Obtaining Documentation and Submitting a Service Request  cix

CHAPTER 1

Using the Command-Line Interface  1
Information About Using the Command-Line Interface  1
Command Modes  1
Understanding Abbreviated Commands  3
No and Default Forms of Commands  3
CLI Error Messages  3
Configuration Logging  4
Using the Help System  4
How to Use the CLI to Configure Features  5
Configuring the Command History  5
Changing the Command History Buffer Size  5
Recalling Commands  6
Disabling the Command History Feature  6
Enabling and Disabling Editing Features  7
Editing Commands Through Keystrokes  7
Editing Command Lines That Wrap  8
Searching and Filtering Output of show and more Commands  9
Accessing the CLI  10
Accessing the CLI Through a Console Connection or Through Telnet  10

PART I

CleanAir  13
CHAPTER 2

**Configuring Cisco CleanAir**  15

Finding Feature Information  15
Prerequisites for CleanAir  15
Restrictions for CleanAir  16
Information About CleanAir  17
Cisco CleanAir Components  17
Terms Used in Cisco CleanAir  19
Interference Types that Cisco CleanAir can Detect  19
Interference Device Merging  20
Persistent Devices  21
Persistent Devices Detection  21
Persistent Device Avoidance  21
EDRRM and AQR Update Mode  21
CleanAir High Availability  21

How to Configure CleanAir  22

Enabling CleanAir for 2.4-GHz Band  22
Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices  22
Configuring Interference Reporting for 2.4-GHz Devices  24
Enabling CleanAir for 5-GHz Band  25
Configuring a CleanAir Alarm for 5-GHz Air-Quality and Devices  26
Configuring Interference Reporting for 5-GHz devices  27
Configuring EDRRM for CleanAir-Events  29
Configuring Persistent Device Avoidance  29
Configuring Cisco CleanAir using the Controller GUI  30
Configuring Cisco Spectrum Expert  30
Configuring Spectrum Expert (CLI)  30
Monitoring CleanAir Parameters  32
Monitoring the Interference Devices  34
Configuration Examples for Configuring CleanAir  34
CleanAir FAQs  35
Additional References  37

PART II

**Interface and Hardware Component**  39
CHAPTER 3  Configuring Interface Characteristics  41

Finding Feature Information  41
Information About Configuring Interface Characteristics  41
Interface Types  41
Port-Based VLANs  42
Switch Ports  42
Routed Ports  43
Switch Virtual Interfaces  44
EtherChannel Port Groups  45
10-Gigabit Ethernet Interfaces  45
Power over Ethernet Ports  45
Using the Switch USB Ports  45
USB Mini-Type B Console Port  46
USB Type A Port  46
Interface Connections  47
Interface Configuration Mode  47
Default Ethernet Interface Configuration  49
Interface Speed and Duplex Mode  50
Speed and Duplex Configuration Guidelines  50
IEEE 802.3x Flow Control  51
Layer 3 Interfaces  51
How to Configure Interface Characteristics  52
Configuring Interfaces  52
Adding a Description for an Interface  53
Configuring a Range of Interfaces  54
Configuring and Using Interface Range Macros  56
Configuring Ethernet Interfaces  57
Setting the Interface Speed and Duplex Parameters  57
Configuring IEEE 802.3x Flow Control  59
Configuring Layer 3 Interfaces  60
Configuring Logical Layer 3 GRE Tunnel Interfaces  62
Configuring SVI Autostate Exclude  63
Shutting Down and Restarting the Interface  64
Feature Information for PoE 126

CHAPTER 10  Configuring the Cisco eXpandable Power System (XPS) 2200 127
Restrictions for Configuring the XPS 2200 127
Information About Configuring the XPS 2200 127
Cisco eXpandable Power System (XPS) 2200 Overview 127
XPS 2200 Power Supply Modes 128
   RPS Mode 128
   Stack Power Mode 129
   Mixed Modes 130
XPS 2200 System Defaults 130
How to Configure the XPS 2200 131
   Configuring System Names 131
   Configuring XPS Ports 132
   Configuring XPS Power Supplies 133
Monitoring and Maintaining the XPS 2200 134
Additional References 134
   Feature History and Information for XPS 2200 135
   Related Documents 135
   Standards 135
   MIBs 135
   RFCs 135
   Technical Assistance 136

CHAPTER 11  Configuring EEE 137

PART III  IPv6 139

CHAPTER 12  Configuring MLD Snooping 141
Finding Feature Information 141
Information About Configuring IPv6 MLD Snooping 141
Understanding MLD Snooping 142
   MLD Messages 143
   MLD Queries 143
Contents

CHAPTER 15

Configuring IPv6 Client IP Address Learning 213
Prerequisites for IPv6 Client Address Learning 213
Information About IPv6 Client Address Learning 213
SLAAC Address Assignment 214
Stateful DHCPv6 Address Assignment 215
Static IP Address Assignment 216
Router Solicitation 216
Router Advertisement 216
Neighbor Discovery 217
Neighbor Discovery Suppression 217
RA Guard 217
RA Throttling 218
Configuring IPv6 Unicast (CLI) 218
Configuring RA Guard Policy (CLI) 219
Applying RA Guard Policy (CLI) 220
Configuring RA Throttle Policy (CLI) 221
Applying RA Throttle Policy on VLAN (CLI) 222
How to Configure IPv6 Neighbor Tracking 223
Configuring IPv6 Snooping (CLI) 225
Configuring IPv6 ND Suppress Policy (CLI) 225
Configuring IPv6 Snooping on VLAN/PortChannel 226
Configuring IPv6 on Switch (CLI) 227
Configuring DHCP Pool (CLI) 228
Configuring Stateless Auto Address Configuration Without DHCP (CLI) 229
Configuring Stateless Auto Address Configuration With DHCP (CLI) 230
Configuring Stateful DHCP Locally (CLI) 231
Configuring Stateful DHCP Externally (CLI) 233
CHAPTER 16

Configuring IPv6 WLAN Security

Prerequisites for IPv6 WLAN Security
Restrictions for IPv6 WLAN Security
Information About IPv6 WLAN Security
How to Configure IPv6 WLAN Security
Configuring Local Authentication
  Creating a Local User
  Creating an Client VLAN and Interface
  Configuring a EAP Profile
  Creating a Local Authentication Model
  Creating a Client WLAN
Configuring Local Authentication with WPA2+AES
Configuring External RADIUS Server
  Configuring RADIUS Authentication Server Host
  Configuring RADIUS Authentication Server Group
  Creating a Client VLAN
  Creating 802.1x WLAN Using an External RADIUS Server
Additonal References
Feature Information for IPv6 WLAN Security

CHAPTER 17

Configuring IPv6 ACL

Prerequisites for IPv6 ACL
Restrictions for IPv6 ACL
Information About IPv6 ACL
Understanding IPv6 ACLs
Types of ACL
  Per User IPv6 ACL
  Filter ID IPv6 ACL
IPv6 ACLs and Switch Stacks
Configuring IPv6 ACLs
# Contents

Additional References 286

Feature Information for IPv6 Web Authentication 287

## CHAPTER 19 Configuring IPv6 Client Mobility 289

- Prerequisites for IPv6 Client Mobility 289
- Restrictions For IPv6 Client Mobility 289
- Information About IPv6 Client Mobility 290
  - Using Router Advertisement 290
  - RA Throttling and NS suppression 291
  - IPv6 Address Learning 292
  - Handling Multiple IP Addresses 292
  - IPv6 Configuration 292
  - High Availability 293
- Verifying IPv6 Client Mobility 293
- Monitoring IPv6 Client Mobility 293
- Additional References 294
  - Feature Information For IPv6 Client Mobility 295

## CHAPTER 20 Configuring IPv6 Mobility 297

- Pre-requisites for IPv6 Mobility 297
- Information About IPv6 Mobility 297
  - Inter Controller Roaming 297
    - Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming 298
- How to Configure IPv6 Mobility 298
- Monitoring IPv6 Mobility 298
- Additional References 300
  - Feature Information for IPv6 Mobility 301

## PART IV IP 303

## CHAPTER 21 Configuring HSRP 305

- Configuring HSRP 305
  - Finding Feature Information 305
  - Information About Configuring HSRP 305
# Configuring IGMP

## Chapter 23

### Finding Feature Information

- Prerequisites for IGMP and IGMP Snooping
  - Prerequisites for IGMP
  - Prerequisites for IGMP Snooping
- Restrictions for IGMP and IGMP Snooping
  - Restrictions for Configuring IGMP
  - Restrictions for IGMP Snooping
- Information About IGMP
  - Role of the Internet Group Management Protocol

### IGMP Multicast Addresses

### IGMP Versions

- IGMP Version 1
- IGMP Version 2
- IGMP Version 3

### IGMPv3 Host Signaling

### IGMP Versions Differences

### IGMP Join and Leave Process

- IGMP Join Process
- IGMP Leave Process

### IGMP Snooping

- Joining a Multicast Group
- Leaving a Multicast Group

### Immediate Leave

- IGMP Configurable-Leave Timer
- IGMP Report Suppression
IGMP Filtering and Throttling 348
Default IGMP Configuration 348
  Default IGMP Snooping Configuration 349
  Default IGMP Filtering and Throttling Configuration 349
How to Configure IGMP 350
  Configuring the Device as a Member of a Group (CLI) 350
  Controlling Access to IP Multicast Group (CLI) 351
  Changing the IGMP Version(CLI) 353
  Modifying the IGMP Host-Query Message Interval (CLI) 355
  Changing the IGMP Query Timeout for IGMPv2 (CLI) 356
  Changing the Maximum Query Response Time for IGMPv2 (CLI) 358
  Configuring the Device as a Statically Connected Member (CLI) 359
  Configuring IGMP Profiles (CLI) 361
  Applying IGMP Profiles (CLI) 363
  Setting the Maximum Number of IGMP Groups (CLI) 364
  Configuring the IGMP Throttling Action (CLI) 365
How to Configure IGMP Snooping 367
  Enabling IGMP Snooping 367
  Enabling or Disabling IGMP Snooping on a VLAN Interface (CLI) 368
  Setting the Snooping Method (CLI) 369
  Configuring a Multicast Router Port (CLI) 370
  Configuring a Host Statical to Join a Group (CLI) 372
  Enabling IGMP Immediate Leave (CLI) 373
  Configuring the IGMP Leave Timer (CLI) 374
  Configuring the IGMP Robustness-Variable (CLI) 376
  Configuring the IGMP Last Member Query Count (CLI) 377
  Configuring TCN-Related Commands 379
  Configuring the IGMP Snooping Querier (CLI) 382
  Disabling IGMP Report Suppression (CLI) 384
Monitoring IGMP 386
  Monitoring IGMP Snooping Information 386
  Monitoring IGMP Filtering and Throttling Configuration 388
Configuration Examples for IGMP 388
  Example: Configuring the Device as a Member of a Multicast Group 388
Example: Controlling Access to Multicast Groups 388
Examples: Configuring IGMP Snooping 389
Example: Configuring IGMP Profiles 390
Example: Applying IGMP Profile 390
Example: Setting the Maximum Number of IGMP Groups 390
Example: Interface Configuration as a Routed Port 390
Example: Interface Configuration as an SVI 391
Additional References 391
Feature History and Information for IGMP 392

CHAPTER 24
Configuring IGMP Proxy 393
Finding Feature Information 393
Prerequisites for IGMP Proxy 393
Information about IGMP Proxy 394
IGMP Proxy 394
How to Configure IGMP Proxy 396
   Configuring the Upstream UDL Device for IGMP UDLR 396
   Configuring the Downstream UDL Device for IGMP UDLR with IGMP Proxy Support 397
Configuration Examples for IGMP Proxy 400
   Example: IGMP Proxy Configuration 400
Additional References 401
Feature History and Information for IGMP Proxy 402

CHAPTER 25
Constraining IP Multicast in Switched Ethernet 403
Finding Feature Information 403
Prerequisites for Constraining IP Multicast in a Switched Ethernet Network 403
Information About IP Multicast in a Switched Ethernet Network 404
   IP Multicast Traffic and Layer 2 Switches 404
   CGMP on Catalyst Switches for IP Multicast 404
   IGMP Snooping 405
   Router-Port Group Management Protocol (RGMP) 405
How to Constrain Multicast in a Switched Ethernet Network 405
   Configuring Switches for IP Multicast 405
   Configuring IGMP Snooping 406
CHAPTER 26

Configuring PIM 411

Finding Feature Information 411
Prerequisites for PIM 411
Restrictions for PIM 412
PIMv1 and PIMv2 Interoperability 412
Restrictions for Configuring PIM Stub Routing 413
Restrictions for Configuring Auto-RP and BSR 413
Restrictions for Auto-RP Enhancement 414
Information About PIM 415
Protocol Independent Multicast Overview 415
PIM Dense Mode 415
PIM Sparse Mode 416
Multicast Source Discovery Protocol (MSDP) 416
Sparse-Dense Mode 417
PIM Versions 417
PIM Stub Routing 418
IGMP Helper 419
Rendezvous Points 419
Auto-RP 420
The Role of Auto-RP in a PIM Network 421
Multicast Boundaries 421
Sparse-Dense Mode for Auto-RP 422
Auto-RP Benefits 422
PIMv2 Bootstrap Router 423
PIM Domain Border 423
Multicast Forwarding 424
Multicast Distribution Source Tree 424
Multicast Distribution Shared Tree 425
Source Tree Advantage 425
Shared Tree Advantage 426
PIM Shared Tree and Source Tree 426
Reverse Path Forwarding 427
RPF Check 428
Default PIM Routing Configuration 429
How to Configure PIM 430
Enabling PIM Stub Routing (CLI) 430
Configuring a Rendezvous Point 432
Manually Assigning an RP to Multicast Groups (CLI) 432
Setting Up Auto-RP in a New Internetwork (CLI) 434
Adding Auto-RP to an Existing Sparse-Mode Cloud (CLI) 437
Preventing Join Messages to False RPs (CLI) 440
Filtering Incoming RP Announcement Messages (CLI) 440
Configuring PIMv2 BSR 442
Defining the PIM Domain Border (CLI) 443
Defining the IP Multicast Boundary (CLI) 444
Configuring Candidate BSRs (CLI) 446
Configuring the Candidate RPs (CLI) 447
Configuring Sparse Mode with Auto-RP (CLI) 449
Delaying the Use of PIM Shortest-Path Tree (CLI) 454
Modifying the PIM Router-Query Message Interval (CLI) 456
Verifying PIM Operations 458
Verifying IP Multicast Operation in a PIM-SM or a PIM-SSM Network 458
Verifying IP Multicast on the First Hop Router 458
Verifying IP Multicast on Routers Along the SPT 459
Verifying IP Multicast Operation on the Last Hop Router 460
Using PIM-Enabled Routers to Test IP Multicast Reachability 464
Configuring Routers to Respond to Multicast Pings 464
Pinging Routers Configured to Respond to Multicast Pings 465
Monitoring and Troubleshooting PIM 466
Monitoring PIM Information 466
Monitoring the RP Mapping and BSR Information 467
Troubleshooting PIMv1 and PIMv2 Interoperability Problems 467
Configuration Examples for PIM 468
Example: Enabling PIM Stub Routing 468
Example: Verifying PIM Stub Routing 468
Example: Manually Assigning an RP to Multicast Groups 469
Example: Configuring Auto-RP 469
Example: Sparse Mode with Auto-RP 469
Example: Defining the IP Multicast Boundary to Deny Auto-RP Information 469
Example: Filtering Incoming RP Announcement Messages 470
Example: Preventing Join Messages to False RPs 470
Example: Configuring Candidate BSRs 470
Example: Configuring Candidate RPs 471
Additional References 471
Feature History and Information for PIM 473

CHAPTER 27
Configuring PIM MIB Extension for IP Multicast 475
Finding Feature Information 475
Information About PIM MIB Extension for IP Multicast 475
PIM MIB Extensions for SNMP Traps for IP Multicast 475
Benefits of PIM MIB Extensions 476
How to Configure PIM MIB Extension for IP Multicast 476
Enabling PIM MIB Extensions for IP Multicast 476
Configuration Examples for PIM MIB Extensions 478
Example Enabling PIM MIB Extensions for IP Multicast 478
Additional References 478

CHAPTER 28
Configuring MSDP 481
Finding Feature Information 481
Information About Using MSDP to Interconnect Multiple PIM-SM Domains 481
Benefits of Using MSDP to Interconnect Multiple PIM-SM Domains 481
482
MSDP Message Types 484
How to Configure Wireless Multicast 528
  Configuring Wireless Multicast-MCMC Mode (CLI) 528
  Configuring Wireless Multicast-MCUCC Mode (CLI) 529
  Configuring IPv6 Snooping (CLI) 530
  Configuring IPv6 Snooping Policy (CLI) 531
  Configuring Layer 2 Port as Multicast Router Port (CLI) 532
  Configuring IPv6 RA Guard (CLI) 532
  Configuring Non-IP Wireless Multicast (CLI) 533
  Configuring Wireless Broadcast (CLI) 534
  Configuring IP Multicast VLAN for WLAN (CLI) 535
Monitoring Wireless Multicast 536
Where to Go Next for Wireless Multicast 537

CHAPTER 30 Configuring SSM 539
  Finding Feature Information 539
  Prerequisites for Configuring SSM 539
  Restrictions for Configuring SSM 540
  Information About SSM 541
    SSM Components Overview 541
    SSM and Internet Standard Multicast (ISM) 541
    SSM IP Address Range 542
    SSM Operations 542
    SSM Mapping 542
    Static SSM Mapping 543
    DNS-Based SSM Mapping 543
  How to Configure SSM 544
    Configuring SSM (CLI) 544
    Configuring Source Specific Multicast Mapping 546
    Configuring Static SSM Mapping (CLI) 546
    Configuring DNS-Based SSM Mapping (CLI) 548
    Configuring Static Traffic Forwarding with SSM Mapping (CLI) 549
  Monitoring SSM 551
    Monitoring SSM Mapping 551
  Where to Go Next for SSM 552
Additional References  552
Feature History and Information for SSM  553

CHAPTER 31

Configuring Basic IP Multicast Routing  555
Finding Feature Information  555
Prerequisites for Basic IP Multicast Routing  555
Restrictions for Basic IP Multicast Routing  556
Information About Basic IP Multicast Routing  556
  Multicast Forwarding Information Base Overview  556
  Default IP Multicast Routing Configuration  557
How to Configure Basic IP Multicast Routing  557
  Configuring Basic IP Multicast Routing  557
  Configuring IP Multicast Forwarding (CLI)  560
  Configuring a Static Multicast Route (mroute) (CLI)  561
  Configuring Optional IP Multicast Routing Features  563
    Defining the IP Multicast Boundary (CLI)  563
    Configuring sdr Listener Support  565
Monitoring and Maintaining Basic IP Multicast Routing  567
  Clearing Caches, Tables, and Databases  567
  Displaying System and Network Statistics  568
  Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing  570
Configuration Examples for IP Multicast Routing  571
  Example: Configuring an IP Multicast Boundary  571
  Example: Responding to mrinfo Requests  571
Additional References  571
Feature History and Information for IP Multicast  573

CHAPTER 32

Configuring the Service Discovery Gateway  575
Finding Feature Information  575
Restrictions for Configuring the Service Discovery Gateway  575
Information about the Service Discovery Gateway and mDNS  576
  mDNS  576
    mDNS-SD  576
  Service Discovery Gateway  577
mDNS Gateway and Subnets 577
Filtering 578

How to Configure the Service Discovery Gateway 579
Configuring the Service List (CLI) 579
Enabling mDNS Gateway and Redistributing Services (CLI) 581

Monitoring Service Discovery Gateway 584

Configuration Examples 584
Example: Specify Alternative Source Interface for Outgoing mDNS Packets 584
Example: Redistribute Service Announcements 584
Example: Disable Bridging of mDNS Packets to Wireless Clients 585
Example: Creating a Service-List, Applying a Filter and Configuring Parameters 585
Example: Enabling mDNS Gateway and Redistributing Services 585
Example: Global mDNS Configuration 586
Example: Interface mDNS Configuration 586

Where to Go Next for Configuring Services Discovery Gateway 586

Additional References 587

Feature History and Information for Services Discovery Gateway 588

CHAPTER 33  IP Multicast Optimization: Optimizing PIM Sparse Mode in a Large IP Multicast Deployment 589
Prerequisites for Optimizing PIM Sparse Mode in a Large IP Multicast Deployment 589
Information About Optimizing PIM Sparse Mode in a Large IP Multicast Deployment 589
PIM Registering Process 589
  PIM Version 1 Compatibility 590
PIM Designated Router 590
PIM Sparse-Mode Register Messages 591
Preventing Use of Shortest-Path Tree to Reduce Memory Requirement 591
  PIM Shared Tree and Source Tree 591
  Benefit of Preventing or Delaying the Use of the Shortest-Path Tree 592
How to Optimize PIM Sparse Mode in a Large IP Multicast Deployment 593
  Optimizing PIM Sparse Mode in a Large Deployment 593
Configuration Examples for Optimizing PIM Sparse Mode in a Large Multicast Deployment 595
  Optimizing PIM Sparse Mode in a Large IP Multicast Deployment Example 595
Additional References 595
### CHAPTER 34

**IP Multicast Optimization: Multicast Subsecond Convergence**

- Finding Feature Information  
- Prerequisites for Multicast Subsecond Convergence  
- Restrictions for Multicast Subsecond Convergence  
- Information About Multicast Subsecond Convergence  
  - Benefits of Multicast Subsecond Convergence  
  - Multicast Subsecond Convergence Scalability Enhancements  
  - PIM Router Query Messages  
  - Reverse Path Forwarding  
  - RPF Checks  
  - Triggered RPF Checks  
  - RPF Failover  
- Topology Changes and Multicast Routing Recovery  
- How to Configure Multicast Subsecond Convergence  
  - Modifying the Periodic RPF Check Interval  
  - Configuring PIM RPF Failover Intervals  
  - Modifying the PIM Router Query Message Interval  
  - Verifying Multicast Subsecond Convergence Configurations  
- Configuration Examples for Multicast Subsecond Convergence  
  - Example Modifying the Periodic RPF Check Interval  
  - Example Configuring PIM RPF Failover Intervals  
  - Modifying the PIM Router Query Message Interval Example  
- Additional References  
- Feature History and Information for Multicast Subsecond Convergence

---

### CHAPTER 35

**IP Multicast Optimization: IP Multicast Load Splitting across Equal-Cost Paths**

- Finding Feature Information  
- Prerequisites for IP Multicast Load Splitting across Equal-Cost Paths  
- Information About IP Multicast Load Splitting across Equal-Cost Paths  
  - Load Splitting Versus Load Balancing  
  - Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist
Methods to Load Split IP Multicast Traffic 610
Overview of ECMP Multicast Load Splitting 610

ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm 610
ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm 610
Predictability As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms 611
Polarization As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms 611
ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address 612
Effect of ECMP Multicast Load Splitting on PIM Neighbor Query and Hello Messages for RPF Path Selection 613
Effect of ECMP Multicast Loading Splitting on Assert Processing in PIM-DM and DF Election in Bidir-PIM 613
Effect of ECMP Multicast Load Splitting on the PIM Assert Process in PIM-SM and PIM-SSM 614

ECMP Multicast Load Splitting and Reconvergence When Unicast Routing Changes 615
Use of BGP with ECMP Multicast Load Splitting 615
Use of ECMP Multicast Load Splitting with Static Mroutes 616
Alternative Methods of Load Splitting IP Multicast Traffic 616

How to Load Split IP Multicast Traffic over ECMP 617
Enabling ECMP Multicast Load Splitting 617
Prerequisites for IP Multicast Load Splitting - ECMP 617
Restrictions 618
Enabling ECMP Multicast Load Splitting Based on Source Address 618
Enabling ECMP Multicast Load Splitting Based on Source and Group Address 620
Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address 622

Configuration Examples for Load Splitting IP Multicast Traffic over ECMP 624
Example Enabling ECMP Multicast Load Splitting Based on Source Address 624
Example Enabling ECMP Multicast Load Splitting Based on Source and Group Address 624
Example Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address 624

Additional References 625
Feature History and Information for Load Splitting IP Multicast Traffic over ECMP 625

CHAPTER 36

IP Multicast Optimization: SSM Channel Based Filtering for Multicast 627
Finding Feature Information 627
How to Configure Spanning-Tree Features 661
  Changing the Spanning-Tree Mode (CLI) 661
  Disabling Spanning Tree (CLI) 662
  Configuring the Root Device (CLI) 663
  Configuring a Secondary Root Device (CLI) 664
  Configuring Port Priority (CLI) 665
  Configuring Path Cost (CLI) 667
  Configuring the Device Priority of a VLAN (CLI) 668
  Configuring the Hello Time (CLI) 669
  Configuring the Forwarding-Delay Time for a VLAN (CLI) 670
  Configuring the Maximum-Aging Time for a VLAN (CLI) 671
  Configuring the Transmit Hold-Count (CLI) 672
Monitoring Spanning-Tree Status 673
Additional References for Spanning-Tree Protocol 673
Feature Information for STP 674

CHAPTER 40 Configuring Multiple Spanning-Tree Protocol 675
  Finding Feature Information 675
  Prerequisites for MSTP 675
  Restrictions for MSTP 676
  Information About MSTP 677
    MSTP Configuration 677
    MSTP Configuration Guidelines 677
  Root Switch 678
  Multiple Spanning-Tree Regions 679
    IST, CIST, and CST 679
      Operations Within an MST Region 680
      Operations Between MST Regions 680
      IEEE 802.1s Terminology 681
    Illustration of MST Regions 681
  Hop Count 682
  Boundary Ports 683
  IEEE 802.1s Implementation 683
    Port Role Naming Change 683
Configuring Persistence with Auto-LAG 769
Monitoring EtherChannel, PAgP, and LACP Status 769
Configuration Examples for Configuring EtherChannels 770
   Configuring Layer 2 EtherChannels: Examples 770
   Configuring Layer 3 EtherChannels: Examples 771
   Configuring LACP Hot-Standby Ports: Example 772
   Configuring Auto LAG: Examples 772
Additional References for EtherChannels 773
Feature Information for EtherChannels 774

CHAPTER 43  Configuring UniDirectional Link Detection 775
   Finding Feature Information 775
   Restrictions for Configuring UDLD 775
   Information About UDLD 776
      Modes of Operation 776
         Normal Mode 776
         Aggressive Mode 776
   Methods to Detect Unidirectional Links 777
      Neighbor Database Maintenance 777
      Event-Driven Detection and Echoing 778
      UDLD Reset Options 778
   Default UDLD Configuration 778
   How to Configure UDLD 779
      Enabling UDLD Globally (CLI) 779
      Enabling UDLD on an Interface (CLI) 780
   Monitoring and Maintaining UDLD 781
   Additional References for UDLD 781
   Feature Information for UDLD 782

PART VII  Lightweight Access Point 783

CHAPTER 44  Configuring the Device for Access Point Discovery 785
   Finding Feature Information 785
   Prerequisites for Configuring the Device for Access Point Discovery 785
Restrictions for Configuring the Device for Access Point Discovery 786
Information About Configuring the Device for Access Point Discovery 786
  Access Point Communication Protocols 786
  Viewing Access Point Join Information 787
  Troubleshooting the Access Point Join Process 787
How to Configure Access Point Discovery 788
  Configuring the Syslog Server for Access Points (CLI) 788
  Monitoring Access Point Join Information (CLI) 788
Configuration Examples for Configuring the Device for Access Point Discovery 789
  Displaying the MAC Addresses of all Access Points: Example 789
  DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example 791
Configuring AP Pass Through 791
  Information About AP Pass Through 791
  Configuring AP Pass Through 791

