frequency seconds**
5. **exit**
6. **ip sla schedule operation-number [life {forever | seconds}] [start-time {hh:mm [ss] | month day | day month} | pending | now | after hh:mm:ss] [ageout seconds] [recurring]
7. **end**

**DETAILED STEPS**

**Step 1**
**configure terminal**
Example:
Switch# configure terminal

**Step 2**
**ip sla operation-number**
Example:
Switch(config)# ip sla 10

**Step 3**
**udp-jitter {destination-ip-address | destination-hostname} destination-port [source-ip {ip-address | hostname}] [source-port port-number] [control {enable | disable}]**

**Purpose**

- Enters the global configuration mode.
- Creates an IP SLA operation, and enters IP SLA configuration mode.
- Configures the IP SLA operation as a UDP jitter operation, and enters UDP jitter configuration mode.
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
</tbody>
</table>

### Example:

Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000

### Step 4

**frequency seconds**

Example:

Switch(config-ip-sla-jitter)# frequency 45

(Optional) Sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.

### Step 5

**exit**

Example:

Switch(config-ip-sla-jitter)# exit

Exits UDP jitter configuration mode, and returns to global configuration mode.

### Step 6

**ip sla schedule operation-number [life {forever | seconds}] [start-time {hh:mm [:ss] [month day] [day month] | pending | now | after hh:mm:ss] [ageout seconds] [recurring]**

Example:

Switch(config)# ip sla schedule 10 start-time now

Configures the scheduling parameters for an individual IP SLA operation.

- **operation-number**—Enter the RTR entry number.
- (Optional) **life**—Sets the operation to run indefinitely (forever) or for a specific number of seconds. The

</tr>
</tbody>
</table>

### Step 7

**Example:**

Switch(config)# end

Returns to privileged EXEC mode.

---

### Configuring a UDP Jitter IP SLA Operation

This example shows how to configure a UDP jitter IP SLA operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 10

Configuring SPAN and RSPAN

- Finding Feature Information, on page 823
- Prerequisites for SPAN and RSPAN, on page 823
- Restrictions for SPAN and RSPAN, on page 824
- Information About SPAN and RSPAN, on page 825
- How to Configure SPAN and RSPAN, on page 837
- Monitoring SPAN and RSPAN Operations, on page 855
- SPAN and RSPAN Configuration Examples, on page 855
- Additional References, on page 858
- Feature History and Information for SPAN and RSPAN, on page 859

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SPAN and RSPAN

SPAN

- You can limit SPAN traffic to specific VLANs by using the `filter vlan` keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

RSPAN

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.
Restrictions for SPAN and RSPAN

SPAN

The restrictions for SPAN are as follows:

- On each switch, you can configure 66 sessions. A maximum of 7 source sessions can be configured and the remaining sessions can be configured as RSPAN destinations sessions. A source session is either a local SPAN session or an RSPAN source session.

- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.

- The destination port cannot be a source port; a source port cannot be a destination port.

- You cannot have two SPAN sessions using the same destination port.

- When you configure a switch port as a SPAN destination port, it is no longer a normal switch port; only monitored traffic passes through the SPAN destination port.

- Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the `no monitor session {session_number | all | local | remote}` global configuration command to delete configured SPAN parameters.

- For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the `encapsulation replicate` keywords are specified. If the keywords are not specified, the packets are sent in native form.

- You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.

- You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.

- Wireshark does not capture egress packets when egress span is active.

- You can run both a local SPAN and an RSPAN source session in the same switch or switch stack. The switch or switch stack supports a total of 66 source and RSPAN destination sessions.

- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.

- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per switch stack.

- SPAN sessions do not interfere with the normal operation of the switch. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.

- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

The switch does not support a combination of local SPAN and RSPAN in a single session.

- An RSPAN source session cannot have a local destination port.
- An RSPAN destination session cannot have a local source port.
- An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same switch or switch stack.

RSPAN

The restrictions for RSPAN are as follows:

- RSPAN does not support BPDU packet monitoring or other Layer 2 switch protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating switches.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the switch does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the switch.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- To use RSPAN, the switch must be running the LAN Base image.

Information About SPAN and RSPAN

SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the switch or on another switch that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.
Local SPAN

Local SPAN supports a SPAN session entirely within one switch; all source ports or source VLANs and destination ports are in the same switch or switch stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

*Figure 56: Example of Local SPAN Configuration on a Single Device*

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port 5.

*Figure 57: Example of Local SPAN Configuration on a Device Stack*

This is an example of a local SPAN in a switch stack, where the source and destination ports reside on different stack members.

*Related Topics*

Creating a Local SPAN Session, on page 837
Remote SPAN

RSPAN supports source ports, source VLANs, and destination ports on different switches (or different switch stacks), enabling remote monitoring of multiple switches across your network.

*Figure 58: Example of RSPAN Configuration*

The figure below shows source ports on Switch A and Switch B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating switches. The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source switch must have either ports or VLANs as RSPAN sources. The destination is always a physical port, as shown on Switch C in the figure.

**SPAN and RSPAN Concepts and Terminology**

- **SPAN Sessions**
• Monitored Traffic
• Source Ports
• Source VLANs
• VLAN Filtering
• Destination Port
• RSPAN VLAN

SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination switch.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

A single RSPAN session with multiple source and destination ports can be in the same session but more than one source session with the source being the same remote vlan is not allowed.

Traffic monitoring in a SPAN session has these restrictions:

• Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.

• The switch supports up to two local SPAN or RSPAN source sessions.
  • You can run both a local SPAN and an RSPAN source session in the same switch or switch stack. The switch or switch stack supports a total of 64 source and RSPAN destination sessions.
  • You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
  • You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per switch stack.
• SPAN sessions do not interfere with the normal operation of the switch. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.

• When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.

• You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

• The switch does not support a combination of local SPAN and RSPAN in a single session.
  • An RSPAN source session cannot have a local destination port.
  • An RSPAN destination session cannot have a local source port.
  • An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same switch or switch stack.

  Example: Configuring Local SPAN, on page 855

Monitored Traffic

SPAN sessions can monitor these traffic types:

• Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the switch. A copy of each packet received by the source is sent to the destination port for that SPAN session.

  Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

  Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

• Transmit (Tx) SPAN—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the switch. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

  Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

  Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

• Both—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.
The default configuration for local SPAN session ports is to send all packets untagged. However, when you enter the `encapsulation replicate` keywords while configuring a destination port, these changes occur:

- Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.
- Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Switch congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

- A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
- An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.
- An egress packet dropped because of switch congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the switch through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

**Source Ports**

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis. In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions. The switch supports any number of source ports (up to the maximum number of available ports on the switch) and any number of source VLANs (up to the maximum number of VLANs supported). However, the switch supports a maximum of (local or RSPAN) with source ports or VLANs. You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.
- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.
Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same switch or switch stack as the source port. For an RSPAN session, it is located on the switch containing the RSPAN destination session. There is no destination port on a switch or switch stack running only an RSPAN source session.
- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.
When QoS is configured on the SPAN destination port, QoS takes effect immediately.

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.
- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can be an EtherChannel group (ON mode only).
- It cannot be a VLAN.
- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).
- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- The maximum number of destination ports in a switch or switch stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:
- For local SPAN, if the encapsulation replicate keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with encapsulation replicate enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.
- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

**RSPAN VLAN**

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:
- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the remote-span VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate switches.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

**SPAN and RSPAN Interaction with Other Features**

SPAN interacts with these features:

- **Routing**—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the switch, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the switch routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.

- **STP**—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.

- **CDP**—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP. Due to limitation in the ASIC, CDP packets are not dropped in RSPAN configured VLAN.

- **VTP**—You can use VTP to prune an RSPAN VLAN between switches.

- **VLAN and trunking**—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.

- **EtherChannel**—You can configure an EtherChannel group as a source port or a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored. If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list. A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a...
SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

- Multicast traffic can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.

- A private-VLAN port cannot be a SPAN destination port.

- A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

**SPAN and RSPAN and Device Stacks**

Because the stack of switches represents one logical switch, local SPAN source ports and destination ports can be in different switches in the stack. Therefore, the addition or deletion of switches in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a switch is removed from the stack or an inactive session can become active when a switch is added to the stack.

**Flow-Based SPAN**

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session. The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.

You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL—Filters only IPv4 packets.
• IPv6 FSPAN ACL—Filters only IPv6 packets.
• MAC FSPAN ACL—Filters only non-IP packets.

If a VLAN-based FSPAN session configured on a stack cannot fit in the hardware memory on one or more switches, it is treated as unloaded on those switches, and traffic meant for the FSPAN ACL and sourcing on that switch is not copied to the SPAN destination ports. The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the switches where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

IPv4 and MAC FSPAN ACLs are supported on all feature sets. IPv6 FSPAN ACLs are supported only in the advanced IP Services feature set.

<td>None configured.</td>
</tr>
</tbody>
</table>

### Configuration Guidelines

**SPAN Configuration Guidelines**

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session** *session_number* source *interface interface-id | vlan vlan-id* global configuration command or the **no monitor session** *session_number* destination interface *interface-id* global configuration command. For destination interfaces, the **encapsulation** options are ignored with the **no** form of the command.
- To monitor all VLANs on the trunk port, use the **no monitor session** *session_number* filter global configuration command.
RSPAN Configuration Guidelines

• All the SPAN configuration guidelines apply to RSPAN.

• As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.

• You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source switches.

• For RSPAN configuration, you can distribute the source ports and the destination ports across multiple switches in your network.

• Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.

• You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
  • The same RSPAN VLAN is used for an RSPAN session in all the switches.
  • All participating switches support RSPAN.

FSPAN and FRSPAN Configuration Guidelines

• When at least one FSPAN ACL is attached, FSPAN is enabled.

• When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

# How to Configure SPAN and RSPAN

## Creating a Local SPAN Session

Beginning in privileged EXEC mode, follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

### SUMMARY STEPS

1. **configure terminal**
2. **no monitor session {session_number | all | local | remote}**
3. **monitor session session_number source {interface interface-id | vlan vlan-id} [ , | - ] [both | rx | tx]**
4. **monitor session session_number destination {interface interface-id [ , | - ] [encapsulation replicate]}**
5. **end**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Removes any existing SPAN configuration for the session.</td>
</tr>
<tr>
<td>**no monitor session {session_number</td>
<td>all</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# no monitor session all</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specifies the SPAN session and the source port (monitored port).</td>
</tr>
<tr>
<td>**monitor session session_number source {interface interface-id</td>
<td>vlan vlan-id} [ ,</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# monitor session 1 source interface gigabitethernet1/0/1</td>
<td></td>
</tr>
</tbody>
</table>
A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.

- (Optional) [ , ] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.

- (Optional) both | rx | tx—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic.
  
  - both—Monitors both received and sent traffic.
  - rx—Monitors received traffic.
  - tx—Monitors sent traffic.

You can use the `monitor session session_number source` command multiple times to configure multiple source ports.

You can use `monitor session session_number destination {interface interface-id [ , ] [encapsulation replicate]}` command multiple times to configure multiple destination ports.

For local SPAN, you must use the same session number for the source and destination interfaces.

- For `session_number`, specify the session number entered in step 3.
- For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.
- (Optional) [ , ] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.

(Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).

You can use `monitor session session_number destination` command multiple times to configure multiple destination ports.
Creating a Local SPAN Session and Configuring Incoming Traffic

Beginning in privileged EXEC mode, follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

SUMMARY STEPS

1. configure terminal
2. no monitor session {session_number | all | local | remote}
3. monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]
4. monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate] [ingress {dot1q vlan vlan-id | isl | untagged vlan vlan-id | vlan vlan-id}]}
5. end

</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# monitor session 2 source gigabitethernet1/0/1 rx</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>`monitor session session_number destination {interface interface-id [,</td>
<td>-] [encapsulation replicate] [ingress {dot1q vlan vlan-id</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6</td>
<td></td>
</tr>
</tbody>
</table>

- For `session_number`, specify the session number entered in Step 3.
- For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.
- (Optional) [, | -]—Specifies a series or range of interfaces. Enter a space before and after the comma or hyphen.
- (Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).
- `ingress` enables forwarding of incoming traffic on the destination port and to specify the encapsulation type:
  - `dot1q vlan vlan-id`—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN.
  - `isl`—Forwards ingress packets with ISL encapsulation.
  - `untagged vlan vlan-id` or `vlan vlan-id`—Accepts incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.

  - `dot1q vlan vlan-id`—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN.
  - `isl`—Forwards ingress packets with ISL encapsulation.
  - `untagged vlan vlan-id` or `vlan vlan-id`—Accepts incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.

### Command or Action

<table>
<thead>
<tr>
<th>Command/Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# monitor session 2 source interface gigabitethernet1/0/2 rx</td>
<td>- For <code>interface-id</code>, specify the source port to monitor. The interface specified must already be configured as a trunk port.</td>
</tr>
</tbody>
</table>

**Step 4**

**monitor session** `session_number` **filter vlan** `vlan-id` `

**Example:**

Switch(config)# monitor session 2 filter vlan 1 - 5 , 9

- Limits the SPAN source traffic to specific VLANs.
  - For `session_number`, enter the session number specified in Step 3.
  - For `vlan-id`, the range is 1 to 4094.
  - (Optional) Use a comma (,) to specify a series of VLANs, or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.

**Step 5**

**monitor session** `session_number` **destination** `{interface `interface-id` `[ , - ] [ encapsulation replicate ] }

**Example:**

Switch(config)# monitor session 2 destination interface gigabitethernet1/0/1

- Specifies the SPAN session and the destination port (monitoring port).
  - For `session_number`, specify the session number entered in Step 3.
  - For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.
  - (Optional) `[ , - ]` Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.
  - (Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).

**Step 6**

**end**

**Example:**

Switch(config)# end

- Returns to privileged EXEC mode.

### Configuring a VLAN as an RSPAN VLAN

Beginning in privileged EXEC mode, follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

**SUMMARY STEPS**

1. `configure terminal`
2. `vlan vlan-id`
3. remote-span
4. end

<td></td>
</tr>
<tr>
<td></td>
<td>Switch(config-vlan)# end</td>
<td></td>
</tr>
</tbody>
</table>

What to do next

You must create the RSPAN VLAN in all switches that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one switch, and VTP propagates it to the other switches in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination switches and any intermediate switches.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the `no remote-span` VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the `no monitor session session_number source {interface interface-id | vlan vlan-id} global configuration command. To remove the RSPAN VLAN from the session, use the `no monitor session session_number destination remote vlan vlan-id`. 
Creating an RSPAN Source Session

Beginning in privileged EXEC mode, follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

**SUMMARY STEPS**

1. configure terminal
2. no monitor session {session_number | all | local | remote}
3. monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]
4. monitor session session_number destination remote vlan vlan-id
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Removes any existing SPAN configuration for the session.</td>
</tr>
<tr>
<td>no monitor session {session_number</td>
<td>all</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# no monitor session 1</td>
<td></td>
</tr>

<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# monitor session 1 source interface gigabitethernet1/0/1 tx</td>
<td></td>
</tr>
</tbody>
</table>

- For *session_number*, the range is 1 to 66.
- For *all*, Removes all SPAN sessions.
- For *local*, Removes all local sessions.
- For *remote*, Removes all remote SPAN sessions.

- For *interface-id*, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces *(port-channel port-channel-number)*. Valid port-channel numbers are 1 to 48.
- For *vlan-id*, specifies the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).

A single session can include multiple sources (ports or VLANs), defined in a series of commands, but you cannot combine source ports and source VLANs in one session.
### Specifying VLANs to Filter

Beginning in privileged EXEC mode, follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

**SUMMARY STEPS**

1. `configure terminal`
2. `no monitor session {session_number | all} [local | remote]`
3. `monitor session session_number source interface interface-id`
4. `monitor session session_number filter vlan vlan-id [ , - ]`
5. `monitor session session_number destination remote vlan vlan-id`
6. `end`

</table>
Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different switch or switch stack; that is, not the switch or switch stack on which the source session was configured.

Beginning in privileged EXEC mode, follow these steps to define the RSPAN VLAN on that switch, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

SUMMARY STEPS

1. configure terminal
2. vlan vlan-id
3. remote-span
4. exit
5. no monitor session {session_number | all | local | remote}
6. monitor session session_number source remote vlan vlan-id
7. monitor session session_number destination interface interface-id
8. end

DETAILED STEPS

</table>
Creating an RSPAN Destination Session and Configuring Incoming Traffic

Beginning in privileged EXEC mode, follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

**SUMMARY STEPS**

1. configure terminal
2. no monitor session \{session_number \| all \| local \| remote\}
3. monitor session session_number source remote vlan vlan-id
4. monitor session session_number destination \{interface interface-id [\| -] [ingress \{dot1q vlan vlan-id | isl | untagged vlan vlan-id | vlan vlan-id\}]\}
5. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> no monitor session {session_number | all | local | remote}</td>
<td>Removes any existing SPAN configuration for the session.</td>
</tr>
<tr>
<td>Example: Switch(config)# no monitor session 2</td>
<td>• For session_number, the range is 1 to 66.</td>
</tr>
<tr>
<td></td>
<td>• all—Removes all SPAN sessions.</td>

<tr>
<td></td>
<td>• local—Removes all local sessions.</td>
</tr>
<tr>
<td></td>
<td>• remote—Removes all remote SPAN sessions.</td>
</tr>
<tr>
<td><strong>Step 3</strong> monitor session session_number source remote vlan vlan-id</td>
<td>Specifies the RSPAN session and the source RSPAN VLAN.</td>
</tr>
<tr>
<td>Example: Switch(config)# monitor session 2 source remote vlan 901</td>
<td>• For session_number, the range is 1 to 66.</td>
</tr>
<tr>
<td></td>
<td>• For vlan-id, specify the source RSPAN VLAN to monitor.</td>
</tr>
<tr>
<td><strong>Step 4</strong> monitor session session_number destination {interface interface-id [| -] [ingress {dot1q vlan vlan-id</td>
<td>isl</td>
</tr>
<tr>
<td>Example: Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6</td>
<td>• For session_number, enter the number defined in Step 4.</td>
</tr>
<tr>
<td></td>
<td>In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port.</td>
</tr>
<tr>
<td></td>
<td>• For interface-id, specify the destination interface. The destination interface must be a physical interface.</td>
</tr>
</tbody>
</table>
| | • Though visible in the command-line help string, encapsulation replicate is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged.
Configuring an FSPAN Session

Beginning in privileged EXEC mode, follow these steps to create a SPAN session, specify the source (monitored) ports or VLANs and the destination (monitoring) ports, and configure FSPAN for the session.

SUMMARY STEPS

1. configure terminal
2. no monitor session {session_number | all | local | remote}
3. monitor session session_number source {interface interface-id | vlan vlan-id} [ , -] [both | rx | tx]
4. monitor session session_number destination {interface interface-id [ , -] [encapsulation replicate]}
5. monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}
6. end
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Switch# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>`no monitor session {session_number</td>
<td>all</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Switch(config)# <code>no monitor session 2</code></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>`monitor session session_number source {interface interface-id</td>
<td>vlan vlan-id} [ ,</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Switch(config)# <code>monitor session 2 source interface gigabitethernet1/0/1</code></td>
<td></td>
</tr>
</tbody>
</table>

- **Purpose:**
  - Enters global configuration mode.
  - Removes any existing SPAN configuration for the session.
    - For `session_number`, the range is 1 to 66.
    - `all`—Removes all SPAN sessions.
    - `local`—Removes all local sessions.
    - `remote`—Removes all remote SPAN sessions.
  - Specifies the SPAN session and the source port (monitored port).
    - For `session_number`, the range is 1 to 66.
    - For `interface-id`, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (`port-channel port-channel-number`). Valid port-channel numbers are 1 to 48.
    - For `vlan-id`, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).
    - A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.
    - (Optional) `[ , | - ]`—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.
    - (Optional) `[both | rx | tx]`— Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic.
      - `both`—Monitors both sent and received traffic. This is the default.
      - `rx`—Monitors received traffic.
      - `tx`—Monitors sent traffic.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong> You can use the <code>monitor session session_number source</code> command multiple times to configure multiple source ports.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 4

**monitorsession session_number destination {interface interface-id [,, -] [encapsulation replicate]}

**Example:**

```
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate
```

- Specifies the SPAN session and the destination port (monitoring port).
  - For `session_number`, specify the session number entered in Step 3.
  - For `destination`, specify the following parameters:
    - For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.
    - (Optional) `[,, -]` Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.
    - (Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).

**Note** For local SPAN, you must use the same session number for the source and destination interfaces.

### Step 5

**monitorsession session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}

**Example:**

```
Switch(config)# monitor session 2 filter ipv6 access-group 4
```

- Specifies the SPAN session, the types of packets to filter, and the ACLs to use in an FSPAN session.
  - For `session_number`, specify the session number entered in Step 3.
  - For `access-list-number`, specify the ACL number that you want to use to filter traffic.
  - For `name`, specify the ACL name that you want to use to filter traffic.

### Step 6

**end

**Example:**

```
Switch(config)# end
```

- Returns to privileged EXEC mode.
Configuring an FRSPAN Session

Beginning in privileged EXEC mode, follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

**SUMMARY STEPS**

1. `configure terminal`
2. `no monitor session {session_number | all | local | remote}`
3. `monitor session session_number source {interface interface-id | vlan vlan-id} [, -] [both | rx | tx]`
4. `monitor session session_number destination remote vlan vlan-id`
5. `vlan vlan-id`
6. `remote-span`
7. `exit`
8. `monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}`
9. `end`

**Note**  
- A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.  
- (Optional) *[]*—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.  
- (Optional) *[both | rx | tx]*—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic.  
  - *both*—Monitors both sent and received traffic. This is the default.  
  - *rx*—Monitors received traffic.  
  - *tx*—Monitors sent traffic.

**Example:**  
Switch(config)# monitor session 2 destination remote vlan 5

**Step 5**  
```
Switch(config)# vlan 10
```  
This specifies that the VLAN you specified in Step 5 is part of the RSPAN VLAN.

**Step 6**  
```
Switch(config-vlan)# remote-span
```  
This returns to global configuration mode.
### Purpose

Command or Action | Purpose
--- | ---
Switch(config-vlan)# **exit** |

#### Step 8

**monitor session** `session_number` **filter** `{ip | ipv6 | mac}` **access-group** `{access-list-number | name}`

*Example:*

Switch(config)# **monitor session 2 filter ip access-group 7**

**Purpose:** Specifies the RSPAN session, the types of packets to filter, and the ACLs to use in an FRSPAN session.

- For `session_number`, specify the session number entered in Step 3.
- For `access-list-number`, specify the ACL number that you want to use to filter traffic.
- For `name`, specify the ACL name that you want to use to filter traffic.

#### Step 9

**end**

*Example:*

Switch(config)# **end**

**Purpose:** Returns to privileged EXEC mode.

### SPAN and RSPAN Configuration Examples

#### Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

Switch(config)# **no monitor session 1**
Switch(config)# **monitor session 1 source interface gigabitethernet1/0/1**
Example: Configuring Local SPAN

Switch(config)# monitor session 1 destination interface gigabitethernet1/0/2
   encapsulation replicate
Switch(config)# end

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

Switch(config)# no monitor session 1 source interface gigabitethernet1/0/1
Switch(config)# end

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

Switch(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source vlan 1 - 3 rx
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2
Switch(config)# monitor session 2 source vlan 10
Switch(config)# end

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with IEEE 802.1Q encapsulation and VLAN 6 as the default ingress VLAN:

Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source gigabitethernet1/0/1 rx
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6
Switch(config)# end

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
Switch(config)# end

Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

Switch(config)# vlan 901
Switch(config-vlan)# remote span
Switch(config-vlan)# end

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

Switch(config)# no monitor session 1
Switch(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Switch(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Switch(config)# monitor session 1 source interface port-channel 2
Switch(config)# monitor session 1 destination remote vlan 901
Switch(config)# end

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
Switch(config)# monitor session 2 destination remote vlan 902
Switch(config)# end

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

Switch(config)# monitor session 1 source remote vlan 901
Switch(config)# monitor session 1 destination interface gigabitethernet2/0/1
Switch(config)# end

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

Switch(config)# monitor session 2 source remote vlan 901
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6
Switch(config)# end

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Wireshark

• Wireshark is supported on Supervisor Engine 7-E, Supervisor Engine 7L-E, Catalyst 3850, Catalyst 3650, Wireless LAN Controller 5700 Series, Catalyst 4500X-16, and Catalyst 4500X-32.

Restrictions for Wireshark

• Starting in Cisco IOS Release XE 3.3.0(SE), global packet capture on Wireshark is not supported.
• Capture filters are not supported.
• The CLI for configuring Wireshark requires that the feature be executed only from EXEC mode. Actions that usually occur in configuration submode (such as defining capture points), are handled at the EXEC
mode instead. All key commands are not NVGEN’d and are not synchronized to the standby supervisor in NSF and SSO scenarios.

- Packets captured in the output direction of an interface might not reflect the changes made by switch rewrite (includes TTL, VLAN tag, CoS, checksum, MAC addresses, DSCP, precedent, UP, etc.).
- Limiting circular file storage by file size is not supported.

**Wireless Packet Capture**

- The only form of wireless capture is a CAPWAP tunnel capture.
- When capturing CAPWAP tunnels, no other interface types can be used as attachment points on the same capture point.
- Capturing multiple CAPWAP tunnels is supported.
- Core filters are not applied and should be omitted when capturing a CAPWAP tunnel.
- To capture a CAPWAP data tunnel, each CAPWAP tunnel is mapped to a physical port and an appropriate ACL will be applied to filter the traffic.
- To capture a CAPWAP non-data tunnel, the switch is set to capture traffic on all ports and apply an appropriate ACL to filter the traffic.

**Configuration Limitations**

- Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.
- Neither VRFs, management ports, nor private VLANs can be used as attachment points.
- Only one ACL of each type (IPv4, IPv6, MAC) is allowed in a Wireshark class map. There can be a maximum of three ACLs in a class map: one for IPv4, one for IPv6, and the other for MAC.
- Wireshark cannot capture packets on a destination SPAN port.
- Wireshark will stop capturing when one of the attachment points (interfaces) attached to a capture point stops working. For example, if the device that is associated with an attachment point is unplugged from the switch. To resume capturing, the capture must be restarted manually.
- CPU-injected packets are considered control plane packets. Therefore, these types of packets will not be captured on an interface egress capture.
- MAC ACL is only used for non-IP packets such as ARP. It will not be supported on a Layer 3 port or SVI.
- IPv6-based ACLs are not supported in VACL.
- Layer 2 and Layer 3 EtherChannels are not supported.
- ACL logging and Wireshark are incompatible. Once Wireshark is activated, it takes priority. All traffic, including that being captured by ACL logging on any ports, will be redirected to Wireshark. We recommended that you deactivate ACL logging before starting Wireshark. Otherwise, Wireshark traffic will be contaminated by ACL logging traffic.
- Wireshark does not capture packets dropped by floodblock.
• If you capture both PACL and RACL on the same port, only one copy is sent to the CPU. If you capture a DTLS-encrypted CAPWAP interface, two copies are sent to Wireshark, one encrypted and the other decrypted. The same behavior will occur if we capture a Layer 2 interface carrying DTLS-encrypted CAPWAP traffic. The core filter is based on the outer CAPWAP header.

Information About Wireshark

Wireshark Overview

Wireshark is a packet analyzer program, formerly known as Ethereal, that supports multiple protocols and presents information in a text-based user interface.

The ability to capture and analyze traffic provides data on network activity. Prior to Cisco IOS Release XE 3.3.0(SE), only two features addressed this need: SPAN and debug platform packet. Both have limitations. SPAN is ideal for capturing packets, but can only deliver them by forwarding them to some specified local or remote destination; it provides no local display or analysis support. The debug platform packet command is specific to the Catalyst 4500 series and only works on packets that come from the software process-forwarding path. Also, the debug platform packet command has limited local display capabilities and no analysis support.

So the need exists for a traffic capture and analysis mechanism that is applicable to both hardware and software forwarded traffic and that provides strong packet capture, display, and analysis support, preferably using a well known interface.

Wireshark dumps packets to a file using a well known format called .pcap, and is applied or enabled on individual interfaces. You specify an interface in EXEC mode along with the filter and other parameters. The Wireshark application is applied only when you enter a start command, and is removed only when Wireshark stops capturing packets either automatically or manually.

Capture Points

A capture point is the central policy definition of the Wireshark feature. The capture point describes all of the characteristics associated with a given instance of Wireshark: which packets to capture, where to capture them from, what to do with the captured packets, and when to stop. Capture points can be modified after creation, and do not become active until explicitly activated with a start command. This process is termed activating the capture point or starting the capture point. Capture points are identified by name and can also be manually or automatically deactivated or stopped.

Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.

Attachment Points

An attachment point is a point in the logical packet process path associated with a capture point. An attachment point is an attribute of the capture point. Packets that impact an attachment point are tested against capture point filters; packets that match are copied and sent to the associated Wireshark instance of the capture point. A specific capture point can be associated with multiple attachment points, with limits on mixing attachment points of different types. Some restrictions apply when you specify attachment points of different types. Attachment points are directional (input or output or both) with the exception of the Layer 2 VLAN attachment point, which is always bidirectional.
Filters

Filters are attributes of a capture point that identify and limit the subset of traffic traveling through the attachment point of a capture point, which is copied and passed to Wireshark. To be displayed by Wireshark, a packet must pass through an attachment point, as well as all of the filters associated with the capture point.

A capture point has the following types of filters:

- Core system filter—The core system filter is applied by hardware, and its match criteria is limited by hardware. This filter determines whether hardware-forwarded traffic is copied to software for Wireshark purposes.
- Display filter—The display filter is applied by Wireshark. Packets that fail the display filter are not displayed.

Core System Filter

You can specify core system filter match criteria by using the class map or ACL, or explicitly by using the CLI.

Note

When specifying CAPWAP as an attachment point, the core system filter is not used.

In some installations, you need to obtain authorization to modify the switch configuration, which can lead to extended delays if the approval process is lengthy. This can limit the ability of network administrators to monitor and analyze traffic. To address this situation, Wireshark supports explicit specification of core system filter match criteria from the EXEC mode CLI. The disadvantage is that the match criteria that you can specify is a limited subset of what class map supports, such as MAC, IP source and destination addresses, ether-type, IP protocol, and TCP/UDP source and destination ports.

If you prefer to use configuration mode, you can define ACLs or have class maps refer capture points to them. Explicit and ACL-based match criteria are used internally to construct class maps and policy maps.

Note The ACL and class map configuration are part of the system and not aspects of the Wireshark feature.

Display Filter

With the display filter, you can direct Wireshark to further narrow the set of packets to display when decoding and displaying from a .pcap file.

Related Topics

Additional References, on page 897

Actions

Wireshark can be invoked on live traffic or on a previously existing .pcap file. When invoked on live traffic, it can perform four types of actions on packets that pass its display filters:

- Captures to buffer in memory to decode and analyze and store
- Stores to a .pcap file
- Decodes and displays
• Stores and displays

When invoked on a .pcap file only, only the decode and display action is applicable.

**Storage of Captured Packets to Buffer in Memory**

Packets can be stored in the capture buffer in memory for subsequent decode, analysis, or storage to a .pcap file.

The capture buffer can be in linear or circular mode. In linear mode, new packets are discarded when the buffer is full. In circular mode, if the buffer is full, the oldest packets are discarded to accommodate the new packets. Although the buffer can also be cleared when needed, this mode is mainly used for debugging network traffic.

---

**Note**

If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

---

**Storage of Captured Packets to a .pcap File**

---

**Note**

When WireShark is used on switches in a stack, packet captures can be stored only on flash or USB flash devices connected to the active switch.

For example, if flash1 is connected to the active switch, and flash2 is connected to the secondary switch, only flash1 can be used to store packet captures.

Attempts to store packet captures on devices other than flash or USB flash devices connected to the active switch will probably result in errors.

---

Wireshark can store captured packets to a .pcap file. The capture file can be located on the following storage devices:

• Switch on-board flash storage (flash:)

• USB drive (usbflash0:)

---

**Note**

Attempts to store packet captures on unsupported devices or devices not connected to the active switch will probably result in errors.

---

When configuring a Wireshark capture point, you can associate a filename. When the capture point is activated, Wireshark creates a file with the specified name and writes packets to it. If the file already exists when the file is associated or the capture point is activated, Wireshark queries you as to whether the file can be overwritten. Only one capture point may be associated with a given filename.

If the destination of the Wireshark writing process is full, Wireshark fails with partial data in the file. You must ensure that there is sufficient space in the file system before you start the capture session. With Cisco IOS Release IOS XE 3.3.0(SE), the file system full status is not detected for some storage devices.
You can reduce the required storage space by retaining only a segment, instead of the entire packet. Typically, you do not require details beyond the first 64 or 128 bytes. The default behavior is to store the entire packet.

To avoid possible packet drops when processing and writing to the file system, Wireshark can optionally use a memory buffer to temporarily hold packets as they arrive. Memory buffer size can be specified when the capture point is associated with a .pcap file.

**Packet Decoding and Display**

Wireshark can decode and display packets to the console. This functionality is possible for capture points applied to live traffic and for capture points applied to a previously existing .pcap file.

---

**Note**

Decoding and displaying packets may be CPU intensive.

Wireshark can decode and display packet details for a wide variety of packet formats. The details are displayed by entering the `monitor capture name start` command with one of the following keyword options, which place you into a display and decode mode:

- `brief`—Displays one line per packet (the default).
- `detailed`—Decodes and displays all the fields of all the packets whose protocols are supported. Detailed modes require more CPU than the other two modes.
- `(hexadecimal) dump`—Displays one line per packet as a hexadecimal dump of the packet data and the printable characters of each packet.

When you enter the `capture` command with the decode and display option, the Wireshark output is returned to Cisco IOS and displayed on the console unchanged.

**Live Traffic Display**

Wireshark receives copies of packets from the core system. Wireshark applies its display filters to discard uninteresting packets, and then decodes and displays the remaining packets.

**.pcap File Display**

Wireshark can decode and display packets from a previously stored .pcap file and direct the display filter to selectively displayed packets.

**Packet Storage and Display**

Functionally, this mode is a combination of the previous two modes. Wireshark stores packets in the specified .pcap file and decodes and displays them to the console. Only the core filters are applicable here.

**Wireshark Capture Point Activation and Deactivation**

After a Wireshark capture point has been defined with its attachment points, filters, actions, and other options, it must be activated. Until the capture point is activated, it does not actually capture packets.
Before a capture point is activated, some functional checks are performed. A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.*

*When performing a wireless capture with a CAPWAP tunneling interface, the core system filter is not required and cannot be used.

The display filters are specified as needed.

After Wireshark capture points are activated, they can be deactivated in multiple ways. A capture point that is storing only packets to a .pcap file can be halted manually or configured with time or packet limits, after which the capture point halts automatically.

When a Wireshark capture point is activated, a fixed rate policer is applied automatically in the hardware so that the CPU is not flooded with Wireshark-directed packets. The disadvantage of the rate policer is that you cannot capture contiguous packets beyond the established rate even if more resources are available.

### Wireshark Features

This section describes how Wireshark features function in the switch environment:

- If port security and Wireshark are applied on an ingress capture, a packet that is dropped by port security will still be captured by Wireshark. If port security is applied on an ingress capture, and Wireshark is applied on an egress capture, a packet that is dropped by port security will not be captured by Wireshark.

- Packets dropped by Dynamic ARP Inspection (DAI) are not captured by Wireshark.

- If a port that is in STP blocked state is used as an attachment point and the core filter is matched, Wireshark will capture the packets that come into the port, even though the packets will be dropped by the switch.

- Classification-based security features—Packets that are dropped by input classification-based security features (such as ACLs and IPSG) are not caught by Wireshark capture points that are connected to attachment points at the same layer. In contrast, packets that are dropped by output classification-based security features are caught by Wireshark capture points that are connected to attachment points at the same layer. The logical model is that the Wireshark attachment point occurs after the security feature lookup on the input side, and symmetrically before the security feature lookup on the output side.

On ingress, a packet goes through a Layer 2 port, a VLAN, and a Layer 3 port/SVI. On egress, the packet goes through a Layer 3 port/SVI, a VLAN, and a Layer 2 port. If the attachment point is before the point where the packet is dropped, Wireshark will capture the packet. Otherwise, Wireshark will not capture the packet. For example, Wireshark capture policies connected to Layer 2 attachment points in the input direction capture packets dropped by Layer 3 classification-based security features. Symmetrically, Wireshark capture policies attached to Layer 3 attachment points in the output direction capture packets dropped by Layer 2 classification-based security features.

- Routed ports and switch virtual interfaces (SVIs)—Wireshark cannot capture the output of an SVI because the packets that go out of an SVI's output are generated by CPU. To capture these packets, include the control plane as an attachment point.

- VLANs—When a VLAN is used as a Wireshark attachment point, packets are captured in the input direction only.
• **Redirection features**—In the input direction, features traffic redirected by Layer 3 (such as PBR and WCCP) are logically later than Layer 3 Wireshark attachment points. Wireshark captures these packets even though they might later be redirected out another Layer 3 interface. Symmetrically, output features redirected by Layer 3 (such as egress WCCP) are logically prior to Layer 3 Wireshark attachment points, and Wireshark will not capture them.

• **SPAN**—Wireshark and SPAN sources are compatible. You can configure an interface as a SPAN source and as a Wireshark attachment point simultaneously. Configuring a SPAN destination port as a Wireshark attachment point is not supported.

• You can capture packets from a maximum of 1000 VLANs at a time, if no ACLs are applied. If ACLs are applied, the hardware will have less space for Wireshark to use. As a result, the maximum number of VLANs than can be used for packet capture at a time will be lower. Using more than 1000 VLANs tunnels at a time or extensive ACLs might have unpredictable results. For example, mobility may go down.

  **Note**  Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

### Wireless Packet Capture in Wireshark

• Wireless traffic is encapsulated inside CAPWAP packets. However, capturing only a particular wireless client's traffic inside a CAPWAP tunnel is not supported when using the CAPWAP tunnel as an attachment point. To capture only a particular wireless client's traffic, use the client VLAN as an attachment point and formulate the core filter accordingly.

• Limited decoding of inner wireless traffic is supported. Decoding of inner wireless packets inside encrypted CAPWAP tunnels is not supported.

• No other interface type can be used with the CAPWAP tunneling interface on the same capture point. A CAPWAP tunneling interface and a Level 2 port cannot be attachment points on the same capture point.

• You cannot specify a core filter when capturing packets for Wireshark via the CAPWAP tunnel. However, you can use the Wireshark display filters for filtering wireless client traffic against a specific wireless client.

• You can capture packets from a maximum of 135 CAPWAP tunnels at a time if no ACLs are applied. If ACLs are applied, the hardware memory will have less space for Wireshark to use. As a result, the maximum number of CAPWAP tunnels than can be used for packet capture at a time will be lower. Using more than 135 CAPWAP tunnels at a time or using extensive ACLs might have unpredictable results. For example, mobility may go down.

  **Note**  Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.
Guidelines for Wireshark

- During Wireshark packet capture, hardware forwarding happens concurrently.

- Before starting a Wireshark capture process, ensure that CPU usage is moderate and that sufficient memory (at least 200 MB) is available.

- If you plan to store packets to a storage file, ensure that sufficient space is available before beginning a Wireshark capture process.

- The CPU usage during Wireshark capture depends on how many packets match the specified conditions and on the intended actions for the matched packets (store, decode and display, or both).

- Where possible, keep the capture to the minimum (limit by packets, duration) to avoid high CPU usage and other undesirable conditions.

- Because packet forwarding typically occurs in hardware, packets are not copied to the CPU for software processing. For Wireshark packet capture, packets are copied and delivered to the CPU, which causes an increase in CPU usage.

To avoid high CPU usage, do the following:

- Attach only relevant ports.

- Use a class map, and secondarily, an access list to express match conditions. If neither is viable, use an explicit, in-line filter.

- Adhere closely to the filter rules. Restrict the traffic type (such as, IPv4 only) with a restrictive, rather than relaxed ACL, which elicits unwanted traffic.

- Always limit packet capture to either a shorter duration or a smaller packet number. The parameters of the capture command enable you to specify the following:
  - Capture duration
  - Number of packets captured
  - File size
  - Packet segment size

- Run a capture session without limits if you know that very little traffic matches the core filter.

- You might experience high CPU (or memory) usage if:
  - You leave a capture session enabled and unattended for a long period of time, resulting in unanticipated bursts of traffic.
  - You launch a capture session with ring files or capture buffer and leave it unattended for a long time, resulting in performance or system health issues.

- During a capture session, watch for high CPU usage and memory consumption due to Wireshark that may impact switch performance or health. If these situations arise, stop the Wireshark session immediately.

- Avoid decoding and displaying packets from a .pcap file for a large file. Instead, transfer the .pcap file to a PC and run Wireshark on the PC.
• You can define up to eight Wireshark instances. An active show command that decodes and displays packets from a .pcap file or capture buffer counts as one instance. However, only one of the instances can be active.

• Whenever an ACL that is associated with a running capture is modified, you must restart the capture for the ACL modifications to take effect. If you do not restart the capture, it will continue to use the original ACL as if it had not been modified.

• To avoid packet loss, consider the following:
  • Use store-only (when you do not specify the display option) while capturing live packets rather than decode and display, which is a CPU-intensive operation (especially in detailed mode).
  • If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.
  • If you use the default buffer size and see that you are losing packets, you can increase the buffer size to avoid losing packets.
  • Writing to flash disk is a CPU-intensive operation, so if the capture rate is insufficient, you may want to use a buffer capture.

• The Wireshark capture session operates normally in streaming mode where packets are both captured and processed. However, when you specify a buffer size of at least 32 MB, the session automatically turns on lock-step mode in which a Wireshark capture session is split into two phases: capture and process. In the capture phase, the packets are stored in the temporary buffer. The duration parameter in lock-step mode serves as capture duration rather than session duration. When the buffer is full or the capture duration or packet limit has been attained, a session transitions to the process phase, wherein it stops accepting packets and starts processing packets in the buffer. You can also stop the capture manually. You will see a message in the output when the capture stops. With this second approach (lock-step mode), a higher capture throughput can be achieved.

  Note If you are capturing packets to a buffer, there is no file storage defined. Hence, you must export your capture from the buffer to a static storage file. Use the monitor capture capture-name export file-location : file-name command.

  • The streaming capture mode supports approximately 1000 pps; lock-step mode supports approximately 2 Mbps (measured with 256-byte packets). When the matching traffic rate exceeds this number, you may experience packet loss.

  • If you want to decode and display live packets in the console window, ensure that the Wireshark session is bounded by a short capture duration.

  Note Warning: A Wireshark session with either a longer duration limit or no capture duration (using a terminal with no auto-more support using the term len 0 command) may make the console or terminal unusable.

  • When using Wireshark to capture live traffic that leads to high CPU, usage, consider applying a QoS policy temporarily to limit the actual traffic until the capture process concludes.

  • All Wireshark-related commands are in EXEC mode; no configuration commands exist for Wireshark.
If you need to use access list or class-map in the Wireshark CLI, you must define an access list and class map with configuration commands.

• No specific order applies when defining a capture point; you can define capture point parameters in any order, provided that CLI allows this. The Wireshark CLI allows as many parameters as possible on a single line. This limits the number of commands required to define a capture point.

• All parameters except attachment points take a single value. Generally, you can replace the value with a new one by reentering the command. After user confirmation, the system accepts the new value and overrides the older one. A no form of the command is unnecessary to provide a new value, but it is necessary to remove a parameter.

• Wireshark allows you to specify one or more attachment points. To add more than one attachment point, reenter the command with the new attachment point. To remove an attachment point, use the no form of the command. You can specify an interface range as an attachment point. For example, enter `monitor capture mycap interface GigabitEthernet1/0/1 in` where interface GigabitEthernet1/0/1 is an attachment point.

If you also need to attach interface GigabitEthernet1/0/2, specify it in another line as follows:

`monitor capture mycap interface GigabitEthernet1/0/2 in`

• You can modify any of the parameters of a capture point while a session is active, but you must restart the session for the modifications to take effect.

• The action you want to perform determines which parameters are mandatory. The Wireshark CLI allows you to specify or modify any parameter prior to entering the start command. When you enter the start command, Wireshark will start only after determining that all mandatory parameters have been provided.

• If the capture file already exists, it provides a warning and receives confirmation before proceeding. This prevents you from mistakenly overwriting a file.

• The core filter can be an explicit filter, access list, or class map. Specifying a newer filter of these types replaces the existing one.

A core filter is required except when using a CAPWAP tunnel interface as a capture point attachment point.

• You can terminate a Wireshark session with an explicit stop command or by entering q in automore mode. The session could terminate itself automatically when a stop condition such as duration or packet capture limit is met.

### Default Wireshark Configuration

The table below shows the default Wireshark configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duration</td>
<td>No limit</td>
</tr>
<tr>
<td>Packets</td>
<td>No limit</td>
</tr>
<tr>
<td>Packet-length</td>
<td>No limit (full packet)</td>
</tr>
</tbody>
</table>
How to Configure Wireshark

To configure Wireshark, perform these basic steps.

1. Define a capture point.
2. (Optional) Add or modify the capture point's parameters.
3. Activate or deactivate a capture point.
4. Delete the capture point when you are no longer using it.

   Activating and Deactivating a Capture Point, on page 880
   Clearing the Capture Point Buffer, on page 881

Defining a Capture Point

The example in this procedure defines a very simple capture point. If you choose, you can define a capture point and all of its parameters with one instance of the `monitor capture` command.

Note

You must define an attachment point, direction of capture, and core filter to have a functional capture point. An exception to needing to define a core filter is when you are defining a wireless capture point using a CAPWAP tunneling interface. In this case, you do not define your core filter. It cannot be used.

In privileged EXEC mode, follow these steps to define a capture point.

SUMMARY STEPS

1. show capwap summary
2. monitor capture {capture-name} {interface interface-type interface-id | control-plane} {in | out | both}
3. monitor capture {capture-name} [match {any | ipv4 any any | ipv6} any any]
4. show monitor capture {capture-name} [parameter]
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
**show capwap summary**<br>**Example:**<br>Switch# show capwap summary | Displays the CAPWAP tunnels available as attachment points for a wireless capture. **Note** Use this command only if you are using a CAPWAP tunnel as an attachment point to perform a wireless capture. See the CAPWAP example in the examples section. |

| **Step 2**  
**monitor capture** `{capture-name}` `{interface interface-type interface-id | control-plane} {in | out | both}`  
**Example:**<br>Switch# monitor capture mycap interface GigabitEthernet1/0/1 in | Defines the capture point, specifies the attachment point with which the capture point is associated, and specifies the direction of the capture. The keywords have these meanings:  
* capture-name—Specifies the name of the capture point to be defined (mycap is used in the example).  
* (Optional) interface interface-type interface-id—Specifies the attachment point with which the capture point is associated (GigabitEthernet1/0/1 is used in the example). **Note** Optionally, you can define multiple attachment points and all of the parameters for this capture point with this one command instance. These parameters are discussed in the instructions for modifying capture point parameters. Range support is also available both for adding and removing attachment points. Use one of the following for interface-type:  
* GigabitEthernet—Specifies the attachment point as GigabitEthernet.  
* vlan—Specifies the attachment point as a VLAN. **Note** Only ingress capture (in) is allowed when using this interface as an attachment point.  
* capwap—Specifies the attachment point as a CAPWAP tunnel. **Note** When using this interface as an attachment point, a core filter cannot be used.  
* (Optional) control-plane—Specifies the control plane as an attachment point. |

---

**Note**

The keywords have these meanings:  
* capture-name—Specifies the name of the capture point to be defined (mycap is used in the example).  
* (Optional) interface interface-type interface-id—Specifies the attachment point with which the capture point is associated (GigabitEthernet1/0/1 is used in the example). **Note** Optionally, you can define multiple attachment points and all of the parameters for this capture point with this one command instance. These parameters are discussed in the instructions for modifying capture point parameters. Range support is also available both for adding and removing attachment points. Use one of the following for interface-type:

* GigabitEthernet—Specifies the attachment point as GigabitEthernet.
* vlan—Specifies the attachment point as a VLAN. **Note** Only ingress capture (in) is allowed when using this interface as an attachment point.
* capwap—Specifies the attachment point as a CAPWAP tunnel. **Note** When using this interface as an attachment point, a core filter cannot be used.
* (Optional) control-plane—Specifies the control plane as an attachment point.
## Defining a Capture Point

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• in</td>
<td>out</td>
</tr>
</tbody>
</table>

**Step 3**

monitor capture {capture-name} [match {any | ipv4 any any | ipv6 any any}]}

**Example:**

Switch# monitor capture mycap interface
GigabitEthernet1/0/1 in match any

Defines the core system filter.

**Note** When using the CAPWAP tunneling interface as an attachment point, do not perform this step because a core filter cannot be used.

The keywords have these meanings:

• **capture-name**—Specifies the name of the capture point to be defined (mycap is used in the example).

• **match**—Specifies a filter. The first filter defined is the core filter.

**Note** A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.

• **ipv4**—Specifies an IP version 4 filter.

• **ipv6**—Specifies an IP version 6 filter.

**Step 4**

show monitor capture {capture-name} [parameter]

**Example:**

Switch# show monitor capture mycap parameter
monitor capture mycap interface
GigabitEthernet1/0/1 in
monitor capture mycap match any

Displays the capture point parameters that you defined in Step 1 and confirms that you defined a capture point.

### Example

To define a capture point with a CAPWAP attachment point:

Switch# show capwap summary

Adding or Modifying Capture Point Parameters

Although listed in sequence, the steps to specify values for the parameters can be executed in any order. You can also specify them in one, two, or several lines. Except for attachment points, which can be multiple, you can replace any value with a more recent value by redefining the same option.

In privileged EXEC mode, follow these steps to modify a capture point's parameters.

Before you begin
A capture point must be defined before you can use these instructions.

SUMMARY STEPS

1. monitor capture  {capture-name}  match  {any | mac  mac-match-string | ipv4  {any | host | protocol}  {any | host} | ipv6  {any | host | protocol}  {any | host}}

2. monitor capture  {capture-name}  limit  { {duration  seconds} {packet-length  size} {packets  num} }
3. `monitor capture {capture-name} file {location filename}`
4. `monitor capture {capture-name} file {buffer-size size}`
5. `show monitor capture {capture-name} [ parameter]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Defines the core system filter (ipv4 any any), defined either explicitly, through ACL or through a class map.</td>
</tr>
<tr>
<td>`monitor capture {capture-name} match {any</td>
<td>mac mac-match-string</td>
</tr>
<tr>
<td>Example: Switch# <code>monitor capture mycap match ipv4 any any</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Specifies the session limit in seconds (60), packets captured, or the packet segment length to be retained by Wireshark (400).</td>
</tr>
<tr>
<td>`monitor capture {capture-name} limit { [duration seconds]</td>
<td>[packet-length size]</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specifies the file association, if the capture point intends to capture packets rather than only display them.</td>
</tr>
<tr>
<td><code>monitor capture {capture-name} file {location filename}</code></td>
<td>Example: Switch# <code>monitor capture mycap file location flash:mycap.pcap</code></td>

<td><code>monitor capture {capture-name} file {buffer-size size}</code></td>
<td>Example: Switch# <code>monitor capture mycap file buffer-size 100</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Displays the capture point parameters that you defined previously.</td>
</tr>
<tr>
<td><code>show monitor capture {capture-name} [ parameter]</code></td>
<td>Example: Switch# <code>show monitor capture mycap parameter</code> <code>monitor capture mycap interface GigabitEthernet1/0/1 in</code> <code>monitor capture mycap match ipv4 any any</code> <code>monitor capture mycap limit duration 60 packet-len 400</code> <code>monitor capture point mycap file location bootdisk:mycap.pcap</code> <code>monitor capture mycap file buffer-size 100</code></td>
</tr>
</tbody>
</table>

**Examples**

**Modifying Parameters**

**Associating or Disassociating a Capture File**
Deleting Capture Point Parameters

Although listed in sequence, the steps to delete parameters can be executed in any order. You can also delete them in one, two, or several lines. Except for attachment points, which can be multiple, you can delete any parameter.