CHAPTER 45
Configuring Data Encryption 793
  Finding Feature Information 793
  Prerequisites for Configuring Data Encryption 793
  Restrictions for Configuring Data Encryption 793
  Information About Data Encryption 794
  How to Configure Data Encryption 794
    Configuring Data Encryption (CLI) 794
  Configuration Examples for Configuring Data Encryption 795
    Displaying Data Encryption States for all Access Points: Examples 795

CHAPTER 46
Configuring Retransmission Interval and Retry Count 797
  Finding Feature Information 797
  Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count 797
  Information About Retransmission Interval and Retry Count 798
  How to Configure Access Point Retransmission Interval and Retry Count 798
    Configuring the Access Point Retransmission Interval and Retry Count (CLI) 798
  Viewing CAPWAP Maximum Transmission Unit Information (CLI) 799
  Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count 800
    Viewing the CAPWAP Retransmission Details: Example 800
Viewing Maximum Transmission Unit Information: Example 800

CHAPTER 47  Configuring Adaptive Wireless Intrusion Prevention System 801
Finding Feature Information 801
Prerequisites for Configuring wIPS 801
How to Configure wIPS on Access Points 801
Configuring wIPS on an Access Point (CLI) 801
Monitoring wIPS Information 803
Configuration Examples for Configuring wIPS on Access Points 804
Displaying the Monitor Configuration Channel Set: Example 804
Displaying wIPS Information: Examples 804

CHAPTER 48  Configuring Authentication for Access Points 807
Finding Feature Information 807
Prerequisites for Configuring Authentication for Access Points 807
Restrictions for Configuring Authentication for Access Points 808
Information about Configuring Authentication for Access Points 808
How to Configure Authentication for Access Points 808
Configuring Global Credentials for Access Points (CLI) 808
Configuring Authentication for Access Points (CLI) 810
Configuring the Switch for Authentication (CLI) 812
Configuration Examples for Configuring Authentication for Access Points 814
Displaying the Authentication Settings for Access Points: Examples 814

CHAPTER 49  Converting Autonomous Access Points to Lightweight Mode 815
Finding Feature Information 815
Prerequisites for Converting Autonomous Access Points to Lightweight Mode 815
Information About Autonomous Access Points Converted to Lightweight Mode 816
Reverting from Lightweight Mode to Autonomous Mode 816
Using DHCP Option 43 and DHCP Option 60 816
How Converted Access Points Send Crash Information to the Device 816
Uploading Memory Core Dumps from Converted Access Points 817
Displaying MAC Addresses for Converted Access Points 817
Configuring a Static IP Address for a Lightweight Access Point 817

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches) xxxix
How to Convert a Lightweight Access Point Back to an Autonomous Access Point 818
Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI) 818
Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server) 818
Authorizing Access Points (CLI) 819
Disabling the Reset Button on Converted Access Points (CLI) 820
Monitoring the AP Crash Log Information 821
How to Configure a Static IP Address on an Access Point 822
Configuring a Static IP Address on an Access Point (CLI) 822
Recovering the Access Point Using the TFTP Recovery Procedure 823
Configuration Examples for Converting Autonomous Access Points to Lightweight Mode 824
Displaying the IP Address Configuration for Access Points: Example 824
Displaying Access Point Crash File Information: Example 824

CHAPTER 50
Using Cisco Workgroup Bridges 825
Finding Feature Information 825
Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges 825
Monitoring the Status of Workgroup Bridges 826
Debugging WGB Issues (CLI) 826
Configuration Examples for Configuring Workgroup Bridges 828
WGB Configuration: Example 828

CHAPTER 51
Configuring Probe Request Forwarding 829
Finding Feature Information 829
Information About Configuring Probe Request Forwarding 829
How to Configure Probe Request Forwarding (CLI) 829

CHAPTER 52
Optimizing RFID Tracking 831
Finding Feature Information 831
Optimizing RFID Tracking on Access Points 831
How to Optimize RFID Tracking on Access Points 831
Optimizing RFID Tracking on Access Points (CLI) 831
Configuration Examples for Optimizing RFID Tracking 833
Displaying all the Access Points in Monitor Mode: Example 833
PART VIII  Mobility  853

CHAPTER 56  Information About Mobility  855

Overview  855
Wired and Wireless Mobility  856
Features of Mobility  856
Sticky Anchoring for Low Latency Roaming  858
Bridge Domain ID and L2/L3 Roaming  858
Link Down Behavior  858
Platform Specific Scale Requirement for the Mobility Controller  858

CHAPTER 57  Mobility Network Elements  861

Mobility Agent  861
Mobility Controller  862
Mobility Oracle  863
Guest Controller  863

CHAPTER 58  Mobility Control Protocols  865

About Mobility Control Protocols  865
Initial Association and Roaming  865
Initial Association  866
Intra Switch Handoff  867
Intra Switch Peer Group Handoff  867
Inter Switch Peer Group Handoff  868
Inter Sub Domain Handoff  869
Inter Mobility Group Handoff  871

CHAPTER 59  Configuring Mobility  873

Configuring Mobility Controller  873
Configuring Converged Access Controllers  873
Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)  873
Configuring Local Mobility Group (CLI)  875
Adding a Peer Mobility Group (CLI)  876
Contents

SNMP Configuration Guidelines 925
## Additional References

### CHAPTER 64 Configuring Local Policies

- Finding Feature Information  
- Restrictions for Configuring Local Policies  
- Information About Configuring Local Policies  
- How to Configure Local Policies  
  - Configuring Local Policies (CLI)  
    - Creating an Interface Template (CLI)  
    - Creating a Parameter Map (CLI)  
    - Creating a Class Map (CLI)  
    - Creating a Policy Map (CLI)  
  - Applying a Local Policy for a Device on a WLAN (CLI)  
- Monitoring Local Policies  
- Examples: Local Policies Configuration  
- Additional References for Configuring Local Policies  
- Feature History for Performing Local Policies Configuration

### CHAPTER 65 Configuring SPAN and RSPAN

- Finding Feature Information  
- Prerequisites for SPAN and RSPAN  
- Restrictions for SPAN and RSPAN  
- Information About SPAN and RSPAN  
  - SPAN and RSPAN  
    - Local SPAN  
    - Remote SPAN  
  - SPAN and RSPAN Concepts and Terminology  
  - SPAN and RSPAN Interaction with Other Features  
  - SPAN and RSPAN and Device Stacks  
- Flow-Based SPAN  
- Default SPAN and RSPAN Configuration  
- Configuration Guidelines  
  - SPAN Configuration Guidelines  
  - RSPAN Configuration Guidelines
Storage of Captured Packets to a .pcap File 1032
Packet Decoding and Display 1032
Packet Storage and Display 1033
Wireshark Capture Point Activation and Deactivation 1033
Wireshark Features 1034
Guidelines for Wireshark 1035
Default Wireshark Configuration 1038
Information About Embedded Packet Capture 1038
Embedded Packet Capture Overview 1038
Benefits of Embedded Packet Capture 1038
Packet Data Capture 1039
Configuring Packet Capture 1039
How to Configure Wireshark 1039
Defining a Capture Point 1040
Adding or Modifying Capture Point Parameters 1045
Deleting Capture Point Parameters 1047
Deleting a Capture Point 1048
Activating and Deactivating a Capture Point 1050
Clearing the Capture Point Buffer 1053
How to Implement Embedded Packet Capture 1055
Managing Packet Data Capture 1055
Monitoring and Maintaining Captured Data 1057
Monitoring Packet Capture 1058
Configuration Examples for Wireshark 1058
Example: Displaying a Brief Output from a .pcap File 1058
Example: Displaying Detailed Output from a .pcap File 1059
Example: Displaying a Packet Dump Output from a .pcap File 1060
Example: Displaying Packets from a .pcap File using a Display Filter 1061
Example: Displaying the Number of Packets Captured in a .pcap File 1061
Example: Displaying a Single Packet Dump from a .pcap File 1061
Example: Displaying Statistics of Packets Captured in a .pcap File 1062
Example: Simple Capture and Display 1062
Example: Simple Capture and Store 1063
Example: Using Buffer Capture 1066

Configuring Flexible NetFlow 1079
Prerequisites for Flexible NetFlow 1079
Restrictions for Flexible NetFlow 1080
Information About Flexible Netflow 1082
Flexible NetFlow Overview 1082
  Wireless Flexible NetFlow Overview 1082
Original NetFlow and Benefits of Flexible NetFlow 1083
Flexible NetFlow Components 1084
  Flow Records 1085
  Flow Exporters 1089
  Flow Monitors 1091
  Flow Samplers 1093
Supported Flexible NetFlow Fields 1094
Default Settings 1098
How to Configure Flexible NetFlow 1098
  Configuring a Customized Flow Record 1098
  Creating a Flow Exporter 1101
  Creating a Customized Flow Monitor 1104
  Configuring and Enabling Flow SamplingCreating a Flow Sampler 1106
  Applying a Flow to an Interface 1108
  Configuring a Bridged NetFlow on a VLAN 1109
  Configuring Layer 2 NetFlow 1110
  Configuring WLAN to Apply Flow Monitor in Data Link Input/Output Direction 1111
  Configuring WLAN to Apply Flow Monitor in IPV4 and IPv6 Input/Output Direction 1112
Monitoring Flexible NetFlow 1114
Configuration Examples for Flexible NetFlow 1114
  Example: Configuring a Flow 1114
  Example: Monitoring IPv4 ingress traffic 1115
Example: Monitoring IPv4 egress traffic  116
Example: Configuring IPv4 Flexible NetFlow in WLAN (Ingress Direction)  117
Example: Configuring IPv6 and Transport Flag Flexible NetFlow in WLAN (Egress Direction)  118
Example: Configuring IPv6 Flexible NetFlow in WLAN (Both Ingress and Egress Directions)  119
Example: Monitoring wireless ingress traffic  119
Additional References  1120

Document Conventions

This document uses the following conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>^ or Ctrl</td>
<td>Both the ^ symbol and Ctrl represent the Control (Ctrl) key on a keyboard. For example, the key combination ^D or Ctrl-D means that you hold down the Control key while you press the D key. (Keys are indicated in capital letters but are not case sensitive.)</td>
</tr>
<tr>
<td><strong>bold</strong> font</td>
<td>Commands and keywords and user-entered text appear in <strong>bold</strong> font.</td>
</tr>
<tr>
<td><em>Italic</em> font</td>
<td>Document titles, new or emphasized terms, and arguments for which you supply values are in <em>italic</em> font.</td>
</tr>
<tr>
<td><strong>Courier</strong> font</td>
<td>Terminal sessions and information the system displays appear in <strong>courier</strong> font.</td>
</tr>
<tr>
<td><strong>Bold Courier</strong> font</td>
<td><strong>Bold Courier</strong> font indicates text that the user must enter.</td>
</tr>
<tr>
<td>[x]</td>
<td>Elements in square brackets are optional.</td>
</tr>
<tr>
<td>...</td>
<td>An ellipsis (three consecutive nonbolded periods without spaces) after a syntax element indicates that the element can be repeated.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>[x</td>
<td>y]</td>
</tr>
<tr>
<td>{x</td>
<td>y}</td>
</tr>
</tbody>
</table>
**Convention** | **Description**
--- | ---
[x {y | z}] | Nested set of square brackets or braces indicate optional or required choices within optional or required elements. Braces and a vertical bar within square brackets indicate a required choice within an optional element.

| string | A nonquoted set of characters. Do not use quotation marks around the string or the string will include the quotation marks. |
| <:> | Nonprinting characters such as passwords are in angle brackets. |
| [ ] | Default responses to system prompts are in square brackets. |
| !, # | An exclamation point (!) or a pound sign (#) at the beginning of a line of code indicates a comment line. |

**Reader Alert Conventions**

This document may use the following conventions for reader alerts:

- **Note**
  Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

- **Tip**
  Means *the following information will help you solve a problem*.

- **Caution**
  Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

- **Timesaver**
  Means *the described action saves time*. You can save time by performing the action described in the paragraph.

- **Warning**
  IMPORTANT SAFETY INSTRUCTIONS

  This warning symbol means danger. You are in a situation that could cause bodily injury. Before you work on any equipment, be aware of the hazards involved with electrical circuitry and be familiar with standard practices for preventing accidents. Use the statement number provided at the end of each warning to locate its translation in the translated safety warnings that accompanied this device. Statement 1071

  SAVE THESE INSTRUCTIONS
Related Documentation

Before installing or upgrading the device, refer to the device release notes.

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly What's New in Cisco Product Documentation, which also lists all new and revised Cisco technical documentation, at:

Subscribe to the What's New in Cisco Product Documentation as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS version 2.0.
Using the Command-Line Interface

**Information About Using the Command-Line Interface**

**Command Modes**

The Cisco IOS user interface is divided into many different modes. The commands available to you depend on which mode you are currently in. Enter a question mark (?) at the system prompt to obtain a list of commands available for each command mode.

You can start a CLI session through a console connection, through Telnet, an SSH, or by using the browser. When you start a session, you begin in user mode, often called user EXEC mode. Only a limited subset of the commands are available in user EXEC mode. For example, most of the user EXEC commands are one-time commands, such as `show` commands, which show the current configuration status, and `clear` commands, which clear counters or interfaces. The user EXEC commands are not saved when the device reboots.

To have access to all commands, you must enter privileged EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. From this mode, you can enter any privileged EXEC command or enter global configuration mode.

Using the configuration modes (global, interface, and line), you can make changes to the running configuration. If you save the configuration, these commands are stored and used when the device reboots. To access the various configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and line configuration mode.

This table describes the main command modes, how to access each one, the prompt you see in that mode, and how to exit the mode.
### Table 1: Command Mode Summary

<table>
<thead>
<tr>
<th>Mode</th>
<th>Access Method</th>
<th>Prompt</th>
<th>Exit Method</th>
<th>About This Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>User EXEC</td>
<td>Begin a session using Telnet, SSH, or console.</td>
<td>Device&gt;</td>
<td>Enter <code>logout</code> or <code>quit</code>.</td>
<td>Use this mode to • Change terminal settings. • Perform basic tests. • Display system information.</td>
</tr>
<tr>
<td>Privileged EXEC</td>
<td>While in user EXEC mode, enter the <code>enable</code> command.</td>
<td>Device#</td>
<td>Enter <code>disable</code> to exit.</td>
<td>Use this mode to verify commands that you have entered. Use a password to protect access to this mode.</td>
</tr>
<tr>
<td>Global configuration</td>
<td>While in privileged EXEC mode, enter the <code>configure</code> command.</td>
<td>Device(config)#</td>
<td>To exit to privileged EXEC mode, enter <code>exit</code> or <code>end</code>, or press <code>Ctrl-Z</code>.</td>
<td>Use this mode to configure parameters that apply to the entire device.</td>
</tr>
<tr>
<td>VLAN configuration</td>
<td>While in global configuration mode, enter the <code>vlan vlan-id</code> command.</td>
<td>Device(config-vlan)#</td>
<td>To exit to global configuration mode, enter the <code>exit</code> command. To return to privileged EXEC mode, press <code>Ctrl-Z</code> or enter <code>end</code>.</td>
<td>Use this mode to configure VLAN parameters. When VTP mode is transparent, you can create extended-range VLANs (VLAN IDs greater than 1005) and save configurations in the device startup configuration file.</td>
</tr>
</tbody>
</table>
### Understanding Abbreviated Commands

You need to enter only enough characters for the device to recognize the command as unique.

This example shows how to enter the `show configuration` privileged EXEC command in an abbreviated form:

```
Device# show conf
```

### No and Default Forms of Commands

Almost every configuration command also has a `no` form. In general, use the `no` form to disable a feature or function or reverse the action of a command. For example, the `no shutdown` interface configuration command reverses the shutdown of an interface. Use the command without the keyword `no` to reenable a disabled feature or to enable a feature that is disabled by default.

Configuration commands can also have a `default` form. The `default` form of a command returns the command setting to its default. Most commands are disabled by default, so the `default` form is the same as the `no` form. However, some commands are enabled by default and have variables set to certain default values. In these cases, the `default` command enables the command and sets variables to their default values.

### CLI Error Messages

This table lists some error messages that you might encounter while using the CLI to configure your device.
Table 2: Common CLI Error Messages

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Meaning</th>
<th>How to Get Help</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Ambiguous command: &quot;show con&quot;</td>
<td>You did not enter enough characters for your device to recognize the command.</td>
<td>Reenter the command followed by a question mark (?) without any space between the command and the question mark. The possible keywords that you can enter with the command appear.</td>
</tr>
<tr>
<td>% Incomplete command.</td>
<td>You did not enter all of the keywords or values required by this command.</td>
<td>Reenter the command followed by a question mark (?) with a space between the command and the question mark. The possible keywords that you can enter with the command appear.</td>
</tr>
<tr>
<td>% Invalid input detected at <code>^</code> marker.</td>
<td>You entered the command incorrectly. The caret (^) marks the point of the error.</td>
<td>Enter a question mark (?) to display all of the commands that are available in this command mode. The possible keywords that you can enter with the command appear.</td>
</tr>
</tbody>
</table>

Configuration Logging

You can log and view changes to the device configuration. You can use the Configuration Change Logging and Notification feature to track changes on a per-session and per-user basis. The logger tracks each configuration command that is applied, the user who entered the command, the time that the command was entered, and the parser return code for the command. This feature includes a mechanism for asynchronous notification to registered applications whenever the configuration changes. You can choose to have the notifications sent to the syslog.

Note

Only CLI or HTTP changes are logged.

Using the Help System

You can enter a question mark (?) at the system prompt to display a list of commands available for each command mode. You can also obtain a list of associated keywords and arguments for any command.

**How to Use the CLI to Configure Features**

**Configuring the Command History**

The software provides a history or record of commands that you have entered. The command history feature is particularly useful for recalling long or complex commands or entries, including access lists. You can customize this feature to suit your needs.

**Changing the Command History Buffer Size**

By default, the device records ten command lines in its history buffer. You can alter this number for a current terminal session or for all sessions on a particular line. This procedure is optional.
SUMMARY STEPS

1. terminal history [size number-of-lines]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>terminal history [size number-of-lines]</td>
<td>Changes the number of command lines that the device records during the current terminal session in privileged EXEC mode. You can configure the size from 0 to 256.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# terminal history size 200</td>
<td></td>
</tr>
</tbody>
</table>

Recalling Commands

To recall commands from the history buffer, perform one of the actions listed in this table. These actions are optional.

Note

The arrow keys function only on ANSI-compatible terminals such as VT100s.

SUMMARY STEPS

1. Ctrl-P or use the up arrow key
2. Ctrl-N or use the down arrow key
3. show history

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Ctrl-P or use the up arrow key</td>
<td>Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall successively older commands.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Ctrl-N or use the down arrow key</td>
<td>Returns to more recent commands in the history buffer after recalling commands with Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>show history</td>
<td>Lists the last several commands that you just entered in privileged EXEC mode. The number of commands that appear is controlled by the setting of the terminal history global configuration command and the history line configuration command.</td>
</tr>
</tbody>
</table>

Disabling the Command History Feature

The command history feature is automatically enabled. You can disable it for the current terminal session or for the command line. This procedure is optional.
**SUMMARY STEPS**

1. terminal no history

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td></td>
</tr>
<tr>
<td>terminal no history</td>
<td>Disables the feature during the current terminal session in privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# terminal no history</td>
<td></td>
</tr>
</tbody>
</table>

**Enabling and Disabling Editing Features**

Although enhanced editing mode is automatically enabled, you can disable it and reenable it.

**SUMMARY STEPS**

1. terminal editing
2. terminal no editing

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td></td>
</tr>
<tr>
<td>terminal editing</td>
<td>Reenables the enhanced editing mode for the current terminal session in privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# terminal editing</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td></td>
</tr>
<tr>
<td>terminal no editing</td>
<td>Disables the enhanced editing mode for the current terminal session in privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# terminal no editing</td>
<td></td>
</tr>
</tbody>
</table>

**Editing Commands Through Keystrokes**

The keystrokes help you to edit the command lines. These keystrokes are optional.

- **Note**
  
The arrow keys function only on ANSI-compatible terminals such as VT100s.

*Table 3: Editing Commands*

<table>
<thead>
<tr>
<th>Editing Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl-B</td>
<td>Moves the cursor back one character.</td>
</tr>
<tr>
<td>Ctrl-F</td>
<td>Moves the cursor forward one character.</td>
</tr>
</tbody>
</table>
CTRL-A Moves the cursor to the beginning of the command line.

CTRL-E Moves the cursor to the end of the command line.

ESC B Moves the cursor back one word.

ESC F Moves the cursor forward one word.

CTRL-T Transposes the character to the left of the cursor with the character located at the cursor.

DELETE or BACKSPACE key Erases the character to the left of the cursor.

CTRL-D Deletes the character at the cursor.

CTRL-K Deletes all characters from the cursor to the end of the command line.

CTRL-U or CTRL-X Deletes all characters from the cursor to the beginning of the command line.

CTRL-W Deletes the word to the left of the cursor.

ESC D Deletes from the cursor to the end of the word.

ESC C Capitalizes at the cursor.

ESC L Changes the word at the cursor to lowercase.

ESC U Capitalizes letters from the cursor to the end of the word.

CTRL-V or ESC Q Designates a particular keystroke as an executable command, perhaps as a shortcut.

RETURN key Scrolls down a line or screen on displays that are longer than the terminal screen can display.

NOTE The More prompt is used for any output that has more lines than can be displayed on the terminal screen, including show command output. You can use the Return and Space bar keystrokes whenever you see the More prompt.

SPACE bar Scrolls down one screen.

CTRL-L or CTRL-R Redisplays the current command line if the device suddenly sends a message to your screen.

Editing Command Lines That Wrap

You can use a wraparound feature for commands that extend beyond a single line on the screen. When the cursor reaches the right margin, the command line shifts ten spaces to the left. You cannot see the first ten characters of the line, but you can scroll back and check the syntax at the beginning of the command. The keystroke actions are optional.

To scroll back to the beginning of the command entry, press CTRL-B or the left arrow key repeatedly. You can also press CTRL-A to immediately move to the beginning of the line.
The arrow keys function only on ANSI-compatible terminals such as VT100s.

The following example shows how to wrap a command line that extends beyond a single line on the screen.

**SUMMARY STEPS**

1. access-list
2. Ctrl-A
3. Return key

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> access-list</td>
<td>Displays the global configuration command entry that extends beyond one line.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.255.255.0</td>
<td>When the cursor first reaches the end of the line, the line is shifted ten spaces to the left and redisplayed. The dollar sign ($) shows that the line has been scrolled to the left. Each time the cursor reaches the end of the line, the line is again shifted ten spaces to the left.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Ctrl-A</td>
<td>Checks the complete syntax.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 255.255.255.0</td>
<td>The dollar sign ($) appears at the end of the line to show that the line has been scrolled to the right.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Return key</td>
<td>Execute the commands.</td>
</tr>
<tr>
<td></td>
<td>The software assumes that you have a terminal screen that is 80 columns wide. If you have a different width, use the terminal width privileged EXEC command to set the width of your terminal. Use line wrapping with the command history feature to recall and modify previous complex command entries.</td>
</tr>
</tbody>
</table>

**Searching and Filtering Output of show and more Commands**

You can search and filter the output for show and more commands. This is useful when you need to sort through large amounts of output or if you want to exclude output that you do not need to see. Using these commands is optional.
SUMMARY STEPS

1. `{show | more} command | {begin | include | exclude} regular-expression`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>`{show</td>
<td>more} command</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> Device# show interfaces</td>
<td>Expressions are case sensitive. For example, if you enter `</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Vlan1 is up, line protocol is up</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Vlan10 is up, line protocol is down</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GigabitEthernet1/0/1 is up, line protocol is down</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GigabitEthernet1/0/2 is up, line protocol is up</td>
</tr>
</tbody>
</table>

Accessing the CLI

You can access the CLI through a console connection, through Telnet, a SSH, or by using the browser.

You manage the switch stack and the stack member interfaces through the active switch. You cannot manage stack members on an individual switch basis. You can connect to the active switch through the console port or the Ethernet management port of one or more stack members. Be careful with using multiple CLI sessions on the active switch. Commands that you enter in one session are not displayed in the other sessions. Therefore, it is possible to lose track of the session from which you entered commands.

We recommend using one CLI session when managing the switch stack.

If you want to configure a specific stack member port, you must include the stack member number in the CLI command interface notation.

To debug the standby switch, use the `session standby ios` privileged EXEC command from the active switch to access the IOS console of the standby switch. To debug a specific stack member, use the `session switch stack-member-number` privileged EXEC command from the active switch to access the diagnostic shell of the stack member. For more information about these commands, see the switch command reference.

To debug a specific stack member, you can start a CLI session from the stack master by using the `session stack-member-number` privileged EXEC command. The stack member number is appended to the system prompt. For example, `Switch-2#` is the prompt for stack member 2 where the system prompt for the stack master is Switch. Only the `show` and `debug` commands are available in a CLI session to a specific stack member. You can also use the `remote command stack-member-number LINE` privileged EXEC command on the stack master to enable debugging on a member switch without first starting a session.

Accessing the CLI Through a Console Connection or Through Telnet

Before you can access the CLI, you must connect a terminal or a PC to the device console or connect a PC to the Ethernet management port and then power on the device, as described in the hardware installation guide that shipped with your device.
If your device is already configured, you can access the CLI through a local console connection or through a remote Telnet session, but your device must first be configured for this type of access.

You can use one of these methods to establish a connection with the device:

**Procedure**

- Connect the device console port to a management station or dial-up modem, or connect the Ethernet management port to a PC. For information about connecting to the console or Ethernet management port, see the device hardware installation guide.
- Use any Telnet TCP/IP or encrypted Secure Shell (SSH) package from a remote management station. The device must have network connectivity with the Telnet or SSH client, and the device must have an enable secret password configured.
  - The device supports up to 16 simultaneous Telnet sessions. Changes made by one Telnet user are reflected in all other Telnet sessions.
  - The device supports up to five simultaneous secure SSH sessions.

After you connect through the console port, through the Ethernet management port, through a Telnet session or through an SSH session, the user EXEC prompt appears on the management station.

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for CleanAir

You can configure Cisco CleanAir only on CleanAir-enabled access points.

Only Cisco CleanAir-enabled access points using the following access point modes can perform Cisco CleanAir spectrum monitoring:

• Local—In this mode, each Cisco CleanAir-enabled access point radio provides air quality and interference detection reports for the current operating channel only.

• Monitor—When Cisco CleanAir is enabled in monitor mode, the access point provides air quality and interference detection reports for all monitored channels.

The following options are available:
Restrictions for CleanAir

- All—All channels
- DCA—Channel selection governed by the DCA list
- Country—All channel legal within a regulatory domain

Note: The access point does not participate in AQ HeatMap in Prime Infrastructure.

- SE-Connect—This mode enables a user to connect a Spectrum Expert application running on an external Microsoft Windows XP or Vista PC to a Cisco CleanAir-enabled access point in order to display and analyze detailed spectrum data. The Spectrum Expert application connects directly to the access point, bypassing the device. An access point in SE-Connect mode does not provide any Wi-Fi, RF, or spectrum data to the device. All CleanAir system functionality is suspended while the AP is in this mode, and no clients are served. This mode is intended for remote troubleshooting only. Up to three active Spectrum Expert connections are possible.