In privileged EXEC mode, follow these steps to delete a capture point's parameters.

### Before you begin

A capture point parameter must be defined before you can use these instructions to delete it.

#### SUMMARY STEPS

1. `no monitor capture {capture-name} match`
   
2. `no monitor capture {capture-name} limit [duration] [packet-length] [packets]`
   
3. `no monitor capture {capture-name} file [location] [buffer-size]`
   
4. `show monitor capture {capture-name} [parameter]`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Deletes all filters defined on capture point (mycap).</td>
</tr>
<tr>
<td><code>no monitor capture {capture-name} match</code></td>
<td>Deletes the session time limit and the packet segment length to be retained by Wireshark. It leaves other specified limits in place.</td>
</tr>
</tbody>
</table>

**Example:**

```
Switch# no monitor capture mycap match
```
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# no monitor capture mycap limit duration packet-len</td>
<td>Deletes the specified capture point (mycap).</td>
</tr>
<tr>
<td>Switch# no monitor capture mycap limit</td>
<td></td>
</tr>
</tbody>
</table>

### Step 3

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>no monitor capture {capture-name} file [location] [buffer-size]</td>
<td>Deletes the file association. The capture point will no longer capture packets. It will only display them. Deletes the file location association. The file location will no longer be associated with the capture point. However, other defined file association will be unaffected by this action.</td>
</tr>
</tbody>
</table>

**Example:**

Switch# no monitor capture mycap file
Switch# no monitor capture mycap file location

### Step 4

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show monitor capture {capture-name} [ parameter]</td>
<td>Displays the capture point parameters that remain defined after your parameter deletion operations. This command can be run at any point in the procedure to see what parameters are associated with a capture point.</td>
</tr>
</tbody>
</table>

**Example:**

Switch# show monitor capture mycap parameter
monitor capture mycap interface
GigabitEthernet1/0/1 in

---

### What to do next

If your capture point contains all of the parameters you want, activate it.

Activating and Deactivating a Capture Point

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show monitor capture mycap parameter</td>
<td>Capture mycap does not exist</td>
</tr>
</tbody>
</table>

What to do next

You can define a new capture point with the same name as the one you deleted. These instructions are usually performed when one wants to start over with defining a capture point.

Related Topics

- How to Configure Wireshark, on page 872
- Defining a Capture Point, on page 872
- Adding or Modifying Capture Point Parameters, on page 876

Activating and Deactivating a Capture Point

In privileged EXEC mode, follow these steps to activate or deactivate a capture point.

Before you begin

A capture point cannot be activated unless an attachment point and a core system filter have been defined and the associated filename (if any) does not already exist. A capture point with no associated filename can only be activated to display. If no capture or display filters are specified, all of the packets captured by the core system filter are displayed. The default display mode is brief.

Note

When using a CAPWAP tunneling interface as an attachment point, core filters are not used, so there is no requirement to define them in this case.

SUMMARY STEPS

1. `monitor capture {capture-name} start [display [display-filter filter-string]] [brief | detailed | dump]
2. `monitor capture {capture-name} stop

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>`monitor capture {capture-name} start [display [display-filter filter-string]] [brief</td>
</tr>
<tr>
<td>Example:</td>
<td>`Switch# monitor capture mycap start display display-filter &quot;stp&quot;</td>
</tr>
<tr>
<td>Step 2</td>
<td>`monitor capture {capture-name} stop</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
Clearing the Capture Point Buffer

In privileged EXEC mode, follow these steps to clear the buffer contents or save them to an external file for storage.

**Note**

If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

**SUMMARY STEPS**

1. `monitor capture {capture-name} [clear | export filename]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`monitor capture {capture-name} [clear</td>
<td>export filename]`</td>
</tr>
</tbody>
</table>

Example: Displaying a Hexadecimal Dump Output from a .pcap File
You can display the hexadecimal dump output by entering:
Switch# show monitor capture file bootflash:mycap.pcap dump

Frame 2: 256 bytes on wire (2048 bits), 256 bytes captured (2048 bits)

Example: Displaying Detailed Output from a .pcap File
Consolidated Platform Configuration Guide, Cisco IOS XE 3.3SE (Catalyst 3650 Switches)

Example: Displaying Packets from a .pcap File
You can display the .pcap file packets output by entering:
Switch# show monitor capture file bootflash:mycap.pcap display-filter "ip.src == 10.1.1.140"
dump
Example: Simple Capture and Display

This example shows how to monitor traffic in the Layer 3 interface Gigabit Ethernet 1/0/1:

**Step 1:** Define a capture point to match the relevant traffic by entering:

```yaml
Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap buffer size 100
```

To avoid high CPU utilization, a low packet count and duration as limits has been set.

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```yaml
Switch# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet1/0/1 in
monitor capture mycap match ipv4 any any
monitor capture mycap buffer size 100
monitor capture mycap limit packets 100 duration 60
```

```yaml
Switch# show monitor capture mycap
```

**Step 3:** Start the capture process and display the results.

```yaml
Switch# monitor capture mycap start display
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```
### Example: Simple Capture and Store

This example shows how to capture packets to a filter:

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap file location flash:mycap.pcap
```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```
Switch# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 in
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location flash:mycap.pcap
  monitor capture mycap limit packets 100 duration 60
```

**Step 3:** Launch packet capture by entering:

```
Switch# monitor capture mycap start
```

**Step 4:** After sufficient time has passed, stop the capture by entering:

```
Switch# monitor capture mycap stop
```
Alternatively, you could allow the capture operation to stop automatically after the time has elapsed or the packet count has been met.

The mycap.pcap file now contains the captured packets.

**Step 5:** Display the packets by entering:

```
Switch# show monitor capture file flash:mycap.pcap
```

```
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

**Step 6:** Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

---

**Example: Using Buffer Capture**

This example shows how to use buffer capture:

**Step 1:** Launch a capture session with the buffer capture option by entering:

```
Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap buffer circular size 1
Switch# monitor capture mycap start
```

**Step 2:** Determine whether the capture is active by entering:

```
Switch# show monitor capture mycap
```

Status Information for Capture mycap

Target Type:
- Interface: GigabitEthernet1/0/1, Direction: in
- Status: Active

Filter Details:
- IPv4
- Source IP: any
- Destination IP: any
- Protocol: any

Buffer Details:
- Buffer Type: CIRCULAR
- Buffer Size (in MB): 1

File Details:
- File not associated

Limit Details:
- Number of Packets to capture: 0 (no limit)
- Packet Capture duration: 0 (no limit)
- Packet Size to capture: 0 (no limit)
Step 3: Display the packets in the buffer by entering:

Switch# show monitor capture mycap buffer brief

0.000000 10.1.1.215 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.216 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.217 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.218 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.219 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.220 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.221 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.222 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.223 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.224 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
10.000000 10.1.1.225 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
11.000000 10.1.1.226 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
12.000000 10.1.1.227 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
13.000000 10.1.1.228 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
14.000000 10.1.1.229 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
15.000000 10.1.1.230 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
16.000000 10.1.1.231 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
17.000000 10.1.1.232 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
18.000000 10.1.1.233 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
19.000000 10.1.1.234 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
20.000000 10.1.1.235 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
21.000000 10.1.1.236 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

Notice that the packets have been buffered.

Step 4: Display the packets in other display modes.

Switch# show monitor capture mycap buffer detailed

Frame 1: 256 bytes on wire (2048 bits), 256 bytes captured (2048 bits)
Arrival Time: Apr 15, 2012 15:50:02.398966000 PDT
Epoch Time: 1334530202.398966000 seconds
[Time delta from previous captured frame: 0.000000000 seconds]
[Time delta from previous displayed frame: 0.000000000 seconds]
[Time since reference or first frame: 0.000000000 seconds]
Frame Number: 1
Frame Length: 256 bytes (2048 bits)
Capture Length: 256 bytes (2048 bits)
[Frame is marked: False]
[Frame is ignored: False]
Ethernet II, Src: 00:00:00:00:03:01 (00:00:00:00:03:01), Dst: 54:75:d0:3a:85:3f (54:75:d0:3a:85:3f)
Destination: 54:75:d0:3a:85:3f (54:75:d0:3a:85:3f)
Source: 00:00:00:00:03:01 (00:00:00:00:03:01)

Switch# show monitor capture mycap buffer dump

0.000000 10.1.1.215 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
0000 54 75 d0 3a 85 3f 00 00 00 00 03 01 08 00 45 00 Tu.:........E.
0010 00 ee 00 00 00 00 40 11 59 25 0a 01 01 d7 14 01 .........@.Y.....
Step 5a: Clear the buffer by entering:

Switch# monitor capture mycap clear

Step 5b: Wait for 10 seconds.

Step 5c: Stop the traffic by entering:

Switch# monitor capture mycap stop

Step 6: Confirm that the same set of packets are displayed after this time gap by entering:

Switch# show monitor capture mycap buffer brief

Step 7: Wait for 10 seconds, then confirm that the same set of packets are displayed after this time gap by entering:

Switch# show monitor capture mycap buffer brief

Step 8: Repeat Step 7.

Step 9: Clear the buffer by entering:

Switch# monitor capture mycap clear

Step 10: Confirm that the buffer is now empty by entering:
Switch# show monitor capture mycap buffer brief

Step 11: Wait about 10 seconds, then display the buffer contents by entering:
Switch# show monitor capture mycap buffer brief

Step 12: Restart the traffic, wait for 10 seconds, then display the buffer contents by entering:
Switch# monitor capture mycap start
wait for 10 seconds...
Switch# show monitor capture mycap buffer brief

Step 13: Store the buffer contents to the mycap1.pcap file in the internal flash: storage device by entering:
Switch# monitor capture mycap export flash:/mycap1.pcap
Exported Successfully

Step 14: Check that the file has been created and that it contains the packets by entering:
Switch# dir flash:/mycap1.pcap
Directory of flash:/mycap1.pcap
14758 -rw- 20152 Apr 15 2012 16:00:28 -07:00 mycap1.pcap
83154284 bytes total (831340544 bytes free)
Switch# show monitor capture file flash:/mycap1.pcap brief
 1 0.000000 10.1.1.2 -> 20.1.1.2  UDP Source port: 20001  Destination port: 20002

Capture test is not active Failed to Initiate Wireshark
Switch# show monitor capture mycap parameter
  monitor capture mycap control-plane both
  monitor capture mycap match any
  monitor capture mycap file location flash:mycap1.1 buffer-size 90
  monitor capture mycap limit duration 10

Switch# monitor capture mycap start display display-filter "udp.port == 20002"
A file by the same capture file name already exists, overwrite?[confirm] [ENTER]
after a minute or so...
Capture mycap is not active Failed to Initiate Wireshark
Example: Capture and Store in Lock-step Mode

This example captures live traffic and stores the packets in lock-step mode.

---

**Note**

The capture rate might be slow for the first 15 seconds. If possible and necessary, start the traffic 15 seconds after the capture session starts.

---

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```plaintext
Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap file location flash:mycap.pcap buffer-size 64
```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```plaintext
Switch# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 in
  monitor capture mycap file location flash:mycap.pcap buffer-size 64
  monitor capture mycap limit packets 100 duration 60
```

**Switch# show monitor capture mycap**

Status Information for Capture mycap

Target Type:
- Interface: GigabitEthernet1/0/1, Direction: in

Status: Inactive

Filter Details:
- Filter not attached

Buffer Details:
- Buffer Type: LINEAR (default)

File Details:
- Associated file name: flash:mycap.pcap
- Size of buffer(in MB): 64
Limit Details:
Number of Packets to capture: 100
Packet Capture duration: 60
Packet Size to capture: 0 (no limit)
Packets per second: 0 (no limit)
Packet sampling rate: 0 (no sampling)

Step 3: Launch packet capture by entering:

Switch# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode

Step 4: Display the packets by entering:

Switch# show monitor capture file flash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

Step 5: Delete the capture point by entering:

Switch# no monitor capture mycap

Example: Simple Capture and Store of Packets in Egress Direction

This example shows how to capture packets to a filter:

Step 1: Define a capture point to match on the relevant traffic and associate it to a file by entering:

Switch# monitor capture mycap interface Gigabit 1/0/1 out match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap file location flash:mycap.pcap buffer-size 90

Step 2: Confirm that the capture point has been correctly defined by entering:

Switch# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 out
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location flash:mycap.pcap buffer-size 90
  monitor capture mycap limit packets 100 duration 60

Switch# show monitor capture mycap

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: out
Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
Protocol: any
Buffer Details:
   Buffer Type: LINEAR (default)
File Details:
   Associated file name: flash:mycap.pcap
   Size of buffer (in MB): 90
Limit Details:
   Number of Packets to capture: 100
   Packet Capture duration: 60
   Packet Size to capture: 0 (no limit)
   Packets per second: 0 (no limit)
   Packet sampling rate: 0 (no sampling)

Step 3: Launch packet capture by entering:

Switch# monitor capture mycap start
A file by the same capture file name already exists, overwrite? [confirm]
Turning on lock-step mode

Switch#

*Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.

---

Note

Allow the capture operation stop automatically after the time has elapsed or the packet count has been met. When you see the following message in the output, will know that the capture operation has stopped:

*Oct 14 09:36:34.632: %BUFCAP-6-DISABLE_ASYNC: Capture Point mycap disabled. Reason: Wireshark Session Ended

The mycap.pcap file now contains the captured packets.

Step 4: Display the packets by entering:

Switch# show monitor capture file flash:mycap.pcap

0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002

Step 5: Delete the capture point by entering:

Switch# no monitor capture mycap

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for QoS

Before configuring standard QoS, you must have a thorough understanding of these items:

- Standard QoS concepts.
- Wireless concepts and network topologies.
- Classic Cisco IOS QoS.
- Modular QoS CLI (MQC).
- Understanding of QoS implementation.
• The types of applications used and the traffic patterns on your network.

• Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?

• Bandwidth requirements and speed of the network.

• Location of congestion points in the network.

**Related Topics**

**QoS Components**

QoS consists of the following key components:

• Classification—Classification is the process of distinguishing one type of traffic from another based upon ACLs, Differentiated Services Code Point (DSCP), Class of Service (CoS), and other factors.

• Marking and mutation—Marking is used on traffic to convey specific information to a downstream device in the network, or to carry information from one interface in a switch to another. When traffic is marked, QoS operations on that traffic can be applied. This can be accomplished directly using the `set` command or through a table map, which takes input values and translates them directly to values on output.

• Shaping and policing—Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that downstream devices are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface. Policing is used to impose a maximum rate on a traffic class. If the rate is exceeded, then a specific action is taken as soon as the event occurs.

• Queuing—Queueing is used to prevent traffic congestion. Traffic is sent to specific queues for servicing and scheduling based upon bandwidth allocation. Traffic is then scheduled or sent out through the port.

• Bandwidth—Bandwidth allocation determines the available capacity for traffic that is subject to QoS policies.

• Trust—Trust enables traffic to pass through the switch, and the DSCP, precedence, or CoS values coming in from the end points are retained in the absence of any explicit policy configuration.

**QoS Terminology**

The following terms are used interchangeably in this QoS configuration guide:

• Upstream (direction towards the switch) is the same as ingress.

• Downstream (direction from the switch) is the same as egress.
Information About QoS

QoS Overview

By configuring the quality of service (QoS), you can provide preferential treatment to specific types of traffic at the expense of other traffic types. Without QoS, the switch offers best-effort service to each packet, regardless of the packet contents or size. The switch sends the packets without any assurance of reliability, delay bounds, or throughput.

The following are specific features provided by QoS:

- Low latency
- Bandwidth guarantee
- Buffering capabilities and dropping disciplines
- Traffic policing
- Enables the changing of the attribute of the frame or packet header
- Relative services

Related Topics

Restrictions for QoS on Wired Targets, on page 936

Modular QoS Command-Line Interface

With the switch, QoS features are enabled through the Modular QoS command-line interface (MQC). The MQC is a command-line interface (CLI) structure that allows you to create traffic policies and attach these policies to interfaces. A traffic policy contains a traffic class and one or more QoS features. A traffic class is used to classify traffic, while the QoS features in the traffic policy determine how to treat the classified traffic. One of the main goals of MQC is to provide a platform-independent interface for configuring QoS across Cisco platforms.

Wireless QoS Overview

Wireless QoS can be configured on the following wireless targets:

- Wireless ports, including all physical ports to which an access point can be associated.
- Radio
- SSID (applicable on a per-radio, per-AP, and per-SSID)
- Client

Note

Upstream is wireless to wired. Downstream is wired to wireless. Wireless to wireless has no specific term.
The following table displays how policies are supported for the wireless targets.

**Table 76: Wireless Targets Policies Support**

<table>
<thead>
<tr>
<th>Wireless Target</th>
<th>Policies on Wireless Targets Supported</th>
<th>Policies Supported Downstream Direction</th>
<th>Policies Supported Upstream Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wireless port</td>

<td>Yes</td>
<td>Yes - user configurable</td>
<td>Yes - user configurable</td>
</tr>
<tr>
<td>Client</td>
<td>Yes</td>
<td>Yes - user configurable</td>
<td>Yes - user configurable</td>
</tr>
</tbody>
</table>

Additional policies that are user configured include multi-destination policers and VLANs.

Wireless QoS supports the following additional features:

- Queuing support
- Policing of wireless traffic
- Shaping of wireless traffic
- Rate limiting in both downstream and upstream direction
- Approximate Fair Drop (AFD)
- Mobility support for QoS
- Compatibility with precious metal QoS policies available on Cisco Unified Wireless Controllers.

**QoS and IPv6 for Wireless**

From this release onwards, the switch supports QoS for both IPv4 and IPv6 traffic, and client policies can now have IPv4 and IPv6 filters.
The following table describes the supported features for both wired and wireless access.

Port Policies

The switch supports port-based policies. The port policies includes port shaper and a child policy (port_child_policy).

Note

Port child policies only apply to wireless ports and not to wired ports on the switch. A wireless port is defined as a port to which APs join. A default port child policy is applied on the switch to the wireless ports at start up. The port shaper rate is limited to 1G.

Port shaper specifies the traffic policy applicable between the device and the AP. This is the sum of the radio rates supported on the access point.

The child policy determines the mapping between packets and queues defined by the port-child policy. The child policy can be configured to include voice, video, class-default, and non-client-nrt classes where voice and video are based on DSCP value (which is the outer CAPWAP header DSCP value). The definition of class-default is known to the system as any value other than voice and video DSCP.

The DSCP value is assigned when the packet reaches the port. Before the packet arrives at the port, the SSID policies are applied on the packet. Port child policy also includes multicast percentage for a given port traffic. By default, the port child policy allocates up to 10 percent of the available rate.

Port Policy Format

This section describes the behavior of the port policies on a switch. The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suit the QoS configuration. The switch is pre configured with a default class map and a policy map.

Default class map:
Class Map match-any non-client-nrt-class
    Match non-client-nrt

The above port policy processes all network traffic to the Q3 queue. You can view the class map by executing the `show class-map` command.

Default policy map:

Policy Map port_child_policy
    Class non-client-nrt-class
    bandwidth remaining ratio 10

---

**Note**

The class map and policy map listed are system-defined policies and cannot be changed.

The following is the system-defined policy map available on the ports on which wireless devices are associated. The format consists of a parent policy and a service child policy (`port_child_policy`). To customize the policies to suit your network needs, you must configure the port child policy.

Policy-map policy_map_name
    Class class-default
        Shape average average_rate
        Service-policy port_child_policy

---

**Note**

The parent policy is system generated and cannot be changed. You must configure the `port_child_policy` policy to suit the QoS requirements on your network.

Depending on the type of traffic in your network, you can configure the port child policy. For example, in a typical wireless network deployment, you can assign specific priorities to voice and video traffic. Here is an example:

Policy-map port_child_policy
    Class voice-policy-name (match dscp ef)
        Priority level 1
            Police (multicast-policer-name-voice) Multicast Policer
    Class video-policy-name (match dscp af41)
        Priority level 2
            Police (multicast-policer-name-video) Multicast Policer
    Class non-client-nrt-class traffic(match non-client-nrt)
        Bandwidth remaining ratio (brr-value-nrt-q2)
    Class class-default (NRT Data)
        Bandwidth remaining ratio (brr-value-q3)

In the above port child policy:

- **voice-policy-name**—Refers to the name of the class that specifies rules for the traffic for voice packets. Here the DSCP value is mapped to a value of 46 (represented by the keyword `ef`). The voice traffic is assigned the highest priority of 1.

- **video-policy-name**—Refers to the name of the class that specifies rules for the traffic for video packets. The DSCP value is mapped to a value of 34 (represented by the keyword `af41`).
• **multicast-policer-name-voice**— If you need to configure multicast voice traffic, you can configure policing for the voice class map.

• **multicast-policer-name-video**— If you need to configure multicast video traffic, you can configure policing for the video class map.

In the above sample configuration, all voice and video traffic is directed to the Q0 and Q1 queues, respectively. These queues maintain a strict priority. The packets in Q0 and Q1 are processed in that order. The bandwidth remaining ratios \( brr-value-nrt-q2 \) and \( brr-value-q3 \) are directed to the Q2 and Q3 respectively specified by the class maps and **class-default** and **non-client-nrt**. The processing of packets on Q2 and Q3 are based on a weighted round-robin approach. For example, if the \( brr-value-nrtq2 \) has a value of 90 and \( brr-value-nrtq3 \) is 10, the packets in queue 2 and queue 3 are processed in the ratio of 9:1.

### Radio Policies

The radio policies are system defined and are not user configurable. Radio wireless targets are only applicable in the downstream direction.

Radio policies are applicable on a per-radio, per-access point basis. The rate limit on the radios is the practical limit of the AP radio rate. This value is equivalent to the sum of the radios supported by the access point.

The following radios are supported:

• 802.11 a/n
• 802.11 b/n
• 802.11 a/c

**Related Topics**

- Restrictions for QoS on Wireless Targets, on page 939
- Supported QoS Features on Wireless Targets, on page 906

### SSID Policies

You can create QoS policies on SSID BSSID (Basic Service Set Identification) in both the upstream and downstream directions. By default, there is no SSID policy. You can configure an SSID policy based on the SSID name. The policy is applicable on a per BSSID.

The types of policies you can create on SSID include marking by using table maps (table-maps), shape rate, and RT1 (Real Time 1) and RT2 (Real Time 2) policers. If traffic is upstream, you usually configure a marking policy on the SSID. If traffic is downstream, you can configure marking and queuing.

There should be a one-to-one mapping between the policies configured on a port and an SSID. For example, if you configure class voice and class video on the port, you can have a similar policy on the SSID.
SSID priorities can be specified by configuring bandwidth remaining ratio. Queuing SSID policies are applied in the downstream direction.

## Client Policies

Client policies are applicable in the upstream and downstream direction. The wireless control module of the switch applies the default client policies when admission control is enabled for WMM clients. When admission control is disabled, there is no default client policy. You can configure policing and marking policies on clients.

**Note**
A client policy can have both IPv4 and IPv6 filters.

You can configure client policies in the following ways:

- **Using AAA**—You can use a combination of AAA and TCLAS, and AAA and SIP snooping when configuring with AAA.
- **Using the Cisco IOS MQC CLI**—You can use a combination of CLI and TCLAS and CLI and SIP snooping.
- **Using the default configuration**

**Note**
When applying client policies on a WLAN, you must disable the WLAN before modifying the client policy. SSID policies can be modified even if the WLAN is enabled.

**Note**
If you configured AAA by configuring the unified wireless controller procedure, and using the MQC QoS commands, the policy configuration performed through the MQC QoS commands takes precedence.

For client policies, the following filters are supported:

- ACL
- DSCP
- COS
- WLAN UP

---

**Consolidated Platform Configuration Guide, Cisco IOS XE 3.3SE (Catalyst 3650 Switches)**
Hierarchical QoS

The switch supports hierarchical QoS (HQoS). HQoS allows you to perform:

• Hierarchical classification—Traffic classification is based upon other classes.
• Hierarchical policing—The process of having the policing configuration at multiple levels in a hierarchical policy.
• Hierarchical shaping—Shaping can also be configured at multiple levels in the hierarchy.

Note
Hierarchical shaping is only supported for the port shaper, where for the parent you only have a configuration for the class default, and the only action for the class default is shaping.

Hierarchical Wireless QoS

The switch supports hierarchical QoS for wireless targets. Hierarchical QoS policies are applicable on port, radio, SSID, and client. QoS policies configured on the device (including marking, shaping, policing) can be applied across the targets. If the network contains non-realtime traffic, the non-realtime traffic is subject to approximate fair drop. Hierarchy refers to the process of application of the various QoS policies on the packets arriving to the device.

Figure 59: Hierarchical QoS

This figure shows the various targets available on a wireless network, as well as a hierarchal wireless configuration. Wireless QoS is applied per-radio constraint, per-WLAN, and per-client constraint.
Wireless Packet Format

Figure 60: Wireless Packet Path in the Egress Direction during First Pass

This figure displays the wireless packet flow and encapsulation used in hierarchical wireless QoS. The incoming packet enters the switch. The switch encapsulates this incoming packet and adds the 802.11e and CAPWAP headers.

Hierarchical AFD

Approximate Fair Dropping (AFD) is a feature provided by the QoS infrastructure in Cisco IOS. For wireless targets, AFD can be configured on SSID (via shaping) and clients (via policing). AFD shaping rate is only applicable for downstream direction. Unicast real-time traffic is not subjected to AFD drops.

QoS Implementation

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide
preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (class) information. Classification can also be carried in the Layer 2 frame.

*Figure 61: QoS Classification Layers in Frames and Packets*

The special bits in the Layer 2 frame or a Layer 3 packet are shown in the following:

**Encapsulated Packet**