- Configuring a CleanAir Alarm for 5-GHz Air-Quality and Devices, on page 26
- Configuring Interference Reporting for 5-GHz devices, on page 27

Restrictions for CleanAir

- Access points in monitor mode do not transmit Wi-Fi traffic or 802.11 packets. They are excluded from radio resource management (RRM) planning and are not included in the neighbor access point list. IDR clustering depends on the device’s ability to detect neighboring in-network access points. Correlating interference device detections from multiple access points is limited between monitor-mode access points.

- Cisco recommends a ratio of 1 monitor mode access point for every 5 local mode access points, this may also vary based on the network design and expert guidance for best coverage.

- Spectrum Expert (Windows XP laptop client) and AP should be pingable, otherwise; it will not work.

Information About CleanAir

Cisco CleanAir is a spectrum intelligence solution designed to proactively manage the challenges of a shared wireless spectrum. All of the users of the shared spectrum can be seen (both native devices and foreign interferers). It also enables the network to act upon this information. For example, the interfering device can be manually removed or the system can automatically change the channel away from the interference.

A Cisco CleanAir system consists of CleanAir-enabled access points, wireless controller modules, mobility controllers, mobility anchors and next generation switches. The access points join the mobility controller directly or through the mobility anchor. They collect information about all devices that operate in the industrial, scientific, and medical (ISM) bands, identify and evaluate the information as a potential interference source, and forward it to the device. The device controls the access points, collects spectrum data, and forwards information to Cisco Prime Infrastructure (PI) or a Cisco Mobility Services Engine (MSE) upon request.

Any networking configurations can be performed only on the mobility controller, configurations cannot be performed in the MA mode. However, any radio level CleanAir configurations can be done using mobility anchor.

For every device operating in the unlicensed band, Cisco CleanAir tells what it is, where it is, how it is impacting the wireless network, and what actions should be taken. It simplifies RF.

Wireless LAN systems operate in unlicensed 2.4-GHz and 5-GHz ISM bands. Many devices like microwave ovens, cordless phones, and Bluetooth devices also operate in these bands and can negatively affect the Wi-Fi operations.

Some of the most advanced WLAN services, such as voice over wireless and IEEE 802.11n radio communications, could be significantly impaired by the interference caused by other legal users of the ISM bands. The integration of Cisco CleanAir functionality addresses this problem of radio frequency (RF) interference.

Cisco CleanAir Components

The basic Cisco CleanAir architecture consists of Cisco CleanAir-enabled APs and device. Cisco Prime Infrastructure (PI), Mobility Services Engine (MSE) and Cisco Spectrum Expert are optional system components. Cisco PI and MSE provide user interfaces for advanced spectrum capabilities such as historic charts, tracking interference devices, location services and impact analysis.
An access point equipped with Cisco CleanAir technology collects information about non-Wi-Fi interference sources, processes it, and forwards it to the MA. The access point sends AQR and IDR reports to the controller.

The mobility controller (MC) controls and configures CleanAir-capable access points, collects and processes spectrum data, and provides it to the PI and/or the MSE. The MC provides local user interfaces (GUI and CLI) to configure basic CleanAir features and services and display current spectrum information. The MC also does detection, merging and mitigation of interference devices using RRM TPC and DCM. For details on Interference Device Merging, see Interference Device Merging, on page 20.

Cisco PI provides advanced user interfaces for CleanAir that include feature enabling and configuration, consolidated display information, historic AQ records and reporting engines. PI also shows charts of interference devices, AQ trends, and alerts.

Cisco MSE is required for location and historic tracking of interference devices, and provides coordination and consolidation of interference reports across multiple controllers. MSE also provides adaptive Wireless Intrusion Prevention System (WIPS) service that provides comprehensive over-the-air threat detection, location and mitigation. MSE also merges all the interference data.

To obtain detailed spectrum data that can be used to generate RF analysis plots similar to those provided by a spectrum analyzer, you can configure a Cisco CleanAir-enabled access point to connect directly to a Microsoft Windows XP or Vista PC running the Cisco Spectrum Expert application.

The device performs the following tasks in a Cisco CleanAir system:

- Configures Cisco CleanAir capabilities on the access point.
- Provides interfaces (CLI, and SNMP) for configuring Cisco CleanAir features and retrieving data.
- Displays spectrum data.
- Collects and processes AQRs from the access point and stores them in the air quality database. AQRs contains information about the total interference from all identified sources represented by Air Quality Index (AQI) and summary for the most severe interference categories. The CleanAir system can also
include unclassified interference information under per interference type reports which enable you to
take action in cases where the interference due to unclassified interfering devices is frequent.
- Collects and processes Interference Device Reports (IDRs) from the access point and stores them in the
  interference device database.
- Forwards spectrum data to Prime Infrastructure and the MSE.

Terms Used in Cisco CleanAir

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AQI</td>
<td>Air Quality Index. The AQI is an indicator of air quality, based on the air pollutants. An AQI of 0 is bad and an AQI &gt; 85 is good.</td>
</tr>
<tr>
<td>AQR</td>
<td>Air Quality Report. AQRs contain information about the total interference from all identified sources represented by AQI and summary of the most severe interference categories. AQRs are sent every 15 minutes to the Mobility Controller and every 30 seconds in the Rapid mode.</td>
</tr>
<tr>
<td>DC</td>
<td>Duty Cycle. Percentage of time that the channel is utilized by a device.</td>
</tr>
<tr>
<td>EDRRM</td>
<td>EDRRM Event Driven RRM. EDRRM allows an access point in distress to bypass normal RRM intervals and immediately change channels.</td>
</tr>
<tr>
<td>IDR</td>
<td>Interference Device Reports that the access point sends to the controller.</td>
</tr>
<tr>
<td>ISI</td>
<td>Interference Severity Index. The ISI is an indicator of the severity of the interference.</td>
</tr>
<tr>
<td>MA</td>
<td>Mobility Agent. An MA is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. An MA is the wireless component that maintains client mobility state machine for a mobile client that is connected to an access point to the device that the MA is running on.</td>
</tr>
<tr>
<td>MC</td>
<td>Mobility Controller. An MC provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members.</td>
</tr>
<tr>
<td>RSSI</td>
<td>Received Signal Strength Indicator. RSSI is a measurement of the power present in a received radio signal. It is the power at which an access point sees the interferer device.</td>
</tr>
</tbody>
</table>

Interference Types that Cisco CleanAir can Detect

Cisco CleanAir can detect interference, report on the location and severity of the interference, and recommend
different mitigation strategies. Two such mitigation strategies are persistent device avoidance and spectrum
event-driven RRM. New

Wi-Fi chip-based RF management systems share these characteristics:
- Any RF energy that cannot be identified as a Wi-Fi signal is reported as noise.
- Noise measurements that are used to assign a channel plan tend to be averaged over a period of time to
  avoid instability or rapid changes that can be disruptive to certain client devices.
- Averaging measurements reduces the resolution of the measurement. As such, a signal that disrupts
  clients might not look like it needs to be mitigated after averaging.
• All RF management systems available today are reactive in nature.
Cisco CleanAir is different and can positively identify not only the source of the noise but also its location and potential impact to a WLAN. Having this information allows you to consider the noise within the context of the network and make intelligent and, where possible, proactive decisions. For CleanAir, two types of interference events are common:
  • Persistent interference
  • Spontaneous interference
Persistant interference events are created by devices that are stationary in nature and have intermittent but largely repeatable patterns of interference. For example, consider the case of a microwave oven located in a break room. Such a device might be active for only 1 or 2 minutes at a time. When operating, however, it can be disruptive to the performance of the wireless network and associated clients. Using Cisco CleanAir, you can positively identify the device as a microwave oven rather than indiscriminate noise. You can also determine exactly which part of the band is affected by the device, and because you can locate it, you can understand which access points are most severely affected. You can then use this information to direct RRM in selecting a channel plan that avoids this source of interference for the access points within its range. Because this interference is not active for a large portion of the day, existing RF management applications might attempt to again change the channels of the affected access points. Persistent device avoidance is unique, however, in that it remains in effect as long as the source of interference is periodically detected to refresh the persistent status. The Cisco CleanAir system knows that the microwave oven exists and includes it in all future planning.
If you move either the microwave oven or the surrounding access points, the algorithm updates RRM automatically.

Spectrum event-driven RRM can be triggered only by Cisco CleanAir-enabled access points in local mode.

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a threshold for air quality (AQ) that, if exceeded, triggers an immediate channel change for the affected access point. Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an access point detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active. Cisco CleanAir also identifies and locates the source of interference so that more permanent mitigation of the device can be performed at a later time.
In the case of Bluetooth devices, Cisco CleanAir-enabled access points can detect and report interference only if the devices are actively transmitting. Bluetooth devices have extensive power save modes. For example, interference can be detected when data or voice is being streamed between the connected devices.

Interference Device Merging

The Interference Devices (ID) messages are processed on a Mobility Controller (MC). The Mobility Anchor (MA) forwards the ID messages from APs and hence they are processed on the MC. The MC has visibility of the neighbor information across APs connected to different MAs.
ID merging logic requires AP neighbor information. Neighbor information is obtained from the RRM module. This api only gives neighbor information to the APs directly connected to MC.
Currently the AP neighbor list on MA is synced to MC once every 3 minutes; hence the AP neighbor list obtained by this api could be at most 3 mins old. This delay results in delay in merging of Devices as they
are discovered. The subsequent periodic merge will pick up the updated neighbor information and merge is performed.

**Persistent Devices**

Some interference devices such as outdoor bridges and Microwave Ovens only transmit when needed. These devices can cause significant interference to the local WLAN due to short duration and periodic operation remain largely undetected by normal RF management metrics. With CleanAir the RRM DCA algorithm can detect, measure, register and remember the impact and adjust the DCA algorithm. This minimizes the use of channels affected by the persistent devices in the channel plan local to the interference source. Cisco CleanAir detects and stores the persistent device information in the device and this information is used to mitigate interfering channels.

**Persistent Devices Detection**

CleanAir-capable Monitor Mode access point collects information about persistent devices on all configured channels and store the information in controller. Local/Bridge mode AP detects interference devices on the serving channels only.

**Persistent Device Avoidance**

When a Persistent Device (PD) is detected in the CleanAir module, it is reported to the RRM module on the MA. This information is used in the channel selection by the subsequent EDRRM Event Driven RRM (ED-RRM) signal sent to the RRM module.

**EDRRM and AQR Update Mode**

EDRRM is a feature that allows an access point that is in distress to bypass normal RRM intervals and immediately change channels. A CleanAir access point always monitors AQ and reports the AQ every 15 minutes. AQ only reports classified interference devices. The key benefit of EDRRM is very fast action time. If an interfering device is operating on an active channel and causes enough AQ degradation to trigger an EDRRM, then no clients will be able to use that channel or the access point. You must remove the access point from the channel. EDRRM is not enabled by default, you must first enable CleanAir and then enable EDRRM.

AQRs are only available on the MC. The mode configuration and timers are held in Radio Control Block (RCB) on MA (for APs connected to MA). There is no change to the current API available for EMS/NMS. No change is required for directly connected APs as RCB (spectrum config and timers) is available locally. For remote APs (APs connected to MA), three new control messages are added. These three messages are for enable, restart timer and disable rapid update mode for a given AP MAC address and slot.

**Related Topics**

Configuring EDRRM for CleanAir-Events, on page 29

**CleanAir High Availability**

CleanAir configuration (network and radio) is stateful during the switchover. On the MC, Embedded Instrumentation Core (EICORE) provides the sync on network configurations across active and standby nodes. The radio configurations are synced using the HA Infrastructure. The CleanAir configurations on MA are pulled from the MC upon joining. The network configuration is not stored in the EICORE on MA, hence it is synced using HA Infrastructure.
CleanAir Data (AQ and IDR) reports are not stateful, that is, the standby and active nodes are not synced. On switchover, the APs send the reports to the current active slot. The RRM Client (HA Infra Client) is used for CleanAir HA sync.

How to Configure CleanAir

Enabling CleanAir for 2.4-GHz Band

**SUMMARY STEPS**

### Configuring Cisco CleanAir using the Controller GUI

### Configuring Cisco Spectrum Expert

### Configuring Spectrum Expert (CLI)

**Before you begin**

- Spectrum Expert (Windows XP laptop client) and access point should be pingable, otherwise it will not work.
- Prior to establishing a connection between the Spectrum Expert console and the access point, make sure that IP address routing is properly configured and the network spectrum interface (NSI) ports are open in any intervening firewalls.
- The access point must be a TCP server listening on ports 37540 for 2.4-GHz and 37550 for 5-GHz frequencies. These ports must be opened for the spectrum expert application to connect to the access point using the NSI protocol.
- You can view the NSI key from the device CLI by using the `show ap name ap_name config dot11 {24ghz | 5ghz}` command.

**Step 1**

To configure the access point for SE-Connect mode, enter this command:

`ap name ap_name mode se-connect`
Example:
Device# ap name Cisco_AP3500 mode se-connect

Step 2  When prompted to reboot the access point, enter Y.
Step 3  To view the NSI key for the access point, enter this command:

    show ap name ap_name config dot11 {24ghz | 5ghz}

Example:
Device# show ap name Cisco_AP3500 config dot11 24ghz

</table>

What to do next

On the Windows PC, download Cisco Spectrum Expert:

- Access the Cisco Software Center from this URL: http://www.cisco.com/cisco/software/navigator.html
- Click Product > Wireless > Cisco Spectrum Intelligence > Cisco Spectrum Expert > Cisco Spectrum Expert Wi-Fi, and then download the Spectrum Expert 4.1.11 executable (*.exe) file.
- Run the Spectrum Expert application on the PC.
- When the Connect to Sensor dialog box appears, enter the IP address of the access point, choose the access point radio, and enter the 16-byte network spectrum interface (NSI) key to authenticate. The Spectrum Expert application opens a TCP/IP connection directly to the access point using the NSI protocol.

    When an access point in SE-Connect mode joins a device, it sends a Spectrum Capabilities notification message, and the device responds with a Spectrum Configuration Request. The request contains the 16-byte random NSI key generated by the device for use in NSI authentication. The device generates one key per access point, which the access point stores until it is rebooted.

    **Note**  You can establish up to three Spectrum Expert console connections per access point radio.

- Verify that the Spectrum Expert console is connected to the access point by selecting the Slave Remote Sensor text box in the bottom right corner of the Spectrum Expert application. If the two devices are connected, the IP address of the access point appears in this text box.
- Use the Spectrum Expert application to view and analyze spectrum data from the access point.
Monitoring CleanAir Parameters

You can monitor CleanAir parameters using the following commands:

**Table 5: Commands for Monitoring CleanAir**

<table>
<thead>
<tr>
<th>Commands</th>

</tr>
</tbody>
</table>
Monitoring the Interference Devices

When a CleanAir-enabled access point detects interference devices, detections of the same device from multiple sensors are merged together to create clusters. Each cluster is given a unique ID. Some devices conserve power by limiting the transmit time until actually needed which results in the spectrum sensor to temporarily stop detecting the device. This device is then correctly marked as down. A down device is correctly removed from the spectrum database. In cases when all the interferer detections for a specific device are reported, the cluster ID is kept alive for an extended period of time to prevent possible device detection bouncing. If the same device is detected again, it is merged with the original cluster ID and the device detection history is preserved.

For example, some bluetooth headsets operate on battery power. These devices employ methods to reduce power consumption, such as turning off the transmitter when not actually needed. Such devices can appear to come and go from the classification. To manage these devices, CleanAir keeps the cluster IDs longer and they are remerged into a single record upon detection. This process smoothens the user records and accurately represents the device history.

Configuration Examples for Configuring CleanAir

Enabling CleanAir on 2.4-GHz Band and an Access Point: Example

This example shows how to enable CleanAir on the 2.4-GHz band and an access point operating in the channel:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair
Device(config)#exit
Device#ap name TAP1 dot11 24ghz cleanair
Device#end
```

Configuring a CleanAir Alarm for 2.4-GHz Air-Quality and Devices: Example

This example shows how to configure a CleanAir Alarm for 2.4-GHz Air-Quality threshold of 50 dBm and an Xbox device:

```
Device#configure terminal
Device(config)#ap dot11 24ghz cleanair alarm air-quality threshold 50
Device(config)#ap dot11 24ghz cleanair alarm device xbox
Device(config)#end
```

Configuring Interference Reporting for 5-GHz Devices: Example

This example shows how to configure interference reporting for 5-GHz devices:

<table>
<thead>
<tr>
<th>Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ap dot11 5ghz cleanair device type video</td>
<td>Displays CleanAir Interferers of type Video Camera for 5-GHz band</td>
</tr>
<tr>
<td>show ap dot11 5ghz cleanair device type wimax-fixed</td>
<td>Displays CleanAir Interferers of type WiMax Fixed for 5-GHz band</td>
</tr>
<tr>
<td>show ap dot11 5ghz cleanair device type wimax-mobile</td>
<td>Displays CleanAir Interferers of type WiMax Mobile for 5-GHz band</td>
</tr>
</tbody>
</table>
Device#configure terminal
Device(config)#ap dot11 5ghz cleanair alarm device xbox
Device(config)#end

Configuring EDRRM for CleanAir-Events: Example

This example shows how to enable an EDRRM clean-air-event in the 2.4-GHz band and configure high sensitivity to non Wi-Fi interference:

Device#configure terminal
Device(config)#ap dot11 24ghz rrm channel cleanair-event
Device(config)#ap dot11 24ghz rrm channel cleanair-event sensitivity high
Device(config)#end

Configuring Persistent Device Avoidance: Example

This example shows how to enable persistent non Wi-Fi device avoidance in the 2.4-GHz band:

Device#configure terminal
Device(config)#ap dot11 24ghz rrm channel device

Configuring an Access Point for SE-Connect Mode: Example

This example shows how to configure an access point in the SE-Connect mode:

Device#ap name Cisco_AP3500 mode se-connect

CleanAir FAQs

Q. How do I check if my MC is up?
A. To check if the MC is up, use the command: show wireless mobility summary.

This example shows how to display the mobility summary:

Device#show wireless mobility summary

Mobility Controller Summary:
Mobility Role : Mobility Controller
Mobility Protocol Port : 16666
Mobility Group Name : MG-AK
Mobility Oracle : Disabled
Mobility Oracle IP Address : 0.0.0.0
DTLS Mode : Enabled
Mobility Domain ID for 802.11r : 0x39b2
Mobility Keepalive Interval : 10
Mobility Keepalive Count : 3
Mobility Control Message DSCP Value : 48
Mobility Domain Member Count : 2
Link Status is Control Link Status : Data Link Status
Controllers configured in the Mobility Domain:
IP Public IP Group Name Multicast IP Link Status
-------------------------------------------------------------------------------
9.6.136.10 - MG-AK 0.0.0.0 UP : UP

Q. Multiple access points detect the same interference device, however, the device shows them as separate clusters or different suspected devices clustered together. Why does this happen?
A. Access points must be RF neighbors for the device to consider the merging of devices that are detected by these access points. The access point takes time to establish neighbor relationships. A few minutes after the device reboots or a change in the RF group and similar events, clustering will not be very accurate.

Q. Can I merge two monitor mode access points using a device?
A. No, you cannot merge two monitor mode access points using a device. You can merge the monitor mode access points only using MSE.

Q. How do I view neighbor access points?
A. To view neighbor access points, use the command: `show ap ap_name auto-rf dot11 {24ghz | 5ghz}`

This example shows how to display the neighbor access points:

```
Device#show ap name AS-5508-5-AP3 auto-rf dot11 24ghz

Nearby APs
 AP 0C85.259E.C350 slot 0 : -12 dBm on 1 (10.10.0.5)
 AP 0C85.25AB.CCA0 slot 0 : -24 dBm on 6 (10.10.0.5)
 AP 0C85.25C7.B7A0 slot 0 : -26 dBm on 11 (10.10.0.5)
 AP 0C85.25DE.2C10 slot 0 : -24 dBm on 6 (10.10.0.5)
 AP 0C85.25DE.C8E0 slot 0 : -14 dBm on 11 (10.10.0.5)
 AP 0C85.25DF.3280 slot 0 : -31 dBm on 6 (10.10.0.5)
 AP 0CD9.96BA.5600 slot 0 : -44 dBm on 6 (10.0.0.2)
 AP 24B6.5734.C570 slot 0 : -48 dBm on 11 (10.0.0.2)
```

Q. What are the debug commands available for CleanAir?
A. The debug commands for CleanAir are:

```
dbg cleanair  {all | error | event | internal-event | nmsp | packet}
dbg rrm  {all | channel | detail | error | group | ha | manager | message | packet | power | prealarm | profile | radar | rf-change | scale | spectrum}
```

Q. Why are CleanAir Alarms not generated for interferer devices?
A. Verify that the access points are CleanAir-capable and CleanAir is enabled both on the access point and the device.

Q. Can the Cisco Catalyst 3850 Series Switches function as a Mobility Agent (MA)?
A. Yes, the Cisco Catalyst 3850 Series Switches can function as an MA.

Q. Are CleanAir configurations available on the MA?
A. From Release 3.3 SE, CleanAir configurations are available on the MA. You can use the following two CleanAir commands on the MA:

```
• show ap dot11 5ghz cleanair config
```
• show ap dot11 24ghz cleanair config

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Interface Characteristics

Interface Types

This section describes the different types of interfaces supported by the device. The rest of the chapter describes configuration procedures for physical interface characteristics.

Note

The stack ports on the rear of the stacking-capable devices are not Ethernet ports and cannot be configured.
**Port-Based VLANs**

A VLAN is a switched network that is logically segmented by function, team, or application, without regard to the physical location of the users. Packets received on a port are forwarded only to ports that belong to the same VLAN as the receiving port. Network devices in different VLANs cannot communicate with one another without a Layer 3 device to route traffic between the VLANs.

VLAN partitions provide hard firewalls for traffic in the VLAN, and each VLAN has its own MAC address table. A VLAN comes into existence when a local port is configured to be associated with the VLAN, when the VLAN Trunking Protocol (VTP) learns of its existence from a neighbor on a trunk, or when a user creates a VLAN. VLANs can be formed with ports across the stack.

To configure VLANs, use the `vlan vlan-id` global configuration command to enter VLAN configuration mode. The VLAN configurations for normal-range VLANs (VLAN IDs 1 to 1005) are saved in the VLAN database. If VTP is version 1 or 2, to configure extended-range VLANs (VLAN IDs 1006 to 4094), you must first set VTP mode to transparent. Extended-range VLANs created in transparent mode are not added to the VLAN database but are saved in the device running configuration. With VTP version 3, you can create extended-range VLANs in client or server mode. These VLANs are saved in the VLAN database.

In a switch stack, the VLAN database is downloaded to all switches in a stack, and all switches in the stack build the same VLAN database. The running configuration and the saved configuration are the same for all switches in a stack.

Add ports to a VLAN by using the `switchport` interface configuration commands:

- Identify the interface.
- For a trunk port, set trunk characteristics, and, if desired, define the VLANs to which it can belong.
- For an access port, set and define the VLAN to which it belongs.

**Switch Ports**

Switch ports are Layer 2-only interfaces associated with a physical port. Switch ports belong to one or more VLANs. A switch port can be an access port or a trunk port. You can configure a port as an access port or trunk port or let the Dynamic Trunking Protocol (DTP) operate on a per-port basis to set the switchport mode by negotiating with the port on the other end of the link. switch ports are used for managing the physical interface and associated Layer 2 protocols and do not handle routing or bridging.

Configure switch ports by using the `switchport` interface configuration commands.

**Access Ports**

An access port belongs to and carries the traffic of only one VLAN (unless it is configured as a voice VLAN port). Traffic is received and sent in native formats with no VLAN tagging. Traffic arriving on an access port is assumed to belong to the VLAN assigned to the port. If an access port receives a tagged packet (Inter-Switch Link [ISL] or IEEE 802.1Q tagged), the packet is dropped, and the source address is not learned.

The types of access ports supported are:

- Static access ports are manually assigned to a VLAN (or through a RADIUS server for use with IEEE 802.1x).

You can also configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.
Trunk Ports

A trunk port carries the traffic of multiple VLANs and by default is a member of all VLANs in the VLAN database.

Although by default, a trunk port is a member of every VLAN known to the VTP, you can limit VLAN membership by configuring an allowed list of VLANs for each trunk port. The list of allowed VLANs does not affect any other port but the associated trunk port. By default, all possible VLANs (VLAN ID 1 to 4094) are in the allowed list. A trunk port can become a member of a VLAN only if VTP knows of the VLAN and if the VLAN is in the enabled state. If VTP learns of a new, enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of that VLAN and traffic is forwarded to and from the trunk port for that VLAN. If VTP learns of a new, enabled VLAN that is not in the allowed list for a trunk port, the port does not become a member of the VLAN, and no traffic for the VLAN is forwarded to or from the port.

Tunnel Ports

Tunnel ports are used in IEEE 802.1Q tunneling to segregate the traffic of customers in a service-provider network from other customers who are using the same VLAN number. You configure an asymmetric link from a tunnel port on a service-provider edge switch to an IEEE 802.1Q trunk port on the customer switch. Packets entering the tunnel port on the edge switch, already IEEE 802.1Q-tagged with the customer VLANs, are encapsulated with another layer of an IEEE 802.1Q tag (called the metro tag), containing a VLAN ID unique in the service-provider network, for each customer. The double-tagged packets go through the service-provider network keeping the original customer VLANs separate from those of other customers. At the outbound interface, also a tunnel port, the metro tag is removed, and the original VLAN numbers from the customer network are retrieved.

Tunnel ports cannot be trunk ports or access ports and must belong to a VLAN unique to each customer.

Routed Ports

A routed port is a physical port that acts like a port on a router; it does not have to be connected to a router. A routed port is not associated with a particular VLAN, as is an access port. A routed port behaves like a regular router interface, except that it does not support VLAN subinterfaces. Routed ports can be configured with a Layer 3 routing protocol. A routed port is a Layer 3 interface only and does not support Layer 2 protocols, such as DTP and STP.

Configure routed ports by putting the interface into Layer 3 mode with the `no switchport` interface configuration command. Then assign an IP address to the port, enable routing, and assign routing protocol characteristics by using the `ip routing` and `router protocol` global configuration commands.

Note

Entering a `no switchport` interface configuration command shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost.

The number of routed ports that you can configure is not limited by software. However, the interrelationship between this number and the number of other features being configured might impact CPU performance because of hardware limitations.
Switch Virtual Interfaces

A switch virtual interface (SVI) represents a VLAN of switch ports as one interface to the routing or bridging function in the system. You can associate only one SVI with a VLAN. You configure an SVI for a VLAN only to route between VLANs or to provide IP host connectivity to the device. By default, an SVI is created for the default VLAN (VLAN 1) to permit remote device administration. Additional SVIs must be explicitly configured.

Note

You cannot delete interface VLAN 1.

SVIs provide IP host connectivity only to the system. SVIs are created the first time that you enter the `vlan` interface configuration command for a VLAN interface. The VLAN corresponds to the VLAN tag associated with data frames on an ISL or IEEE 802.1Q encapsulated trunk or the VLAN ID configured for an access port. Configure a VLAN interface for each VLAN for which you want to route traffic, and assign it an IP address.

You can also use the interface range command to configure existing VLAN SVIs within the range. The commands entered under the interface range command are applied to all existing VLAN SVIs within the range. You can enter the command `interface range create vlan x - y` to create all VLANs in the specified range that do not already exist. When the VLAN interface is created, `interface range vlan id` can be used to configure the VLAN interface.

Although the switch stack or device supports a total of 1005 VLANs and SVIs, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might impact CPU performance because of hardware limitations.

When you create an SVI, it does not become active until it is associated with a physical port.

SVI Autostate Exclude

The line state of an SVI with multiple ports on a VLAN is in the up state when it meets these conditions:

- The VLAN exists and is active in the VLAN database on the device
- The VLAN interface exists and is not administratively down.
- At least one Layer 2 (access or trunk) port exists, has a link in the up state on this VLAN, and is in the spanning-tree forwarding state on the VLAN.

Note

The protocol link state for VLAN interfaces come up when the first switchport belonging to the corresponding VLAN link comes up and is in STP forwarding state.

The default action, when a VLAN has multiple ports, is that the SVI goes down when all ports in the VLAN go down. You can use the SVI autostate exclude feature to configure a port so that it is not included in the SVI line-state up-or-down calculation. For example, if the only active port on the VLAN is a monitoring port,
you might configure autostate exclude on that port so that the VLAN goes down when all other ports go down. When enabled on a port, **autostate exclude** applies to all VLANs that are enabled on that port.

The VLAN interface is brought up when one Layer 2 port in the VLAN has had time to converge (transition from STP listening-learning state to forwarding state). This prevents features such as routing protocols from using the VLAN interface as if it were fully operational and minimizes other problems, such as routing black holes.

**EtherChannel Port Groups**

EtherChannel port groups treat multiple switch ports as one switch port. These port groups act as a single logical port for high-bandwidth connections between devices or between devices and servers. An EtherChannel balances the traffic load across the links in the channel. If a link within the EtherChannel fails, traffic previously carried over the failed link changes to the remaining links. You can group multiple trunk ports into one logical trunk port, group multiple access ports into one logical access port, group multiple tunnel ports into one logical tunnel port, or group multiple routed ports into one logical routed port. Most protocols operate over either single ports or aggregated switch ports and do not recognize the physical ports within the port group. Exceptions are the DTP, the Cisco Discovery Protocol (CDP), and the Port Aggregation Protocol (PAgP), which operate only on physical ports.

When you configure an EtherChannel, you create a port-channel logical interface and assign an interface to the EtherChannel. For Layer 3 interfaces, you manually create the logical interface by using the `interface port-channel` global configuration command. Then you manually assign an interface to the EtherChannel by using the `channel-group` interface configuration command. For Layer 2 interfaces, use the `channel-group` interface configuration command to dynamically create the port-channel logical interface. This command binds the physical and logical ports together.

**10-Gigabit Ethernet Interfaces**

A 10-Gigabit Ethernet interface operates only in full-duplex mode. The interface can be configured as a switched or routed port.

For more information about the Cisco TwinGig Converter Module, see the device hardware installation guide and your transceiver module documentation.

**Power over Ethernet Ports**

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

**Using the Switch USB Ports**

The device has two USB ports on the front panel — a USB mini-Type B console port and a USB Type A port.
USB Mini-Type B Console Port

The device has the following console ports:

- USB mini-Type B console connection
- RJ-45 console port

Console output appears on devices connected to both ports, but console input is active on only one port at a time. By default, the USB connector takes precedence over the RJ-45 connector.

**Note**
Windows PCs require a driver for the USB port. See the hardware installation guide for driver installation instructions.

Use the supplied USB Type A-to-USB mini-Type B cable to connect a PC or other device to the device. The connected device must include a terminal emulation application. When the device detects a valid USB connection to a powered-on device that supports host functionality (such as a PC), input from the RJ-45 console is immediately disabled, and input from the USB console is enabled. Removing the USB connection immediately reenables input from the RJ-45 console connection. An LED on the device shows which console connection is in use.

### Console Port Change Logs

At software startup, a log shows whether the USB or the RJ-45 console is active. Each device in a stack issues this log. Every device always first displays the RJ-45 media type.

In the sample output, Device 1 has a connected USB console cable. Because the bootloader did not change to the USB console, the first log from Device 1 shows the RJ-45 console. A short time later, the console changes and the USB console log appears. Device 2 and Device 3 have connected RJ-45 console cables.