```
Layer 2 header | IP header | Data
```

**Layer 2 ISL Frame**

```
ISL header (26 bytes) | Encapsulated frame 1... (24.3 KB) | FCS (4 bytes)
```

3 bits used for CoS

**Layer 2 802.1Q and 802.1p Frame**

```
Preamble | Start frame delimiter | DA | SA | Tag | PT | Data | FCS
```

3 bits used for CoS (user priority)

**Layer 3 IPv4 Packet**

```
Version length | ToS (1 byte) | Len | ID | Offset | TTL | Proto | FCS | IP-SA | IP-DA | Data
```

IP precedence or DSCP

**Layer 3 IPv6 Packet**

```
Version | Traffic class (1 byte) | Flow label | Payload length | Next header | HOP limit | Source address | Dest. address
```

IP precedence or DSCP

**Layer 2 Frame Prioritization Bits**

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.
Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.

End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

Packet Classification

Packet classification is the process of identifying a packet as belonging to one of several classes in a defined policy, based on certain criteria. The Modular QoS CLI (MQC) is a policy-class based language. The policy class language is used to define the following:

- Class-map template with one or several match criteria
- Policy-map template with one or several classes associated to the policy map

The policy map template is then associated to one or several interfaces on the switch.

Packet classification is the process of identifying a packet as belonging to one of the classes defined in the policy map. The process of classification will exit when the packet being processed matches a specific filter in a class. This is referred to as first-match exit. If a packet matches multiple classes in a policy, irrespective of the order of classes in the policy map, it would still exit the classification process after matching the first class.

If a packet does not match any of the classes in the policy, it would be classified into the default class in the policy. Every policy map has a default class, which is a system-defined class to match packets that do not match any of the user-defined classes.

Packet classification can be categorized into the following types:
• Classification based on information that is propagated with the packet
• Classification based on information that is switch specific
• Hierarchical classification

**Classification Based on Information That is Propagated with the Packet**

Classification that is based on information that is part of the packet and propagated either end-to-end or between hops, typically includes the following:

• Classification based on Layer 3 or 4 headers
• Classification based on Layer 2 information

**Classification Based on Layer 3 or Layer 4 Header**

This is the most common deployment scenario. Numerous fields in the Layer 3 and Layer 4 headers can be used for packet classification.

At the most granular level, this classification methodology can be used to match an entire flow. For this deployment type, an access control list (ACLs) can be used. ACLs can also be used to match based on various subsets of the flow (for example, source IP address only, or destination IP address only, or a combination of both).

Classification can also be done based on the precedence or DSCP values in the IP header. The IP precedence field is used to indicate the relative priority with which a particular packet needs to be handled. It is made up of three bits in the IP header's type of service (ToS) byte.

The following table shows the different IP precedence bit values and their names.

**Note**  
IP precedence is not supported for wireless QoS.

*Table 79: IP Precedence Values and Names*

<table>
<thead>
<tr>
<th>IP Precedence Value</th>
<th>IP Precedence Bits</th>
<th>IP Precedence Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>000</td>

<td>110</td>
<td>Internetwork control</td>
</tr>
<tr>
<td>7</td>
<td>111</td>
<td>Network control</td>
</tr>
</tbody>
</table>
All routing control traffic in the network uses IP precedence value 6 by default. IP precedence value 7 also is reserved for network control traffic. Therefore, the use of IP precedence values 6 and 7 is not recommended for user traffic.

The DSCP field is made up of 6 bits in the IP header and is being standardized by the Internet Engineering Task Force (IETF) Differentiated Services Working Group. The original ToS byte contained the DSCP bits has been renamed the DSCP byte. The DSCP field is part of the IP header, similar to IP precedence. The DSCP field is a super set of the IP precedence field. Therefore, the DSCP field is used and is set in ways similar to what was described with respect to IP precedence.

The DSCP field definition is backward-compatible with the IP precedence values.

Classification Based on Layer 2 Header

A variety of methods can be used to perform classification based on the Layer 2 header information. The most common methods include the following:

- MAC address-based classification (only for access groups)—Classification is based upon the source MAC address (for policies in the input direction) and destination MAC address (for policies in the output direction).
- Class-of-Service—Classification is based on the 3 bits in the Layer 2 header based on the IEEE 802.1p standard. This usually maps to the ToS byte in the IP header.
- VLAN ID—Classification is based on the VLAN ID of the packet.

Some of these fields in the Layer 2 header can also be set using a policy.

Classification Based on Information that is Device Specific (QoS Groups)

The switch also provides classification mechanisms that are available where classification is not based on information in the packet header or payload.

At times you might be required to aggregate traffic coming from multiple input interfaces into a specific class in the output interface. For example, multiple customer edge routers might be going into the same access switch on different interfaces. The service provider might want to police all the aggregate voice traffic going into the core to a specific rate. However, the voice traffic coming in from the different customers could have a different ToS settings. QoS group-based classification is a feature that is useful in these scenarios.

Policies configured on the input interfaces set the QoS group to a specific value, which can then be used to classify packets in the policy enabled on output interface.

The QoS group is a field in the packet data structure internal to the switch. It is important to note that a QoS group is an internal label to the switch and is not part of the packet header.
Hierarchical Classification

The switch permits you to perform a classification based on other classes. Typically, this action may be required when there is a need to combine the classification mechanisms (that is, filters) from two or more classes into a single class map.

QoS Wired Model

To implement QoS, the switch must perform the following tasks:

- Traffic classification—Distinguishes packets or flows from one another.
- Traffic marking and policing—Assigns a label to indicate the given quality of service as the packets move through the switch, and then make the packets comply with the configured resource usage limits.
- Queuing and scheduling—Provides different treatment in all situations where resource contention exists.
- Shaping—Ensures that traffic sent from the switch meets a specific traffic profile.

Ingress Port Activity

The following activities occur at the ingress port of the switch:

- Classification—Classifying a distinct path for a packet by associating it with a QoS label. For example, the switch maps the CoS or DSCP in the packet to a QoS label to distinguish one type of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.
- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).

Note

Applying polices on the wireless ingress port is not supported on the switch.

Egress Port Activity

The following activities occur at the egress port of the switch:

- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).
- Queueing—Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, Weighted Tail Drop (WTD) differentiates traffic classes and
subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.

Classification

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is enabled on the switch. By default, QoS is enabled on the switch.

During classification, the switch performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.

Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:

- If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.
- If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.
- If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the switch offers best-effort service to the packet.
- If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

Note

When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP or rate-limit the class). This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the access-list global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the mac access-list extended global configuration command.

Class Maps

A class map is a mechanism that you use to name a specific traffic flow (or class) and isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create
another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

You create a class map by using the `class-map` global configuration command or the `class` policy-map configuration command. You should use the `class-map` command when the map is shared among many ports. When you enter the `class-map` command, the switch enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the `match` class-map configuration command.

You can create a default class by using the `class class-default` policy-map configuration command. The default class is system-defined and cannot be configured. Unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as default traffic.

Related Topics
- Creating a Traffic Class (CLI), on page 942
- Examples: Classification by Access Control Lists, on page 996

Policy Maps

A policy map specifies which traffic class to act on. Actions can include the following:

- Setting a specific DSCP or IP precedence value in the traffic class
- Setting a CoS value in the traffic class
- Setting a QoS group
- Setting a wireless LAN (WLAN) value in the traffic class
- Specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile

Before a policy map can be effective, you must attach it to a port.

You create and name a policy map using the `policy-map` global configuration command. When you enter this command, the switch enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the `class` or `set` policy-map configuration and policy-map class configuration commands.

The policy map can also be configured using the `police` and `bandwidth` policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded. In addition, the policy-map can further be configured using the `priority` policy-map class configuration command, to schedule priority for the class or the queueing policy-map class configuration commands, `queue-buffers` and `queue-limit`.

To enable the policy map, you attach it to a port by using the `service-policy` interface configuration command.

- Creating a Traffic Policy (CLI), on page 944
- Port Policy Format, on page 907

Policy Map on Physical Port

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions can include setting a specific DSCP or IP precedence value in the traffic class, specifying the traffic bandwidth limitations for each matched traffic class (policer), and taking action when the traffic is out of profile (marking).

A policy map also has these characteristics:
• A policy map can contain multiple class statements, each with different match criteria and polices.

• A policy map can contain a predefined default traffic class explicitly placed at the end of the map.

  When you configure a default traffic class by using the `class class-default` policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (`class-default`).

• A separate policy-map class can exist for each type of traffic received through a port.

Related Topics
  Attaching a Traffic Policy to an Interface (CLI), on page 956

Policy Map on VLANs

The switch supports a VLAN QoS feature that allows the user to perform QoS treatment at the VLAN level (classification and QoS actions) using the incoming frame’s VLAN information. In VLAN-based QoS, a service policy is applied to an SVI interface. All physical interfaces belonging to a VLAN policy map then need to be programmed to refer to the VLAN-based policy maps instead of the port-based policy map.

Although the policy map is applied to the VLAN SVI, any policing (rate-limiting) action can only be performed on a per-port basis. You cannot configure the policer to take account of the sum of traffic from a number of physical ports. Each port needs to have a separate policer governing the traffic coming into that port.

Related Topics
  Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps (CLI), on page 964
  Examples: Policer VLAN Configuration, on page 1006

Wireless QoS Rate Limiting

QoS per Client Rate Limit—Wireless

QoS policies can be configured to rate-limit client traffic using policers. This includes both real-time and non-real-time traffic. The non-real-time traffic is policed using AFD policers. These policers can only be one rate two color.

Note

For client policy, the voice and video rate limits are applied at the same time.

QoS Downstream Rate Limit—Wireless

Downstream rate limiting is done using policing at the SSID level. AFD cannot drop real-time traffic, it can only be policed in the traffic queues. Real-time policing and AFD shaping is performed at the SSID level.

The radio has a default shaping policy. This shaping limit is the physical limit of the radio itself. You can check the policy maps on the radio by using the `show policy-map interface wireless radio` command.

Wireless QoS Multicast

You can configure multicast policing rate at the port level.

Related Topics
  Configuring QoS Policies for Multicast Traffic (CLI), on page 992
  Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic, on page 1000
After a packet is classified and has a DSCP-based, CoS-based, or QoS-group label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are out of profile or nonconforming. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP or CoS value of the packet and allowing the packet to pass through.

To avoid out-of-order packets, both conform and nonconforming traffic typically exit the same queue.

**Note**

All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can only configure policing on a physical port.

After you configure the policy map and policing actions, attach the policy to an ingress port or SVI by using the `service-policy` interface configuration command.

**Related Topics**

- Configuring Police (CLI), on page 979
- Examples: Policing Action Configuration, on page 1006

**Token-Bucket Algorithm**

Policing uses a token-bucket algorithm. As each frame is received by the switch, a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the switch verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).

How quickly the bucket fills is a function of the bucket depth (burst-byte), the rate at which the tokens are removed (rate-bps), and the duration of the burst above the average rate. The size of the bucket imposes an upper limit on the burst length and limits the number of frames that can be transmitted back-to-back. If the burst is short, the bucket does not overflow, and no action is taken against the traffic flow. However, if a burst is long and at a higher rate, the bucket overflows, and the policing actions are taken against the frames in that burst.

You configure the bucket depth (the maximum burst that is tolerated before the bucket overflows) by using the burst-byte option of the `police` policy-map class configuration command. You configure how fast (the average rate) that the tokens are removed from the bucket by using the rate option of the `police` policy-map class configuration command.

Marking

Marking is used to convey specific information to a downstream device in the network, or to carry information from one interface in a switch to another.

Marking can be used to set certain field/bits in the packet headers, or marking can also be used to set certain fields in the packet structure that is internal to the switch. Additionally, the marking feature can be used to define mapping between fields. The following marking methods are available for QoS:

- Packet header
- Device (switch) specific information
- Table maps

Packet Header Marking

Marking on fields in the packet header can be classified into two general categories:

- IPv4/v6 header bit marking
- Layer 2 header bit marking

The marking feature at the IP level is used to set the precedence or the DSCP in the IP header to a specific value to get a specific per-hop behavior at the downstream device (switch or router), or it can also be used to aggregate traffic from different input interfaces into a single class in the output interface. The functionality is currently supported on both the IPv4 and IPv6 headers.

Marking in the Layer 2 headers is typically used to influence dropping behavior in the downstream devices (switch or router). It works in tandem with the match on the Layer 2 headers. The bits in the Layer 2 header that can be set using a policy map are class of service.

Switch Specific Information Marking

This form of marking includes marking of fields in the packet data structure that are not part of the packets header, so that the marking can be used later in the data path. This is not propagated between the switches. Marking of QoS-group falls into this category. This form of marking is only supported in policies that are enabled on the input interfaces. The corresponding matching mechanism can be enabled on the output interfaces on the same switch and an appropriate QoS action can be applied.

Table Map Marking

Table map marking enables the mapping and conversion from one field to another using a conversion table. This conversion table is called a table map.

Depending upon the table map attached to an interface, CoS, DSCP, and UP values (UP specific to wireless packets) of the packet are rewritten. The switch allows configuring both ingress table map policies and egress table map policies.

---

**Note**

The switch stack supports a total of 14 table maps. Only one table map is supported per wired port, per direction.
As an example, a table map can be used to map the Layer 2 CoS setting to a precedence value in Layer 3. This feature enables combining multiple set commands into a single table, which indicates the method to perform the mapping. This table can be referenced in multiple policies, or multiple times in the same policy.

The following table shows the currently supported forms of mapping:

**Table 80: Packet-Marking Types Used for Establishing a To-From Relationship**

<table>
<thead>
<tr>
<th>The To Packet-Marking Type</th>
<th>The From Packet-Marking Type</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

A table map-based policy supports the following capabilities:

- **Mutation**—You can have a table map that maps from one DSCP value set to another DSCP value set, and this can be attached to an egress port.
- **Rewrite**—Packets coming in are rewritten depending upon the configured table map.
- **Mapping**—Table map based policies can be used instead of set policies.

The following steps are required for table map marking:

1. Define the table map—Use the `table-map` global configuration command to map the values. The table does not know of the policies or classes within which it will be used. The default command in the table map is used to indicate the value to be copied into the to field when there is no matching from field.

2. Define the policy map—You must define the policy map where the table map will be used.

3. Associate the policy to an interface.

---

**Note**

A table map policy on an input port changes the trust setting of that port to the from type of qos-marking.

Traffic Conditioning

To support QoS in a network, traffic entering the service provider network needs to be policed on the network boundary routers to ensure that the traffic rate stays within the service limit. Even if a few routers at the network boundary start sending more traffic than what the network core is provisioned to handle, the increased traffic load leads to network congestion. The degraded performance in the network makes it difficult to deliver QoS for all the network traffic.

Traffic policing functions (using the police feature) and shaping functions (using the traffic shaping feature) manage the traffic rate, but differ in how they treat traffic when tokens are exhausted. The concept of tokens comes from the token bucket scheme, a traffic metering function.

When running QoS tests on network traffic, you may see different results for the shaper and policing data. Network traffic data from shaping provides more accurate results.

This table compares the policing and shaping functions.

Table 81: Comparison Between Policing and Shaping Functions

<table>
<thead>
<tr>
<th>Policing Function</th>
<th>Shaping Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sends conforming traffic up to the line rate and allows bursts.</td>
<td>Smooths traffic and sends it out at a constant rate.</td>
</tr>
<tr>
<td>When tokens are exhausted, action is taken immediately.</td>
<td>When tokens are exhausted, it buffers packets and sends them out later, when tokens are available.</td>
</tr>
<tr>
<td>Policing has multiple units of configuration – in bits per second, packets per second and cells per second.</td>
<td>Shaping has only one unit of configuration - in bits per second.</td>
</tr>
<tr>
<td>Policing has multiple possible actions associated with an event, marking and dropping being example of such actions.</td>
<td>Shaping does not have the provision to mark packets that do not meet the profile.</td>
</tr>
<tr>
<td>Works for both input and output traffic.</td>
<td>Implemented for output traffic only.</td>
</tr>
<tr>
<td>Transmission Control Protocol (TCP) detects the line at line speed but adapts to the configured rate when a packet drop occurs by lowering its window size.</td>
<td>TCP can detect that it has a lower speed line and adapt its retransmission timer accordingly. This results in less scope of retransmissions and is TCP-friendly.</td>
</tr>
</tbody>
</table>

Policing

The QoS policing feature is used to impose a maximum rate on a traffic class. The QoS policing feature can also be used with the priority feature to restrict priority traffic. If the rate is exceeded, then a specific action is taken as soon as the event occurs. The rate (committed information rate [CIR] and peak information rate [PIR]) and the burst parameters (conformed burst size [B_c] and extended burst size [B_e]) are all configured in bytes per second.

The following policing forms or policers are supported for QoS:
• Single-rate two-color policing
• Dual-rate three-color policing

Note
Single-rate three-color policing is not supported.

Single-Rate Two-Color Policing

Single-rate two-color policer is the mode in which you configure only a CIR and a $B_c$.

The $B_c$ is an optional parameter, and if it is not specified it is computed by default. In this mode, when an incoming packet has enough tokens available, the packet is considered to be conforming. If at the time of packet arrival, enough tokens are not available within the bounds of $B_c$, the packet is considered to have exceeded the configured rate.

Note
For information about the token-bucket algorithm, see Token-Bucket Algorithm, on page 921.

Related Topics
Configuring Police (CLI), on page 979
Examples: Single-Rate Two-Color Policing Configuration, on page 1007

Dual-Rate Three-Color Policing

With the dual rate policer, the switch supports only color-blind mode. In this mode, you configure a committed information rate (CIR) and a peak information rate (PIR). As the name suggests, there are two token buckets in this case, one for the peak rate, and one for the conformed rate.

Note
For information about the token-bucket algorithm, see Token-Bucket Algorithm, on page 921.

In the color-blind mode, the incoming packet is first checked against the peak rate bucket. If there are not enough tokens available, the packet is said to violate the rate. If there are enough tokens available, then the tokens in the conformed rate buckets are checked to determine if there are enough tokens available. The tokens in the peak rate bucket are decremented by the size of the packet. If it does not have enough tokens available, the packet is said to have exceeded the configured rate. If there are enough tokens available, then the packet is said to conform, and the tokens in both the buckets are decremented by the size of the packet.

The rate at which tokens are replenished depends on the packet arrival. Assume that a packet comes in at time T1 and the next one comes in at time T2. The time interval between T1 and T2 determines the number of tokens that need to be added to the token bucket. This is calculated as:

Time interval between packets (T2-T1) * CIR/8 bytes

Examples: Dual-Rate Three-Color Policing Configuration, on page 1008
Shaping

Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that the downstream switches and routers are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface.

Shaping has a buffer associated with it that ensures that packets which do not have enough tokens are buffered as opposed to being immediately dropped. The number of buffers available to the subset of traffic being shaped is limited and is computed based on a variety of factors. The number of buffers available can also be tuned using specific QoS commands. Packets are buffered as buffers are available, beyond which they are dropped.

Class-Based Traffic Shaping

The switch uses class-based traffic shaping. This shaping feature is enabled on a class in a policy that is associated to an interface. A class that has shaping configured is allocated a number of buffers to hold the packets that do not have tokens. The buffered packets are sent out from the class using FIFO. In the most common form of usage, class-based shaping is used to impose a maximum rate for an physical interface or logical interface as a whole. The following shaping forms are supported in a class:

- Average rate shaping
- Hierarchical shaping

Shaping is implemented using a token bucket. The values of CIR, Bc and Be determine the rate at which the packets are sent out and the rate at which the tokens are replenished.

Note

For information about the token-bucket algorithm, see Token-Bucket Algorithm, on page 921.

Average Rate Shaping

You use the `shape average` policy-map class command to configure average rate shaping.

This command configures a maximum bandwidth for a particular class. The queue bandwidth is restricted to this value even though the port has more bandwidth available. The switch supports configuring shape average by either a percentage or by a target bit rate value.

Related Topics

- Configuring Shaping (CLI), on page 989
- Examples: Average Rate Shaping Configuration, on page 1004

Hierarchical Shaping

Shaping can also be configured at multiple levels in a hierarchy. This is accomplished by creating a parent policy with shaping configured, and then attaching child policies with additional shaping configurations to the parent policy.

There are two supported types of hierarchical shaping:

- Port shaper
- User-configured shaping
The port shaper uses the class default and the only action permitted in the parent is shaping. The queueing action is in the child with the port shaper. With the user configured shaping, you cannot have queueing action in the child.

**Related Topics**

Configuring Shaping (CLI), on page 989

## Queueing and Scheduling

The switch uses both queueing and scheduling to help prevent traffic congestion. The switch supports the following queueing and scheduling features:

- Bandwidth
- Weighted Tail Drop
- Priority queues
- Queue buffers

### Bandwidth

The switch supports the following bandwidth configurations:

- Bandwidth percent
- Bandwidth remaining ratio

**Related Topics**

Configuring Bandwidth (CLI), on page 977

### Bandwidth Percent

You can use the `bandwidth percent` policy-map class command to allocate a minimum bandwidth to a particular class. The total sum cannot exceed 100 percent and in case the total sum is less than 100 percent, then the rest of the bandwidth is divided equally among all bandwidth queues.

---

**Note**

A queue can oversubscribe bandwidth in case the other queues do not utilize the entire port bandwidth.

You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.

### Bandwidth Remaining Ratio

You use the `bandwidth remaining ratio` policy-map class command to create a ratio for sharing unused bandwidth in specified queues. Any unused bandwidth will be used by these specific queues in the ratio that is specified by the configuration. Use this command when the `priority` command is also used for certain queues in the policy.

When you assign ratios, the queues will be assigned certain weights which are inline with these ratios.
You can specify ratios using a range from 0 to 100. For example, you can configure a bandwidth remaining ratio of 2 on one class, and another queue with a bandwidth remaining ratio of 4 on another class. The bandwidth remaining ratio of 4 will be scheduled twice as often as the bandwidth remaining ratio of 2.

The total bandwidth ratio allocation for the policy can exceed 100. For example, you can configure a queue with a bandwidth remaining ratio of 50, and another queue with a bandwidth remaining ratio of 100.

**Weighted Tail Drop**

The switch egress queues use an enhanced version of the tail-drop congestion-avoidance mechanism called weighted tail drop (WTD). WTD is implemented on queues to manage the queue lengths and to provide drop precedences for different traffic classifications.

As a frame is enqueued to a particular queue, WTD uses the frame’s assigned QoS label to subject it to different thresholds. If the threshold is exceeded for that QoS label (the space available in the destination queue is less than the size of the frame), the switch drops the frame.

Each queue has three configurable threshold values. The QoS label determines which of the three threshold values is subjected to the frame.

*Figure 62: WTD and Queue Operation*

The following figure shows an example of WTD operating on a queue whose size is 1000 frames. Three drop percentages are configured: 40 percent (400 frames), 60 percent (600 frames), and 100 percent (1000 frames). These percentages indicate that up to 400 frames can be queued at the 40-percent threshold, up to 600 frames at the 60-percent threshold, and up to 1000 frames at the 100-percent threshold.

In the example, CoS value 6 has a greater importance than the other CoS values, and is assigned to the 100-percent drop threshold (queue-full state). CoS values 4 is assigned to the 60-percent threshold, and CoS values 3 is assigned to the 40-percent threshold. All of these threshold values are assigned using the `queue-limit cos` command.

Assuming the queue is already filled with 600 frames, and a new frame arrives. It contains CoS value 4 and is subjected to the 60-percent threshold. If this frame is added to the queue, the threshold will be exceeded, so the switch drops it.

**Related Topics**

- Configuring Queue Limits (CLI), on page 987
- Examples: Queue-limit Configuration, on page 1004

**Weighted Tail Drop Default Values**

The following are the Weighted Tail Drop (WTD) default values and the rules for configuring WTD threshold values.

- If you configure less than three queue-limit percentages for WTD, then WTD default values are assigned to these thresholds.
The following are the WTD threshold default values:

**Table 82: WTD Threshold Default Values**

<table>
<thead>
<tr>
<th>Threshold</th>
<th>Default Value Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>90</td>
</tr>
<tr>
<td>2</td>
<td>400</td>
</tr>
</tbody>
</table>

- If 3 different WTD thresholds are configured, then the queues are programmed as configured.
- If 2 WTD thresholds are configured, then the maximum value percentage will be 400.
- If a WTD single threshold is configured as x, then the maximum value percentage will be 400.
  - If the value of x is less than 90, then threshold1=90 and threshold 0= x.
  - If the value of x equals 90, then threshold1=90, threshold 0=80.
  - If the value x is greater than 90, then threshold1=x, threshold 0=80.

**Priority Queues**

Each port supports eight egress queues, of which two can be given a priority.

You use the `priority level` policy class-map command to configure the priority for two classes. One of the classes has to be configured with a priority queue level 1, and the other class has to be configured with a priority queue level 2. Packets on these two queues are subjected to less latency with respect to other queues.

**Related Topics**

Configuring Priority (CLI), on page 982

**Queue Buffer**

Each 1-gigabit port on the switch is allocated 168 buffers for a wireless port and 300 buffers for a wired port. Each 10-gigabit port is allocated 1800 buffers. At boot time, when there is no policy map enabled on the wired port, there are two queues created by default. Wired ports can have a maximum of 8 queues configured using MQC-based policies. The following table shows which packets go into which one of the queues:

**Table 83: DSCP, Precedence, and CoS - Queue Threshold Mapping Table**

<table>
<thead>
<tr>
<th>DSCP, Precedence or CoS</th>
<th>Queue</th>
<th>Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control Packets</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>Rest of Packets</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
You can guarantee the availability of buffers, set drop thresholds, and configure the maximum memory allocation for a queue. You use the `queue-buffers` policy-map class command to configure the queue buffers. You use the `queue-limit` policy-map class command to configure the maximum thresholds.

There are two types of buffer allocations: hard buffers, which are explicitly reserved for the queue, and soft buffers, which are available for other ports when unused by a given port.

For the wireless port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 67 buffers are allocated for Queue 0 in the context of 1-gigabit ports. The soft maximum for this queue is set to 268 (calculated as 67 * 400/100) for 1-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

For the wired port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 120 buffers are allocated for Queue 0 in the context of 1-gigabit ports, and 720 buffers in the context of 10-gigabit ports. The soft maximum for this queue is set to 480 (calculated as 120 * 400/100) for 1-gigabit ports and 2880 for 10-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

Queue 1 does not have any hard buffers allocated. The default soft buffer limit is set to 400 (which is the maximum threshold). The threshold would determine the maximum number of soft buffers that can be borrowed from the common pool.

**Queue Buffer Allocation**

The buffer allocation to any queue can be tuned using the `queue-buffers ratio` policy-map class configuration command.

**Related Topics**

- Configuring Queue Buffers (CLI), on page 984
- Examples: Queue Buffers Configuration, on page 1005

**Dynamic Threshold and Scaling**

Traditionally, reserved buffers are statically allocated for each queue. No matter whether the queue is active or not, its buffers are held up by the queue. In addition, as the number of queues increases, the portion of the reserved buffers allocated for each queue can become smaller and smaller. Eventually, a situation may occur where there are not enough reserved buffers to support a jumbo frame for all queues.

The switch supports Dynamic Thresholding and Scaling (DTS), which is a feature that provides a fair and efficient allocation of buffer resources. When congestion occurs, this DTS mechanism provides an elastic buffer allocation for the incoming data based on the occupancy of the global/port resources. Conceptually, DTS scales down the queue buffer allocation gradually as the resources are used up to leave room for other queues, and vice versa. This flexible method allows the buffers to be more efficiently and fairly utilized.

As mentioned in the previous sections, there are two limits configured on a queue—a hard limit and a soft limit.

Hard limits are not part of DTS. These buffers are available only for that queue. The sum of the hard limits should be less than the globally set up hard maximum limit. The global hard limit configured for egress queuing is currently set to 5705. In the default scenario when there are no MQC policies configured, the 24 1-gigabit ports would take up 24 * 67 = 1608, and the 4 10-gigabit ports would take up 4 * 720 = 2880, for a total of 4488 buffers, allowing room for more hard buffers to be allocated based upon the configuration.
Soft limit buffers participate in the DTS process. Additionally, some of the soft buffer allocations can exceed the global soft limit allocation. The global soft limit allocation for egress queuing is currently set to 7607. The sum of the hard and soft limits add up to 13312, which in turn translates to 3.4 MB. Because the sum of the soft buffer allocations can exceed the global limit, it allows a specific queue to use a large number of buffers when the system is lightly loaded. The DTS process dynamically adjusts the per-queue allocation as the system becomes more heavily loaded.

**Queuing in Wireless**

Queuing in the wireless component is performed based on the port policy and is applicable only in the downstream direction. The wireless module supports the following four queues:

- **Voice**—This is a strict priority queue. Represented by Q0, this queue processes control traffic and multicast or unicast voice traffic. All control traffic (such as CAPWAP packets) is processed through the voice queue. The QoS module uses a different threshold within the voice queue to process control and voice packets to ensure that control packets get higher priority over other non-control packets.

- **Video**—This is a strict priority queue. Represented by Q1, this queue processes multicast or unicast video traffic.

- **Data NRT**—Represented by Q2, this queue processes all non-real-time unicast traffic.

- **Multicast NRT**—Represented by Q3, this queue processes Multicast NRT traffic. Any traffic that does not match the traffic in Q0, Q1, or Q2 is processed through Q3.

---

**Note**

By default, the queues Q0 and Q1 are not enabled.

---

**Note**

A weighted round-robin policy is applied for traffic in the queues Q2 and Q3.

For upstream direction only one queue is available. Port and radio policies are applicable only in the downstream direction.

---

**Note**

The wired ports support eight queues.

---

**Trust Behavior**

**Trust Behavior for Wired and Wireless Ports**

For wired or wireless ports that are connected to the switch (end points such as IP phones, laptops, cameras, telepresence units, or other devices), their DSCP, precedence, or CoS values coming in from these end points are trusted by the switch and therefore are retained in the absence of any explicit policy configuration.

This trust behavior is applicable to both upstream and downstream QoS.

The packets are enqueued to the appropriate queue per the default initial configuration. No priority queuing at the switch is done by default. This is true for unicast and multicast packets.
In scenarios where the incoming packet type differs from the outgoing packet type, the trust behavior and the queuing behavior are explained in the following table. Note that the default trust mode for a port is DSCP based. The trust mode ‘falls back’ to CoS if the incoming packet is a pure Layer 2 packet. You can also change the trust setting from DSCP to CoS. This setting change is accomplished by using an MQC policy that has a class default with a 'set cos cos table default default-cos' action, where default-cos is the name of the table map created (which only performs a default copy).

</table>

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the switch came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired switch, all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

The default trust behavior in the case of wireless ports could be changed by using the `qos wireless default untrust` command.

**Note**

If you upgrade from Cisco IOS XE 3.2 SE Release to a later release, the default behavior of the wireless traffic is still untrusted. In this situation, you can use the `no qos wireless-default untrust` command to enable trust behavior for wireless traffic. However, if you install Cisco IOS XE 3.3 SE or a later release on the switch, the default QoS behavior for wireless traffic is trust. Starting with Cisco IOS XE 3.3 SE Release and later, the packet markings are preserved in both egress and ingress directions for new installations (not upgrades) for wireless traffic.

**Related Topics**

- Configuring Trust Behavior for Wireless Traffic (CLI), on page 970
- Example: Table Map Configuration to Retain CoS Markings, on page 1009

**Port Security on a Trusted Boundary for Cisco IP Phones**

In a typical network, you connect a Cisco IP Phone to a switch port and cascade devices that generate data packets from the back of the telephone. The Cisco IP Phone guarantees the voice quality through a shared data link by marking the CoS level of the voice packets as high priority (CoS = 5) and by marking the data packets as low priority (CoS = 0). Traffic sent from the telephone to the switch is typically marked with a tag.
that uses the 802.1Q header. The header contains the VLAN information and the class of service (CoS) 3-bit field, which is the priority of the packet.

For most Cisco IP Phone configurations, the traffic sent from the telephone to the switch should be trusted to ensure that voice traffic is properly prioritized over other types of traffic in the network. By using the trust device interface configuration command, you configure the switch port to which the telephone is connected to trust the traffic received on that port.

The trust device device_type command available in interface configuration mode is a stand-alone command on the switch. When using this command in an AutoQoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.

With the trusted setting, you also can use the trusted boundary feature to prevent misuse of a high-priority queue if a user bypasses the telephone and connects the PC directly to the switch. Without trusted boundary, the CoS labels generated by the PC are trusted by the switch (because of the trusted CoS setting). By contrast, trusted boundary uses CDP to detect the presence of a Cisco IP Phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a switch port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the switch port and prevents misuse of a high-priority queue. Note that the trusted boundary feature is not effective if the PC and Cisco IP Phone are connected to a hub that is connected to the switch.

### Wireless QoS Mobility

Wireless QoS mobility enables you to configure QoS policies so that the network provides the same service anywhere in the network. A wireless client can roam from one location to another and as a result the client can get associated to different access points associated with a different switch. Wireless client roaming can be classified into two types:

- Intra-switch roaming
- Inter-switch roaming

The client policies must be available on all of the switches in the mobility group. The same SSID and port policy must be applied to all switches in the mobility group so that the clients get consistent treatment.

### Inter-Switch Roaming

When a client roams from one location to another, the client can get associated to access points either associated to the same switch (anchor switch) or a different switch (foreign switch). Inter-switch roaming refers to the scenario where the client gets associated to an access point that is not associated to the same device before the client roamed. The host device is now foreign to the device to which the client was initially anchored.

In the case of inter-switch roaming, the client QoS policy is always executed on the foreign controller. When a client roams from anchor switch to foreign switch, the QoS policy is uninstalled on the anchor switch and installed on the foreign switch. In the mobility handoff message, the anchor device passes the name of the
policy to the foreign switch. The foreign switch should have a policy with the same name configured for the QoS policy to be applied correctly.

In the case of inter-switch roaming, all of the QoS policies are moved from the anchor device to the foreign device. While the QoS policies are in transition from the anchor device to the foreign device, the traffic on the foreign device is provided the default treatment. This is comparable to a new policy installation on the client target.

**Note**  
If the foreign device is not configured with the user-defined physical port policy, the default port policy is applicable to all traffic is routed through the NRT queue, except the control traffic which goes through RT1 queue. The network administrator must configure the same physical port policy on both the anchor and foreign devices symmetrically.

---

**Intra-Switch Roaming**

With intra-switch roaming, the client gets associated to an access point that is associated to the same switch before the client roamed, but this association to the device occurs through a different access point.

**Note**  
QoS policies remain intact in the case of intra-switch roaming.

---

**Precious Metal Policies for Wireless QoS**

Wireless QoS is backward compatible with the precious metal policies offered by the unified wireless controller platforms. The precious metal policies are system-defined policies that are available on the controller.

The following policies are available:

- **Platinum**—Used for VoIP clients.
- **Gold**—Used for video clients.
- **Silver**—Used for traffic that can be considered best-effort.
- **Bronze**—Used for NRT traffic.

These policies (also known as profiles) can be applied to a WLAN based on the traffic. We recommend the configuration using the Cisco IOS MQC configuration. The policies are available in the system based on the precious metal policy required.

Based on the policies applied, the 802.1p, 802.11e (WMM), and DSCP fields in the packets are affected. These values are preconfigured and installed when the switch is booted.

**Note**  
Unlike the precious metal policies that were applicable in the Cisco Unified Wireless controllers, the attributes rt-average-rate, nrt-average-rate, and peak rates are not applicable for the precious metal policies configured on this switch platform.

Configuring Precious Metal Policies (CLI), on page 991

Standard QoS Default Settings

Default Wired QoS Configuration

There are two queues configured by default on each wired interface on the switch. All control traffic traverses and is processed through queue 0. All other traffic traverses and is processed through queue 1.

DSCP Maps

Default CoS-to-DSCP Map

You use the CoS-to-DSCP map to map CoS values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default CoS-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

<table>
<thead>
<tr>
<th>CoS Value</th>
<th>DSCP Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>

**Default Wireless QoS Configuration**

The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suite the QoS configuration. The switch is preconfigured with a default class map and a policy map.

**Restrictions for QoS on Wired Targets**

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio polices are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID
and client targets are supported. Downstream indicates that traffic is flowing from the switch to the wireless client. Upstream indicates that traffic is flowing from wireless client to the switch.

The following are restrictions for applying QoS features on the switch for the wired target:

- A maximum of 8 queuing classes are supported on the switch port for the wired target.
- A maximum of 63 policers are supported per policy on the wired port for the wired target.
- No more than two levels are supported in a QoS hierarchy.
- In a hierarchical policy, overlapping actions between parent and child are not allowed, except when a policy has the port shaper in the parent and queueing features in the child policy.
- A QoS policy cannot be attached to any EtherChannel interface.
- Policing in both the parent and child is not supported in a QoS hierarchy.
- Marking in both the parent and child is not supported in a QoS hierarchy.
- A mixture of queue limit and queue buffer in the same policy is not supported.

---

**Note**

The queue-limit percent is not supported on the switch because the `queue-buffer` command handles this functionality. Queue limit is only supported with the DSCP and CoS extensions.

- With shaping, there is an IPG overhead of 20Bytes for every packet that is accounted internally in the hardware. Shaping accuracy will be effected by this, specially for packets of small size.
- The classification sequence for all wired queuing-based policies should be the same across all wired upstream ports (10-Gigabit Ethernet), and the same for all downstream wired ports (1-Gigabit Ethernet).
- Empty classes are not supported.
- Class-maps with empty actions are not supported. If there are two policies with the same order of class-maps and if there are class-maps with no action in one of the policies, there may be traffic drops. As a workaround, allocate minimal bandwidth for all the classes in PRIORITY_QUE.
- A maximum of 256 classes are supported per policy on the wired port for the wired target.
- The actions under a policer within a policy map have the following restrictions:
  - The conform action must be transmit.
  - The exceed/violate action for markdown type can only be cos2cos, prec2prec, dscp2dscp.
  - The markdown types must be the same within a policy.
- A port-level input marking policy takes precedence over an SVI policy; however, if no port policy is configured, the SVI policy takes precedence. For a port policy to take precedence, define a port-level policy; so that the SVI policy is overwritten.
- Classification counters have the following specific restrictions:
  - Classification counters count packets instead of bytes.
  - Filter-based classification counters are not supported.
• Only QoS configurations with marking or policing trigger the classification counter.

• The classification counter is not port based. This means that the classification counter aggregates all packets belonging to the same class of the same policy which attach to different interfaces.

• As long as there is policing or marking action in the policy, the class-default will have classification counters.

• When there are multiple match statements in a class, then the classification counter only shows the traffic counter for one of the match statements.

• Table maps have the following specific restrictions:
  
  • Only one table map for policing exceeding the markdown and one table map for policing violating the markdown per direction per target is supported.
  
  • Table maps must be configured under the class-default; table maps are unsupported for a user-defined class.

• Hierarchical policies are required for the following:
  
  • Port-shapers
  
  • Aggregate policers
  
  • PV policy
  
  • Parent shaping and child marking/policing

• For ports with wired targets, these are the only supported hierarchical policies:
  
  • Police chaining in the same policy is unsupported, except for wireless client.
  
  • Hierarchical queueing is unsupported in the same policy (port shaper is the exception).
  
  • In a parent class, all filters must have the same type. The child filter type must match the parent filter type with the following exceptions:
    
    • If the parent class is configured to match IP, then the child class can be configured to match the ACL.
    
    • If the parent class is configured to match CoS, then the child class can be configured to match the ACL.

• The **trust device** `device_type` command available in interface configuration mode is a stand-alone command on the switch. When using this command in an AutoQoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.

The following are restrictions for applying QoS features on the VLAN to the wired target:

• For a flat or nonhierarchical policy, only marking or a table map is supported.

The following are restrictions and considerations for applying QoS features on EtherChannel and channel member interfaces:

• QoS is not supported on an EtherChannel interface.
• QoS is supported on EtherChannel member interfaces in both ingress and egression directions. All EtherChannel members must have the same QoS policy applied. If the QoS policy is not the same, each individual policy on the different link acts independently.

• On attaching a service policy to channel members, the following warning message appears to remind the user to make sure the same policy is attached to all ports in the EtherChannel: ’Warning: add service policy will cause inconsistency with port xxx in ether channel xxx.’.

• Auto QoS is not supported on EtherChannel members.

Note

On attaching a service policy to an EtherChannel, the following message appears on the console: ’Warning: add service policy will cause inconsistency with port xxx in ether channel xxx.’. This warning message should be expected. This warning message is a reminder to attach the same policy to other ports in the same EtherChannel. The same message will be seen during boot up. This message does not mean there is a discrepancy between the EtherChannel member ports.

Restrictions for QoS on Wireless Targets

General Restrictions

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio policies are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the switch to the wireless client. Upstream indicates that traffic is flowing from wireless client to the switch.

• Only port, SSID, and client (using AAA and Cisco IOS command-line interface) policies are user-configurable. Radio policies are set by the wireless control module and are not user-configurable.

• Port and radio policies are applicable only in the downstream direction.

• SSID and client support non-queuing policies in the upstream direction.

• One policy per target per direction is supported.

Wireless QoS Restrictions on Ports

The following are restrictions for applying QoS features on a wireless port target:

• All wireless ports have similar parent policy with one class-default and one action shape under class-default. Shape rates are dependent on the 802.11a/b/g/ac bands.
• You can create a maximum of four classes in a child policy by modifying the `port_child_policy`.

• If there are four classes in the `port_child_policy` at the port level, one must be a non-client-nrt class and one must be class-default.

• No two classes can have the same priority level. Only priority level 1 (for voice traffic and control traffic) and 2 (for video) are supported.

• Priority is not supported in the multicast NRT class (non-client-nrt class) and `class-default`.

• If four classes are configured, two of them have to be priority classes. If only three classes are configured, at least one of them should be a priority class. If three classes are configured and there is no non-client-nrt class, both priority levels must be present.

• Only match DSCP is supported.

• The port policy applied by the wireless control module cannot be removed using the CLI.

• Both priority rate and police CIR (using MQC) in the same class is unsupported.

• Queue limit (which is used to configure Weighted Tail Drop) is unsupported.

**Wireless QoS Restrictions on SSID**

The following are restrictions for applying QoS features on SSID:

• One table map is supported at the ingress policy.

• Table maps are supported for the parent class-default only. Up to two table maps are supported in the egress direction and three table-maps can be configured when a QoS group is involved.

  __Note__

  Table-maps are not supported at the client targets.

• If a wireless port has a default policy with only two queues (one for multicast-NRT, one for class-default), the policy at SSID level cannot have voice and video class in the egress direction.

• Policing without priority is not supported in the egress direction.

• Priority configuration at the SSID level is used only to configure the RT1 and RT2 policers (AFD for policer). Priority configuration does not include the shape rate. Therefore, priority is restricted for SSID policies without police.

• The mapping in the DSCP2DSCP and COS2COS table should be based on the classification function for the voice and video classes in the port level policy.

• No action is allowed under the class-default of a child policy.

• For a flat policy (non hierarchical), in the ingress direction, the policy configuration must be a set (table map) or policing or both.

**Wireless QoS Restrictions on Clients**

The following are restrictions for applying QoS policies on client targets:

• Queuing is not supported.
• Attaching, removing, or modifying client policies on a WLAN in the enabled state is not supported. You must shut down the WLAN to apply, remove, or modify a policy.

• Table-map configuration is not supported for client targets.

• Policing and set configured together in class-default is blocked in both the upstream and downstream direction:

```
policy-map foo
class class-default
police X
set dscp Y
```

• Child policy is not supported under class-default if the parent policy contains other user-defined class maps in it.

• Hierarchical client policies are only supported in the egress direction.

• For flat egress client policy, policing in class-default and marking action in other classes are not supported.

• Restrictions for ACLs:
  
  • All the filters in classes in a policy map for client policy must have the same attributes. Filters matching on protocol-specific attributes such as IPv4 or IPv6 addresses are considered as different attribute sets.

  • For filters matching on ACLs, all ACEs (Access Control Entry) in the access list should have the same type and number of attributes. For example, the following is an invalid access list as they match on different attributes:

```
policy map foo
  class acl-101 (match on 3 tuple)
police X
  class acl-102 (match on 5 tuple)
police Y
```

  • For filters matching on marking attributes, all filters in the policy-map must match on the same marking attribute. For example, If filter matches on DSCP, then all filters in the policy must match on DSCP.

  • ACL matching on port ranges and subnet are only supported in ingress direction.

• If an ingress SSID policy is configured along with an ingress client policy matching ACLs with port ranges, the SSID policy takes precedence over the client policy. As a result, the client policy will not take effect.

How to Configure QoS

Configuring Class, Policy, and Table Maps

Creating a Traffic Class (CLI)

To create a traffic class containing match criteria, use the `class-map` command to specify the traffic class name, and then use the following `match` commands in class-map configuration mode, as needed.

**Before you begin**

All match commands specified in this configuration task are considered optional, but you must configure at least one match criterion for a class.

**SUMMARY STEPS**

1. `configure terminal`
2. `class-map {class-map name | match-any}`
3. `match access-group {index number | name}`
4. `match class-map class-map name`
5. `match cos cos value`
6. `match dscp dscp value`
7. `match ip {dscp dscp value | precedence precedence value}`
8. `match non-client-nrt`
9. `match qos-group qos group value`
10. `match vlan vlan value`
11. `match wlan user-priority wlan value`
12. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> class-map {class-map name</td>
<td>match-any}</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# class-map test_1000</td>
<td></td>
</tr>
<tr>
<td>Switch(config-cmap)#</td>
<td></td>
</tr>
</tbody>
</table>

- Creates a class map to be used for matching packets to the class whose name you specify.
- If you specify `match-any`, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.
<table>
<thead>
<tr>
<th><strong>Step</strong></th>
<th><strong>Command or Action</strong></th>
<th><strong>Purpose</strong></th>
</tr>
</thead>
</table>
| Step 3   | `match access-group {index number | name}` | The following parameters are available for this command:  
  - access-group  
  - class-map  
  - cos  
  - dscp  
  - ip  
  - non-client-nrt  
  - precedence  
  - qos-group  
  - vlan  
  - wlan user priority  
  (Optional) For this example, enter the access-group ID:  
  - Access list index (value from 1 to 2799)  
  - Named access list |
| Step 4   | `match class-map class-map name` | (Optional) Matches to another class-map name. |
| Step 5   | `match cos cos value` | (Optional) Matches IEEE 802.1Q or ISL class of service (user) priority values.  
  - Enters up to 4 CoS values separated by spaces (0 to 7). |
| Step 6   | `match dscp dscp value` | (Optional) Matches the DSCP values in IPv4 and IPv6 packets. |
| Step 7   | `match ip {dscp dscp value | precedence precedence value}` | (Optional) Matches IP values including the following:  
  - `dscp`—Matches IP DSCP (DiffServ codepoints).  
  - `precedence`—Matches IP precedence (0 to 7). |
### Creating a Traffic Policy (CLI)

To create a traffic policy, use the `policy-map` global configuration command to specify the traffic policy name.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-cmap)#</td>
<td>Purpose</td>
</tr>
<tr>
<td><strong>Step 8</strong> match non-client-nrt</td>
<td>(Optional) Matches non-client NRT (Non-Real-Time).</td>
</tr>
</tbody>
</table>
| **Example:**
| Switch(config-cmap)# match non-client-nrt |
| **Note** This match is applicable only for policies on a wireless port. It carries all the multi-destination and AP (non-client) bound traffic. |
| **Step 9** match qos-group qos group value | (Optional) Matches QoS group value (from 0 to 31). |
| **Example:**
| Switch(config-cmap)# match qos-group 10 |
| **Step 10** match vlan vlan value | (Optional) Matches a VLAN ID (from 1 to 4095). |
| **Example:**
| Switch(config-cmap)# match vlan 210 |
| **Step 11** match wlan user-priority wlan value | (Optional) Matches 802.11e specific values. Enter the user priority 802.11e user priority (0 to 7). |
| **Example:**
| Switch(config-cmap)# match wlan user-priority 7 |
| **Step 12** end | Saves the configuration changes. |
| **Example:**
| Switch(config-cmap)# end |

### What to do next
Configure the policy map.

### Related Topics
- Class Maps, on page 918

---

**Creating a Traffic Policy (CLI)**

To create a traffic policy, use the `policy-map` global configuration command to specify the traffic policy name.
The traffic class is associated with the traffic policy when the `class` command is used. The `class` command must be entered after you enter the policy map configuration mode. After entering the `class` command, the switch is automatically in policy map class configuration mode, which is where the QoS policies for the traffic policy are defined.

The following policy map class-actions are supported:

- **admit**—Admits the request for Call Admission Control (CAC).
- **bandwidth**—Bandwidth configuration options.
- **exit**—Exits from the QoS class action configuration mode.
- **no**—Negates or sets default values for the command.
- **police**—Policer configuration options.
- **priority**—Strict scheduling priority configuration options for this class.
- **queue-buffers**—Queue buffer configuration options.
- **queue-limit**—Queue maximum threshold for Weighted Tail Drop (WTD) configuration options.
- **service-policy**—Configures the QoS service policy.
- **set**—Sets QoS values using the following options:
  - CoS values
  - DSCP values
  - Precedence values
  - QoS group values
  - WLAN values
- **shape**—Traffic-shaping configuration options.

**Before you begin**

You should have first created a class map.

**SUMMARY STEPS**

1. `configure terminal`
2. `policy-map policy-map name`
3. `class {class-name | class-default}`
4. `admit`
5. `bandwidth {kb/s kb/s value | percent percentage | remaining {percent | ratio} }`
6. `exit`
7. `no`
8. `police {target_bit_rate | cir | rate}`
9. `priority {kb/s | level level value | percent percentage value}`
10. `queue-buffers ratio ratio limit`
11. `queue-limit {packets | cos | dscp | percent}`
12. `service-policy policy-map name`
13. `set {cos | dscp | ip | precedence | qos-group | wlan}`
14. `shape average {target_bit_rate | percent}`
15. `end`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Switch# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td><code>policy-map policy-map name</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Switch(config)# policy-map test_2000&lt;br&gt;Switch(config-pmap)#</td>
<td>Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</td>
</tr>
<tr>
<td>3</td>
<td>`class {class-name</td>
<td>class-default}`&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Switch(config-pmap)# class test_1000&lt;br&gt;Switch(config-pmap-c)#</td>
</tr>
<tr>
<td>4</td>
<td><code>admit</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Switch(config-pmap-c)# admit cac wmm-tspec&lt;br&gt;Switch(config-pmap-c)#</td>
<td>(Optional) Admits the request for Call Admission Control (CAC). For a more detailed example of this command and its usage, see Configuring Call Admission Control (CLI), on page 970.&lt;br&gt;<strong>Note</strong> This command only configures CAC for wireless QoS.</td>
</tr>
<tr>
<td>5</td>
<td>`bandwidth {kb/s kb/s value</td>
<td>percent percentage</td>
</tr>
<tr>
<td>6</td>
<td><code>exit</code>&lt;br&gt;<strong>Example:</strong></td>
<td>(Optional) Exits from QoS class action configuration mode.</td>
</tr>
</tbody>
</table>
### Command or Action

| Step 7 | no |

**Example:**