```plaintext
switch-stack-1
*Mar 1 00:01:00.171: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
*Mar 1 00:01:00.431: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.

switch-stack-2
*Mar 1 00:01:09.835: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.

switch-stack-3
*Mar 1 00:01:10.523: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

When the USB cable is removed or the PC de-activates the USB connection, the hardware automatically changes to the RJ-45 console interface:

```plaintext
switch-stack-1
Mar 1 00:20:48.635: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

You can configure the console type to always be RJ-45, and you can configure an inactivity timeout for the USB connector.

### USB Type A Port

The USB Type A port provides access to external USB flash devices, also known as thumb drives or USB keys. The port supports Cisco USB flash drives with capacities from 128 MB to 8 GB (USB devices with port densities of 128 MB, 256 MB, 1 GB, 4 GB, 8 GB are supported). You can use standard Cisco IOS
command-line interface (CLI) commands to read, write, erase, and copy to or from the flash device. You can also configure the device to boot from the USB flash drive.

**Interface Connections**

Devices within a single VLAN can communicate directly through any switch. Ports in different VLANs cannot exchange data without going through a routing device. With a standard Layer 2 device, ports in different VLANs have to exchange information through a router. By using the device with routing enabled, when you configure both VLAN 20 and VLAN 30 with an SVI to which an IP address is assigned, packets can be sent from Host A to Host B directly through the device with no need for an external router.

*Figure 2: Connecting VLANs with the Switch*

When the IP Services image is running on the device or the active device, the device uses two methods to forward traffic between interfaces: routing and fallback bridging. If the IP Base image is on the device or the active device, only basic routing (static routing and RIP) is supported. Whenever possible, to maintain high performance, forwarding is done by the device hardware. However, only IPv4 packets with Ethernet II encapsulation are routed in hardware. Non-IP traffic and traffic with other encapsulation methods are fallback-bridged by hardware.

- The routing function can be enabled on all SVIs and routed ports. The device routes only IP traffic. When IP routing protocol parameters and address configuration are added to an SVI or routed port, any IP traffic received from these ports is routed.
- Fallback bridging forwards traffic that the device does not route or traffic belonging to a nonroutable protocol, such as DECnet. Fallback bridging connects multiple VLANs into one bridge domain by bridging between two or more SVIs or routed ports. When configuring fallback bridging, you assign SVIs or routed ports to bridge groups with each SVI or routed port assigned to only one bridge group. All interfaces in the same group belong to the same bridge domain.

**Interface Configuration Mode**

The device supports these interface types:

- Physical ports—device ports and routed ports
• VLANs—switch virtual interfaces
• Port channels—EtherChannel interfaces

You can also configure a range of interfaces.

To configure a physical interface (port), specify the interface type, stack member number (only stacking-capable switches), module number, and device port number, and enter interface configuration mode.

• Type—Gigabit Ethernet (gigabitethernet or gi) for 10/100/1000 Mb/s Ethernet ports, 10-Gigabit Ethernet (tengigabitethernet or te) for 10,000 Mb/s, or small form-factor pluggable (SFP) module Gigabit Ethernet interfaces (gigabitethernet or gi).

• Stack member number—The number that identifies the device within the stack. The device number range is 1 to 9 and is assigned the first time the device initializes. The default device number, before it is integrated into a device stack, is 1. When a device has been assigned a stack member number, it keeps that number until another is assigned to it.

You can use the switch port LEDs in Stack mode to identify the stack member number of a device.

• Module number—The module or slot number on the device: switch (downlink) ports are 0, and uplink ports are 1.

• Port number—The interface number on the device. The 10/100/1000 port numbers always begin at 1, starting with the far left port when facing the front of the device, for example, gigabitethernet1/0/1 or gigabitethernet1/0/8.

On a device with SFP uplink ports, the module number is 1 and the port numbers restart. For example, if the device has 24 10/100/1000 ports, the SFP module ports are gigabitethernet1/1/1 through gigabitethernet1/1/4 or tengigabitethernet1/1/1 through tengigabitethernet1/1/4.

You can identify physical interfaces by physically checking the interface location on the device. You can also use the show privileged EXEC commands to display information about a specific interface or all the interfaces on the switch. The remainder of this chapter primarily provides physical interface configuration procedures.

These are examples of how to identify interfaces on a stacking-capable device:

• To configure 10/100/1000 port 4 on a standalone device, enter this command:

  Device(config)# interface gigabitethernet1/0/4

• To configure 10-Gigabit Ethernet port 1 on a standalone device, enter this command:

  Device(config)# interface tengigabitethernet1/0/1

• To configure 10-Gigabit Ethernet port on stack member 3, enter this command:

  Device(config)# interface tengigabitethernet3/0/1

• To configure the first SFP module (uplink) port on a standalone device, enter this command:

  Device(config)# interface gigabitethernet1/1/1
Default Ethernet Interface Configuration

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

This table shows the Ethernet interface default configuration, including some features that apply only to Layer 2 interfaces.

**Table 6: Default Layer 2 Ethernet Interface Configuration**

### Interface Speed and Duplex Mode

Ethernet interfaces on the switch operate at 10, 100, 1000, or 10,000 Mb/s and in either full- or half-duplex mode. In full-duplex mode, two stations can send and receive traffic at the same time. Normally, 10-Mb/s ports operate in half-duplex mode, which means that stations can either receive or send traffic.

Switch models include Gigabit Ethernet (10/100/1000-Mb/s) ports, 10-Gigabit Ethernet ports, and small form-factor pluggable (SFP) module slots supporting SFP modules.

### Speed and Duplex Configuration Guidelines

When configuring an interface speed and duplex mode, note these guidelines:

- The 10-Gigabit Ethernet ports do not support the speed and duplex features. These ports operate only at 10,000 Mb/s and in full-duplex mode.

- Gigabit Ethernet (10/100/1000-Mb/s) ports support all speed options and all duplex options (auto, half, and full). However, Gigabit Ethernet ports operating at 1000 Mb/s do not support half-duplex mode.

- For SFP module ports, the speed and duplex CLI options change depending on the SFP module type:
  - The 1000BASE-x (where -x is -BX, -CWDM, -LX, -SX, and -ZX) SFP module ports support the `nonegotiate` keyword in the `speed` interface configuration command. Duplex options are not supported.
  - The 1000BASE-T SFP module ports support the same speed and duplex options as the 10/100/1000-Mb/s ports.

- If both ends of the line support autonegotiation, we highly recommend the default setting of `auto` negotiation.

- If one interface supports autonegotiation and the other end does not, configure duplex and speed on both interfaces; do not use the `auto` setting on the supported side.

- When STP is enabled and a port is reconfigured, the device can take up to 30 seconds to check for loops. The port LED is amber while STP reconfigures.
Caution

Changing the interface speed and duplex mode configuration might shut down and re-enable the interface during the reconfiguration.

IEEE 802.3x Flow Control

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If one port experiences congestion and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note

Flow control is not supported on Catalyst 3850 and Catalyst 3650 Series Switches (CSCul33405).

Note

The switch ports can receive, but not send, pause frames.

You use the flowcontrol interface configuration command to set the interface’s ability to receive pause frames to on, off, or desired. The default state is off.

When set to desired, an interface can operate with an attached device that is required to send flow-control packets or with an attached device that is not required to but can send flow-control packets.

These rules apply to flow control settings on the device:

• receive on (or desired): The port cannot send pause frames but can operate with an attached device that is required to or can send pause frames; the port can receive pause frames.

• receive off: Flow control does not operate in either direction. In case of congestion, no indication is given to the link partner, and no pause frames are sent or received by either device.

Layer 3 Interfaces

The device supports these types of Layer 3 interfaces:

• SVIs: You should configure SVIs for any VLANs for which you want to route traffic. SVIs are created when you enter a VLAN ID following the interface vlan global configuration command. To delete an SVI, use the no interface vlan global configuration command. You cannot delete interface VLAN 1.

Note

When you create an SVI, it does not become active until it is associated with a physical port.

When configuring SVIs, you can also configure SVI autostate exclude on a port in the SVI to exclude that port from being included in determining SVI line-state status.
• Routed ports: Routed ports are physical ports configured to be in Layer 3 mode by using the `no switchport` interface configuration command.

• Layer 3 EtherChannel ports: EtherChannel interfaces made up of routed ports.

A Layer 3 device can have an IP address assigned to each routed port and SVI. There is no defined limit to the number of SVIs and routed ports that can be configured in a device or in a device stack. However, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might have an impact on CPU usage because of hardware limitations. If the device is using its maximum hardware resources, attempts to create a routed port or SVI have these results:

• If you try to create a new routed port, the device generates a message that there are not enough resources to convert the interface to a routed port, and the interface remains as a switchport.

• If you try to create an extended-range VLAN, an error message is generated, and the extended-range VLAN is rejected.

• If the device is notified by VLAN Trunking Protocol (VTP) of a new VLAN, it sends a message that there are not enough hardware resources available and shuts down the VLAN. The output of the `show vlan` user EXEC command shows the VLAN in a suspended state.

• If the device attempts to boot up with a configuration that has more VLANs and routed ports than hardware can support, the VLANs are created, but the routed ports are shut down, and the device sends a message that this was due to insufficient hardware resources.

All Layer 3 interfaces require an IP address to route traffic. This procedure shows how to configure an interface as a Layer 3 interface and how to assign an IP address to an interface.

---

**Note**

If the physical port is in Layer 2 mode (the default), you must enter the `no switchport` interface configuration command to put the interface into Layer 3 mode. Entering a `no switchport` command disables and then re-enables the interface, which might generate messages on the device to which the interface is connected. Furthermore, when you put an interface that is in Layer 2 mode into Layer 3 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

---

**How to Configure Interface Characteristics**

**Configuring Interfaces**

These general instructions apply to all interface configuration processes.

**Procedure**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>

**Configuring a Range of Interfaces**

To configure multiple interfaces with the same configuration parameters, use the `interface range` global configuration command. When you enter the interface-range configuration mode, all command parameters that you enter are attributed to all interfaces within that range until you exit this mode.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface range {port-range | macro macro_name}`
4. `end`
5. `show interfaces [interface-id]`
6. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

<tr>
<td></td>
<td>• You can use the <code>interface range</code> command to configure up to five port ranges or a previously defined macro.</td>
</tr>
<tr>
<td></td>
<td>• The <code>macro</code> variable is explained in the Configuring and Using Interface Range Macros, on page 56.</td>
</tr>
<tr>
<td></td>
<td>• In a comma-separated <code>port-range</code>, you must enter the interface type for each entry and enter spaces before and after the comma.</td>
</tr>
<tr>
<td></td>
<td>• In a hyphen-separated <code>port-range</code>, you do not need to re-enter the interface type, but you must enter a space before the hyphen.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Use the normal configuration commands to apply the configuration parameters to all interfaces in the range. Each command is executed as it is entered.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td>Example:</td>
</tr>
</tbody>
</table>
## Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

### Step 5

**Purpose:** Verifies the configuration of the interfaces in the range.

**Command or Action:**

- `show interfaces [interface-id]`

**Example:**

```
Device# show interfaces
```

### Step 6

**Purpose:** (Optional) Saves your entries in the configuration file.

**Command or Action:**

- `copy running-config startup-config`

**Example:**

```
Device# copy running-config startup-config
```

---

## Configuring and Using Interface Range Macros

You can create an interface range macro to automatically select a range of interfaces for configuration. Before you can use the `macro` keyword in the `interface range macro` global configuration command string, you must use the `define interface-range` global configuration command to define the macro.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `define interface-range macro_name interface-range`
4. `interface range macro macro_name`
5. `end`
6. `show running-config | include define`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>define interface-range macro_name interface-range</code></td>
<td>Defines the interface-range macro, and save it in NVRAM.</td>
</tr>
</tbody>
</table>
### Configuring Ethernet Interfaces

#### Setting the Interface Speed and Duplex Parameters

**SUMMARY STEPS**

1. enable
2. configure terminal

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| `Device(config)# define interface-range enet_list gigabitethernet1/0/1 - 2` | - The `macro_name` is a 32-character maximum character string.  
- A macro can contain up to five comma-separated interface ranges.  
- Each `interface-range` must consist of the same port type.  

**Note** Before you can use the `macro` keyword in the `interface range macro` global configuration command string, you must use the `define interface-range` global configuration command to define the macro. |
| **Step 4** `interface range macro ` | Selects the interface range to be configured using the values saved in the interface-range macro called `macro_name`.  
You can now use the normal configuration commands to apply the configuration to all interfaces in the defined macro. |
| `macro_name` | |
| **Example:** | |
| `Device(config)# interface range macro enet_list` |         |
| **Step 5** `end` | Returns to privileged EXEC mode. |
| **Example:** | |
| `Device(config)# end` |         |
| **Step 6** `show running-config | include define` | Shows the defined interface range macro configuration. |
| **Example:** | |
| `Device# show running-config | include define` |         |
| **Step 7** `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
| **Example:** | |
| `Device# copy running-config startup-config` |         |
3. **interface** interface-id
4. **speed** {10 | 100 | 1000 | 2500 | 5000 | 10000 | auto [10 | 100 | 1000 | 2500 | 5000 | 10000] | nonegotiate}
5. **duplex** {auto | full | half}
6. **end**
7. **show interfaces** interface-id
8. **copy running-config startup-config**
9. **copy running-config startup-config**

### DETAILED STEPS

### Configuring IEEE 802.3x Flow Control

#### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `flowcontrol {receive} {on | off | desired}
4. `end`
5. `show interfaces interface-id`
6. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td>`flowcontrol {receive} {on</td>
<td>off</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><code>show interfaces interface-id</code></td>
<td>Displays the interface speed and duplex mode configuration.</td>

<tr>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

**interface interface-id**

**Example:**

Device(config)# interface gigabitethernet1/0/1

**Purpose:**

Specifies the physical interface to be configured, and enter interface configuration mode.

**Step 3**

**flowcontrol {receive} {on | off | desired}**

**Example:**

Device(config-if)# flowcontrol receive on

**Purpose:**

Configures the flow control mode for the port.

**Step 4**

**end**

**Example:**

Device(config-if)# end

**Purpose:**

Returns to privileged EXEC mode.

**Step 5**

**show interfaces interface-id**

**Example:**

Device# show interfaces gigabitethernet1/0/1

**Purpose:**

Verifies the interface flow control settings.

**Step 6**

**copy running-config startup-config**

**Example:**

Device# copy running-config startup-config

**Purpose:**

(Optional) Saves your entries in the configuration file.

---

### Configuring Layer 3 Interfaces

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface {gigabitethernet interface-id} | {vlan vlan-id} | {port-channel port-channel-number}
4. no switchport
5. ip address ip_address subnet_mask
6. no shutdown
7. end
8. show interfaces [interface-id]
9. copy running-config startup-config
**DETAILED STEPS**

### Configuring Logical Layer 3 GRE Tunnel Interfaces

#### Before you begin

Generic Routing Encapsulation (GRE) is a tunneling protocol used to encapsulate network layer protocols inside virtual point-to-point links. A GRE tunnel only provides encapsulation and not encryption.

#### Attention

Beginning in Cisco IOS XE Release 3.7.2E, GRE tunnels are supported on the hardware on Cisco Catalyst switches. When GRE is configured without tunnel options, packets are hardware-switched. When GRE is configured with tunnel options (such as key, checksum, etc.), packets are switched in the software. A maximum of 10 GRE tunnels are supported.

#### Note

Other features like Access Control Lists (ACL) and Quality of Service (QoS) are not supported for the GRE tunnels.

To configure a GRE tunnel, perform this task:

### SUMMARY STEPS

1. `interface tunnel number`
2. `ip address ip_address subnet_mask`
3. `tunnel source {ip_address | type_number}`
4. `tunnel destination {host_name | ip_address}`
5. `tunnel mode gre ip`
6. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

`interface tunnel number`  
**Example:**  
Device(config)#interface tunnel 2

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 2**

`ip address ip_address subnet_mask`  
**Example:**  
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
</table>

(Optional) Saves your entries in the configuration file.
### Configuring SVI Autostate Exclude

#### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. switchport autostate exclude
5. end
6. show running config interface interface-id
7. copy running-config startup-config

#### DETAILED STEPS

</tbody>
</table>
### Shutting Down and Restarting the Interface

Shutting down an interface disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface is not mentioned in any routing updates.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface {vlan vlan-id} | {gigabitethernet interface-id} | {port-channel port-channel-number}`
4. `shutdown`
5. `no shutdown`
6. `end`
7. `show running-config`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        |         |
| `configure terminal` | Enters global configuration mode. |
| Example:           |         |
| Device# `configure terminal` |         |

| **Step 3**        |         |
| `interface {vlan vlan-id} | {gigabitethernetinterface-id} | {port-channel port-channel-number}` | Selects the interface to be configured. |
| Example:           |         |
| Device(config)# `interface gigabitethernet1/0/2` |         |

| **Step 4**        |         |
| `shutdown`        | Shuts down an interface. |
| Example:           |         |
| Device(config-if)# `shutdown` |         |

| **Step 5**        |         |
| `no shutdown`     | Restarts an interface. |
| Example:           |         |
| Device(config-if)# `no shutdown` |         |

| **Step 6**        |         |
| `end`             | Returns to privileged EXEC mode. |
| Example:           |         |
| Device(config-if)# `end` |         |

| **Step 7**        |         |
| `show running-config` | Verifies your entries. |
| Example:           |         |
| Device# `show running-config` |         |
Configuring the Console Media Type

Follow these steps to set the console media type to RJ-45. If you configure the console as RJ-45, USB console operation is disabled, and input comes only through the RJ-45 connector.

This configuration applies to all switches in a stack.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. line console 0
4. media-type rj45
5. end
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> line console 0</td>
<td>Configures the console and enters line configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# line console 0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> media-type rj45</td>
<td>Configures the console media type to be only RJ-45 port. If you do not enter this command and both types are connected, the USB port is used by default.</td>
</tr>
<tr>
<td>Example: Device(config-line)# media-type rj45</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

(Optional) Saves your entries in the configuration file.

### Command or Action

**Step 6**

```
copy running-config startup-config
```

**Example:**

```
Device# copy running-config startup-config
```

### Configuring the USB Inactivity Timeout

The configurable inactivity timeout reactivates the RJ-45 console port if the USB console port is activated but no input activity occurs on it for a specified time period. When the USB console port is deactivated due to a timeout, you can restore its operation by disconnecting and reconnecting the USB cable.

### Note

The configured inactivity timeout applies to all devices in a stack. However, a timeout on one device does not cause a timeout on other devices in the stack.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `line console 0`
4. `usb-inactivity-timeout timeout-minutes`
5. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>line console 0</code></td>
<td>Configures the console and enters line configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# line console 0</code></td>
<td></td>
</tr>
</tbody>
</table>
## Monitoring Interface Characteristics

### Monitoring Interface Status

Commands entered at the privileged EXEC prompt display information about the interface, including the versions of the software and the hardware, the configuration, and statistics about the interfaces.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>

### Configuration Examples for Interface Characteristics

#### Adding a Description to an Interface: Example

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTRL/Z.
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# description Connects to Marketing
Device(config-if)# end
Device# show interfaces gigabitethernet1/0/2 description
Interface Status    Protocol Description
Gi1/0/2   admin down down Connects to Marketing
```

Note: The `clear counters` privileged EXEC command does not clear counters retrieved by using Simple Network Management Protocol (SNMP), but only those seen with the `show interface` privileged EXEC command.
Configuring a Range of Interfaces: Examples

This example shows how to use the `interface range` global configuration command to set the speed to 100 Mb/s on ports 1 to 4 on switch 1:

```
Device# configure terminal
Device(config)# interface range gigabitethernet1/0/1 - 4
Device(config-if-range)# speed 100
```

This example shows how to use a comma to add different interface type strings to the range to enable Gigabit Ethernet ports 1 to 3 and 10-Gigabit Ethernet ports 1 and 2 to receive flow-control pause frames:

```
Device# configure terminal
Device(config)# interface range gigabitethernet1/0/1 - 3, tengigabitethernet1/0/1 - 2
Device(config-if-range)# flowcontrol receive on
```

If you enter multiple configuration commands while you are in interface-range mode, each command is executed as it is entered. The commands are not batched and executed after you exit interface-range mode. If you exit interface-range configuration mode while the commands are being executed, some commands might not be executed on all interfaces in the range. Wait until the command prompt reappears before exiting interface-range configuration mode.

Configuring and Using Interface Range Macros: Examples

This example shows how to define an interface-range named `enet_list` to include ports 1 and 2 on switch 1 and to verify the macro configuration:

```
Device# configure terminal
Device(config)# define interface-range enet_list gigabitethernet1/0/1 - 2
Device(config)# end
Device# show running-config | include define
define interface-range enet_list GigabitEthernet1/0/1 - 2
```

This example shows how to create a multiple-interface macro named `macro1`:

```
Device# configure terminal
Device(config)# define interface-range macro1 gigabitethernet1/0/1 - 2, gigabitethernet1/0/5 - 7, tengigabitethernet1/0/1 -2
Device(config)# end
```

This example shows how to enter interface-range configuration mode for the interface-range macro `enet_list`:

```
Device# configure terminal
Device(config)# interface range macro enet_list
Device(config-if-range)#
```

This example shows how to delete the interface-range macro `enet_list` and to verify that it was deleted.

```
Device# configure terminal
Device(config)# no define interface-range enet_list
Device(config)# end
Device# show run | include define
```
Setting Interface Speed and Duplex Mode: Example

This example shows how to set the interface speed to 100 Mb/s and the duplex mode to half on a 10/100/1000 Mb/s port:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/3
Device(config-if)# speed 10
Device(config-if)# duplex half
```

This example shows how to set the interface speed to 100 Mb/s on a 10/100/1000 Mb/s port:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# speed 100
```

Configuring Layer 3 Interfaces: Example

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 192.20.135.21 255.255.255.0
Device(config-if)# no shutdown
```

Configuring the Console Media Type: Example

This example disables the USB console media type and enables the RJ-45 console media type.

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# media-type rj45
```

This configuration terminates any active USB console media type in the stack. A log shows that this termination has occurred. This example shows that the console on switch 1 reverted to RJ-45.

```
*Mar 1 00:25:36.860: %USB_CONSOLE-6-CONFIG_DISABLE: Console media-type USB disabled by system configuration, media-type reverted to RJ45.
```

At this point no switches in the stack allow a USB console to have input. A log entry shows when a console cable is attached. If a USB console cable is connected to switch 2, it is prevented from providing input.

```
*Mar 1 00:34:27.498: %USB_CONSOLE-6-CONFIG_DISALLOW: Console media-type USB is disallowed by system configuration, media-type remains RJ45. (switch-stk-2)
```

This example reverses the previous configuration and immediately activates any USB console that is connected.

```
Device# configure terminal
```
Configuring the USB Inactivity Timeout: Example

This example configures the inactivity timeout to 30 minutes:

Device# configure terminal
Device(config)# line console 0
Device(config-line)# usb-inactivity-timeout 30

To disable the configuration, use these commands:

Device# configure terminal
Device(config)# line console 0
Device(config-line)# no usb-inactivity-timeout

If there is no (input) activity on a USB console port for the configured number of minutes, the inactivity timeout setting applies to the RJ-45 port, and a log shows this occurrence:

*Mar 1 00:47:25.625: %USB_CONSOLE-6-INACTIVITY_DISABLE: Console media-type USB disabled due to inactivity, media-type reverted to RJ45.

At this point, the only way to reactivate the USB console port is to disconnect and reconnect the cable. When the USB cable on the switch has been disconnected and reconnected, a log similar to this appears:

*Mar 1 00:48:28.640: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.

Configuring Auto-MDIX

Prerequisites for Auto-MDIX

To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the `switchport` interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration.

Automatic medium-dependent interface crossover (auto-MDIX) is enabled by default.

Auto-MDIX is supported on all 10/100/1000-Mb/s and on 10/100/1000BASE-TX small form-factor pluggable (SFP)-module interfaces. It is not supported on 1000BASE-SX or -LX SFP module interfaces.

Restrictions for Auto-MDIX

The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MDIX is enabled on the switch port.
Information about Configuring Auto-MDIX

Auto-MDIX on an Interface

When automatic medium-dependent interface crossover (auto-MDIX) is enabled on an interface, the interface automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting devices without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other devices or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

This table shows the link states that result from auto-MDIX settings and correct and incorrect cabling.

### Example for Configuring Auto-MDIX

This example shows how to enable auto-MDIX on a port:

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
```
Device(config-if)# speed auto
Device(config-if)# duplex auto
Device(config-if)# mdix auto
Device(config-if)# end

CHAPTER 5

Configuring Ethernet Management Port

• Finding Feature Information, on page 79
• Prerequisites for Ethernet Management Ports, on page 79
• Information about the Ethernet Management Port, on page 79
• How to Configure the Ethernet Management Port, on page 82
• Additional References, on page 83
• Feature Information for Ethernet Management Ports, on page 84

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Ethernet Management Ports

When connecting a PC to the Ethernet management port, you must first assign an IP address.

Information about the Ethernet Management Port

The Ethernet management port, also referred to as the Gi0/0 or GigabitEthernet0/0 port, is a VRF (VPN routing/forwarding) interface to which you can connect a PC. You can use the Ethernet management port instead of the device console port for network management. When managing a device stack, connect the PC to the Ethernet management port on a stack member.
Ethernet Management Port Direct Connection to a Device

Figure 3: Connecting a Switch to a PC

This figure displays how to connect the Ethernet management port to the PC for a device or a standalone device.

Ethernet Management Port Connection to Stack Devices using a Hub

In a stack with only stack devices, all the Ethernet management ports on the stack members are connected to a hub to which the PC is connected. The active link is from the Ethernet management port on the active switch through the hub, to the PC. If the active device fails and a new active device is elected, the active link is now from the Ethernet management port on the new active device to the PC.

Figure 4: Connecting a Device Stack to a PC

This figure displays how a PC uses a hub to connect to a device stack.

<p>| | |</p>
<table>
<thead>
<tr>

<td>Management port</td>
</tr>
<tr>
<td>3</td>
<td>Hub</td>
</tr>
<tr>
<td>4</td>
<td>PC</td>
</tr>
</tbody>
</table>

Ethernet Management Port and Routing

By default, the Ethernet management port is enabled. The device cannot route packets from the Ethernet management port to a network port, and the reverse. Even though the Ethernet management port does not support routing, you may need to enable routing protocols on the port.
Enable routing protocols on the Ethernet management port when the PC is multiple hops away from the device and the packets must pass through multiple Layer 3 devices to reach the PC.

In the above figure, if the Ethernet management port and the network ports are associated with the same routing process, the routes are propagated as follows:

- The routes from the Ethernet management port are propagated through the network ports to the network.
- The routes from the network ports are propagated through the Ethernet management port to the network.

Because routing is not supported between the Ethernet management port and the network ports, traffic between these ports cannot be sent or received. If this happens, data packet loops occur between the ports, which disrupt the device and network operation. To prevent the loops, configure route filters to avoid routes between the Ethernet management port and the network ports.

**Supported Features on the Ethernet Management Port**

The Ethernet management port supports these features:

- Express Setup (only in switch stacks)
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SMNP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features
  - Speed—10 Mb/s, 100 Mb/s, 1000 Mb/s, and autonegotiation
  - Duplex mode—Full, half, and autonegotiation
  - Loopback detection
- Cisco Discovery Protocol (CDP)
- DHCP relay agent
Before enabling a feature on the Ethernet management port, make sure that the feature is supported. If you try to configure an unsupported feature on the Ethernet Management port, the feature might not work properly, and the device might fail.

How to Configure the Ethernet Management Port

Disabling and Enabling the Ethernet Management Port

SUMMARY STEPS

1. configure terminal
2. interface gigabitethernet0/0
3. shutdown
4. no shutdown
5. exit
6. show interfaces gigabitethernet0/0

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

LLDP, LLDP-MED, and Wired Location Service Overview

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, switches, and controllers). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the device supports the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol
LLDP Supported TLVs

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. This protocol can advertise details such as configuration information, device capabilities, and device identity.

The switch supports these basic management TLVs. These are mandatory LLDP TLVs.

- Port description TLV
- System name TLV
- System description TLV
- System capabilities TLV
- Management address TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

- Port VLAN ID TLV (IEEE 802.1 organizationally specific TLVs)
- MAC/PHY configuration/status TLV (IEEE 802.3 organizationally specific TLVs)

LLDP and Cisco Device Stacks

A device stack appears as a single device in the network. Therefore, LLDP discovers the device stack, not the individual stack members.

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices such as devices. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet, inventory management and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED Supported TLVs

LLDP-MED supports these TLVs:

- LLDP-MED capabilities TLV
  Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and has enabled.
- Network policy TLV
  Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify a phone of the VLAN number that it should use. The phone can connect to any device, obtain its VLAN number, and then start communicating with the call control.
By defining a network-policy profile TLV, you can create a profile for voice and voice-signaling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

- **Power management TLV**

  Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows devices and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

  LLDP-MED also supports an extended power TLV to advertise fine-grained power requirements, end-point power priority, and end-point and network connectivity-device power status. LLDP is enabled and power is applied to a port, the power TLV determines the actual power requirement of the endpoint device so that the system power budget can be adjusted accordingly. The device processes the requests and either grants or denies power based on the current power budget. If the request is granted, the switch updates the power budget. If the request is denied, the device turns off power to the port, generates a syslog message, and updates the power budget. If LLDP-MED is disabled or if the endpoint does not support the LLDP-MED power TLV, the initial allocation value is used throughout the duration of the connection.

  You can change power settings by entering the `power inline {auto [max max-wattage] | never | static [max max-wattage]}` interface configuration command. By default the PoE interface is in `auto` mode; If no value is specified, the maximum is allowed (30 W).

- **Inventory management TLV**

  Allows an endpoint to send detailed inventory information about itself to the device, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

- **Location TLV**

  Provides location information from the device to the endpoint device. The location TLV can send this information:

  - **Civic location information**

    Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

  - **ELIN location information**

    Provides the location information of a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

  - **Geographic location information**

    Provides the geographical details of a switch location such as latitude, longitude, and altitude of a switch.

  - **custom location**

    Provides customized name and value of a switch location.
Wired Location Service

The device uses the location service feature to send location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired device or controller. The device notifies the MSE of device link up and link down events through the Network Mobility Services Protocol (NMSP) location and attachment notifications.

The MSE starts the NMSP connection to the device, which opens a server port. When the MSE connects to the device there are a set of message exchanges to establish version compatibility and service exchange information followed by location information synchronization. After connection, the device periodically sends location and attachment notifications to the MSE. Any link up or link down events detected during an interval are aggregated and sent at the end of the interval.

When the device determines the presence or absence of a device on a link-up or link-down event, it obtains the client-specific information such as the MAC address, IP address, and username. If the client is LLDP-MED- or CDP-capable, the device obtains the serial number and UDI through the LLDP-MED location TLV or CDP.

Depending on the device capabilities, the device obtains this client information at link up:

- Slot and port specified in port connection
- MAC address specified in the client MAC address
- IP address specified in port connection
- 802.1X username if applicable
- Device category is specified as a wired station
- State is specified as new
- Serial number, UDI
- Model number
- Time in seconds since the device detected the association

Depending on the device capabilities, the device obtains this client information at link down:

- Slot and port that was disconnected
- MAC address
- IP address
- 802.1X username if applicable
- Device category is specified as a wired station
- State is specified as delete
- Serial number, UDI
- Time in seconds since the device detected the disassociation

When the device shuts down, it sends an attachment notification with the state delete and the IP address before closing the NMSP connection to the MSE. The MSE interprets this notification as disassociation for all the wired clients associated with the device.
If you change a location address on the device, the device sends an NMSP location notification message that identifies the affected ports and the changed address information.

### Default LLDP Configuration

**Table 10: Default LLDP Configuration**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLDP global state</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP holdtime (before discarding)</td>
<td>120 seconds</td>
</tr>
<tr>
<td>LLDP timer (packet update frequency)</td>
<td>30 seconds</td>
</tr>
<tr>
<td>LLDP reinitialization delay</td>
<td>2 seconds</td>
</tr>
<tr>
<td>LLDP tlv-select</td>
<td>Disabled to send and receive all TLVs</td>
</tr>
<tr>
<td>LLDP interface state</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP receive</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP transmit</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP med-tlv-select</td>
<td>Disabled to send all LLDP-MED TLVs. When LLDP is globally enabled, LLDP-MED-TLV is also enabled.</td>
</tr>
</tbody>
</table>

**Restrictions for LLDP**

- If the interface is configured as a tunnel port, LLDP is automatically disabled.
- If you first configure a network-policy profile on an interface, you cannot apply the `switchport voice vlan` command on the interface. If the `switchport voice vlan vlan-id` is already configured on an interface, you can apply a network-policy profile on the interface. This way the interface has the voice or voice-signaling VLAN network-policy profile applied on the interface.
- You cannot configure static secure MAC addresses on an interface that has a network-policy profile.

### How to Configure LLDP, LLDP-MED, and Wired Location Service

#### Enabling LLDP

**SUMMARY STEPS**

1. enable
2. configure terminal
3. lldp run
### Enabling LLDP

4. `interface interface-id`
5. `lldp transmit`
6. `lldp receive`
7. `end`
8. `show lldp`
9. `copy running-config startup-config`

#### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>

<td></td>
</tr>
</tbody>
</table>

**Configuring LLDP Characteristics**

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, and the initialization delay time. You can also select the LLDP and LLDP-MED TLVs to send and receive.

**Note**

Steps 2 through 5 are optional and can be performed in any order.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. lldp holdtime seconds
4. lldp reinit delay
5. lldp timer rate
6. lldp tlv-select
7. interface interface-id
8. lldp med-tlv-select
9. end
10. show lldp-select
11. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1:</td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
**Command or Action** | **Purpose**
---|---
Device> *enable* |  

**Step 2**  
**configure terminal**  
*Example:*  
Device# *configure terminal*

**Step 3**  
*lldp holdtime seconds*  
*Example:*  
Device(config)# *lldp holdtime 120*  
*(Optional) Specifies the amount of time a receiving device should hold the information from your device before discarding it. The range is 0 to 65535 seconds; the default is 120 seconds.*

**Step 4**  
*lldp reinit delay*  
*Example:*  
Device(config)# *lldp reinit 2*  
*(Optional) Specifies the delay time in seconds for LLDP to initialize on an interface. The range is 2 to 5 seconds; the default is 2 seconds.*

**Step 5**  
*lldp timer rate*  
*Example:*  
Device(config)# *lldp timer 30*  
*(Optional) Sets the sending frequency of LLDP updates in seconds. The range is 5 to 65534 seconds; the default is 30 seconds.*

**Step 6**  
*lldp tlv-select*  
*Example:*  
Device(config)# *tlv-select*

**Step 7**  
*interface interface-id*  
*Example:*  
Device (config)# *interface gigabitethernet2/0/1*  
*SpecifystheinterfaceonwhichyouareenablingLLDP,*  
*andenterinterfaceconfigurationmode.*

**Step 8**  
*lldp med-tlv-select*  
*Example:*  
Device (config-if)# *lldp med-tlv-select inventory management*  
*(Optional) Specifies the LLDP-MED TLVs to send or receive.*

**Step 9**  
*end*  
*Example:*  
Returns to privileged EXEC mode.
<table>
<thead>
<tr>

</tbody>
</table>

**Step 10**

**show lldp**

*Example:*

Device# show lldp

**Step 11**

**copy running-config startup-config**

*Example:*

Device# copy running-config startup-config

---

### Configuring LLDP-MED TLVs

By default, the device only sends LLDP packets until it receives LLDP-MED packets from the end device. It then sends LLDP packets with MED TLVs, as well. When the LLDP-MED entry has been aged out, it again only sends LLDP packets.

By using the `lldp` interface configuration command, you can configure the interface not to send the TLVs listed in the following table.

<table>
<thead>
<tr>
<th>LLDP-MED TLV</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inventory-management</td>
<td>LLDP-MED inventory management TLV</td>
</tr>
<tr>
<td>location</td>
<td>LLDP-MED location TLV</td>
</tr>
<tr>
<td>network-policy</td>
<td>LLDP-MED network policy TLV</td>
</tr>
<tr>
<td>power-management</td>
<td>LLDP-MED power management TLV</td>
</tr>
</tbody>
</table>

Follow these steps to enable a TLV on an interface:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `lldp med-tlv-select`
5. `end`
6. `copy running-config startup-config`
## DETAILED STEPS

<table>
<thead>
<tr>

</tbody>
</table>

## Configuring Network-Policy TLV

### SUMMARY STEPS

1. enable
2. configure terminal
3. network-policy profile *profile number*
4. `{voice | voice-signaling} vlan [vlan-id {cos cvalue | dscp dvalue}] | [[dot1p {cos cvalue | dscp dvalue}] | none | untagged]`

5. `exit`

6. `interface interface-id`

7. `network-policy profile number`

8. `lldp med-tlv-select network-policy`

9. `end`

10. `show network-policy profile`

11. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device&gt; enable</code></td>
</tr>
<tr>
<td></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device# configure terminal</code></td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>network-policy profile profile number</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# network-policy profile 1</code></td>
</tr>
<tr>
<td></td>
<td>Specifies the network-policy profile number, and enter network-policy configuration mode. The range is 1 to 4294967295.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>`{voice</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config-network-policy)# voice vlan 100 cos 4</code></td>
</tr>
<tr>
<td></td>
<td>Configures the policy attributes:</td>
</tr>
<tr>
<td></td>
<td>• <code>voice</code>—Specifies the voice application type.</td>
</tr>
<tr>
<td></td>
<td>• <code>voice-signaling</code>—Specifies the voice-signaling application type.</td>
</tr>
<tr>
<td></td>
<td>• <code>vlan</code>—Specifies the native VLAN for voice traffic.</td>
</tr>
<tr>
<td></td>
<td>• <code>vlan-id</code>—(Optional) Specifies the VLAN for voice traffic. The range is 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• <code>cos cvalue</code>—(Optional) Specifies the Layer 2 priority class of service (CoS) for the configured VLAN. The range is 0 to 7; the default is 5.</td>
</tr>
<tr>
<td></td>
<td>• <code>dscp dvalue</code>—(Optional) Specifies the differentiated services code point (DSCP) value for the configured VLAN. The range is 0 to 63; the default is 46.</td>
</tr>
</tbody>
</table>
### Configuring Network-Policy TLV

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <em>dot1p</em>—(Optional) Configures the telephone to use IEEE 802.1p priority tagging and use VLAN 0 (the native VLAN).</td>
</tr>
<tr>
<td></td>
<td>• <em>none</em>—(Optional) Do not instruct the IP telephone about the voice VLAN. The telephone uses the configuration from the telephone keypad.</td>
</tr>
<tr>
<td></td>
<td>• <em>untagged</em>—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone.</td>
</tr>
<tr>
<td></td>
<td>• <em>untagged</em>—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone.</td>
</tr>
</tbody>
</table>

#### Step 5
**exit**

*Example:*

```
Device(config)# exit
```

Returns to global configuration mode.

#### Step 6
**interface interface-id**

*Example:*

```
Device(config)# interface gigabitethernet2/0/1
```

Specifies the interface on which you are configuring a network-policy profile, and enter interface configuration mode.

#### Step 7
**network-policy profile number**

*Example:*

```
Device(config-if)# network-policy 1
```

Specifies the network-policy profile number.

#### Step 8
**lldp med-tlv-select network-policy**

*Example:*

```
Device(config-if)# lldp med-tlv-select network-policy
```

Specifies the network-policy TLV.

#### Step 9
**end**

*Example:*

```
Device(config)# end
```

Returns to privileged EXEC mode.

#### Step 10
**show network-policy profile**

*Example:*

Verifies the configuration.
Purpose

**Command or Action**

Device# show network-policy profile

**Step 11**

**copy running-config startup-config**

*(Optional) Saves your entries in the configuration file.*

Example:

Device# copy running-config startup-config

---

# Configuring Location TLV and Wired Location Service

Beginning in privileged EXEC mode, follow these steps to configure location information for an endpoint and to apply it to an interface.

**SUMMARY STEPS**

1. configure terminal
2. location {admin-tag string | civic-location identifier {id | host} | elin-location string identifier id | custom-location identifier {id | host} | geo-location identifier {id | host}}
3. exit
4. interface interface-id
5. location {additional-location-information word | civic-location-id {id | host} | elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host}}
6. end
7. Use one of the following:
   - *show location admin-tag string*
   - *show location civic-location identifier id*
   - *show location elin-location identifier id*
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

configure terminal

Example:

Device# configure terminal

| **Step 2**

location {admin-tag string | civic-location identifier {id | host} | elin-location string identifier id | custom-location identifier {id | host} | geo-location identifier {id | host}}

Example:

<table>
<thead>
<tr>
<th><strong>Purpose</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Specifies the location information for an endpoint.</td>
</tr>
<tr>
<td>- <strong>admin-tag</strong>—Specifies an administrative tag or site information.</td>
</tr>
<tr>
<td>- <strong>civic-location</strong>—Specifies civic location information.</td>
</tr>
<tr>
<td>Command or Action</td>
</tr>
<tr>
<td>-------------------</td>
</tr>
<tr>
<td><strong>Device(config)# location civic-location identifier 1</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# number 3550</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# primary-road-name “Cisco Way”</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# city “San Jose”</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# state CA</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# building 19</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# room C6</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# county &quot;Santa Clara&quot;</strong></td>
</tr>
<tr>
<td><strong>Device(config-civic)# country US</strong></td>
</tr>
</tbody>
</table>

**Step 3**

**exit**

*Example:*

```
Device(config-civic)# exit
```

Returns to global configuration mode.

**Step 4**

**interface interface-id**

*Example:*

```
Device(config)# interface gigabitethernet2/0/1
```

Specifies the interface on which you are configuring the location information, and enter interface configuration mode.

**Step 5**

```
location {additional-location-information word | civic-location-id {id | host} | elin-location-id id | custom-location-id {id | host} | geo-location-id {id | host} }
```

*Example:*

```
Device(config-if)# location elin-location-id 1
```

Enters location information for an interface:

• **additional-location-information**—Specifies additional information for a location or place.
• **civic-location-id**—Specifies global civic location information for an interface.
• **elin-location-id**—Specifies emergency location information for an interface.
• **custom-location-id**—Specifies custom location information for an interface.
• **geo-location-id**—Specifies geo-spatial location information for an interface.
• **host**—Specifies the host location identifier.
• **word**—Specifies a word or phrase with additional location information.
• **id**—Specifies the ID for the civic, ELIN, custom, or geo location. The ID range is 1 to 4095.

### Enabling Wired Location Service on the Device

**Before you begin**

For wired location to function, you must first enter the `ip device tracking` global configuration command.

### SUMMARY STEPS

1. enable
2. configure terminal
3. nmsp notification interval {attachment | location} interval-seconds
4. end
5. show network-policy profile
6. copy running-config startup-config

Configuration Examples for LLDP, LLDP-MED, and Wired Location Service

Configuring Network-Policy TLV: Examples

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
# configure terminal
(config)# network-policy 1
(config-network-policy)# voice vlan 100 cos 4
(config-network-policy)# exit
(config)# interface gigabitethernet1/0/1
(config-if)# network-policy profile 1
(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
(config-network-policy)# voice vlan dot1p cos 4
(config-network-policy)# voice vlan dot1p dscp 34
```

Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service

Commands for monitoring and maintaining LLDP, LLDP-MED, and wired location service.

<table>
<thead>
<tr>

CHAPTER 7

Configuring System MTU

- Finding Feature Information, on page 105
- Information about the MTU, on page 105
- How to Configure MTU Sizes, on page 106
- Configuration Examples for System MTU, on page 109
- Configuration Examples for System MTU, on page 109
- Additional References for System MTU, on page 109
- Feature Information for System MTU, on page 110

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about the MTU

The default maximum transmission unit (MTU) size for frames received and sent on all device interfaces is 1500 bytes.

Restrictions for System MTU

When configuring the system MTU values, follow these guidelines:

- The device does not support the MTU on a per-interface basis.

- If you enter the `system mtu bytes` global configuration command, the command does not take effect on the device. This command only affects the system MTU size on Fast Ethernet switch ports.
System MTU Value Application

In a switch stack, the MTU values applied to member switches depends upon the stack configuration. The following stack configurations are supported:

This table shows how the MTU values are applied.

Table 12: MTU Values

<table>
<thead>
<tr>
<th>Configuration</th>
<th>system mtu command</th>
<th>ip mtu command</th>
<th>ipv6 mtu command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standalone switch or switch stack</td>
<td>You can enter the system mtu command on a switch or switch stack, but system MTU value does not take effect. The range is from 1500 to 9198 bytes.</td>
<td>Use the ip mtu bytes command. The range is from 68 up to the system MTU value (in bytes). Note The IP MTU value is the applied value, not the configured value.</td>
<td>Use the ipv6 mtu bytes command. The range is from 1280 to the system jumbo MTU value (in bytes). Note The IPv6 MTU value is the applied value, not the configured value.</td>
</tr>
</tbody>
</table>

The upper limit of the IP or IPv6 MTU value is based on the switch or switch stack configuration and refers to the currently applied system MTU value. For more information about setting the MTU sizes, see the system mtu global configuration command in the command reference for this release.

How to Configure MTU Sizes

Configuring the System MTU

Follow these steps to change the MTU size for switched and routed packets:

SUMMARY STEPS

1. enable
2. configure terminal
3. system mtu bytes
4. end
5. copy running-config startup-config
6. reload
7. show system mtu
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `enable` | Enables privileged EXEC mode. Enter your password if prompted.  
            Example:  
            Device> enable |
| Step 2 | `configure terminal` | Enters global configuration mode.  
            Example:  
            Device# configure terminal |
| Step 3 | `system mtu bytes` | (Optional) Changes the MTU size for all Gigabit Ethernet and 10-Gigabit Ethernet interfaces.  
            Example:  
            Device(config)# system mtu 1900 |
| Step 4 | `end` | Returns to privileged EXEC mode.  
            Example:  
            Device(config)# end |
| Step 5 | `copy running-config startup-config` | Saves your entries in the configuration file.  
            Example:  
            Device# copy running-config startup-config |
| Step 6 | `reload` | Reloads the operating system.  
            Example:  
            Device# reload |
| Step 7 | `show system mtu` | Verifies your settings.  
            Example:  
            Device# show system mtu |

## Configuring Protocol-Specific MTU

Beginning in privileged EXEC mode, follow these steps to change the MTU size for routed ports:

### SUMMARY STEPS

1. `configure terminal`
2. `interface interface`
3. `ip mtu bytes`
4. `ipv6 mtu bytes`
5. `end`
6. `copy running-config startup-config`
7. `reload`
8. show system mtu

**DETAILED STEPS**

Information About Internal Power Supplies

See the device installation guide for information about the power supplies.

How to Configure Internal Power Supplies

Configuring Internal Power Supply

You can use the `powersupply` EXEC command to configure and manage the internal power supply on the device. The device does not support the `nopowersupply` EXEC command.

Follow these steps beginning in user EXEC mode:

**SUMMARY STEPS**

1. `powersupply switch_number slot{A | B} {off | on}`
2. `show environment power`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

| power supply switch_number slot{A | B} {off | on} |
| Example: |

Device# `powersupply 1 slot A on` | Sets the specified power supply to off or on by using one of these keywords:

- A — Selects the power supply in slot A.
- B — Selects power supply in slot B. |
### PurposeCommand or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note</strong> Power supply slot B is the closest to the outer edge of the device.</td>
</tr>
<tr>
<td></td>
<td>• off — Set the power supply off.</td>
</tr>
<tr>
<td></td>
<td>• on — Set the power supply on.</td>
</tr>
<tr>
<td></td>
<td>By default, the device power supply is on.</td>
</tr>
</tbody>
</table>

### Step 2

**Example:**

Device# `show environment power`

Verifies your settings.

### Monitoring Internal Power Supplies

**Table 13: Show Commands for Power Supplies**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show environment power [ all</td>
<td>switch switch_number ]`</td>
</tr>
</tbody>
</table>

### Configuration Examples for Internal Power Supplies

This example shows how to set the power supply in slot A to off:

Device# `power supply 1 slot A off`

Disabling Power supply A may result in a power loss to PoE devices and/or switches ...

Continue? (yes/[no]): **yes**

Device#

Jun 10 04:52:54.389: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered off

Jun 10 04:52:56.717: %PLATFORM_ENV-1-FAN_NOT_PRESENT: Fan is not present

Device#

This example shows how to set the power supply in slot A to on:

Device# `power supply 1 slot A on`

Jun 10 04:54:39.600: %PLATFORM_ENV-6-FRU_PS_OIR: FRU Power Supply 1 powered on

This example shows the output of the `show env power` command:

Device# `show env power`
## Table 14: show env power Status Descriptions

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software images. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about PoE

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

• a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
• an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Supported Protocols and Standards

The device uses these protocols and standards to support PoE:
• CDP with power consumption—The powered device notifies the device of the amount of power it is consuming. The device does not reply to the power-consumption messages. The device can only supply power to or remove power from the PoE port.

• Cisco intelligent power management—The powered device and the device negotiate through power-negotiation CDP messages for an agreed-upon power-consumption level. The negotiation allows a high-power Cisco powered device, which consumes more than 7 W, to operate at its highest power mode. The powered device first boots up in low-power mode, consumes less than 7 W, and negotiates to obtain enough power to operate in high-power mode. The device changes to high-power mode only when it receives confirmation from the device.

High-power devices can operate in low-power mode on devices that do not support power-negotiation CDP.

Cisco intelligent power management is backward-compatible with CDP with power consumption; the device responds according to the CDP message that it receives. CDP is not supported on third-party powered devices; therefore, the device uses the IEEE classification to determine the power usage of the device.

• IEEE 802.3af—The major features of this standard are powered-device discovery, power administration, disconnect detection, and optional powered-device power classification. For more information, see the standard.

• The Cisco UPOE feature provides the capability to source up to 60 W of power (2 x 30 W) over both signal and spare pairs of the RJ-45 Ethernet cable by using the Layer-2 power negotiation protocols such as CDP or LLDP. An LLDP and CDP request of 30 W and higher in presence of the 4-wire Cisco Proprietary spare-pair power TLV can provide power on the spare pair.

**Related Topics**

Cisco Universal Power Over Ethernet, on page 120

### Powered-Device Detection and Initial Power Allocation

The device detects a Cisco pre-standard or an IEEE-compliant powered device when the PoE-capable port is in the no-shutdown state, PoE is enabled (the default), and the connected device is not being powered by an AC adaptor.