```
Switch(config-pmap-c) # no
Switch(config-pmap-c) #
```

(Optional) Negates the command.

| Step 8 | `police {target_bit_rate | cir | rate}` |

**Example:**

```
Switch(config-pmap-c) # police 100000
Switch(config-pmap-c) #
```

(Optional) Configures the policer:

- `target_bit_rate`—Enter the bit rate per second, enter a value between 8000 and 10000000000.
- `cir`—Committed Information Rate
- `rate`—Specify police rate, PCR for hierarchical policies or SCR for single-level ATM 4.0 policer policies.

For a more detailed example of this command and its usage, see Configuring Police (CLI), on page 979.

| Step 9 | `priority {kb/s | level level value | percent percentage value}` |

**Example:**

```
Switch(config-pmap-c) # priority percent 50
Switch(config-pmap-c) #
```

(Optional) Sets the strict scheduling priority for this class. Command options include:

- `kb/s`—Kilobits per second, enter a value between 1 and 2000000.
- `level`—Establishes a multi-level priority queue. Enter a value (1 or 2).
- `percent`—Enter a percent of the total bandwidth for this priority.

For a more detailed example of this command and its usage, see Configuring Priority (CLI), on page 982.

| Step 10 | `queue-buffers ratio ratio limit` |

**Example:**

```
Switch(config-pmap-c) # queue-buffers ratio 10
Switch(config-pmap-c) #
```

(Optional) Configures the queue buffer for the class. Enter the queue buffers ratio limit (0 to 100).

For a more detailed example of this command and its usage, see Configuring Queue Buffers (CLI), on page 984.

| Step 11 | `queue-limit {packets | cos | dscp | percent}` |

**Example:**

```
Switch(config-pmap-c) # queue-limit cos 7 percent 50
```

(Optional) Specifies the queue maximum threshold for the tail drop:

- `packets`—Packets by default, enter a value between 1 to 2000000.
- `cos`—Enter the parameters for each COS value.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Switch(config-pmap-c)# | • **dscp**—Enter the parameters for each DSCP value.  
| | • **percent**—Enter the percentage for the threshold.  
| | For a more detailed example of this command and its usage, see Configuring Queue Limits (CLI), on page 987. |

**Step 12**

**service-policy policy-map name**  
Example:  
Switch(config-pmap-c)# service-policy test_2000  
Switch(config-pmap-c)#  
(Optional) Configures the QoS service policy.

**Step 13**

| set {cos | dscp | ip | precedence | qos-group | wlan} | (Optional) Sets the QoS values. Possible QoS configuration values include: |
|----------------|-----------------------------------------------|
| Example:       | • **cos**—Sets the IEEE 802.1Q/ISL class of service/user priority. |
|                | • **dscp**—Sets DSCP in IP(v4) and IPv6 packets. |
|                | • **ip**—Sets IP specific values. |
|                | • **precedence**—Sets precedence in IP(v4) and IPv6 packet. |
|                | • **qos-group**—Sets the QoS Group. |
|                | • **wlan**—Sets the WLAN user-priority. |
|                | Switch(config-pmap-c)# set cos 7  
|                | Switch(config-pmap-c)# |

**Step 14**

**shape average {target_bit_rate | percent}**  
Example:  
Switch(config-pmap-c) #shape average percent 50  
Switch(config-pmap-c) #  
(Optional) Sets the traffic shaping. Command parameters include:  
• **target_bit_rate**—Target bit rate.  
• **percent**—Percentage of interface bandwidth for Committed Information Rate.  
For a more detailed example of this command and its usage, see Configuring Shaping (CLI), on page 989.

**Step 15**

**end**  
Example:  
Switch(config-pmap-c) #end  
Switch(config-pmap-c) #  
Saves the configuration changes.

**What to do next**  
Configure the interface.
Configuring Client Policies (GUI)

**Step 1**
Choose Configuration > Wireless.

**Step 2**
Expand the QoS node by clicking on the left pane and choose QOS-Policy.

The QOS-Policy page is displayed.

**Step 3**
Click Add New to create a new QoS Policy.

The Create QoSPolicy page is displayed.

**Step 4**
Select Client from the Policy Type drop-down menu.

**Step 5**
Select the direction into which the policy needs to be applied from the Policy Direction drop-down menu.

The available options are:

- **Ingress**
- **Egress**

**Step 6**
Specify a policy name in the Policy Name text box.

**Step 7**
Provide a description to the policy in the Description text box.

**Step 8**
(Optional) Configure the default voice or video configuration parameters by checking the Enable Voice or Enable Video checkbox.

The following options are available:

- **Trust**—Specify the classification type behavior on this policy. The options available are:
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
  - **User Priority**—This option is available when the Policy Direction is ingress. Enter the 802.11e user priority. The range is from 0 to 7.
  - **COS**—This option is available when the Policy Direction is egress. Matches IEEE 802.1Q class of service. The range is from 0 to 7.

- **Mark**—Specify the marking label for each packet. The following options are available:
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
  - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
  - **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.

- **Police(kbps)**—Specify the policing rate in kbps.

**Note**
The marking and policing options are optional.

**Step 9**
Specify the Class-default parameters.

The following options are available:

- **Mark**—Specify the marking label for each packet. The following options are available:
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
CoS—Matches IEEE 802.1Q class of service. The range is from 0 to 7.

User Priority—Enter the 802.11e user priority. The range is from 0 to 7.

Police (kbps)—This option is available when the Policy Direction is egress. This option Specify the policing rate in kbps.

Step 10 (Optional) To configure user defined classes, check the User Defined Classes checkbox.

The following options are available:

Trust—Specify the classification type behavior on this policy.

DSCP—Assigns a label to indicate the given quality of service. The range is from 0 to 63.

User Priority—This option is available when the Policy Direction is ingress. Enter the 802.11e user priority. The range is from 0 to 7.

COS—This option is available when the Policy Direction is egress. Matches IEEE 802.1Q class of service. The range is from 0 to 7.

Mark—Specify the marking label for each packet. The following options are available:

DSCP—Assigns a label to indicate the given quality of service. The range is from 0 to 63.

CoS—Matches IEEE 802.1Q class of service. The range is from 0 to 7.

User Priority—Enter the 802.11e user priority. The range is from 0 to 7.

Police (kbps)—This option is available when the Policy Direction is egress. This option Specify the policing rate in kbps.

Step 11 Click Add to add the policy.

Configuring Class-Based Packet Marking (CLI)

This procedure explains how to configure the following class-based packet marking features on your switch:

CoS value

DSCP value

IP value

Precedence value

QoS group value

WLAN value

Before you begin
You should have created a class map and a policy map before beginning this procedure.
SUMMARY STEPS

1. configure terminal
2. policy-map policy name
3. class class name
4. set cos {cos value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}
5. set dscp {dscp value | default | dscp table table-map name | ef | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}
6. set ip {dscp | precedence}
7. set precedence {precedence value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}
8. set qos-group {qos-group value | dscp table table-map name | precedence table table-map name}
9. set wlan user-priority {wlan user-priority value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name | wlan table table-map name}
10. end
11. show policy-map

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> policy-map policy name</td>
<td>Enters policy map configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> class class name</td>
<td>Enters policy class map configuration mode.</td>
</tr>
</tbody>
</table>

Example:

1. Switch# configure terminal
2. Switch(config)# policy-map policy1
3. Switch(config-pmap)#
4. Switch(config-pmap-c)#

Command options for policy class map configuration mode include the following:

- **admit**—Admits the request for Call Admission Control (CAC).
- **bandwidth**—Bandwidth configuration options.
- **exit**—Exits from the QoS class action configuration mode.
- **no**—Negates or sets default values for the command.
- **police**—Policer configuration options.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• priority — Strict scheduling priority configuration options for this class.</td>
<td></td>
</tr>
<tr>
<td>• queue-buffers — Queue buffer configuration options.</td>
<td></td>
</tr>
<tr>
<td>• queue-limit — Queue maximum threshold for Weighted Tail Drop (WTD) configuration options.</td>
<td></td>
</tr>
<tr>
<td>• service-policy — Configures the QoS service policy.</td>
<td></td>
</tr>
<tr>
<td>• set — Sets QoS values using the following options:</td>
<td></td>
</tr>
<tr>
<td>• Cos values</td>
<td></td>
</tr>
<tr>
<td>• DSCP values</td>
<td></td>
</tr>
<tr>
<td>• Precedence values</td>
<td></td>
</tr>
<tr>
<td>• QoS group values</td>
<td></td>
</tr>
<tr>
<td>• WLAN values</td>
<td></td>
</tr>
<tr>
<td>• shape — Traffic-shaping configuration options.</td>
<td></td>
</tr>
</tbody>
</table>

Note

This procedure describes the available configurations using `set` command options. The other command options (admit, bandwidth, etc.) are described in other sections of this guide. Although this lists all of the possible `set` commands, only one `set` command is supported per class.

**Step 4**

```plaintext
set cos {cos value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}
```

(Optional) Sets the specific IEEE 802.1Q Layer 2 CoS value of an outgoing packet. Values are from 0 to 7.

Example:

```
Switch(config-pmap)# set cos 5
Switch(config-pmap)#
```

**Step 5**

```plaintext
set dscp {dscp value | default | dscp table table-map name | ef | precedence table table-map name | qos-group table}
```

(Optional) Sets the DSCP value.

You can also set the following values using the `set cos` command:

• `cos table` — Sets the CoS value based on a table map.

• `dscp table` — Sets the code point value based on a table map.

• `precedence table` — Sets the code point value based on a table map.

• `qos-group table` — Sets the CoS value from QoS group based on a table map.

• `wlan user-priority table` — Sets the CoS value from the WLAN user priority based on a table map.
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`table-map name</td>
<td>wlan user-priority table table-map name`</td>
</tr>
<tr>
<td></td>
<td><em>default</em>—Matches packets with default DSCP value (000000).</td>
</tr>
<tr>
<td></td>
<td><em>dscp table</em>—Sets the packet DSCP value from DSCP based on a table map.</td>
</tr>
<tr>
<td></td>
<td><em>ef</em>—Matches packets with EF DSCP value (101110).</td>
</tr>
<tr>
<td></td>
<td><em>precedence table</em>—Sets the packet DSCP value from precedence based on a table map.</td>
</tr>
<tr>
<td></td>
<td><em>qos-group table</em>—Sets the packet DSCP value from a QoS group based upon a table map.</td>
</tr>
<tr>
<td></td>
<td><em>wlan user-priority table</em>—Sets the packet DSCP value based upon a WLAN user-priority based upon a table map.</td>
</tr>
</tbody>
</table>

**Example:**

```
Switch(config-pmap)# set dscp af11
Switch(config-pmap)#
```

### Step 6

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`set ip {dscp</td>
<td>precedence}`</td>
</tr>
<tr>
<td></td>
<td>You can set the following values using the <code>set ip dscp</code> command:</td>
</tr>
<tr>
<td></td>
<td><em>dscp value</em>—Sets a specific DSCP value.</td>
</tr>
<tr>
<td></td>
<td><em>default</em>—Matches packets with default DSCP value (000000).</td>
</tr>
<tr>
<td></td>
<td><em>dscp table</em>—Sets the packet DSCP value from DSCP based on a table map.</td>
</tr>
<tr>
<td></td>
<td><em>ef</em>—Matches packets with EF DSCP value (101110).</td>
</tr>
<tr>
<td></td>
<td><em>precedence table</em>—Sets the packet DSCP value from precedence based on a table map.</td>
</tr>
<tr>
<td></td>
<td><em>qos-group table</em>—Sets the packet DSCP value from a QoS group based upon a table map.</td>
</tr>
<tr>
<td></td>
<td><em>wlan user-priority table</em>—Sets the packet DSCP value based upon a WLAN user-priority based upon a table map.</td>
</tr>
</tbody>
</table>

**Example:**

```
Switch(config-pmap)# set ip dscp c3
Switch(config-pmap)#
```

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>set ip precedence</code></td>
<td>You can set the following values using the <code>set ip precedence</code> command:</td>
</tr>
<tr>
<td></td>
<td><em>precedence value</em>—Sets the precedence value (from 0 to 7).</td>
</tr>
<tr>
<td></td>
<td><em>cos table</em>—Sets the packet precedence value from Layer 2 CoS based on a table map.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **set precedence** `{precedence value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name}` | • **dscp table**—Sets the packet precedence from DSCP value based on a table map.  
• **precedence table**—Sets the precedence value from precedence based on a table map  
• **qos-group table**—Sets the precedence value from a QoS group based upon a table map.  

**Step 7**

- **Example**:  
  
  Switch(config-pmap)# set precedence 5  
  Switch(config-pmap)#

| Step 8 | **set qos-group** `{qos-group value | dscp table table-map name | precedence table table-map name}` | (Optional) Sets QoS group values. You can set the following values using this command:  
• **qos-group value**—A number from 1 to 31.  
• **dscp table**—Sets the code point value from DSCP based on a table map.  
• **precedence table**—Sets the code point value from precedence based on a table map.  

- **Example**:  
  
  Switch(config-pmap)# set qos-group 10  
  Switch(config-pmap)#

| Step 9 | **set wlan user-priority** `{wlan user-priority value | cos table table-map name | dscp table table-map name | qos-group table table-map name | wlan table table-map name}` | (Optional) Sets the WLAN user priority value. You can set the following values using this command:  
• **wlan user-priority value**—A value between 0 to 7.  
• **cos table**—Sets the WLAN user priority value from CoS based on a table map.  
• **dscp table**—Sets the WLAN user priority value from DSCP based on a table map.  
• **qos-group table**—Sets the WLAN user priority value from QoS group based on a table map.  

- **Example**:  
  
  Switch(config-pmap)# set wlan user-priority 1  
  Switch(config-pmap)#
/QoS

Configuring Class Maps for Voice and Video (CLI)

To configure class maps for voice and video traffic, follow these steps:

**SUMMARY STEPS**

1. `configure terminal`
2. `class-map class-map-name`
3. `match dscp dscp-value-for-voice`
4. `end`
5. `configure terminal`
6. `class-map class-map-name`
7. `match dscp dscp-value-for-video`
8. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> class-map class-map-name</td>
<td>Creates a class map.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# class-map voice</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 3</td>
<td><code>match dscp dscp-value-for-voice</code></td>
<td>Matches the DSCP value in the IPv4 and IPv6 packets. Set this value to 46.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch(config-cmap)# match dscp 46</code></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch(config)# end</code></td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td><code>class-map class-map-name</code></td>
<td>Configures a class map.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch(config)# class-map video</code></td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td><code>match dscp dscp-value-for-video</code></td>
<td>Matches the DSCP value in the IPv4 and IPv6 packets. Set this value to 34.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch(config-cmap)# match dscp 34</code></td>
<td></td>
</tr>
<tr>
<td>Step 8</td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Switch(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

### Attaching a Traffic Policy to an Interface (CLI)

After the traffic class and traffic policy are created, you must use the `service-policy` interface configuration command to attach a traffic policy to an interface, and to specify the direction in which the policy should be applied (either on packets coming into the interface or packets leaving the interface).

**Before you begin**

A traffic class and traffic policy must be created before attaching a traffic policy to an interface.

### SUMMARY STEPS

1. `configure terminal`
2. `interface type`
3. `service-policy {input policy-map | output policy-map}`
4. `end`
5. `show policy map`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters interface configuration mode and configures an interface. |
| interface type    | Command parameters for the interface configuration include: |
| Example:          | • Auto Template — Auto-template interface |
| Switch(config)# interface GigabitEthernet1/0/1 | • Capwap — CAPWAP tunnel interface |
| Switch(config-if)# | • GigabitEthernet — Gigabit Ethernet IEEE 802 |
|                   | • GroupVI — Group virtual interface |
|                   | • Internal Interface — Internal interface |
|                   | • Loopback — Loopback interface |
|                   | • Null — Null interface |
|                   | • Port-channel — Ethernet Channel of interface |
|                   | • TenGigabitEthernet — 10-Gigabit Ethernet |
|                   | • Tunnel — Tunnel interface |
|                   | • Vlan — Catalyst VLANs |
|                   | • Range — Interface range |

| **Step 3**        | Attaches a policy map to an input or output interface. This policy map is then used as the service policy for that interface. |
| service-policy {input policy-map | output policy-map |} | In this example, the traffic policy evaluates all traffic leaving that interface. |
| Example:          |         |
| Switch(config-if)# service-policy output policy_map_01 |         |
| Switch(config-if)# |         |

| **Step 4**        | Saves configuration changes. |
| end               |         |
| Example:          |         |
| Switch(config-if)# end |         |
| Switch#           |         |

| **Step 5**        | (Optional) Displays statistics for the policy on the specified interface. |
| show policy map   |         |
| Example:          |         |
### Configuring SSID Policies (GUI)

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Choose <strong>Configuration &gt; Wireless</strong>.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Expand the <strong>QoS</strong> node by clicking on the left pane and choose <strong>QOS-Policy</strong>. The Create QoS Policy page is displayed.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Click <strong>Add New</strong> to create a new QoSPolicy. The QoS Policy page is displayed.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Select <strong>SSID</strong> from the <strong>Policy Type</strong> drop-down menu.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Select the direction into which the policy needs to be applied from the <strong>Policy Direction</strong> drop-down list. The available options are:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Ingress</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Egress</strong></td>
</tr>
<tr>
<td>Note</td>
<td>Voice and video configurations are available only in the egress direction.</td>
</tr>
<tr>
<td>Note</td>
<td>When creating an egress SSID policy for voice and video classes, if the <strong>port_child_policy</strong> is already configured with voice and video classes having priority level, the existing <strong>port_child_policy</strong> is used. If a <strong>port_child_policy</strong> does not exist with voice and video classes, the switch will create voice and video classes with priority levels 1 and 2 under <strong>port_child_policy</strong> for voice and video traffic.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Specify a policy name in the <strong>Policy Name</strong> text box.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Provide a description to the policy in the <strong>Description</strong> text box.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Select the trust parameter from the <strong>Trust</strong> drop-down list. The following options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>DSCP</strong>—Assigns a label to indicate the given quality of service as DSCP.</td>
</tr>
<tr>
<td></td>
<td>• <strong>COS</strong>—Matches IEEE 802.1Q class of service. This option is not available when the <strong>Policy Direction</strong> is egress.</td>
</tr>
<tr>
<td></td>
<td>• <strong>User Priority</strong>—Enter the 802.11e user priority. This option is not available when the <strong>Policy Direction</strong> is egress.</td>
</tr>
<tr>
<td></td>
<td>• <strong>None</strong>—This option is available when the <strong>Policy Direction</strong> is egress. This option is available only for egress policies.</td>
</tr>
</tbody>
</table>
Step 9

If you chose **Egress** policy above, the following options are available:

- **Bandwidth**—Specifies the bandwidth rate. The following options are available:
  - **Rate**—Specifies the bandwidth in kbps. Enter a value in kbps in the **Value** field.
  - **Remaining Ratio**—Specifies the bandwidth in BRR (bandwidth remaining ratio). Enter the percentage in the **Percent** field.

  **Note**  If you choose the **Rate** option for the **Bandwidth** parameter, this value must be greater than the sum of the policing values for voice and video traffic.

- **Enable Voice**—Click on the **Enable Voice** checkbox to enable voice traffic on this policy. Specify the following properties:
  - **Priority**—Sets the priority for this policy for strict scheduling. The priority level is set to 1.
  - **Police (kbps)**—Specifies the police rate in Kilobits per second.
  - **CAC**—Enables or disables CAC. If CAC is enabled, you must specify the following options:
    - **User priority**—This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7. By default, a value of 6 is assigned.
    - **Rate (kbps)**

      **Note**  The CAC rate must be less than the police rate.

- **Enable Video**—Check the **Enable Video** checkbox to enable video traffic on this policy. Specify the following properties:
  - **Priority**—Sets the priority for this policy for strict scheduling.
  - **Police (kbps)**—Specifies the police rate in Kilobits per second.

Step 10

Click **Apply**.

---

**Applying an SSID or Client Policy on a WLAN (CLI)**

**Before you begin**

You must have a service-policy map configured before applying it on an SSID.

**SUMMARY STEPS**

1. `configure terminal`
2. `wlan profile-name`
3. `service-policy [ input | output ] policy-name`
4. `service-policy client [ input | output ] policy-name`
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> wlan profile-name</td>
<td>Enters the WLAN configuration submode. The profile-name is the profile name of the configured WLAN.</td>
</tr>
<tr>
<td>Example: Switch# wlan test4</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> service-policy [ input</td>
<td>output ] policy-name</td>
</tr>
<tr>
<td>Example: Switch(config-wlan)# service-policy input policy-map-ssid</td>
<td>• input—Assigns the policy map to WLAN ingress traffic.</td>
</tr>
<tr>
<td></td>
<td>• output—Assigns the policy map to WLAN egress traffic.</td>
</tr>
<tr>
<td><strong>Step 4</strong> service-policy client [ input</td>
<td>output ] policy-name</td>
</tr>
<tr>
<td>Example: Switch(config-wlan)# service-policy client input policy-map-client</td>
<td>• input—Assigns the client policy for ingress direction on the WLAN.</td>
</tr>
<tr>
<td></td>
<td>• output—Assigns the client policy for egress direction on the WLAN.</td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# end</td>
<td></td>

**Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps (CLI)**

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions supported are remarking and policing.

**Before you begin**
You should have already decided upon the classification, policing, and marking of your network traffic by policy maps prior to beginning this procedure.
SUMMARY STEPS

1. configure terminal
2. class-map { class-map name | match-any }
3. match access-group { access list index | access list name }
4. policy-map policy-map-name
5. class {class-map-name | class-default}
6. set { cos | dscp | ip | precedence | qos-group | wlan user-priority }
7. police { target_bit_rate | cir | rate }
8. exit
9. exit
10. interface interface-id
11. service-policy input policy-map-name
12. end
13. show policy-map [policy-map-name [class class-map-name]]
14. copy running-config startup-config

### Notes

- **precedence**—Matches precedence in IPv4 and IPv6 packets.
- **qos-group**—Matches to a QoS group.
- **vlan**—Matches to a VLAN.
- **wlan**—Matches to a wireless LAN.

### Example:

1. **Step 4**
   - `policy-map policy-map-name`
   - Example:
     - `Switch(config)# policy-map flowit Switch(config-pmap)#`

2. **Step 5**
   - `class {class-map-name | class-default}`
   - Example:
     - `Switch(config-pmap)# class ipclass1 Switch(config-pmap-c)#`

3. **Step 6**
   - `set {cos | dscp | ip | precedence | qos-group | wlan user-priority}`
   - Example:
     - `Switch(config-pmap-c)# set dscp 45 Switch(config-pmap-c)#`

4. **Step 7**
   - `police {target_bit_rate | cir | rate}`
   - Example:
     - `Switch(config-pmap-c)#`

---

QoS  
Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps (CLI)
### Command or Action

Switch(config-pmap-c)# police 100000
conform-action transmit exceed-action drop
Switch(config-pmap-c)#

### Purpose

- **cir**—Committed Information Rate.
- **rate**—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.

In this example, the `police` command adds a policer to the class where any traffic beyond the 100000 set target bit rate is dropped.

### Step 8

**exit**

Example:

Switch(config-pmap-c)# exit

Returns to policy map configuration mode.

### Step 9

**exit**

Example:

Switch(config-pmap)# exit

Returns to global configuration mode.

### Step 10

**interface interface-id**

Example:

Switch(config)# interface
gigabitethernet 2/0/1

Specifies the port to attach to the policy map, and enters interface configuration mode.

Valid interfaces include physical ports.

### Step 11

**service-policy input policy-map-name**

Example:

Switch(config-if)# service-policy input flowit

Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported.

### Step 12

**end**

Example:

Switch(config-if)# end

Returns to privileged EXEC mode.

### Step 13

**show policy-map [policy-map-name [class class-map-name]]**

Example:

Switch# show policy-map

(Optional) Verifies your entries.
**What to do next**

If applicable to your QoS configuration, configure classification, policing, and marking of traffic on SVIs by using policy maps.

### Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps (CLI)

#### Before you begin

You should have already decided upon the classification, policing, and marking of your network traffic by using policy maps prior to beginning this procedure.

#### SUMMARY STEPS

1. configure terminal
2. class-map \{ class-map name  | match-any \}  
3. match vlan vlan number  
4. policy-map policy-map-name  
5. description description  
6. class \{class-map-name | class-default\}  
7. set \{ cos  | dscp  | ip  | precedence  | qos-group  | wlan user-priority\}  
8. police \{ target_bit_rate  | cir  | rate\}  
9. exit  
10. exit  
11. interface interface-id  
12. service-policy input policy-map-name  
13. end  
14. show policy-map [policy-map-name [class class-map-name]]  
15. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 14 copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong> class-map {class-map name</td>
<td>match-any }</td>
</tr>
</tbody>
</table>

- Creates a class map to be used for matching packets to the class whose name you specify.
- If you specify `match-any`, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.

<table>
<thead>
<tr>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# class-map class_vlan100</td>
</tr>
</tbody>
</table>

| **Step 3** match vlan vlan number | Specifies the VLAN to match to the class map. |
| Example: |
| Switch(config-cmap)# match vlan 100 |
| Switch(config-cmap)# exit |
| Switch(config)# |

| **Step 4** policy-map policy-map-name | Creates a policy map by entering the policy map name, and enters policy-map configuration mode. |
| Example: |
| Switch(config)# policy-map policy_vlan100 |
| Switch(config-pmap)# |

By default, no policy maps are defined.

| **Step 5** description description | (Optional) Enters a description of the policy map. |
| Example: |
| Switch(config-pmap)# description vlan 100 |

| **Step 6** class {class-map-name | class-default} | Defines a traffic classification, and enters the policy-map class configuration mode. |
| Example: |
| Switch(config-pmap)# class class_vlan100 |
| Switch(config-pmap-c)# |

By default, no policy map class-maps are defined.

If a traffic class has already been defined by using the `class-map` global configuration command, specify its name for `class-map-name` in this command.

A `class-default` traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied `match any` included in the `class-default` class, all packets that have not already matched the other traffic classes will match `class-default`.

| **Step 7** set {cos | dscp | ip | precedence | qos-group | wlan user-priority} | (Optional) Sets the QoS values. Possible QoS configuration values include: |
| Example: |
| Switch(config-pmap-c)# set dscp af23 |

- **cos**—Sets the IEEE 802.1Q/ISL class of service/user priority.
- **dscp**—Sets DSCP in IPv(v4) and IPv6 packets.
### Command or Action