After device detection, the device determines the device power requirements based on its type:

• The initial power allocation is the maximum amount of power that a powered device requires. The device initially allocates this amount of power when it detects and powers the powered device. As the device receives CDP messages from the powered device and as the powered device negotiates power levels with the device through CDP power-negotiation messages, the initial power allocation might be adjusted.

• The device classifies the detected IEEE device within a power consumption class. Based on the available power in the power budget, the device determines if a port can be powered. Table 15: IEEE Power Classifications, on page 116 lists these levels.

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum Power Level Required from the Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (class status unknown)</td>
<td>15.4 W</td>
</tr>
<tr>
<td>1</td>
<td>4 W</td>
</tr>
</tbody>
</table>

Table 15: IEEE Power Classifications
The device monitors and tracks requests for power and grants power only when it is available. The device tracks its power budget (the amount of power available on the device for PoE). The device performs power-accounting calculations when a port is granted or denied power to keep the power budget up to date.

After power is applied to the port, the device uses CDP to determine the CDP-specific power consumption requirement of the connected Cisco powered devices, which is the amount of power to allocate based on the CDP messages. The device adjusts the power budget accordingly. This does not apply to third-party PoE devices. The device processes a request and either grants or denies power. If the request is granted, the device updates the power budget. If the request is denied, the device ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. Powered devices can also negotiate with the device for more power.

With PoE+, powered devices use IEEE 802.3at and LLDP power with media dependent interface (MDI) type, length, and value descriptions (TLVs), Power-via-MDI TLVs, for negotiating power up to 30 W. Cisco pre-standard devices and Cisco IEEE powered devices can use CDP or the IEEE 802.3at power-via-MDI power negotiation mechanism to request power levels up to 30 W.

### Note
The initial allocation for Class 0, Class 3, and Class 4 powered devices is 15.4 W. When a device starts up and uses CDP or LLDP to send a request for more than 15.4 W, it can be allocated up to the maximum of 30 W.

### Note
The CDP-specific power consumption requirement is referred to as the actual power consumption requirement in the software configuration guides and command references.

If the device detects a fault caused by an undervoltage, overvoltage, overtemperature, oscillator-fault, or short-circuit condition, it turns off power to the port, generates a syslog message, and updates the power budget and LEDs.

The PoE feature operates the same whether or not the device is a stack member. The power budget is per device and independent of any other device in the stack. Election of a new active device does not affect PoE operation. The active device keeps track of the PoE status for all devices and ports in the stack and includes the status in output displays.

The stacking-capable device also supports StackPower, which allows the power supplies to share the load across multiple systems in a stack when you connect the devices with power stack cables. You can manage the power supplies of up to four stack members as a one large power supply.

**Power Management Modes**

The device supports these PoE modes:

<table>
<thead>
<tr>
<th>Class</th>
<th>Maximum Power Level Required from the Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>7 W</td>
</tr>
<tr>
<td>3</td>
<td>15.4 W</td>
</tr>
<tr>
<td>4</td>
<td>30 W (For IEEE 802.3at Type 2 powered devices)</td>
</tr>
</tbody>
</table>
• **auto**—The device automatically detects if the connected device requires power. If the device discovers a powered device connected to the port and if the device has enough power, it grants power, updates the power budget, turns on power to the port on a first-come, first-served basis, and updates the LEDs. For LED information, see the hardware installation guide.

If the device has enough power for all the powered devices, they all come up. If enough power is available for all powered devices connected to the device, power is turned on to all devices. If there is not enough available PoE, or if a device is disconnected and reconnected while other devices are waiting for power, it cannot be determined which devices are granted or are denied power.

If granting power would exceed the system power budget, the device denies power, ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. After power has been denied, the device periodically rechecks the power budget and continues to attempt to grant the request for power.

If a device being powered by the device is then connected to wall power, the device might continue to power the device. The device might continue to report that it is still powering the device whether the device is being powered by the device or receiving power from an AC power source.

If a powered device is removed, the device automatically detects the disconnect and removes power from the port. You can connect a nonpowered device without damaging it.

You can specify the maximum wattage that is allowed on the port. If the IEEE class maximum wattage of the powered device is greater than the configured maximum value, the device does not provide power to the port. If the device powers a powered device, but the powered device later requests through CDP messages more than the configured maximum value, the device removes power to the port. The power that was allocated to the powered device is reclaimed into the global power budget. If you do not specify a wattage, the device delivers the maximum value. Use the **auto** setting on any PoE port. The auto mode is the default setting.

• **static**—The device pre-allocates power to the port (even when no powered device is connected) and guarantees that power will be available for the port. The device allocates the port configured maximum wattage, and the amount is never adjusted through the IEEE class or by CDP messages from the powered device. Because power is pre-allocated, any powered device that uses less than or equal to the maximum wattage is guaranteed to be powered when it is connected to the static port. The port no longer participates in the first-come, first-served model.

However, if the powered-device IEEE class is greater than the maximum wattage, the device does not supply power to it. If the device learns through CDP messages that the powered device is consuming more than the maximum wattage, the device shuts down the powered device.

If you do not specify a wattage, the device pre-allocates the maximum value. The device powers the port only if it discovers a powered device. Use the **static** setting on a high-priority interface.

• **never**—The device disables powered-device detection and never powers the PoE port even if an unpowered device is connected. Use this mode only when you want to make sure that power is never applied to a PoE-capable port, making the port a data-only port.

For most situations, the default configuration (auto mode) works well, providing plug-and-play operation. No further configuration is required. However, perform this task to configure a PoE port for a higher priority, to make it data only, or to specify a maximum wattage to disallow high-power powered devices on a port.

Stacking-capable devices also support StackPower, which allows device power supplies to share the load across multiple systems in a stack by connecting up to four devices with power stack cables.
Power Monitoring and Power Policing

When policing of the real-time power consumption is enabled, the device takes action when a powered device consumes more power than the maximum amount allocated, also referred to as the cutoff-power value.

When PoE is enabled, the device senses the real-time power consumption of the powered device. The device monitors the real-time power consumption of the connected powered device; this is called power monitoring or power sensing. The device also polices the power usage with the power policing feature.

Power monitoring is backward-compatible with Cisco intelligent power management and CDP-based power consumption. It works with these features to ensure that the PoE port can supply power to the powered device.

The device senses the real-time power consumption of the connected device as follows:

1. The device monitors the real-time power consumption on individual ports.
2. The device records the power consumption, including peak power usage. The device reports the information through the CISCO-POWER-ETHERNET-EXT-MIB.
3. If power policing is enabled, the device polices power usage by comparing the real-time power consumption to the maximum power allocated to the device. The maximum power consumption is also referred to as the cutoff power on a PoE port.
   - If the device uses more than the maximum power allocation on the port, the device can either turn off power to the port, or the device can generate a syslog message and update the LEDs (the port LED is now blinking amber) while still providing power to the device based on the device configuration. By default, power-usage policing is disabled on all PoE ports.
   - If error recovery from the PoE error-disabled state is enabled, the device automatically takes the PoE port out of the error-disabled state after the specified amount of time.
   - If error recovery is disabled, you can manually re-enable the PoE port by using the shutdown and no shutdown interface configuration commands.
4. If policing is disabled, no action occurs when the powered device consumes more than the maximum power allocation on the PoE port, which could adversely affect the device.

Power Consumption Values

You can configure the initial power allocation and the maximum power allocation on a port. However, these values are only the configured values that determine when the device should turn on or turn off power on the PoE port. The maximum power allocation is not the same as the actual power consumption of the powered device. The actual cutoff power value that the device uses for power policing is not equal to the configured power value.

When power policing is enabled, the device polices the power usage at the switch port, which is greater than the power consumption of the device. When you are manually set the maximum power allocation, you must consider the power loss over the cable from the switch port to the powered device. The cutoff power is the sum of the rated power consumption of the powered device and the worst-case power loss over the cable.

We recommend that you enable power policing when PoE is enabled on your device. For example, if policing is disabled and you set the cutoff-power value by using the power inline auto max 6300 interface configuration command, the configured maximum power allocation on the PoE port is 6.3 W (6300 mW). The device provides power to the connected devices on the port if the device needs up to 6.3 W. If the CDP-power negotiated value or the IEEE classification value exceeds the configured cutoff value, the device does not provide power to the connected device. After the device turns on power on the PoE port, the device does not police the real-time power consumption of the device, and the device can consume more power than the
maximum allocated amount, which could adversely affect the device and the devices connected to the other PoE ports.

Because a standalone device supports internal power supplies, the total amount of power available for the powered devices varies depending on the power supply configuration.

- If a power supply is removed and replaced by a new power supply with less power and the device does not have enough power for the powered devices, the device denies power to the PoE ports in auto mode in descending order of the port numbers. If the device still does not have enough power, the device then denies power to the PoE ports in static mode in descending order of the port numbers.

- If the new power supply supports more power than the previous one and the device now has more power available, the device grants power to the PoE ports in static mode in ascending order of the port numbers. If it still has power available, the device then grants power to the PoE ports in auto mode in ascending order of the port numbers.

The stacking-capable device also supports StackPower, which allows power supplies to share the load across multiple systems in a stack by connecting the devices with power stack cables. You can collectively manage the power supplies of up to four stack members as a one large power supply.

**Cisco Universal Power Over Ethernet**

Cisco Universal Power Over Ethernet (Cisco UPOE) is a Cisco proprietary technology that extends the IEEE 802.3at PoE standard to provide the capability to source up to 60 W of power over standard Ethernet cabling infrastructure (Class D or better) by using the spare pair of an RJ-45 cable (wires 4,5,7,8) with the signal pair (wires 1,2,3,6). Power on the spare pair is enabled when the switch port and end device mutually identify themselves as Cisco UPOE-capable using CDP or LLDP and the end device requests for power to be enabled on the spare pair. When the spare pair is powered, the end device can negotiate up to 60 W of power from the switch using CDP or LLDP.

If the end device is PoE-capable on both signal and spare pairs but does not support the CDP or LLDP extensions required for Cisco UPOE, a 4-pair forced mode configuration automatically enables power on both signal and spare pairs from the switch port.

**How to Configure PoE**

**Configuring a Power Management Mode on a PoE Port**

---

**Note**

When you make PoE configuration changes, the port being configured drops power. Depending on the new configuration, the state of the other PoE ports, and the state of the power budget, the port might not be powered up again. For example, port 1 is in the auto and on state, and you configure it for static mode. The device removes power from port 1, detects the powered device, and repowers the port. If port 1 is in the auto and on state and you configure it with a maximum wattage of 10 W, the device removes power from the port and then redetects the powered device. The device repowers the port only if the powered device is a class 1, class 2, or a Cisco-only powered device.

---
### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. power inline \{auto [max max-wattage] | never | static [max max-wattage]\}
5. end
6. show power inline [interface-id | module switch-number]
7. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable&lt;br&gt;Example: Device&gt; enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

</tr>
<tr>
<td>• static — Enables powered-device detection. Pre-allocate (reserve) power for a port before the device discovers the powered device. The device reserves power for this port even when no device is connected and guarantees that power will be provided upon device detection. The device allocates power to a port configured in static mode before it allocates power to a port configured in auto mode.</td>
<td></td>
</tr>
</tbody>
</table>
| Step 5 | end  
Example:  
Device(config-if)# end |
| Returns to privileged EXEC mode. |
| Step 6 | show power inline [interface-id | module switch-number]  
Example:  
Device# show power inline |
| Displays PoE status for a device or a device stack, for the specified interface, or for a specified stack member. The module switch-number keywords are supported only on stacking-capable devices. |
| Step 7 | copy running-config startup-config  
Example:  
Device# copy running-config startup-config |
| (Optional) Saves your entries in the configuration file. |

### Enabling Power on Signal/Spare Pairs

**Note**

Do not enter this command if the end device cannot source inline power on the spare pair or if the end device supports the CDP or LLDP extensions for Cisco UPOE.

**SUMMARY STEPS**

1. configure terminal  
2. interface interface-id  
3. power inline four-pair forced  
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>

| Step 1 | configure terminal  
Example:  |
| Enters global configuration mode. |
Configuring Power Policing

By default, the device monitors the real-time power consumption of connected powered devices. You can configure the device to police the power usage. By default, policing is disabled.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. power inline police [action {log | errdisable}]
5. exit
6. Use one of the following:
   - errdisable detect cause inline-power
   - errdisable recovery cause inline-power
   - errdisable recovery interval interval
7. exit
8. Use one of the following:
   - show power inline police
   - show errdisable recovery
9. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

---

### Purpose

**Command or Action**

Device# configure terminal

**Step 2**

interface interface-id

**Example:**

Device(config)# interface gigabitethernet2/0/1

**Purpose**

Specifies the physical port to be configured, and enters interface configuration mode.

**Step 3**

power inline four-pair forced

**Example:**

Device(config-if)# power inline four-pair forced

**Purpose**

Enables power on both signal and spare pairs from a switch port.

**Step 4**

end

**Example:**

Device(config-if)# end

**Purpose**

Returns to privileged EXEC mode.
### Configuring Power Policing

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Device&gt; enable</strong></td>
<td><strong>Purpose</strong></td>
</tr>
</tbody>
</table>

**Step 2** configure terminal

**Example:**

Device# configure terminal

**Step 3** interface interface-id

**Example:**

Device(config)# interface gigabitethernet2/0/1

**Step 4** power inline police [action {log | errdisable}]

**Example:**

Device(config-if)# power inline police

If the real-time power consumption exceeds the maximum power allocation on the port, configures the device to take one of these actions:

- **power inline police**—Shuts down the PoE port, turns off power to it, and puts it in the error-disabled state.

**Note** You can enable error detection for the PoE error-disabled cause by using the `errdisable detect cause inline-power` global configuration command. You can also enable the timer to recover from the PoE error-disabled state by using the `errdisable recovery cause inline-power interval interval` global configuration command.

- **power inline police action errdisable**—Turns off power to the port if the real-time power consumption exceeds the maximum power allocation on the port.

- **power inline police action log**—Generates a syslog message while still providing power to the port.

If you do not enter the `action log` keywords, the default action shuts down the port and puts the port in the error-disabled state.

**Step 5** exit

**Example:**

Device(config-if)# exit

**Step 6** Use one of the following:

- errdisable detect cause inline-power
- errdisable recovery cause inline-power
- errdisable recovery interval interval

(Optional) Enables error recovery from the PoE error-disabled state, and configures the PoE recover mechanism variables.

By default, the recovery interval is 300 seconds.
Purpose

**Command or Action**

**Example:**

Device(config)# errdisable detect cause inline-power

Device(config)# errdisable recovery cause inline-power

Device(config)# errdisable recovery interval 100

**Step 7**

**exit**

**Example:**

Device(config)# exit

**Step 8**

Use one of the following:

- show power inline police
- show errdisable recovery

**Example:**

Device# show power inline police

Device# show errdisable recovery

**Step 9**

**copy running-config startup-config**

**Example:**

Device# copy running-config startup-config

**Monitoring Power Status**

Restrictions for Configuring the XPS 2200

- When using the XPS power supplies in the RPS mode for backing up switch power supplies, the smallest power supply in the XPS must be greater than the largest power supply in a switch connected to an XPS port in RPS mode.
- In RPS mode, each XPS power supply can back up one and only one switch power supply, regardless of the size.
- If you remove a power supply from the power stack (from a switch or the XPS), be sure that removing it does not deplete available power enough to cause load shedding.

Information About Configuring the XPS 2200

Cisco eXpandable Power System (XPS) 2200 Overview

The Cisco eXpandable Power System (XPS) 2200 is a standalone power system that you can connect to Catalyst switches. The XPS 2200 can provide backup power to connected devices that experience a power supply failure or, in a Catalyst switch power stack, it can supply additional power to the power stack budget. The XPS 2200 power ports and internal power supplies can operate in redundant power supply (RPS) mode or stack power (SP) mode.

Stack-power mode is used only on stacking-capable switches in a power stack. With no XPS, a power stack operates in ring topology with a maximum of four switches in the stack. If you merge two stacks, the total
number of switches cannot exceed four. When an XPS is in the power stack, you can connect up to nine switches in the stack plus the XPS, providing power budgets to power stack members similar to stack-power ring topology operation.

All Catalyst switches connected to an XPS on SP ports are part of the same power stack, and all power from the XPS and the switch is shared across all switches in the stack. Power sharing is the default mode, but the XPS supports the same stack power modes that are supported in a ring topology (strict and nonstrict power-sharing or redundant modes).

When two power supplies are present, the system can operate in mixed mode, where one power supply operates in RPS mode and the other in SP mode. You can configure the ports and power supplies for the way that you plan to use the XPS 2200.

The XPS 2000 has nine power ports that can operate in an RPS role or in an automatic stack power (Auto-SP) role (the default), where mode of operation is determined by the type of switch connected to the port. You can also use the CLI to force the mode to be RPS for stackable switches.

- When a Catalyst switch running the LAN base image, or a Catalyst (nonstackable) switch is connected to the port, the mode is RPS, and the XPS 2200 acts as a backup if the switch power supply goes down.
- When a Catalyst (stackable) switch running the IP base or IP services license is connected to the port, the mode is SP, which enables the switch to be part of the stack power system.

You configure the XPS through any switch connected to a power port. You can use any XPS port for configuration, and you can configure any port from any switch connected to the XPS. If you enter XPS configuration commands on more than one switch, the last configuration applied takes effect.

Although all XPS configuration is done through a switch, the XPS 2200 also runs its own software. You can upgrade this software through the XPS Service Port.

**XPS 2200 Power Supply Modes**

The XPS has two power supplies that can also be in either RPS or SP mode.

In SP mode, all SP ports on the XPS belong to the same power stack. When a power stack includes an XPS, the stack topology is a star topology and consists of up to nine member switches plus the XPS 2200. The XPS power supply or power supplies that are in SP mode are considered in the power budgeting. If both XPS power supplies are in RPS mode, the power stack consists only of the switches connected to XPS ports in SP mode, and the power budget is determined by the power supplies in these switches.

If there is a power supply role mismatch, for example, if an XPS port is configured for RPS and both power supplies are in SP mode, the XPS detects the mismatch, and an error message is sent.

**RPS Mode**

When both XPS power supplies are in RPS mode, the XPS can back up two power supply failures for switch power supplies of equal value or less. The smallest power supply in the XPS must be greater than the largest power supply in a switch connected to an XPS port in RPS mode.

If only one supply is in RPS mode, the XPS can back up only one power supply, even when the failed power supply is much smaller. For example, if an XPS 1100 W power supply is in RPS mode and two 350 W switch power supplies fail, the XPS can back up only one of the switch power supplies.

When one XPS power supply in RPS mode is backing up a switch power supply and another switch power supply fails, a message appears that the XPS backup is not available. When the failed power supply comes up, the XPS becomes available to back up other power supplies.
If the XPS is backing up two failed power supplies in a single switch (both XPS power supplies in RPS mode), the XPS is not available to back up other switch power supplies until both of the failed supplies are repaired or replaced.

In mixed mode, with one power supply in RPS mode and one in SP mode, if two power supplies in a single switch fail, because the XPS can back up only one of them, it denies power to both power supplies, and the switch shuts down. This occurs only in mixed power mode.

If a switch is connected to a port configured as RPS, but neither of the power supplies is RPS, the RPS port configuration is rejected and the XPS attempts to add the switch to a power stack. If the switch is not capable of operating in SP mode (is not a stackable switch), the port is disabled.

Ports in RPS mode have a configurable priority. The default priority is based on the XPS port number, with port 1 as the highest priority port. A higher priority port has a higher precedence for backup than a lower priority port. If a switch connected to a higher priority port has a power supply failure while a switch connected to a low priority port is being backed up, the XPS drops power to the low priority port to supply power to the high priority port.

**Stack Power Mode**

Stack-power mode is used only on Catalyst switches in a power stack. With no XPS, a power stack operates in ring topology with a maximum of four switches in the stack. When an XPS is in the power stack, you can connect up to nine switches in the stack plus the XPS, providing power budgets to power stack members similar to stack-power ring topology operation.

All Catalyst switches connected to an XPS on SP ports are part of the same power stack, and all power from the XPS and the switches is shared across all switches in the stack. Power sharing is the default mode, but the XPS supports the same stack power modes that are supported in a ring topology (strict and nonstrict power-sharing or redundant modes).

The XPS uses neighbor discovery to create the power stack. When it discovers a Catalyst switch on an unconfigured port, it marks the port as an SP port, and the switch joins the power stack. The XPS notifies the switch, begins the power-budgeting process, and assigns budgets to each switch in the power stack based on their requirements, priorities, current power allocations, and the stack aggregate power capability.

The XPS sends the power budget to each switch. If not enough input power is available to provide every switch with its maximum requested power, power is distributed based on priority. Switches with the highest priority receive required power first, followed by any powered devices that have already been allocated power, in order of their priority. Any remaining power is distributed equally through the stack.

The RPS port priority (1 through 9) does not affect stack power priority. Each switch participating in stack power has its own system priority and a high and low priority for devices connected to its ports. These priorities are used for stack power, as is the case in a ring topology. You configure stack power priority for the system and for high and low-priority ports by using the `power-priority switch`, `power-priority high`, and `power-priority low` commands in switch stack power configuration mode. If a system or set of powered devices are using the default priority, the XPS automatically assigns a priority (1 through 27), with lower MAC addresses receiving higher priorities.

There are four power stack modes: power sharing, strict power sharing, redundant, or strict redundant. You configure the power stack mode by using the `mode {power-sharing | redundant} [strict]` command in power-stack configuration mode. The `power-sharing` or `redundant` configurations affect the power budgeting aspect of the stack; `strict` or non-strict affects the actions of the PoE application when a budget reduction does not result in load shedding.

- In power sharing modes (strict or nonstrict), the stack power budget is the cumulative capacity of all the power supplies in the stack (minus 30 W reserved power). This is the default.
• In redundant modes (strict or nonstrict), the stack power budget is the total available power (minus 30 W) after the capacity of the largest power supply in the power stack is subtracted. Redundant mode guarantees that no switch or powered device loses power or experiences load sheds if a single power supply fails, but load sheds can occur if more than one power supply fails.

• In strict modes, if a loss of input power results in reduced power budgets but does not result in any hardware load shedding, the XPS automatically begins denying power to low-priority powered devices and then the high-priority powered devices until the amount of allocated power is less than or equal to the amount of available PoE power.

• In nonstrict modes, in the event of a power reduction, the amount of allocated power is allowed to fall under budget.

For example, a system with a total PoE budget (available power) of 400 W can allocate 390 W of the budget (allocated power) to powered devices. The allocated power of a device is the maximum amount of power that the device needs. The actual power consumption (consumed power) for a set of powered devices is usually not equal to the allocated power. In this example, the actual power might be approximately 200 W. If a power loss in the stack reduces the available power to 210 W, this amount is enough to sustain the power being consumed by the powered devices, but less than the worst-case allocated power, which would put the system under budget. In strict mode, the stack would immediately deny power to powered devices until the allocated power was 210 W or less. In nonstrict mode, no action is taken, and the state is allowed to persist. In nonstrict mode if the actual power consumption becomes more than 210 W, this triggers a load shed and can result in the loss of power to all powered devices or switches with the lowest priority level.

**Mixed Modes**

The XPS 2200 can also operate in mixed mode, where some ports connected to switches are RPS and others are SP. At least one power supply must be an RPS power supply in this configuration. The power supply in the XPS can back up only one switch power supply and the XPS supply must be greater than the largest power supply in a switch connected to an XPS port in RPS mode.

Switches connected to SP ports belong to a single power stack. If the SP switches have a large enough power budget, an SP power supply is not required on the XPS. When an XPS power supply is configured, its power is added to the power pool shared by the power stack.

**XPS 2200 System Defaults**

The default role for a port is Auto-SP, where the power mode is determined by the switch connected to the port (RPS for Catalyst running the LAN base image, or SP for Catalyst switches running the IP base or IP services image).

The default for the XPS power supply A (PS1) is RPS mode. The default for power supply B (PS2) is SP mode.

The default mode for all ports and power supplies is enabled.

On ports configured for RPS, the default priority is the same as the port number.
How to Configure the XPS 2200

You can configure the XPS from any switch connected to an XPS port. If you enter XPS configuration commands on more than one switch, the last configuration applied takes effect. Only the switch and port name are saved in the switch configuration file.

Configuring System Names

SUMMARY STEPS

1. enable
2. configure terminal
3. power xps switch-number name {name | serialnumber}
4. power xps switch-number port {name | hostname | serialnumber}
5. end
6. show env xps system
7. copy running-config startup-config

| Step 2 | `power xps switch-number port [number | connected] mode [disable | enable]` | **Note** The `switch-number` appears only on Catalyst switches and represents the switch number in the data stack, a value from 1 to 9. Sets the port to be enabled or disabled. |
|---------|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|         |                                                             | **Note** The `switch-number` appears only on Catalyst switches and represents the switch number in the data stack, a value from 1 to 9. Sets the port to be enabled or disabled. |
|         |                                                             | **Number**—Enter the XPS 2200 port number. The range is 1 to 9. |
|         |                                                             | **Connected**—Enter this keyword if you do not know the port number to which the switch is connected. |
Configuring XPS Power Supplies

### SUMMARY STEPS

1. enable
2. `power xps switch-number supply {A | B} mode {rps | sp}`
3. `power xps switch-number supply {A | B} {on | off}`
4. end
5. show env xps power

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `power xps switch-number port {number | connected} role {auto | rps}` | **Note** The `switch-number` represents the switch number in the data stack, a value from 1 to 9. Sets the role of the XPS port. 
- **role auto**—The port mode is determined by the switch connected to the port. This is the default. 
- **role RPS**—The XPS acts as a back up if the switch power supply fails. At least one RPS power supply must be in RPS mode for this configuration.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `power xps switch-number port {number | connected} priority port-priority` | **Note** The `switch-number` represents the switch number in the data stack, a value from 1 to 9. Sets the RPS priority of the port, where higher priority ports take precedence over low priority ports if multiple power supplies fail. This command takes effect only when the port mode is RPS. When the port mode is stack power, you set priority by using the stack power commands.

Configuring MLD Snooping

This module contains details of configuring MLD snooping

• Finding Feature Information, on page 141
• Information About Configuring IPv6 MLD Snooping, on page 141
• How to Configure IPv6 MLD Snooping, on page 145
• Displaying MLD Snooping Information, on page 153
• Configuration Examples for Configuring MLD Snooping, on page 153

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 MLD Snooping

---

**Note**

To use IPv6 MLD Snooping, the switch must be running the LAN Base image.

---

You can use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP Version 6 (IPv6) multicast data to clients and routers in a switched network on the switch. Unless otherwise noted, the term switch refers to a standalone switch and to a switch stack.

---

**Note**

Stacking is supported only on Catalyst 2960-X switches running the LAN base image.
To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch.

On switches running the LAN Base feature set, the routing template is not supported.

For complete syntax and usage information for the commands used in this chapter, see the command reference for this release or the Cisco IOS documentation referenced in the procedures.

### Understanding MLD Snooping

In IP Version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on the links that are directly attached to the routers and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD Version 1 (MLDv1) is equivalent to IGMPv2, and MLD Version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol Version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

The switch does not support MLDv2 enhanced snooping, which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

According to IPv6 multicast standards, the switch derives the MAC multicast address by performing a logical-OR of the four low-order octets of the switch MAC address with the MAC address of 33:33:00:00:00:00. For example, the IPv6 MAC address of FF02:DEAD:BEEF:1:3 maps to the Ethernet MAC address of 33:33:00:01:00:03.
A multicast packet is unmatched when the destination IPv6 address does not match the destination MAC address. The switch forwards the unmatched packet in hardware based on the MAC address table. If the destination MAC address is not in the MAC address table, the switch floods the packet to all ports in the same VLAN as the receiving port.

**MLD Messages**

MLDv1 supports three types of messages:

- Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
- Multicast Listener Reports are the equivalent of IGMPv2 reports
- Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.

MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages. Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

**MLD Queries**

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast group address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

---

**Note**

When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the Catalyst 2960, 2960-S, 2960-C, 2960-X or 2960-CX switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.
Multicast Client Aging Robustness

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

Multicast Router Discovery

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
- IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.
- Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether or not MLD snooping is enabled on the switch.
- After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address is entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port.
The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the `ipv6 mld snooping last-listener-query count` global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the `ipv6 mld snooping last-listener-query-interval` global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

When Immediate Leave is not enabled and a port receives an MLD Done message, the switch generates MASQs on the port and sends them to the IPv6 multicast address for which the Done message was sent. You can optionally configure the number of MASQs that are sent and the length of time the switch waits for a response before deleting the port from the multicast group.

When you enable MLDv1 Immediate Leave, the switch immediately removes a port from a multicast group when it detects an MLD Done message on that port. You should only use the Immediate-Leave feature when there is a single receiver present on every port in the VLAN. When there are multiple clients for a multicast group on the same port, you should not enable Immediate-Leave in a VLAN.

### Topology Change Notification Processing

When topology change notification (TCN) solicitation is enabled by using the `ipv6 mld snooping tcn query solicit` global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the `ipv6 mld snooping tcn flood query count` global configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This is same as done in IGMP snooping.

### How to Configure IPv6 MLD Snooping

#### Default MLD Snooping Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>MLD snooping (Global)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLD snooping (per VLAN)</td>
<td>Enabled. MLD snooping must be globally enabled for VLAN</td>
</tr>
<tr>
<td>IPv6 Multicast addresses</td>
<td>None configured.</td>
</tr>
<tr>
<td>IPv6 Multicast router ports</td>
<td>None configured.</td>
</tr>
<tr>

<td>Disabled.</td>
</tr>
<tr>
<td>Feature</td>
<td>Default Setting</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| MLD snooping robustness variable | Global: 2; Per VLAN: 0.  
**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
| Last listener query count     | Global: 2; Per VLAN: 0.  
**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
| Last listener query interval  | Global: 1000 (1 second); VLAN: 0.  
**Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global interval. |
| TCN query solicit             | Disabled.                                                                      |
| TCN query count               | 2.                                                                             |
| MLD listener suppression      | Disabled.                                                                      |

### MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the `ipv6 mld snooping` global configuration command for the configuration to take effect.

- When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch.

- The maximum number of multicast entries allowed on the switch or switch stack is determined by the configured SDM template.

- The maximum number of address entries allowed for the switch or switch stack is 4000.

### Enabling or Disabling MLD Snooping on the Switch (CLI)

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).
You can enable and disable MLD snooping on a per-VLAN basis or for a range of VLANs, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

Beginning in privileged EXEC mode, follow these steps to globally enable MLD snooping on the switch:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ipv6 mld snooping</td>
<td>Enables MLD snooping on the switch.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ipv6 mld snooping</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> reload</td>
<td>Reload the operating system.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# reload</td>
<td></td>
</tr>
</tbody>
</table>

**Enabling or Disabling MLD Snooping on a VLAN (CLI)**

Beginning in privileged EXEC mode, follow these steps to enable MLD snooping on a VLAN.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a Static Multicast Group (CLI)

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

Beginning in privileged EXEC mode, follow these steps to add a Layer 2 port as a member of a multicast group:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Configures a multicast group with a Layer 2 port as a member of a multicast group:</td>
</tr>
<tr>
<td>ipv6 mld snooping vlan vlan-id static ipv6_multicast_address interface interface-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 mld snooping vlan 1 static FF12::3 interface gigabitethernet 0/1</td>
<td></td>
</tr>
</tbody>
</table>

- `vlan-id` is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094.
- `ipv6_multicast_address` is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373.
### Configuring a Multicast Router Port (CLI)

**Note**
Static connections to multicast routers are supported only on switch ports.

Beginning in privileged EXEC mode, follow these steps to add a multicast router port to a VLAN:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>ipv6 mld snooping vlan vlan-id mrouter interface interface-id</td>
<td>Specifies the multicast router VLAN ID, and specify the interface to the multicast router.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# ipv6 mld snooping vlan 1 mrouter interface gigabitethernet 0/2</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Enabling MLD Immediate Leave (CLI)

Beginning in privileged EXEC mode, follow these steps to enable MLDv1 Immediate Leave:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td>Enables MLD Immediate Leave on the VLAN interface.</td>
</tr>
<tr>
<td>ipv6 mld snooping vlan  vlan-id  immediate-leave</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ipv6 mld snooping vlan 1  immediate-leave</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>Verifies that Immediate Leave is enabled on the VLAN interface.</td>
</tr>
<tr>
<td>show ipv6 mld snooping vlan  vlan-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ipv6 mld snooping vlan 1</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring MLD Snooping Queries (CLI)

Beginning in privileged EXEC mode, follow these steps to configure MLD snooping query characteristics for the switch or for a VLAN:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device(config)# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

`ipv6 mld snooping robustness-variable value`

*Example:*

```
Device(config)# ipv6 mld snooping robustness-variable 3
```

(Optional) Sets the number of queries that are sent before switch will delete a listener (port) that does not respond to a general query. The range is 1 to 3; the default is 2.

**Step 3**

`ipv6 mld snooping vlan vlan-id robustness-variable value`

*Example:*

```
Device(config)# ipv6 mld snooping vlan 1 robustness-variable 3
```

(Optional) Sets the robustness variable on a VLAN basis, which determines the number of general queries that MLD snooping sends before aging out a multicast address when there is no MLD report response. The range is 1 to 3; the default is 0. When set to 0, the number used is the global robustness variable value.

**Step 4**

`ipv6 mld snooping last-listener-query-count count`

*Example:*

```
Device(config)# ipv6 mld snooping last-listener-query-count 7
```

(Optional) Sets the number of MASQs that the switch sends before aging out an MLD client. The range is 1 to 7; the default is 2. The queries are sent 1 second apart.

**Step 5**

`ipv6 mld snooping vlan vlan-id last-listener-query-count count`

*Example:*

```
Device(config)# ipv6 mld snooping vlan 1 last-listener-query-count 7
```

(Optional) Sets the last-listener query count on a VLAN basis. This value overrides the value configured globally. The range is 1 to 7; the default is 0. When set to 0, the global count value is used. Queries are sent 1 second apart.

**Step 6**

`ipv6 mld snooping last-listener-query-interval interval`

*Example:*

```
Device(config)# ipv6 mld snooping last-listener-query-interval 2000
```

(Optional) Sets the maximum response time that the switch waits after sending out a MASQ before deleting a port from the multicast group. The range is 100 to 32,768 thousands of a second. The default is 1000 (1 second).

**Step 7**

`ipv6 mld snooping vlan vlan-id last-listener-query-interval interval`

*Example:*

```
Device(config)# ipv6 mld snooping vlan 1 last-listener-query-interval 2000
```

(Optional) Sets the last-listener query interval on a VLAN basis. This value overrides the value configured globally. The range is 0 to 32,768 thousands of a second. The default is 0. When set to 0, the global last-listener query interval is used.

**Step 8**

`ipv6 mld snooping tcn query solicit`

*Example:*

```
Device(config)# ipv6 mld snooping tcn query solicit
```

(Optional) Enables topology change notification (TCN) solicitation, which means that VLANs flood all IPv6 multicast traffic for the configured number of queries before sending multicast data to only those ports requesting to receive it. The default is for TCN to be disabled.
### Disabling MLD Listener Message Suppression (CLI)

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

Beginning in privileged EXEC mode, follow these steps to disable MLD listener message suppression:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td><code>no ipv6 mld snooping listener-message-suppression</code></td>
<td>Disable MLD message suppression.</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config)# no ipv6 mld snooping listener-message-suppression</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><code>end</code></td>
<td>Return to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td><code>show ipv6 mld snooping</code></td>
<td>Verify that IPv6 MLD snooping report suppression is disabled.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# show ipv6 mld snooping</td>
<td></td>
</tr>
</tbody>
</table>

### Disabling MLD Listener Message Suppression (CLI)

(Optional) When TCN is enabled, specifies the number of TCN queries to be sent. The range is from 1 to 10; the default is 2.

Example:

```
Device(config)# ipv6 mld snooping tcn flood query count 5
```

(Optional) Verifies that the MLD snooping querier information for the switch or for the VLAN.

Example:

```
Device(config)# show ipv6 mld snooping querier vlan 1
```
Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display IPv6 group address multicast entries for a VLAN configured for MLD snooping.

Table 19: Commands for Displaying MLD Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ipv6 mld snooping [ vlan vlan-id ]</code></td>
<td>Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN. (Optional) Enter <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td><code>show ipv6 mld snooping mrouter [ vlan vlan-id ]</code></td>
<td>Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces. (Optional) Enters <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td><code>show ipv6 mld snooping querier [ vlan vlan-id ]</code></td>
<td>Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN. (Optional) Enters <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
</tbody>
</table>
| `show ipv6 mld snooping address [ vlan vlan-id ] [ count | dynamic | user ]` | Displays all IPv6 multicast address information or specific IPv6 multicast address information for the switch or a VLAN.  
  • Enters `count` to show the group count on the switch or in a VLAN.  
  • Enters `dynamic` to display MLD snooping learned group information for the switch or for a VLAN.  
  • Enters `user` to display MLD snooping user-configured group information for the switch or for a VLAN. |
| `show ipv6 mld snooping address vlan vlan-id [ ipv6-multicast-address ]` | Displays MLD snooping for the specified VLAN and IPv6 multicast address. |

Configuration Examples for Configuring MLD Snooping

Configuring a Static Multicast Group: Example

This example shows how to statically configure an IPv6 multicast group:
**Configuring a Multicast Router Port: Example**

This example shows how to add a multicast router port to VLAN 200:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet 0/2
Device(config)# exit
```

**Enabling MLD Immediate Leave: Example**

This example shows how to enable MLD Immediate Leave on VLAN 130:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 130 immediate-leave
Device(config)# exit
```

**Configuring MLD Snooping Queries: Example**

This example shows how to set the MLD snooping global robustness variable to 3:

```
Device# configure terminal
Device(config)# ipv6 mld snooping robustness-variable 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```
Device# configure terminal
Device(config)# ipv6 mld snooping last-listener-query-interval 2000
Device(config)# exit
```
Configuring IPv6 Unicast Routing

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IPv6 Unicast Routing

This chapter describes how to configure IPv6 unicast routing on the switch.

Note

To use all IPv6 features in this chapter, the switch or stack master must be running the IP services feature set. Switches running the IP base feature set support IPv6 static routing, RIP for IPv6, and OSPF. Switches running the LAN base feature set support only IPv6 host functionality.

Understanding IPv6

IPv4 users can move to IPv6 and receive services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to:

For information about IPv6 and other features in this chapter

- See the Cisco IOS IPv6 Configuration Library.
- Use the Search field on Cisco.com to locate the Cisco IOS software documentation. For example, if you want information about static routes, you can enter Implementing Static Routes for IPv6 in the search field to learn about static routes.

**IPv6 Addresses**

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses, or anycast addresses.

The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: n:n:n:n:n:n:n. This is an example of an IPv6 address:

2031:0000:130F:0000:0000:09C0:080F:130B

For easier implementation, leading zeros in each field are optional. This is the same address without leading zeros:

2031:0:130F:0:0:9C0:80F:130B

You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:

2031:0:130F::09C0:080F:130B

For more information about IPv6 address formats, address types, and the IPv6 packet header, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of Cisco IOS IPv6 Configuration Library on Cisco.com.

In the “Information About Implementing Basic Connectivity for IPv6” chapter, these sections apply to the switch:

- IPv6 Address Formats
- IPv6 Address Type: Unicast
- IPv6 Address Type: Multicast
- IPv6 Address Output Display
- Simplified IPv6 Packet Header

**Supported IPv6 Unicast Routing Features**

These sections describe the IPv6 protocol features supported by the switch:

The switch provides IPv6 routing capability over Routing Information Protocol (RIP) for IPv6, and Open Shortest Path First (OSPF) Version 3 Protocol. It supports up to 16 equal-cost routes and can simultaneously forward IPv4 and IPv6 frames at line rate.

**128-Bit Wide Unicast Addresses**

The switch supports aggregatable global unicast addresses and link-local unicast addresses. It does not support site-local unicast addresses.
• **Aggregatable global unicast addresses** are IPv6 addresses from the aggregatable global unicast prefix. The address structure enables strict aggregation of routing prefixes and limits the number of routing table entries in the global routing table. These addresses are used on links that are aggregated through organizations and eventually to the Internet service provider.

  These addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). Addresses with a prefix of 2000::/3(001) through E000::/3(111) must have 64-bit interface identifiers in the extended unique identifier (EUI)-64 format.

• **Link local unicast addresses** can be automatically configured on any interface by using the link-local prefix FE80::/10(1111111010) and the interface identifier in the modified EUI format. Link-local addresses are used in the neighbor discovery protocol (NDP) and the stateless autoconfiguration process. Nodes on a local link use link-local addresses and do not require globally unique addresses to communicate. IPv6 routers do not forward packets with link-local source or destination addresses to other links.

For more information, see the section about IPv6 unicast addresses in the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

**DNS for IPv6**

IPv6 supports Domain Name System (DNS) record types in the DNS name-to-address and address-to-name lookup processes. The DNS AAAA resource record types support IPv6 addresses and are equivalent to an A address record in IPv4. The switch supports DNS resolution for IPv4 and IPv6.

**Path MTU Discovery for IPv6 Unicast**

The switch supports advertising the system maximum transmission unit (MTU) to IPv6 nodes and path MTU discovery. Path MTU discovery allows a host to dynamically discover and adjust to differences in the MTU size of every link along a given data path. In IPv6, if a link along the path is not large enough to accommodate the packet size, the source of the packet handles the fragmentation.

**ICMPv6**

The Internet Control Message Protocol (ICMP) in IPv6 generates error messages, such as ICMP destination unreachable messages, to report errors during processing and other diagnostic functions. In IPv6, ICMP packets are also used in the neighbor discovery protocol and path MTU discovery.

**Neighbor Discovery**

The switch supports NDP for IPv6, a protocol running on top of ICMPv6, and static neighbor entries for IPv6 stations that do not support NDP. The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), to verify the reachability of the neighbor, and to keep track of neighboring routers.

The switch supports ICMPv6 redirect for routes with mask lengths less than 64 bits. ICMP redirect is not supported for host routes or for summarized routes with mask lengths greater than 64 bits.

Neighbor discovery throttling ensures that the switch CPU is not unnecessarily burdened while it is in the process of obtaining the next hop forwarding information to route an IPv6 packet. The switch drops any additional IPv6 packets whose next hop is the same neighbor that the switch is actively trying to resolve. This drop avoids further load on the CPU.
Default Router Preference

The switch supports IPv6 default router preference (DRP), an extension in router advertisement messages. DRP improves the ability of a host to select an appropriate router, especially when the host is multihomed and the routers are on different links. The switch does not support the Route Information Option in RFC 4191.

An IPv6 host maintains a default router list from which it selects a router for traffic to offlink destinations. The selected router for a destination is then cached in the destination cache. NDP for IPv6 specifies that routers that are reachable or probably reachable are preferred over routers whose reachability is unknown or suspect. For reachable or probably reachable routers, NDP can either select the same router every time or cycle through the router list. By using DRP, you can configure an IPv6 host to prefer one router over another, provided both are reachable or probably reachable.

For more information about DRP for IPv6, see the Cisco IOS IPv6 Configuration Library on Cisco.com.

IPv6 Stateless Autoconfiguration and Duplicate Address Detection

The switch uses stateless autoconfiguration to manage link, subnet, and site addressing changes, such as management of host and mobile IP addresses. A host autonomously configures its own link-local address, and booting nodes send router solicitations to request router advertisements for configuring interfaces.

For more information about autoconfiguration and duplicate address detection, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of Cisco IOS IPv6 Configuration Library on Cisco.com.

IPv6 Applications

The switch has IPv6 support for these applications:

- Ping, traceroute, Telnet, and TFTP
- Secure Shell (SSH) over an IPv6 transport
- HTTP server access over IPv6 transport
- DNS resolver for AAAA over IPv4 transport
- Cisco Discovery Protocol (CDP) support for IPv6 addresses

For more information about managing these applications, see the Cisco IOS IPv6 Configuration Library on Cisco.com.

DHCP for IPv6 Address Assignment

DHCPv6 enables DHCP servers to pass configuration parameters, such as IPv6 network addresses, to IPv6 clients. The address assignment feature manages non-duplicate address assignment in the correct prefix based on the network where the host is connected. Assigned addresses can be from one or multiple prefix pools. Additional options, such as default domain and DNS name-server address, can be passed back to the client. Address pools can be assigned for use on a specific interface, on multiple interfaces, or the server can automatically find the appropriate pool.

For more information and to configure these features, see the Cisco IOS IPv6 Configuration Guide.

This document describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.
**Static Routes for IPv6**

Static routes are manually configured and define an explicit route between two networking devices. Static routes are useful for smaller networks with only one path to an outside network or to provide security for certain types of traffic in a larger network.

For more information about static routes, see the “Implementing Static Routes for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**RIP for IPv6**

Routing Information Protocol (RIP) for IPv6 is a distance-vector protocol that uses hop count as a routing metric. It includes support for IPv6 addresses and prefixes and the all-RIP-routers multicast group address FF02::9 as the destination address for RIP update messages.

For more information about RIP for IPv6, see the “Implementing RIP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**OSPF for IPv6**

The switch running the IP Base feature set supports Open Shortest Path First (OSPF) for IPv6, a link-state protocol for IP. For more information, see Cisco IOS IPv6 Configuration Library on Cisco.com.

**Configuring HSRP for IPv6**

HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.

An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address. Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

---

**Note**

When configuring HSRP for IPv6, you must enable HSRP version 2 (HSRPv2) on the interface.

---

**EIGRP IPv6**

Switches support the Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address. Switches running IP Lite only support EIGRPv6 stub routing.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv6 address, so any IPv6 node always has an available router ID. However, EIGRP IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv6 router ID.

For more information about EIGRP for IPv6, see the “Implementing EIGRP for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

**EIGRPv6 Stub Routing**

The EIGRPv6 stub routing feature, reduces resource utilization by moving routed traffic closer to the end user.
In a network using EIGRPv6 stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with EIGRPv6 stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRPv6 stub routing, you need to configure the distribution and remote routers to use EIGRPv6 and to configure only the switch as a stub. Only specified routes are propagated from the switch. The switch responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In the figure given below, switch B is configured as an EIGRPv6 stub router. Switches A and C are connected to the rest of the WAN. Switch B advertise connected, static, redistribution, and summary routes to switch A and C. Switch B does not advertise any routes learned from switch A (and the reverse).

**Figure 6: EIGRP Stub Router Configuration**

For more information about EIGRPv6 stub routing, see “Implementing EIGRP for IPv6” section of the *Cisco IOS IP Configuration Guide, Volume 2 of 3: Routing Protocols, Release 12.4*.

### SNMP and Syslog Over IPv6

To support both IPv4 and IPv6, IPv6 network management requires both IPv6 and IPv4 transports. Syslog over IPv6 supports address data types for these transports.

SNMP and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and to modify the SNMP agent to support traps for an IPv6 host
- SNMP- and syslog-related MIBs to support IPv6 addressing
- Configuration of IPv6 hosts as trap receivers

For support over IPv6, SNMP modifies the existing IP transport mapping to simultaneously support IPv4 and IPv6. These SNMP actions support IPv6 transport management:

- Opens User Datagram Protocol (UDP) SNMP socket with default settings
- Provides a new transport mechanism called `SR_IPV6_TRANSPORT`
• Sends SNMP notifications over IPv6 transport
• Supports SNMP-named access lists for IPv6 transport
• Supports SNMP proxy forwarding using IPv6 transport
• Verifies SNMP Manager feature works with IPv6 transport

For information on SNMP over IPv6, including configuration procedures, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

For information about syslog over IPv6, including configuration procedures, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

HTTP(S) Over IPv6

The HTTP client sends requests to both IPv4 and IPv6 HTTP servers, which respond to requests from both IPv4 and IPv6 HTTP clients. URLs with literal IPv6 addresses must be specified in hexadecimal using 16-bit values between colons.

The accept socket call chooses an IPv4 or IPv6 address family. The accept socket is either an IPv4 or IPv6 socket. The listening socket continues to listen for both IPv4 and IPv6 signals that indicate a connection. The IPv6 listening socket is bound to an IPv6 wildcard address.

The underlying TCP/IP stack supports a dual-stack environment. HTTP relies on the TCP/IP stack and the sockets for processing network-layer interactions.

Basic network connectivity (ping) must exist between the client and the server hosts before HTTP connections can be made.

For more information, see the “Managing Cisco IOS Applications over IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

Unsupported IPv6 Unicast Routing Features

The switch does not support these IPv6 features:
• IPv6 virtual private network (VPN) routing and forwarding (VRF) table support
• IPv6 packets destined to site-local addresses
• Tunneling protocols, such as IPv4-to-IPv6 or IPv6-to-IPv4
• The switch as a tunnel endpoint supporting IPv4-to-IPv6 or IPv6-to-IPv4 tunneling protocols
• IPv6 unicast reverse-path forwarding
• IPv6 Web Cache Communication Protocol (WCCP)

IPv6 Feature Limitations

Because IPv6 is implemented in switch hardware, some limitations occur due to the IPv6 compressed addresses in the hardware memory. These hardware limitations result in some loss of functionality and limits some features.

These are feature limitations.
• The switch cannot forward SNAP-encapsulated IPv6 packets in hardware. They are forwarded in software.
• The switch cannot apply QoS classification on source-routed IPv6 packets in hardware.

IPv6 and Switch Stacks

The switch supports IPv6 forwarding across the stack and IPv6 host functionality on the stack master. The stack master runs the IPv6 unicast routing protocols and computes the routing tables. They receive the tables and create hardware IPv6 routes for forwarding. The stack master also runs all IPv6 applications.

Note
To route IPv6 packets in a stack, all switches in the stack should be running the IP Base feature set.

If a new switch becomes the stack master, it recomputes the IPv6 routing tables and distributes them to the member switches. While the new stack master is being elected and is resetting, the switch stack does not forward IPv6 packets. The stack MAC address changes, which also changes the IPv6 address. When you specify the stack IPv6 address with an extended unique identifier (EUI) by using the `ipv6 address ipv6-prefix/prefix length eui-64` interface configuration command, the address is based on the interface MAC address. See the Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI), on page 163.

If you configure the persistent MAC address feature on the stack and the stack master changes, the stack MAC address does not change for approximately 4 minutes.

These are the functions of IPv6 stack master and members:

• Stack master:
  • runs IPv6 routing protocols
  • generates routing tables
  • distributes routing tables to stack members that use dCEFv6
  • runs IPv6 host functionality and IPv6 applications

• Stack member (must be running the IP services feature set):
  • receives CEFv6 routing tables from the stack master
  • programs the routes into hardware

Note
IPv6 packets are routed in hardware across the stack if the packet does not have exceptions (IPv6 Options) and the switches in the stack have not run out of hardware resources.

• flushes the CEFv6 tables on master re-election
Default IPv6 Configuration

Configuring IPv6 Addressing and Enabling IPv6 Routing (CLI)

This section describes how to assign IPv6 addresses to individual Layer 3 interfaces and to globally forward IPv6 traffic on the switch.

Before configuring IPv6 on the switch, consider these guidelines:

- Not all features discussed in this chapter are supported by the switch. See the Unsupported IPv6 Unicast Routing Features, on page 161.

- In the `ipv6 address` interface configuration command, you must enter the `ipv6-address` and `ipv6-prefix` variables with the address specified in hexadecimal using 16-bit values between colons. The `prefix-length` variable (preceded by a slash `/`) is a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address).

To forward IPv6 traffic on an interface, you must configure a global IPv6 address on that interface. Configuring an IPv6 address on an interface automatically configures a link-local address and activates IPv6 for the interface. The configured interface automatically joins these required multicast groups for that link:

- solicited-node multicast group FF02::1:ff00::/104 for each unicast address assigned to the interface (this address is used in the neighbor discovery process.)

- all-nodes link-local multicast group FF02::1

- all-routers link-local multicast group FF02::2

To remove an IPv6 address from an interface, use the `no ipv6 address ipv6-prefix/prefix length eui-64` or `no ipv6 address ipv6-address link-local` interface configuration command. To remove all manually configured IPv6 addresses from an interface, use the `no ipv6 address` interface configuration command without arguments.

To disable IPv6 processing on an interface that has not been explicitly configured with an IPv6 address, use the `no ipv6 enable` interface configuration command. To globally disable IPv6 routing, use the `no ipv6 unicast-routing` global configuration command.

For more information about configuring IPv6 routing, see the “Implementing Addressing and Basic Connectivity for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.
Beginning in privileged EXEC mode, follow these steps to assign an IPv6 address to a Layer 3 interface and enable IPv6 routing:

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code>&lt;br&gt;<strong>Example:</strong> Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
| 2    | `sdm prefer dual-ipv4-and-ipv6 { advanced | vlan}`<br>**Example:** Device(config)# sdm prefer dual-ipv4-and-ipv6 default | Selects an SDM template that supports IPv4 and IPv6.  
- **advanced**—Sets the switch to the default template to balance system resources.  
- **vlan**—Maximizes VLAN configuration on the switch with no routing supported in hardware.  
**Note** Advanced is available at all license levels. VLAN template is available only in LAN Base license. |
<p>| 3    | <code>end</code>&lt;br&gt;<strong>Example:</strong> Device(config)# end | Returns to privileged EXEC mode. |
| 4    | <code>reload</code>&lt;br&gt;<strong>Example:</strong> Device# reload | Reloads the operating system. |
| 5    | <code>configure terminal</code>&lt;br&gt;<strong>Example:</strong> Device# configure terminal | Enters global configuration mode after the switch reloads. |
| 6    | <code>interface interface-id</code>&lt;br&gt;<strong>Example:</strong> Device(config)# interface gigabitethernet 1/0/1 | Enters interface configuration mode, and specifies the Layer 3 interface to configure. The interface can be a physical interface, a switch virtual interface (SVI), or a Layer 3 EtherChannel. |
| 7    | <code>no switchport</code>&lt;br&gt;<strong>Example:</strong> | Removes the interface from Layer 2 configuration mode (if it is a physical interface). |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-if)# no switchport</td>
<td>Specifies a global IPv6 address with an extended unique identifier (EUI) in the low-order 64 bits of the IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address. This enables IPv6 processing on the interface.</td>
</tr>
</tbody>
</table>

**Step 8**

Use one of the following:

- `ipv6 address ipv6-prefix/prefix length eui-64`
- `ipv6 address ipv6-address/prefix length`
- `ipv6 address ipv6-address link-local`
- `ipv6 enable`
- `ipv6 address WORD`
- `ipv6 address autoconfig`
- `ipv6 address dhcp`

**Example:**

```
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
```

```
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64
```

```
Device(config-if)# ipv6 address 2001:0DB8:c18:1::
```

```
Device(config-if)# ipv6 address 2001:0DB8:c18:1:: link-local
```

```
Device(config-if)# ipv6 enable
```

**Step 9**

`exit`

**Example:**

```
Device(config-if)# exit
```

**Step 10**

`ip routing`

**Example:**

```
Device(config)# ip routing
```

**Step 11**

`ipv6 unicast-routing`

**Example:**

```
Device(config)# ipv6 unicast-routing
```

**Step 12**

`end`

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.
### Configuring IPv4 and IPv6 Protocol Stacks (CLI)

Beginning in privileged EXEC mode, follow these steps to configure a Layer 3 interface to support both IPv4 and IPv6 and to enable IPv6 routing.