```bash
Switch(config-pmap-c)#
```

### Purpose

- **ip**—Sets IP specific values.
- **precedence**—Sets precedence in IP(v4) and IPv6 packet.
- **qos-group**—Sets QoS group.
- **wlan-user-priority**—Sets WLAN user-priority.

In this example, the **set dscp** command classifies the IP traffic by matching the packets with a DSCP value of AF23 (010010).

### Step 8

**police {target_bit_rate | cir | rate}**

**Example:**

```bash
Switch(config-pmap-c)# police 200000
correct-action transmit
exceed-action drop
```

(Optional) Configures the policer:

- **target_bit_rate**—Specifies the bit rate per second. Enter a value between 8000 and 10000000000.
- **cir**—Committed Information Rate.
- **rate**—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.

In this example, the **police** command adds a policer to the class where any traffic beyond the 200000 set target bit rate is dropped.

### Step 9

**exit**

**Example:**

```bash
Switch(config-pmap-c)# exit
```

Returns to policy map configuration mode.

### Step 10

**exit**

**Example:**

```bash
Switch(config-pmap-c)# exit
```

Returns to global configuration mode.

### Step 11

**interface interface-id**

**Example:**

```bash
Switch(config)# interface
gigabitethernet 1/0/3
```

Specifies the port to attach to the policy map, and enters interface configuration mode.

Valid interfaces include physical ports.

### Step 12

**service-policy input policy-map-name**

**Example:**

```bash
Switch(config-if)# service-policy
input policy_vlan100
```

Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported.
### Command or Action | Purpose
--- | ---
**Step 13** | 
end  
*Example:*  
Switch(config-if)# end | Returns to privileged EXEC mode.

**Step 14** | 
show policy-map [policy-map-name [class class-map-name]]  
*Example:*  
Switch# show policy-map | (Optional) Verifies your entries.

**Step 15** | 
copy running-config startup-config  
*Example:*  
Switch# copy-running-config startup-config | (Optional) Saves your entries in the configuration file.

**Configuring Table Maps (CLI)**

Table maps are a form of marking, and also enable the mapping and conversion of one field to another using a table. For example, a table map can be used to map and convert a Layer 2 CoS setting to a precedence value in Layer 3.

**Note**
A table map can be referenced in multiple policies or multiple times in the same policy.

**SUMMARY STEPS**

1. configure terminal  
2. `table-map name {default {default value | copy | ignore} | exit | map {from value to to value } | no}`  
3. `map from value to value`  
4. `exit`  
5. `exit`  
6. `show table-map`  
7. configure terminal  
8. `policy-map`  
9. `class class-default`  
10. `set cos dscp table table map name`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 2** | **table-map name {default {default value | copy | ignore} | exit | map {from from value to to value } | no}** | Creates a table map and enters the table map configuration mode. In table map configuration mode, you can perform the following tasks:  
  - **default**—Configures the table map default value, or sets the default behavior for a value not found in the table map to copy or ignore.  
  - **exit**—Exits from the table map configuration mode.  
  - **map**—Maps a *from* to a *to* value in the table map.  
  - **no**—Negates or sets the default values of the command. |
| | **Example:** Switch(config)# table-map table01  
Switch(config-tablemap)# | |
| **Step 3** | **map from value to value** | In this step, packets with DSCP values 0 are marked to the CoS value 2, DSCP value 1 to the CoS value 4, DSCP value 24 to the CoS value 3, DSCP value 40 to the CoS value 6 and all others to the CoS value 0.  
**Note** The mapping from CoS values to DSCP values in this example is configured by using the `set policy map class configuration` command as described in a later step in this procedure. |
| | **Example:** Switch(config-tablemap)# map from 0 to 2  
Switch(config-tablemap)# map from 1 to 4  
Switch(config-tablemap)# map from 24 to 3  
Switch(config-tablemap)# map from 40 to 6  
Switch(config-tablemap)# default 0  
Switch(config-tablemap)# | |
| **Step 4** | **exit** | Returns to global configuration mode. |
| | **Example:** Switch(config-tablemap)# exit  
Switch(config)# | |
| **Step 5** | **exit** | Returns to privileged EXEC mode. |
| | **Example:** Switch(config) exit  
Switch# | |
| **Step 6** | **show table-map** | Displays the table map configuration. |
| | **Example:** | |
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Configures the policy map for the table map.</td>
</tr>
<tr>
<td>Matches the class to the system default.</td>
</tr>
<tr>
<td>If this policy is applied on input port, that port will have trust DSCP enabled on that port and marking will take place depending upon the specified table map.</td>
</tr>
<tr>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

#### What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.

Configuring Trust

Configuring Trust Behavior for Wireless Traffic (CLI)

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the switch came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired switch, all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

SUMMARY STEPS

1. configure terminal
2. qos wireless-default-untrust
3. end

<td></td>
</tr>
<tr>
<td><strong>Step 35</strong></td>
<td>shape average {target bit rate</td>
</tr>
<tr>
<td>Example:</td>
<td>Configures the average shape rate. You can configure the average shape rate by target bit rates (bits per second) or</td>
</tr>
</tbody>
</table>
**Step 36**

Configure the relative buffer size for the queue.

`queue-buffers {ratio ratio value}`

**Example:**

Switch(config-pmap-c)# queue-buffers ratio 0

**Note:**

- The sum of all configured buffers in a policy must be less than or equal to 100 percent.
- Unallocated buffers are evenly distributed to all the remaining queues. Ensure sufficient buffers are allocated to all queues including the priority queues.

**Step 37**

Specify the policy map for the service policy.

`service-policy policy_map_name`

**Example:**

Switch(config-pmap-c)# service-policy ssid_child_cac

**Step 38**

Save configuration changes.

`end`

**Example:**

Switch(config-pmap-c)# end
Switch#

**Step 39**

(Optional) Display policy configuration information for all classes configured for all service policies.

`show policy-map`

**Example:**

Switch# show policy-map

### What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

For additional information about CAC, refer to the System Management Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3650 Switches).

### Configuring Bandwidth (CLI)

This procedure explains how to configure bandwidth on your switch.
**Before you begin**

You should have created a class map for bandwidth before beginning this procedure.

**SUMMARY STEPS**

1. `configure terminal`
2. `policy-map policy name`
3. `class class name`
4. `bandwidth {Kb/s | percent percentage | remaining { ratio ratio }}`
5. `end`
6. `show policy-map`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> policy-map policy name</td>
<td>Enters policy map configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</td>
</tr>
<tr>
<td>Switch(config)# policy-map policy_bandwidth01</td>
<td></td>
</tr>
<tr>
<td>Switch(config-pmap)#</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> class class name</td>
<td>Enters policy class map configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</td>
</tr>
<tr>
<td>Switch(config-pmap)# class class_bandwidth01</td>
<td></td>
</tr>
<tr>
<td>Switch(config-pmap-c)#</td>
<td>• <em>word</em>—Class map name.</td>
</tr>
<tr>
<td><strong>Step 4</strong> bandwidth {Kb/s</td>
<td>percent percentage</td>
</tr>
<tr>
<td>Example:</td>
<td>• <em>Kb/s</em>—Configures a specific value in kilobits per second (from 20000 to 10000000).</td>
</tr>
<tr>
<td>Switch(config-pmap-c)# bandwidth 200000</td>
<td>• <em>percent</em>—Allocates minimum bandwidth to a particular class based on a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.</td>
</tr>
<tr>
<td>Switch(config-pmap-c)#</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
---|---
• remaining — Allocates minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the priority command is used for certain queues in the policy. You can also assign ratios rather than percentages to each queue; the queues will be assigned certain weights which are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.

**Note** You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.

<table>
<thead>
<tr>
<th>Step 5</th>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Saves configuration changes.</td>
</tr>
<tr>
<td>Switch(config-pmap-c)# end</td>
<td></td>
</tr>
<tr>
<td>Switch#</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 6</th>
<th>show policy-map</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>(Optional) Displays policy configuration information for all classes configured for all service policies.</td>
</tr>
<tr>
<td>Switch# show policy-map</td>

<td>bc</td>
</tr>
<tr>
<td>Example: Switch(config-pmap-c)# police 8000 conform-action transmit exceed-action drop Switch(config-pmap-c)#</td>
<td>- <strong>target_bit_rate</strong>—Bits per second (from 8000 to 10000000000).</td>
</tr>
<tr>
<td></td>
<td>- <strong>burst bytes</strong>—Enter a value from 1000 to 512000000.</td>
</tr>
<tr>
<td></td>
<td>- <strong>bc</strong>—Conform burst.</td>
</tr>
<tr>
<td></td>
<td>- <strong>conform-action</strong>—Action taken when rate is less than conform burst.</td>
</tr>
<tr>
<td></td>
<td>- <strong>pir</strong>—Peak Information Rate.</td>
</tr>
<tr>
<td></td>
<td>- <strong>cir</strong>—Committed Information Rate.</td>
</tr>
<tr>
<td></td>
<td>- <strong>target_bit_rate</strong>—Target bit rate (8000 to 10000000000).</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>• percent — Percentage of interface bandwidth for CIR.</td>
<td></td>
</tr>
<tr>
<td>• rate — Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.</td>
<td></td>
</tr>
<tr>
<td>• target_bit_rate — Target Bit Rate (8000 to 10000000000).</td>
<td></td>
</tr>
<tr>
<td>• percent — Percentage of interface bandwidth for rate.</td>
<td></td>
</tr>
</tbody>
</table>

The following **police conform-action transmit exceed-action** subcommand options are available:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• drop — Drops the packet.</td>
<td></td>
</tr>
<tr>
<td>• set-cos-transmit — Sets the CoS value and sends it.</td>
<td></td>
</tr>
<tr>
<td>• set-dscp-transmit — Sets the DSCP value and sends it.</td>
<td></td>
</tr>
<tr>
<td>• set-prec-transmit — Rewrites the packet precedence and sends it.</td>
<td></td>
</tr>
<tr>
<td>• transmit — Transmits the packet.</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the switch.

**Step 5**

**Example:**

```
Switch(config-pmap-c)# end
Switch#
```

Saves configuration changes.

**Step 6**

**Example:**

```
Switch# show policy-map
```

(Optional) Displays policy configuration information for all classes configured for all service policies.

**What to do next**

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.
Configuring Priority (CLI)

This procedure explains how to configure priority on your switch. The switch supports giving priority to specified queues. There are two priority levels available (1 and 2).

**Note**
Queues supporting voice and video should be assigned a priority level of 1.

**Before you begin**
You should have created a class map for priority before beginning this procedure.

**SUMMARY STEPS**

1. `configure terminal`
2. `policy-map policy name`
3. `class class name`
5. `end`
6. `show policy-map`

**DETAILED STEPS**

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>policy-map policy name</code></td>
<td>Enters policy map configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</td>
</tr>
<tr>
<td><code>Switch(config)# policy-map policy_priority01</code></td>
<td></td>
</tr>
<tr>
<td><code>Switch(config-pmap)#</code></td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
</tbody>
</table>
| 3    | **class class name** | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:  
  - *class*-Class map name.  
  - *class-default*-System default class matching any otherwise unclassified packets. |
|      | Example:          |         |
|      | Switch(config-pmap)# **class class_priority01** \nSwitch(config-pmap-c)# |         |
| 4    | **priority [Kb/s [burst_in_bytes]] | level level_value [Kb/s [burst_in_bytes]] | percent percentage [burst_in_bytes]] | percent percentage [burst_in_bytes]] |  
  (Optional) The **priority** command assigns a strict scheduling priority for the class.  
  The command options include:  
  - *Kb/s*-Specifies the kilobits per second (from 1 to 2000000).  
    - *burst_in_bytes*-Specifies the burst in bytes (from 32 to 2000000).  
  - *level level_value*-Specifies the multilevel (1-2) priority queue.  
    - *Kb/s*-Specifies the kilobits per second (from 1 to 2000000).  
      - *burst_in_bytes*-Specifies the burst in bytes (from 32 to 2000000).  
    - *percent*-Percentage of the total bandwidth.  
      - *burst_in_bytes*-Specifies the burst in bytes (from 32 to 2000000).  
  - *percent*-Percentage of the total bandwidth.  
    - *burst_in_bytes*-Specifies the burst in bytes (32 to 2000000).  
  **Note** Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth. |
|      | Example:          |         |
|      | Switch(config-pmap-c)# **priority level 1** \nSwitch(config-pmap-c)# |         |
| 5    | **end** | Saves configuration changes. |
|      | Example:          |         |
|      | Switch(config-pmap-c)# **end** \nSwitch# |         |
### Configuring Queues and Shaping

#### Configuring Egress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you may need to perform all of the procedures in this section. You need to make decisions about these characteristics:

- Which packets are mapped by DSCP, CoS, or QoS group value to each queue and threshold ID?
- What drop percentage thresholds apply to the queues, and how much reserved and maximum memory is needed for the traffic type?
- How much of the fixed buffer space is allocated to the queues?
- Does the bandwidth of the port need to be rate limited?
- How often should the egress queues be serviced and which technique (shaped, shared, or both) should be used?

### Configuring Queue Buffers (CLI)

The switch allows you to allocate buffers to queues. If there is no allocation made to buffers, then they are divided equally for all queues. You can use the queue-buffer ratio to divide it in a particular ratio. Since by default DTS (Dynamic Threshold and Scaling) is active on all queues, these are soft buffers.

### Note

The queue-buffer ratio is supported on both wired and wireless ports, but the queue-buffer ratio cannot be configured with a queue-limit.

</table>
### Configuring Queue Buffers (CLI)

#### Command or Action

| Switch(config-pmap-c)# |

#### Purpose

- **percent**—Allocates a minimum bandwidth to a particular class using a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.

- **remaining**—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the **priority** command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.

**Note**  You cannot mix bandwidth types on a policy map.

---

### Step 5

**queue-buffers** `{ratio ratio value}

**Example:**

Switch(config-pmap-c)# queue-buffers ratio 10

Switch(config-pmap-c)#

**Configures the relative buffer size for the queue.**

**Note**  The sum of all configured buffers in a policy must be less than or equal to 100 percent. Unallocated buffers are are evenly distributed to all the remaining queues. Ensure sufficient buffers are allocated to all queues including the priority queues.

**Note**  Protocol Data Units(PDUs) for network control protocols such as spanning-tree and LACP utilize the priority queue or queue 0 (when a priority queue is not configured). Ensure sufficient buffers are allocated to these queues for the protocols to function.

---

### Step 6

**end**

**Example:**

Switch(config-pmap-c)# end

Switch#

**Saves configuration changes.**

---

### Step 7

**show policy-map**

**Example:**

Switch# show policy-map

**(Optional) Displays policy configuration information for all classes configured for all service policies.**
What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the `service-policy` command.

Configuring Queue Limits (CLI)

You use queue limits to configure Weighted Tail Drop (WTD). WTD ensures the configuration of more than one threshold per queue. Each class of service is dropped at a different threshold value to provide for QoS differentiation. With the switch, each queue has 3 explicit programmable threshold classes—0, 1, 2. Therefore, the enqueue/drop decision of each packet per queue is determined by the packet’s threshold class assignment, which is determined by the DSCP, CoS, or QoS group field of the frame header.

WTD also uses a soft limit, and therefore you are allowed to configure the queue limit to up to 400 percent (maximum four times the reserved buffer from common pool). This soft limit prevents overrunning the common pool without impacting other features.

---

Note

You can only configure queue limits on the switch egress queues on wired ports.

Before you begin

The following are prerequisites for this procedure:

- You should have created a class map for the queue limits before beginning this procedure.
- You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue limits.

SUMMARY STEPS

1. `configure terminal`
2. `policy-map policy name`
3. `class class name`
4. `bandwidth {Kb/s | percent percentage | remaining { ratio ratio value }}`
5. `queue-limit {packets packets | cos {cos value {maximum threshold value | percent percentage} | values {cos value | percent percentage} | dscp {dscp value {maximum threshold value | percent percentage} | values {dscp value | percent percentage} | ef {maximum threshold value | percent percentage} | dscp values dscp value} | percent percentage} | match packet {maximum threshold value | percent percentage} | default {maximum threshold value | percent percentage} | dscp values dscp value} | percent percentage}}`
6. `end`
7. `show policy-map`

- Weighted Tail Drop, on page 928
- Examples: Queue-limit Configuration, on page 1004

### Configuring Shaping (CLI)

You use the `shape` command to configure shaping (maximum bandwidth) for a particular class. The queue's bandwidth is restricted to this value even though the port has additional bandwidth left. You can configure shaping as an average percent, as well as a shape average value in bits per second.
Before you begin

You should have created a class map for shaping before beginning this procedure.

SUMMARY STEPS

1. configure terminal
2. policy-map policy name
3. class class name
4. shape average \{target bit rate | percent percentage\}
5. end
6. show policy-map

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** policy-map policy name | Enters policy map configuration mode. | |
| Example: Switch(config)# policy-map policy_shaping01 Switch(config-pmap)# | Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy. |

| **Step 3** class class name | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: | |
| Example: Switch(config-pmap)# class class_shaping01 Switch(config-pmap-c)# | • word—Class map name. |
| | • class-default—System default class matching any otherwise unclassified packets. |

| **Step 4** shape average \{target bit rate | percent percentage\} | Configures the average shape rate. You can configure the average shape rate by target bit rates (bits per second) or by percentage of interface bandwidth for the Committed Information Rate (CIR). | |
| Example: Switch(config-pmap-c)# shape average percent 50 Switch(config-pmap-c)# | |

| **Step 5** end | Saves configuration changes. | |
| Example: Switch(config-pmap-c)# end | |
### Configuring Precious Metal Policies (CLI)

You can configure precious metal QoS policies on a per-WLAN basis.

#### SUMMARY STEPS

1. Configure terminal
2. `wlan wlan-name`
3. `service-policy output policy-name`
4. `end`
5. `show wlan {wlan-id | wlan-name}`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Configures the WLAN with the QoS policy. To configure the WLAN with precious metal policies, you must enter one of the following keywords: <em>platinum, gold, silver</em>, or <em>bronze</em>. The upstream policy is specified with the keyword <em>platinum-up</em> as shown in the example.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the WLAN configuration submode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enters global command mode.</td>
</tr>
</tbody>
</table>

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

### Configuration Examples for QoS

#### Examples: Classification by Access Control Lists

This example shows how to classify packets for QoS by using access control lists (ACLs):

```bash
Switch# configure terminal
Switch(config)# access-list 101 permit ip host 12.4.1.1 host 15.2.1.1
Switch(config)# class-map acl-101
Switch(config-cmap)# description match on access-list 101
Switch(config-cmap)# match access-group 101
Switch(config-cmap)#
```

After creating a class map by using an ACL, you then create a policy map for the class, and apply the policy map to an interface for QoS.

**Related Topics**
- [Creating a Traffic Class (CLI)], on page 942
- [Class Maps], on page 918
Examples: Class of Service Layer 2 Classification

This example shows how to classify packets for QoS using a class of service Layer 2 classification:

```
Switch# configure terminal
Switch(config)# class-map cos
Switch(config-cmap)# match cos ?
  <0-7>  Enter up to 4 class-of-service values separated by white-spaces
Switch(config-cmap)# match cos 3 4 5
Switch(config-cmap)#
```

After creating a class map by using a CoS Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Class of Service DSCP Classification

This example shows how to classify packets for QoS using a class of service DSCP classification:

```
Switch# configure terminal
Switch(config)# class-map dscp
Switch(config-cmap)# match dscp af21 af22 af23
Switch(config-cmap)#
```

After creating a class map by using a DSCP classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: VLAN ID Layer 2 Classification

This example shows how to classify for QoS using a VLAN ID Layer 2 classification:

```
Switch# configure terminal
Switch(config)# class-map vlan-120
Switch(config-cmap)# match vlan ?
  <1-4095>  VLAN id
Switch(config-cmap)# match vlan 120
Switch(config-cmap)#
```

After creating a class map by using a VLAN Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Classification by DSCP or Precedence Values

This example shows how to classify packets by using DSCP or precedence values:

```
Switch# configure terminal
Switch(config)# class-map prec2
Switch(config-cmap)# description matching precedence 2 packets
Switch(config-cmap)# match ip precedence 2
Switch(config-cmap)# exit
Switch(config)# class-map ef
Switch(config-cmap)# description EF traffic
```
Switch(config-cmap)# match ip dscp ef
Switch(config-cmap)#

After creating a class map by using a DSCP or precedence values, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Hierarchical Classification

The following is an example of a hierarchical classification, where a class named parent is created, which matches another class named child. The class named child matches based on the IP precedence being set to 2.

Switch# configure terminal
Switch(config)# class-map child
Switch(config-cmap)# match ip precedence 2
Switch(config-cmap)# exit
Switch(config)# class-map parent
Switch(config-cmap)# match class child
Switch(config-cmap)#

After creating the parent class map, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Hierarchical Policy Configuration

The following is an example of a configuration using hierarchical polices:

Switch# configure terminal
Switch(config)# class-map c1
Switch(config-cmap)# match dscp 30
Switch(config-cmap)# exit
Switch(config)# class-map c2
Switch(config-cmap)# match precedence 4
Switch(config-cmap)# exit
Switch(config)# class-map c3
Switch(config-cmap)# exit
Switch(config)# policy-map child
Switch(config-pmap)# class c1
Switch(config-pmap-c)# priority level 1
Switch(config-pmap-c)# police rate percent 20 conform-action transmit exceed action drop
Switch(config-pmap-c-policer)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# class c2
Switch(config-pmap-c)# bandwidth 20000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# bandwidth 20000
Switch(config-pmap-c)# exit
Related Topics
Hierarchical QoS, on page 911

Examples: Classification for Voice and Video

This example describes how to classify packet streams for voice and video using switch specific information.

In this example, voice and video are coming in from end-point A into GigabitEthernet1/0/1 on the switch and have precedence values of 5 and 6, respectively. Additionally, voice and video are also coming from end-point B into GigabitEthernet1/0/2 on the switch with DSCP values of EF and AF11, respectively.

Assume that all the packets from the both the interfaces are sent on the uplink interface, and there is a requirement to police voice to 100 Mbps and video to 150 Mbps.

To classify per the above requirements, a class to match voice packets coming in on GigabitEthernet1/0/1 is created, named voice-interface-1, which matches precedence 5. Similarly another class for voice is created, named voice-interface-2, which will match voice packets in GigabitEthernet1/0/2. These classes are associated to two separate policies named input-interface-1, which is attached to GigabitEthernet1/0/1, and input-interface-2, which is attached to GigabitEthernet1/0/2. The action for this class is to mark the qos-group to 10. To match packets with QoS-group 10 on the output interface, a class named voice is created which matches on QoS-group 10. This is then associated to another policy named output-interface, which is associated to the uplink interface. Video is handled in the same way, but matches on QoS-group 20.

The following example shows how classify using the above switch specific information:

Switch(config)#
Switch(config)# class-map voice-interface-1
Switch(config-cmap)# match ip precedence 5
Switch(config-cmap)# exit

Switch(config)# class-map video-interface-1
Switch(config-cmap)# match ip precedence 6
Switch(config-cmap)# exit

Switch(config)# class-map voice-interface-2
Switch(config-cmap)# match ip dscp ef
Switch(config-cmap)# exit

Switch(config)# class-map video-interface-2
Switch(config-cmap)# match ip dscp af11
Switch(config-cmap)# exit

Switch(config)# policy-map input-interface-1
Switch(config-pmap)# class voice-interface-1
Switch(config-pmap-c)# set qos-group 10
Switch(config-pmap-c)# exit

Switch(config-pmap)# class video-interface-1
Switch(config-pmap-c)# set qos-group 20
Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic

The following example provides a template for creating a port child policy for managing quality of service for voice and video traffic.

```
Policy-map port_child_policy
  Class voice (match dscp ef)
    Priority level 1
    Police Multicast Policer
  Class video (match dscp af41)
    Priority level 2
    Police Multicast Policer
  Class mcast-data (match non-client-nrt)
    Bandwidth remaining ratio <>
  Class class-default (NRT Data)
    Bandwidth remaining ratio <>
```

Note

Multicast Policer in the example above is not a keyword. It refers to the policing policy configured.

Two class maps with name voice and video are configured with DSCP assignments of 46 and 34. The voice traffic is assigned the priority of 1 and the video traffic is assigned the priority level 2 and is processed using Q0 and Q1. If your network receives multicast voice and video traffic, you can configure multicast policers. The non-client NRT data and NRT data are processed using the Q2 and Q3 queues.

Related Topics

- Port Policies, on page 907
Examples: Configuring Downstream SSID Policy

To configure a downstream BSSID policy, you must first configure a port child policy with priority level queuing.

Configuring a User-Defined Port Child Policy

The following is an example of configuring a user-defined port child policy:

```conf
policy-map port_child_policy
  class voice
    priority level 1 20000
  class video
    priority level 2 10000
  class non-client-nrt-class
    bandwidth remaining ratio 10
  class class-default
    bandwidth remaining ratio 15
```

Configuring Downstream BSSID Policy

The following configuration example displays how to configure a downstream BSSID policy:

```conf
policy-map bssid-policer
  queue-buffer ratio 0
  class class-default
    shape average 30000000
  set dscp dscp table dscp2dscp
  set wlan user-priority dscp table dscp2up
  service-policy ssid_child_qos
```

The SSID child QoS policy may be defined as below:

```conf
Policy Map ssid-child_qos
  Class voice
    priority level 1
    police cir 5m
    admit cac wmm-tspec
    UP 6,7 / tells WCM allow ‘voice’ TSPEC\SIP snoop for this ssid
    rate 4000 / must be police rate value is in kbps
  Class video
    priority level 2
    police cir 60000
```

Related Topics

- Applying an SSID or Client Policy on a WLAN (CLI), on page 959
- Configuring SSID Policies (GUI), on page 958
Examples: Client Policies

The following example shows a default client policy in the downstream direction. Any incoming traffic contains the user-priority as 0:

```
Note
The default client policy is enabled only on WMM clients that are ACM-enabled.
```

```
Policy-map client-def-down
  class class-default
    set wlan user-priority 0
```

The following example shows the default client policy in the upstream direction. Any traffic that is sent to the wired network from wireless network will result in the DSCP value being set to 0.

```
Note
The default client policy is enabled only on WMM clients that are ACM-enabled.
```

```
Policy-map client-def-up
  class class-default
    set dscp 0
```

The following examples show client policies that are generated automatically and applied to the WMM client when the client authenticates to a profile in AAA with a QoS-level attribute configured.

```
Policy Map platinum-WMM
Class voice-plat
  set wlan user-priority 6
Class video-plat
  set wlan user-priority 4
Class class-default
  set wlan user-priority 0
```

```
Policy Map gold-WMM
Class voice-gold
  set wlan user-priority 4
Class video-gold
  set wlan user-priority 4
Class class-default
  set wlan user-priority 0
```

The following is an example of non-WMM client precious metal policies:

```
Policy Map platinum
  set wlan user-priority 6
```
Any traffic matching class voice1 the user priority is set to a pre-defined value. The class can be set to assign a DSCP or ACL.

```
Policy Map client1-down
Class voice1  //match dscp, cos
    set wlan user-priority <>
Class voice2  //match acl
    set wlan user-priority <>
Class voice3
    set wlan user-priority <>
Class class-default
    set wlan user-priority 0
```

The following is an example of a client policy based on AAA and TCLAS:

```
Policy Map client2-down[ AAA+ TCLAS pol example]
Class voice\match dscp
    police <>
    set <>
Class class-default
    set <>
Class voice1|| voice2 [match acls]
    police <>
    class voice1
    set <>
    class voice2
    set <>
```

The following is an example of a client policy for voice and video for traffic in the downstream direction:

```
Policy Map client3-down
   class voice \match dscp, cos
      police X
   class video
      police Y
   class class-default
      police Z
```

The following is an example of a client policy for voice and video for traffic in the upstream direction using policing:

```
Policy Map client1-up
   class voice \match dscp, up, cos
      police X
   class video
      police Y
   class class-default
      police Z
```

The following is an example of a client policy for voice and video based on DSCP:

```
Policy Map client2-up
   class voice \match dscp, up, cos
   set dscp <>
   class video
      set dscp <>
   class class-default
      set dscp <>
   ```
Examples: Average Rate Shaping Configuration

The following example shows how to configure average rate shaping:

```plaintext
Switch# configure terminal
Switch(config)# class-map prec1
Switch(config-cmap)# description matching precedence 1 packets
Switch(config-cmap)# match ip precedence 1
Switch(config-cmap)# end

Switch# configure terminal
Switch(config)# class-map prec2
Switch(config-cmap)# description matching precedence 2 packets
Switch(config-cmap)# match ip precedence 2
Switch(config-cmap)# exit

Switch(config)# policy-map shaper
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# shape average 512000
Switch(config-pmap-c)# exit

Switch(config-pmap)# policy-map shaper
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# shape average 512000
Switch(config-pmap-c)# exit

Switch(config-pmap)# class class-default
Switch(config-pmap-c)# shape average 1024000
```

After configuring the class maps, policy map, and shape averages for your configuration, proceed to then apply the policy map to the interface for QoS.

Examples: Queue-limit Configuration

The following example shows how to configure a queue-limit policy based upon DSCP values and percentages:

```plaintext
Switch# configure terminal
Switch(config)# policy-map port-queue
Switch(config-pmap)# class dscp-1-2-3
Switch(config-pmap-c)# bandwidth percent 20
Switch(config-pmap-c)# queue-limit dscp 1 percent 80
Switch(config-pmap-c)# queue-limit dscp 2 percent 90
Switch(config-pmap-c)# queue-limit dscp 3 percent 100
Switch#(config-pmap-c)# exit
```
Switch#(config-pmap) class dscp-4-5-6
Switch#(config-pmap-c) bandwidth percent 20
Switch#(config-pmap-c) queue-limit dscp 4 percent 20
Switch#(config-pmap-c) queue-limit dscp 5 percent 30
Switch#(config-pmap-c) queue-limit dscp 6 percent 20
Switch#(config-pmap-c) exit
Switch#(config-pmap) class dscp-7-8-9
Switch#(config-pmap-c) bandwidth percent 20
Switch#(config-pmap-c) queue-limit dscp 7 percent 20
Switch#(config-pmap-c) queue-limit dscp 8 percent 30
Switch#(config-pmap-c) queue-limit dscp 9 percent 20
Switch#(config-pmap-c) exit
Switch#(config-pmap) class dscp-10-11-12
Switch#(config-pmap-c) bandwidth percent 20
Switch#(config-pmap-c) queue-limit dscp 10 percent 20
Switch#(config-pmap-c) queue-limit dscp 11 percent 30
Switch#(config-pmap-c) queue-limit dscp 12 percent 20
Switch#(config-pmap-c) exit
Switch#(config-pmap) class dscp-13-14-15
Switch#(config-pmap-c) bandwidth percent 10
Switch#(config-pmap-c) queue-limit dscp 13 percent 20
Switch#(config-pmap-c) queue-limit dscp 14 percent 30
Switch#(config-pmap-c) queue-limit dscp 15 percent 20
Switch#(config-pmap-c) end
Switch#

After finishing with the above policy map queue-limit configuration, you can then proceed to apply the policy map to an interface for QoS.

Examples: Queue Buffers Configuration

The following example shows how configure a queue buffer policy and then apply it to an interface for QoS:

Switch# configure terminal
Switch(config)# policy-map policy1001
Switch(config-pmap)# class class1001
Switch(config-pmap-c)# bandwidth remaining ratio 10
Switch(config-pmap-c)# queue-buffer ratio ?
  <0-100> Queue-buffers ratio limit
Switch(config-pmap-c)# queue-buffer ratio 20
Switch(config-pmap-c)# end

Switch# configure terminal
Switch(config)# interface gigabitEthernet2/0/3
Switch(config-if)# service-policy output policy1001
Switch(config-if)# end

Related Topics
Configuring Queue Buffers (CLI), on page 984
Examples: Policing Action Configuration

The following example displays the various policing actions that can be associated to the policer. These actions are accomplished using the conforming, exceeding, or violating packet configurations. You have the flexibility to drop, mark and transmit, or transmit packets that have exceeded or violated a traffic profile.

For example, a common deployment scenario is one where the enterprise customer polices traffic exiting the network towards the service provider and marks the conforming, exceeding and violating packets with different DSCP values. The service provider could then choose to drop the packets marked with the exceeded and violated DSCP values under cases of congestion, but may choose to transmit them when bandwidth is available.

Note

The Layer 2 fields can be marked to include the CoS fields, and the Layer 3 fields can be marked to include the precedence and the DSCP fields.

One useful feature is the ability to associate multiple actions with an event. For example, you could set the precedence bit and the CoS for all conforming packets. A submode for an action configuration could then be provided by the policing feature.

This is an example of a policing action configuration:

```
Switch# configure terminal
Switch(config)# policy-map police
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# police cir 1000000 pir 2000000
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Switch(config-pmap-c-police)# violate-action set-dscp-transmit dscp table violate-markdown-table
Switch(config-pmap-c-police)# end
```

In this example, the exceed-markdown-table and violate-markdown-table are table maps.

Note

Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the switch.

Examples: Policer VLAN Configuration

The following example displays a VLAN policer configuration. At the end of this configuration, the VLAN policy map is applied to an interface for QoS.

```
Switch# configure terminal
```
Switch(config)# class-map vlan100
Switch(config-cmap)# match vlan 100
Switch(config-cmap)# exit
Switch(config)# policy-map vlan100
Switch(config-pmap)# policy-map class vlan100
Switch(config-pmap-c)# police 100000 bc conform-action transmit exceed-action drop
Switch(config-pmap-c-policy)# end
Switch# configure terminal
Switch(config)# interface gigabitEthernet1/0/5
Switch(config-if)# service-policy input vlan100

Examples: Policing Units

The following examples display the various units of policing that are supported for QoS. The policing unit is the basis on which the token bucket works.

The following units of policing are supported:

- CIR and PIR are specified in bits per second. The burst parameters are specified in bytes. This is the default mode; it is the unit that is assumed when no units are specified. The CIR and PIR can also be configured in percent, in which case the burst parameters have to be configured in milliseconds.

- CIR and PIR are specified in packets per second. In this case, the burst parameters are configured in packets as well.

The following is an example of a policer configuration in bits per second:

Switch(config)# policy-map bps-policer
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# police rate 256000 bps burst 1000 bytes
conform-action transmit exceed-action drop

The following is an example of a policer configuration in packets per second. In this configuration, a dual-rate three-color policer is configured where the units of measurement is packet. The burst and peak burst are all specified in packets.

Switch(config)# policy-map pps-policer
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# police rate 5000 pps burst 100 packets
peaks-rate 10000 pps peak-burst 200 packets conform-action transmit
exceed-action drop violate-action drop

Related Topics
Configuring Police (CLI), on page 979
Token-Bucket Algorithm, on page 921

Examples: Single-Rate Two-Color Policing Configuration

The following example shows how to configure a single-rate two-color policer:
Examples: Dual-Rate Three-Color Policing Configuration

The following example shows how to configure a dual-rate three-color policer:

```
Switch# configure terminal
Switch(config)# policy-Map dual-rate-3color-policer
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# police cir 64000 bc 2000 pir 128000 be 2000
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Switch(config-pmap-c-police)# violate-action set-dscp-transmit dscp table violate-markdown-table
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)#
```

In this example, the exceed-markdown-table and violate-markdown-table are table maps.

Note

Policer based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the switch.

Examples: Table Map Marking Configuration

The following steps and examples show how to use table map marking for your QoS configuration:

1. Define the table map.

Define the table-map using the `table-map` command and indicate the mapping of the values. This table does not know of the policies or classes within which it will be used. The default command in the table map indicates the value to be copied into the ‘to’ field when there is no matching ‘from’ field. In the example, a table map named `table-map1` is created. The mapping defined is to convert the value from 0 to 1 and from 2 to 3, while setting the default value to 4.

```
Switch(config)# table-map table-map1
```
2. Define the policy map where the table map will be used.

In the example, the incoming CoS is mapped to the DSCP based on the mapping specified in the table table-map1. For this example, if the incoming packet has a DSCP of 0, the CoS in the packet is set 1. If no table map name is specified the command assumes a default behavior where the value is copied as is from the ‘from’ field (DSCP in this case) to the ‘to’ field (CoS in this case). Note however, that while the CoS is a 3-bit field, the DSCP is a 6-bit field, which implies that the CoS is copied to the first three bits in the DSCP.

```
Switch(config)# policy map policy1
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# set cos dscp table table-map1
Switch(config-pmap-c)# exit
```

3. Associate the policy to an interface.

```
Switch(config)# interface GigabitEthernet1/0/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# exit
```

- Table Map Marking, on page 922

**Example: Table Map Configuration to Retain CoS Markings**

The following example shows how to use table maps to retain CoS markings on an interface for your QoS configuration.

The cos-trust-policy policy (configured in the example) is enabled in the ingress direction to retain the CoS marking coming into the interface. If the policy is not enabled, only the DSCP is trusted by default. If a pure Layer 2 packet arrives at the interface, then the CoS value will be rewritten to 0 when there is no such policy in the ingress port for CoS.

```
Switch# configure terminal
Switch(config)# table-map cos2cos
Switch(config-tablemap)# default copy
Switch(config-tablemap)# exit

Switch(config)# policy map cos-trust-policy
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# set cos cos table cos2cos
Switch(config-pmap-c)# exit

Switch(config)# interface GigabitEthernet1/0/2
Switch(config-if)# service-policy input cos-trust-policy
```
Switch(config-if)# exit

• Troubleshooting Auto-QoS, on page 1021
• Configuration Examples for Auto-QoS, on page 1021
• Where to Go Next for Auto-QoS, on page 1050
• Additional References for Auto-QoS, on page 1050
• Feature History and Information for Auto-QoS, on page 1051

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Auto-QoS

The prerequisites for auto-QoS are the same as the prerequisites for standard QoS.

Restrictions for Auto-QoS

The following are restrictions for auto-QoS:

• Auto-qos is not supported on SVI interfaces.

• The trust device device_type command available in interface configuration mode is a stand-alone command on the switch. When using this command, if the connected peer device is not a corresponding
device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.

- You must exercise caution when copying a pre-3.2.2 software version to this switch. If you do copy a pre-3.2.2 software version to this switch, then you must follow the auto-QoS upgrade procedure described later in this chapter.

- Do not configure the `auto qos voip cisco-phone` option for IP phones that support video. This option causes DSCP markings of video packets to get overwritten, because these packets do not have Expedited Forwarding priority, which results in these packets getting classified in the class-default class.

- Auto-QoS does not generate configuration when it is pushed from the startup-configuration using the `auto qos voip cisco-phone` command to the running-configuration. This is expected behavior and this is to prevent overwriting of user-created customized QoS policies by the default configuration, if any, every time the command `auto qos voip cisco-phone` is pushed from the startup-config.

You can use any of the following workarounds for this limitation:

- Configure the `auto qos voip cisco-phone` command manually on the switch interfaces.
- For new switches, if you push auto-QoS commands through startup-config, the command should include each of the following as part of the standard template

  1. Interface-level:

     - `trust device cisco-phone`
     - `auto qos voip cisco-phone`
     - `service-policy input` AutoQos-4.0-CiscoPhone-Input-Policy
     - `service-policy output` AutoQos-4.0-Output-Policy

  2. Global-level:

     - Class-map
     - Policy-map
     - ACL(ACE)

- If the `auto qos voip cisco-phone` command is already configured on an interface but policies are not being generated, disable the command from all the interfaces and reconfigure the command on each interface manually.

Information About Configuring Auto-QoS

Auto-QoS Overview

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows.

The switch employs the MQC model. This means that instead of using certain global configurations, auto-QoS applied to any interface on a switch configures several global class maps and policy maps.
Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

QoS is needed in both directions, both on inbound and outbound. When inbound, the switch port needs to trust the DSCP in the packet (done by default). When outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

**Auto-QoS Global Configuration Templates**

In general, an auto-QoS command generates a series of class maps that either match on ACLs or on DSCP and/or CoS values to differentiate traffic into application classes. An input policy is also generated, which matches the generated classes and in some cases, polices the classes to a set bandwidth. Eight egress-queue class maps are generated. The actual egress output policy assigns a queue to each one of these eight egress-queue class maps.

The auto-QoS commands only generate templates as needed. For example, the first time any new auto-QoS command is used, global configurations that define the eight queue egress service-policy are generated. From this point on, auto-QoS commands applied to other interfaces do not generate templates for egress queuing because all auto-QoS commands rely on the same eight queue models, which have already been generated from the first time a new auto-QoS command was used.

**Auto-QoS Policy and Class Maps**

After entering the appropriate auto-QoS command, the following actions occur:

- Specific class maps are created.
- Specific policy maps (input and output) are created.
- Policy maps are attached to the specified interface.
- Trust level for the interface is configured.

**Related Topics**

[Configuring Auto-QoS (CLI), on page 1016](#)

**Effects of Auto-QoS on Running Configuration**

When auto-QoS is enabled, the **auto qos** interface configuration commands and the generated global configuration are added to the running configuration.

The switch applies the auto-QoS-generated commands as if the commands were entered from the CLI. An existing user configuration can cause the application of the generated commands to fail or to be overridden by the generated commands. These actions may occur without warning. If all the generated commands are successfully applied, any user-entered configuration that was not overridden remains in the running configuration. Any user-entered configuration that was overridden can be retrieved by reloading the switch without saving the current configuration to memory. If the generated commands are not applied, the previous running configuration is restored.
How to Configure Auto-QoS

Configuring Auto-QoS (CLI)

For optimum QoS performance, configure auto-QoS on all the devices in your network.

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. Depending on your auto-QoS configuration, use one of the following commands:
   - auto qos voip {cisco-phone | cisco-softphone | trust}
   - auto qos video {cts | ip-camera | media-player}
   - auto qos classify [police]
   - auto qos trust {cos | dscp}
4. end
5. show auto qos interface interface-id

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td>Specifies the port that is connected to a VoIP port, video device, or the uplink port that is connected to another trusted switch or router in the network interior, and enters the interface configuration mode.</td>
</tr>
<tr>
<td>Example: Switch(config)# interface gigabitethernet 3/0/1</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 3** Depending on your auto-QoS configuration, use one of the following commands: • auto qos voip {cisco-phone | cisco-softphone | trust} | The following commands enable auto-QoS for VoIP:

   - **auto qos voip cisco-phone**—If the port is connected to a Cisco IP Phone, the QoS labels of incoming packets are only trusted (conditional trust through CDP) when the telephone is detected.
### Command or Action

- `auto qos video {cts | ip-camera | media-player}`
- `auto qos classify [police]`
- `auto qos trust {cos | dscp}`

#### Purpose

**Note**

Do not configure the `auto qos voip cisco-phone` option for IP phones that support video. This option causes DSCP markings of video packets to get overwritten, because these packets do not have Expedited Forwarding priority, which results in these packets getting classified in the class-default class.

- **auto qos voip cisco-softphone** — The port is connected to device running the Cisco SoftPhone feature. This command generates a QoS configuration for interfaces connected to PCs running the Cisco IP SoftPhone application and mark, as well as police traffic coming from such interfaces. Ports configured with this command are considered untrusted.

- **auto qos voip trust** — The uplink port is connected to a trusted switch or router, and the VoIP traffic classification in the ingress packet is trusted.

The following commands enable auto-QoS for the specified video device (system, camera, or media player):

- **auto qos video cts** — A port connected to a Cisco Telepresence system. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco TelePresence is detected.

- **auto qos video ip-camera** — A port connected to a Cisco video surveillance camera. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco camera is detected.

- **auto qos video media-player** — A port connected to a CDP-capable Cisco digital media player. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a digital media player is detected.

The following command enables auto-QoS for classification:

- **auto qos classify police** — This command generates a QoS configuration for untrusted interfaces. The configuration places a service-policy on the interface to classify traffic coming from untrusted desktops/devices and mark them accordingly. The service-policies generated do police.

The following commands enable auto-QoS for trusted interfaces:

- **auto qos trust cos** — Class of service.
### Upgrading Auto-QoS (CLI)

This procedure should only be followed after copying a pre-3.2.2 software version to this switch. If you do copy a pre-3.2.2 software version to this switch, then you must follow this auto-QoS upgrade procedure.

**Before you begin**

Prior to upgrading, you need to remove all auto-QoS configurations currently on the switch. This sample procedure describes that process.

After following this sample procedure, you must then reboot the switch with the new or upgraded software image and reconfigure auto-QoS.

**SUMMARY STEPS**

1. show auto qos
2. no auto qos
3. show running-config | i autoQos
4. no policy-map policy-map_name
5. show running-config | i AutoQoS
6. show auto qos
7. write memory

**DETAILED STEPS**

**Step 1**

show auto qos

**Example:**

- **Step 4**

  end
  
  Example:
  
  Switch(config-if)# end

  **Step 5**

  show auto qos interface interface-id
  
  Example:
  
  Switch# show auto qos interface gigabitethernet 3/0/1

  (Optional) Displays the auto-QoS command on the interface on which auto-QoS was enabled. Use the `show running-config` command to display the auto-QoS configuration and user modifications.

**Related Topics**

- Auto-QoS Policy and Class Maps, on page 1015
Switch# show auto qos

GigabitEthernet2/0/3
  auto qos voip cisco-phone
GigabitEthernet2/0/27
  auto qos voip cisco-softphone

In privileged EXEC mode, record all current auto QoS configurations by entering this command.

**Step 2**  
**no auto qos**

**Example:**

Switch(config-if)# no auto qos

In interface configuration mode, run the appropriate **no auto qos** command on each interface that has an auto QoS configuration.

**Step 3**  
**show running-config | i autoQos**

**Example:**

Switch# show running-config | i autoQos

Return to privileged EXEC mode, and record any remaining auto QoS maps class maps, policy maps, access lists, table maps, or other configurations by entering this command.

**Step 4**  
**no policy-map policy-map_name**

**Example:**

Switch(config)# no policy-map pmap_101
Switch(config)# no class-map cmap_101
Switch(config)# no ip access-list extended AutoQos-101
Switch(config)# no table-map 101
Switch(config)# no table-map policed-dscp

In global configuration mode, remove the QoS class maps, policy maps, table maps, and any other auto QoS configurations by entering these commands:

- **no policy-map policy-map-name**
- **no class-map class-map-name**
- **no ip access-list extended Auto-QoS-x**
- **no table-map table-map-name**
- **no table-map policed-dscp**

**Step 5**  
**show running-config | i AutoQoS**

**Example:**
Switch# show running-config | i AutoQos

Return to privileged EXEC mode, run this command again to ensure that no auto-QoS configuration or remaining parts of the auto-QoS configuration exists.

**Step 6**

**show auto qos**

**Example:**

Switch# show auto qos

Run this command to ensure that no auto-QoS configuration or remaining parts of the configuration exists.

**Step 7**

**write memory**

**Example:**

Switch# write memory

Write the changes to the auto QoS configuration to NV memory by entering the `write memory` command.

---

**What to do next**

Reboot the switch with the new or upgraded software image.

After rebooting with the new or upgraded software image, re-configure auto-QoS for the appropriate switch interfaces as determined by running the `show auto qos` command described in step 1.

---

**Note**

There is only one table-map for exceed and another table-map for violate markdown per switch or stack. If the switch already has a table-map under the exceed action, then the auto-qos policy cannot be applied.

</tr>
</thead>
<tbody>
<tr>
<td><code>show auto qos [interface [interface-id]]</code></td>
<td>Displays the initial auto-QoS configuration. You can compare the <code>show auto qos</code> and the <code>show running-config</code> command output to identify the user-defined QoS settings.</td>
</tr>
</tbody>
</table>
Troubleshooting Auto-QoS

To troubleshoot auto-QoS, use the `debug auto qos` privileged EXEC command. For more information, see the `debug auto qos` command in the command reference for this release.

To disable auto-QoS on a port, use the `no` form of the `auto qos` command interface configuration command, such as `no auto qos voip`. Only the auto-QoS-generated interface configuration commands for this port are removed. If this is the last port on which auto-QoS is enabled and you enter the `no auto qos voip` command, auto-QoS is considered disabled even though the auto-QoS-generated global configuration commands remain (to avoid disrupting traffic on other ports affected by the global configuration).

Configuration Examples for Auto-QoS

Example: auto qos trust cos

The following is an example of the `auto qos trust cos` command and the applied policies and class maps.

The following policy maps are created and applied when running this command:
  - AutoQos-4.0-Trust-Cos-Input-Policy
  - AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:
  - class-default (match-any)
  - AutoQos-4.0-Output-Priority-Queue (match-any)
  - AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
  - AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
  - AutoQos-4.0-Output-Trans-Data-Queue (match-any)
  - AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
  - AutoQos-4.0-Output-Scavenger-Queue (match-any)
  - AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

```

Example: auto qos voip cisco-softphone
The following is an example of the `auto qos classify police` command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-Classify-Police-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- AutoQos-4.0-Multimedia-Conf-Class (match-any)
- AutoQos-4.0-Bulk-Data-Class (match-any)
- AutoQos-4.0-Transaction-Class (match-any)
- AutoQos-4.0-Scavanger-Class (match-any)
- AutoQos-4.0-Signaling-Class (match-any)
- AutoQos-4.0-Default-Class (match-any)
- class-default (match-any)
- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
- AutoQos-4.0-Output-Trans-Data-Queue (match-any)
- AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
- AutoQos-4.0-Output-Scavenger-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

```bash
Switch(config)# interface gigabitEthernet1/0/6
Switch(config-if)# auto qos classify police
Switch(config-if)# end
Switch# show policy-map interface gigabitEthernet1/0/6