#### Note
To disable IPv6 processing on an interface that has not been configured with an IPv6 address, use the `no ipv6 enable` interface configuration command.

#### SUMMARY STEPS

1. configure terminal
2. ip routing
3. ipv6 unicast-routing
4. interface `interface-id`
5. no switchport
6. ip address `ip-address mask` [secondary]
7. Use one of the following:
   - `ipv6 address ipv6-prefix/prefix length eui-64`
   - `ipv6 address ipv6-address/prefix length`
   - `ipv6 address ipv6-address link-local`
   - `ipv6 enable`
   - `ipv6 addressWORD`
   - `ipv6 addressautoconfig`
   - `ipv6 addressdhcp`
8. end
9. Use one of the following:
   - `show interface interface-id`
   - `show ip interface interface-id`
   - `show ipv6 interface interface-id`
### IPv6

**Purpose**: Configuring IPv4 and IPv6 Protocol Stacks (CLI)

<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> Use one of the following: • ipv6 address ipv6-prefix/prefix length eui-64 • ipv6 address ipv6-address/prefix length • ipv6 address ipv6-address link-local • ipv6 enable • ipv6 address WORD • ipv6 address autoconfig</td>
<td>• Specifies a global IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address. • Specifies a link-local address on the interface to be used instead of the automatically configured link-local address when IPv6 is enabled on the interface.</td>
</tr>
</tbody>
</table>
### Configuring Default Router Preference (CLI)

Router advertisement messages are sent with the default router preference (DRP) configured by the `ipv6 nd router-preference` interface configuration command. If no DRP is configured, RAs are sent with a medium preference.

A DRP is useful when two routers on a link might provide equivalent, but not equal-cost routing, and policy might dictate that hosts should prefer one of the routers.

For more information about configuring DRP for IPv6, see the “Implementing IPv6 Addresses and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to configure a DRP for a router on an interface.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
</tbody>
</table>

---

**Purpose Command or Action**

- **• ipv6 address dhcp**  
  - Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link.

**Note**  
To remove all manually configured IPv6 addresses from an interface, use the `no ipv6 address` interface configuration command without arguments.

**Step 8**  
*Example:*  

```
Switch(config)# end
```

Returns to privileged EXEC mode.

**Step 9**  
*Use one of the following:*  

- **• show interface interface-id**  
- **• show ip interface interface-id**  
- **• show ipv6 interface interface-id**

Verifies your entries.

**Step 10**  
*Example:*  

```
Switch# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
### Purpose

**Command or Action**

- **Step 2:** `interface interface-id`
  - **Example:**
    ```
    Device(config)# interface gigabitethernet 1/0/1
    ```
  - Enters interface configuration mode and identifies the Layer 3 interface on which you want to specify the DRP.

- **Step 3:** `ipv6 nd router-preference {high | medium | low}`
  - **Example:**
    ```
    Device(config-if)# ipv6 nd router-preference medium
    ```
  - Specifies a DRP for the router on the switch interface.

- **Step 4:** `end`
  - **Example:**
    ```
    Device(config)# end
    ```
  - Returns to privileged EXEC mode.

- **Step 5:** `show ipv6 interface`
  - **Example:**
    ```
    Device# show ipv6 interface
    ```
  - Verifies the configuration.

- **Step 6:** `copy running-config startup-config`
  - **Example:**
    ```
    Device# copy running-config startup-config
    ```
  - (Optional) Saves your entries in the configuration file.

---

### Configuring IPv6 ICMP Rate Limiting (CLI)

ICMP rate limiting is enabled by default with a default interval between error messages of 100 milliseconds and a bucket size (maximum number of tokens to be stored in a bucket) of 10.

Beginning in privileged EXEC mode, follow these steps to change the ICMP rate-limiting parameters:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring CEF and dCEF for IPv6

Cisco Express Forwarding (CEF) is a Layer 3 IP switching technology to improve network performance. CEF implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. It is less CPU-intensive than fast-switching route-caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed CEF (dCEF) in the stack. IPv4 CEF and dCEF are enabled by default. IPv6 CEF and dCEF are disabled by default, but automatically enabled when you configure IPv6 routing.

IPv6 CEF and dCEF are automatically disabled when IPv6 routing is unconfigured. IPv6 CEF and dCEF cannot be disabled through configuration. You can verify the IPv6 state by entering the `show ipv6 cef` privileged EXEC command.

To route IPv6 unicast packets, you must first globally configure forwarding of IPv6 unicast packets by using the `ipv6 unicast-routing` global configuration command, and you must configure an IPv6 address and IPv6 processing on an interface by using the `ipv6 address` interface configuration command.

For more information about configuring CEF and dCEF, see *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Configuring Static Routing for IPv6 (CLI)

Before configuring a static IPv6 route, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on at least one Layer 3 interface by configuring an IPv6 address on the interface.

For more information about configuring static IPv6 routing, see the “Implementing Static Routes for IPv6” chapter in the Cisco IOS IPv6 Configuration Library on Cisco.com.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>`ipv6 route ipv6-prefix/prefix length {ipv6-address</td>
<td>interface-id [ipv6-address]} [administrative distance]`</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> <code>Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130</code></td>
<td></td>
</tr>
</tbody>
</table>

- **ipv6-prefix/prefix length** — The IPv6 network that is the destination of the static route. It can also be a hostname when static host routes are configured.
- **ipv6-address** — The IPv6 address of the next hop that can be used to reach the specified network. The IPv6 address of the next hop need not be directly connected; recursion is done to find the IPv6 address of the directly connected next hop. The address must be in the form documented in RFC 2373, specified in hexadecimal using 16-bit values between colons.
- **interface-id** — Specifies direct static routes from point-to-point and broadcast interfaces. With point-to-point interfaces, there is no need to specify the IPv6 address of the next hop. With broadcast interfaces, you should always specify the IPv6 address of the next hop, or ensure that the specified prefix is assigned to the link, specifying a link-local address as the next hop. You can optionally specify the IPv6 address of the next hop to which packets are sent.

Note: You must specify an `interface-id` when using a link-local address as the next hop (the link-local next hop must also be an adjacent router).
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• administrative distance—(Optional) An administrative distance. The range is 1 to 254; the default value is 1, which gives static routes precedence over any other type of route except connected routes. To configure a floating static route, use an administrative distance greater than that of the dynamic routing protocol.</td>
<td></td>
</tr>
</tbody>
</table>

Step 3  
**end**  
**Example:**  
Device(config)# end  

Returns to privileged EXEC mode.

Step 4  
**Use one of the following:**  
- **show ipv6 static**  
  - ipv6-address | ipv6-prefix/prefix length  
  - [interface interface-id] [detail]  
  - [recursive]  
- **show ipv6 route static** [updated]  
**Example:**  
Device# show ipv6 static 2001::0DB8::/32 interface gigabitethernet2/0/1  
or  
Device# show ipv6 route static  

Verifies your entries by displaying the contents of the IPv6 routing table.

- **interface interface-id**—(Optional) Displays only those static routes with the specified interface as an egress interface.
- **recursive**—(Optional) Displays only recursive static routes. The recursive keyword is mutually exclusive with the interface keyword, but it can be used with or without the IPv6 prefix included in the command syntax.
- **detail**—(Optional) Displays this additional information:
  - For valid recursive routes, the output path set, and maximum resolution depth.
  - For invalid routes, the reason why the route is not valid.

Step 5  
**copy running-config startup-config**  
**Example:**  
Device# copy running-config startup-config  

(Optional) Saves your entries in the configuration file.

---

### Configuring RIP for IPv6 (CLI)

Before configuring the switch to run IPv6 RIP, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on any Layer 3 interfaces on which IPv6 RIP is to be enabled.

For more information about configuring RIP routing for IPv6, see the “Implementing RIP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.
## Procedure

| Step 1 | configure terminal  
| Example:  
| Device# configure terminal | Enters global configuration mode. |
| Step 2 | ipv6 router rip name  
| Example:  
| Device(config)# ipv6 router rip cisco | Configures an IPv6 RIP routing process, and enters router configuration mode for the process. |
| Step 3 | maximum-paths number-paths  
| Example:  
| Device(config-router)# maximum-paths 6 | (Optional) Define the maximum number of equal-cost routes that IPv6 RIP can support. The range is from 1 to 32, and the default is 16 routes. |
| Step 4 | exit  
|Example:  
|Device(config-router)# exit | Returns to global configuration mode. |
| Step 5 | interface interface-id  
|Example:  
|Device(config)# interface gigabitethernet 1/0/1 | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| Step 6 | ipv6 rip name enable  
|Example:  
|Device(config-if)# ipv6 rip cisco enable | Enables the specified IPv6 RIP routing process on the interface. |
| Step 7 | ipv6 rip name default-information {only | originate}  
|Example:  
|Device(config-if)# ipv6 rip cisco default-information only | (Optional) Originates the IPv6 default route (::/0) into the RIP routing process updates sent from the specified interface. |

**Note**  
To avoid routing loops after the IPv6 default route (::/0) is originated from any interface, the routing process ignores all default routes received on any interface.  
- **only**—Select to originate the default route, but suppress all other routes in the updates sent on this interface.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Step 8**

Example:

Device(config)# end

**Step 9**

Use one of the following:

- show ipv6 rip [name] [ interfaceinterface-id] [ database ] [ next-hops ]
- show ipv6 rip

Example:

Device# show ipv6 rip cisco interface gigabitethernet2/0/1

or

Device# show ipv6 rip

**Step 10**

copy running-config startup-config

(Optional) Saves your entries in the configuration file.

Example:

Device# copy running-config startup-config

---

**Configuring OSPF for IPv6 (CLI)**

You can customize OSPF for IPv6 for your network. However, the defaults for OSPF in IPv6 are set to meet the requirements of most customers and features.

Follow these guidelines:

- Be careful when changing the defaults for IPv6 commands. Changing the defaults might adversely affect OSPF for the IPv6 network.

- Before you enable IPv6 OSPF on an interface, you must enable routing by using the `ip routing` global configuration command, enable the forwarding of IPv6 packets by using the `ipv6 unicast-routing` global configuration command, and enable IPv6 on Layer 3 interfaces on which you are enabling IPv6 OSPF.

For more information about configuring OSPF routing for IPv6, see the “Implementing OSPF for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.
### Procedure

<table>

</table>

### Configuring EIGRP for IPv6

Before configuring the switch to run IPv6 EIGRP, enable routing by entering the `ip routing global configuration` command, enable the forwarding of IPv6 packets by entering the `ipv6 unicast-routing global configuration` command, and enable IPv6 on any Layer 3 interfaces on which you want to enable IPv6 EIGRP.

To set an explicit router ID, use the `show ipv6 eigrp` command to see the configured router IDs, and then use the `router-id` command.
As with EIGRP IPv4, you can use EIGRPv6 to specify your EIGRP IPv6 interfaces and to select a subset of those as passive interfaces. Use the `passive-interface` command to make an interface passive, and then use the `no passive-interface` command on selected interfaces to make them active. EIGRP IPv6 does not need to be configured on a passive interface.

For more configuration procedures, see the “Implementing EIGRP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### Configuring IPv6 Unicast Reverse Path Forwarding

The unicast Reverse Path Forwarding (unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

- Unicast RPF is supported only in IP services.
- Do not configure Unicast RPF if the switch is in a mixed hardware stack combining more than one switch type.

For detailed IP unicast RPF configuration information, see the *Other Security Features* chapter in the *Cisco IOS Security Configuration Guide, Release 12.4*.

### Displaying IPv6

For complete syntax and usage information on these commands, see the Cisco IOS command reference publications.

### Configuring DHCP for IPv6 Address Assignment

This section describes only the DHCPv6 address assignment. For more information about configuring the DHCPv6 client, server, or relay agent functions, see the “Implementing DHCP for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

### Default DHCPv6 Address Assignment Configuration

By default, no DHCPv6 features are configured on the switch.

### DHCPv6 Address Assignment Configuration Guidelines

When configuring DHCPv6 address assignment, consider these guidelines:

- In the procedures, the specified interface must be one of these Layer 3 interfaces:
  - DHCPv6 IPv6 routing must be enabled on a Layer 3 interface.
  - SVI: a VLAN interface created by using the `interface vlan vlan_id` command.
  - EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the `interface port-channel port-channel-number` command.

- The switch can act as a DHCPv6 client, server, or relay agent. The DHCPv6 client, server, and relay function are mutually exclusive on an interface.
The DHCPv6 client, server, or relay agent runs only on the master switch. When there is a stack master re-election, the new master switch retains the DHCPv6 configuration. However, the local RAM copy of the DHCP server database lease information is not retained.

### Enabling DHCPv6 Server Function (CLI)

Use the `no` form of the DHCP pool configuration mode commands to change the DHCPv6 pool characteristics. To disable the DHCPv6 server function on an interface, use the `no ipv6 dhcp server` interface configuration command.

Beginning in privileged EXEC mode, follow these steps to enable the DHCPv6 server function on an interface.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>ipv6 dhcp pool poolname</code></td>
<td>Enters DHCP pool configuration mode, and define the name for the IPv6 DHCP pool. The pool name can be a symbolic string (such as Engineering) or an integer (such as 0).</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# ipv6 dhcp pool 7</code></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>`address prefix IPv6-prefix {lifetime} {t1 t1</td>
<td>infinite}`</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-dhcpv6)# address prefix 2001:1000::0/64 lifetime 3600</code></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>link-address IPv6-prefix</code></td>
<td>(Optional) Specifies a link-address IPv6 prefix. When an address on the incoming interface or a link-address in the packet matches the specified IPv6 prefix, the server uses the configuration information pool. This address must be in hexadecimal, using 16-bit values between colons.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-dhcpv6)# link-address 2001:1002::0/64</code></td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td><code>vendor-specific vendor-id</code></td>

## Configuration Examples for IPv6 Unicast Routing

### Configuring IPv6 Addressing and Enabling IPv6 Routing: Example

This example shows how to enable IPv6 with both a link-local address and a global address based on the IPv6 prefix 2001:0DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the `show ipv6 interface` EXEC command is included to show how the interface ID (20B:46FF:FE2F:D940) is appended to the link-local prefix FE80::/64 of the interface.

```
Device(config)# ipv6 unicast-routing
Device(config)# interface gigabitethernet1/0/11
Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
Device# show ipv6 interface gigabitethernet1/0/11
```

GigabitEthernet1/0/11 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
Global unicast address(es):
2001:0DB8:c18:1:20B:46FF:FE2F:D940, subnet is 2001:0DB8:c18:1::/64 [EUI]
Joined group address(es):
FF02::1
FF02::2
FF02::1:FF2F:D940
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
Hosts use stateless autoconfig for addresses.
Configuring Default Router Preference: Example

This example shows how to configure a DRP of `high` for the router on an interface.

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ipv6 nd router-preference high
Device(config-if)# end
```

Configuring IPv4 and IPv6 Protocol Stacks: Example

This example shows how to enable IPv4 and IPv6 routing on an interface.

```
Device(config)# ip routing
Device(config)# ipv6 unicast-routing
Device(config)# interface fastethernet1/0/11
Device(config-if)# no switchport
Device(config-if)# ip address 192.168.99.1 255.255.255.0
Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
```

Enabling DHCPv6 Server Function: Example

This example shows how to configure a pool called `engineering` with an IPv6 address prefix:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool engineering
Device(config-dhcpv6)# address prefix 2001:1000::0/64
Device(config-dhcpv6)# end
```

This example shows how to configure a pool called `testgroup` with three link-addresses and an IPv6 address prefix:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool testgroup
Device(config-dhcpv6)# link-address 2001:1001::0/64
Device(config-dhcpv6)# link-address 2001:1002::0/64
Device(config-dhcpv6)# link-address 2001:2000::0/48
Device(config-dhcpv6)# address prefix 2001:1003::0/64
Device(config-dhcpv6)# end
```

This example shows how to configure a pool called `350` with vendor-specific options:

```
Device# configure terminal
Device(config)# ipv6 dhcp pool 350
Device(config-dhcpv6)# address prefix 2001:1005::0/48
Device(config-dhcpv6)# vendor-specific 9
Device(config-dhcpv6-vs)# suboption 1 address 1000:235D::1
Device(config-dhcpv6-vs)# suboption 2 ascii "IP-Phone"
Device(config-dhcpv6-vs)# end
```
Enabling DHCPv6 Client Function: Example

This example shows how to acquire an IPv6 address and to enable the rapid-commit option:

```
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ipv6 address dhcp rapid-commit
```

Configuring IPv6 ICMP Rate Limiting: Example

This example shows how to configure an IPv6 ICMP error message interval of 50 milliseconds and a bucket size of 20 tokens.

```
Device(config)# ipv6 icmp error-interval 50 20
```

Configuring Static Routing for IPv6: Example

This example shows how to configure a floating static route to an interface with an administrative distance of 130:

```
Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130
```

Configuring RIP for IPv6: Example

This example shows how to enable the RIP routing process `cisco` with a maximum of eight equal-cost routes and to enable it on an interface:

```
Device(config)# ipv6 router rip cisco
Device(config-router)# maximum-paths 8
Device(config)# exit
Device(config)# interface gigabitethernet2/0/11
Device(config-if)# ipv6 rip cisco enable
```

Displaying IPv6: Example

This is an example of the output from the `show ipv6 interface` privileged EXEC command:

```
Device# show ipv6 interface
Vlan1 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
Global unicast address(es):
   3FFE:C000:0:1:20B:46FF:FE2F:D940, subnet is 3FFE:C000:0:1::/64 [EUI]
Joined group address(es):
   FF02::1
   FF02::2
   FF02::1:FF2F:D940
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
```
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
<output truncated>
Implementing IPv6 Multicast

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Implementing IPv6 Multicast Routing

This chapter describes how to implement IPv6 multicast routing on the switch.

Traditional IP communication allows a host to send packets to a single host (unicast transmission) or to all hosts (broadcast transmission). IPv6 multicast provides a third scheme, allowing a host to send a single data stream to a subset of all hosts (group transmission) simultaneously.

IPv6 Multicast Overview

An IPv6 multicast group is an arbitrary group of receivers that want to receive a particular data stream. This group has no physical or geographical boundaries—receivers can be located anywhere on the Internet or in any private network. Receivers that are interested in receiving data flowing to a particular group must join the group by signaling their local switch. This signaling is achieved with the MLD protocol.

Switches use the MLD protocol to learn whether members of a group are present on their directly attached subnets. Hosts join multicast groups by sending MLD report messages. The network then delivers data to a potentially unlimited number of receivers, using only one copy of the multicast data on each subnet. IPv6 hosts that wish to receive the traffic are known as group members.
Packets delivered to group members are identified by a single multicast group address. Multicast packets are delivered to a group using best-effort reliability, just like IPv6 unicast packets.

The multicast environment consists of senders and receivers. Any host, regardless of whether it is a member of a group, can send to a group. However, only members of a group can listen to and receive the message.

A multicast address is chosen for the receivers in a multicast group. Senders use that address as the destination address of a datagram to reach all members of the group.

Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time.

How active a multicast group is, its duration, and its membership can vary from group to group and from time to time. A group that has members may have no activity.

### IPv6 Multicast Routing Implementation

The Cisco IOS software supports the following protocols to implement IPv6 multicast routing:

- **MLD** is used by IPv6 switches to discover multicast listeners (nodes that want to receive multicast packets destined for specific multicast addresses) on directly attached links. There are two versions of MLD:
  - MLD version 1 is based on version 2 of the Internet Group Management Protocol (IGMP) for IPv4, and
  - MLD version 2 is based on version 3 of the IGMP for IPv4. IPv6 multicast for Cisco IOS software uses both MLD version 2 and MLD version 1. MLD version 2 is fully backward-compatible with MLD version 1 (described in RFC 2710). Hosts that support only MLD version 1 will interoperate with a switch running MLD version 2. Mixed LANs with both MLD version 1 and MLD version 2 hosts are likewise supported.

- **PIM-SM** is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs.

- **PIM in Source Specific Multicast (PIM-SSM)** is similar to PIM-SM with the additional ability to report interest in receiving packets from specific source addresses (or from all but the specific source addresses) to an IP multicast address.

### IPv6 Multicast Listener Discovery Protocol

To start implementing multicasting in the campus network, users must first define who receives the multicast. The MLD protocol is used by IPv6 switches to discover the presence of multicast listeners (for example, nodes that want to receive multicast packets) on their directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes. It is used for discovering local group and source-specific group membership.

The MLD protocol provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

### Multicast Queriers and Hosts

A multicast querier is a network device, such as a switch, that sends query messages to discover which network devices are members of a given multicast group.

A multicast host is a receiver, including switches, that send report messages to inform the querier of a host membership.
A set of queriers and hosts that receive multicast data streams from the same source is called a multicast group. Queriers and hosts use MLD reports to join and leave multicast groups and to begin receiving group traffic. MLD uses the Internet Control Message Protocol (ICMP) to carry its messages. All MLD messages are link-local with a hop limit of 1, and they all have the switch alert option set. The switch alert option implies an implementation of the hop-by-hop option header.

**MLD Access Group**

The MLD access group provides receiver access control in Cisco IOS IPv6 multicast switches. This feature limits the list of groups a receiver can join, and it allows or denies sources used to join SSM channels.

**Explicit Tracking of Receivers**

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network. This feature also enables the fast leave mechanism to be used with MLD version 2 host reports.

**Protocol Independent Multicast**

Protocol Independent Multicast (PIM) is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs. PIM works independently of the unicast routing protocol to perform send or receive multicast route updates like other protocols. Regardless of which unicast routing protocols are being used in the LAN to populate the unicast routing table, Cisco IOS PIM uses the existing unicast table content to perform the Reverse Path Forwarding (RPF) check instead of building and maintaining its own separate routing table.

You can configure IPv6 multicast to use either PIM-SM or PIM-SSM operation, or you can use both PIM-SM and PIM-SSM together in your network.

**PIM-Sparse Mode**

IPv6 multicast provides support for intradomain multicast routing using PIM-SM. PIM-SM uses unicast routing to provide reverse-path information for multicast tree building, but it is not dependent on any particular unicast routing protocol.

PIM-SM is used in a multicast network when relatively few switches are involved in each multicast and these switches do not forward multicast packets for a group, unless there is an explicit request for the traffic. PIM-SM distributes information about active sources by forwarding data packets on the shared tree. PIM-SM initially uses shared trees, which requires the use of an RP.

Requests are accomplished via PIM joins, which are sent hop by hop toward the root node of the tree. The root node of a tree in PIM-SM is the RP in the case of a shared tree or the first-hop switch that is directly connected to the multicast source in the case of a shortest path tree (SPT). The RP keeps track of multicast groups and the hosts that send multicast packets are registered with the RP by that host's first-hop switch.

As a PIM join travels up the tree, switches along the path set up multicast forwarding state so that the requested multicast traffic will be forwarded back down the tree. When multicast traffic is no longer needed, a switch sends a PIM prune up the tree toward the root node to prune (or remove) the unnecessary traffic. As this PIM prune travels hop by hop up the tree, each switch updates its forwarding state appropriately. Ultimately, the forwarding state associated with a multicast group or source is removed.

A multicast data sender sends data destined for a multicast group. The designated switch (DR) of the sender takes those data packets, unicast-encapsulates them, and sends them directly to the RP. The RP receives these encapsulated data packets, de-encapsulates them, and forwards them onto the shared tree. The packets then
follow the (*) G multicast tree state in the switches on the RP tree, being replicated wherever the RP tree branches, and eventually reaching all the receivers for that multicast group. The process of encapsulating data packets to the RP is called register, and the encapsulation packets are called PIM register packets.

IPv6 BSR: Configure RP Mapping

PIM switches in a domain must be able to map each multicast group to the correct RP address. The BSR protocol for PIM-SM provides a dynamic, adaptive mechanism to distribute group-to-RP mapping information rapidly throughout a domain. With the IPv6 BSR feature, if an RP becomes unreachable, it will be detected and the mapping tables will be modified so that the unreachable RP is no longer used, and the new tables will be rapidly distributed throughout the domain.

Every PIM-SM multicast group needs to be associated with the IP or IPv6 address of an RP. When a new multicast sender starts sending, its local DR will encapsulate these data packets in a PIM register message and send them to the RP for that multicast group. When a new multicast receiver joins, its local DR will send a PIM join message to the RP for that multicast group. When any PIM switch sends a (*, G) join message, the PIM switch needs to know which is the next switch toward the RP so that G (Group) can send a message to that switch. Also, when a PIM switch is forwarding data packets using (*, G) state, the PIM switch needs to know which is the correct incoming interface for packets destined for G, because it needs to reject any packets that arrive on other interfaces.

A small set of switches from a domain are configured as candidate bootstrap switches (C-BSRs) and a single BSR is selected for that domain. A set of switches within a domain are also configured as candidate RPs (C-RPs); typically, these switches are the same switches that are configured as C-BSRs. Candidate RPs periodically unicast candidate-RP-advertisement (C-RP-Adv) messages to the BSR of that domain, advertising their willingness to be an RP. A C-RP-Adv message includes the address of the advertising C-RP, and an optional list of group addresses and mask length fields, indicating the group prefixes for which the candidacy is advertised. The BSR then includes a set of these C-RPs, along with their corresponding group prefixes, in bootstrap messages (BSMs) it periodically originates. BSMs are distributed hop-by-hop throughout the domain.

Bidirectional BSR support allows bidirectional RPs to be advertised in C-RP messages and bidirectional ranges in the BSM. All switches in a system must be able to use the bidirectional range in the BSM; otherwise, the bidirectional RP feature will not function.

PIM-Source Specific Multicast

PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM-SM. However, unlike PIM-SM where data from all multicast sources are sent when there is a PIM join, the SSM feature forwards datagram traffic to receivers from only those multicast sources that the receivers have explicitly joined, thus optimizing bandwidth utilization and denying unwanted Internet broadcast traffic. Further, instead of the use of RP and shared trees, SSM uses information found on source addresses for a multicast group. This information is provided by receivers through the source addresses relayed to the last-hop switches by MLD membership reports, resulting in shortest-path trees directly to the sources.

In SSM, delivery of datagrams is based on (S, G) channels. Traffic for one (S, G) channel consists of datagrams with an IPv6 unicast source address S and the multicast group address G as the IPv6 destination address. Systems will receive this traffic by becoming members of the (S, G) channel. Signaling is not required, but receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources.

MLD version 2 is required for SSM to operate. MLD allows the host to provide source information. Before SSM can run with MLD, SSM must be supported in the Cisco IOS IPv6 switch, the host where the application is running, and the application itself.
Routable Address Hello Option

When an IPv6 interior gateway protocol is used to build the unicast routing table, the procedure to detect the upstream switch address assumes the address of a PIM neighbor is always same as the address of the next-hop switch, as long as they refer to the same switch. However, it may not be the case when a switch has multiple addresses on a link.

Two typical situations can lead to this situation for IPv6. The first situation can occur when the unicast routing table is not built by an IPv6 interior gateway protocol such as multicast BGP. The second situation occurs when the address of an RP shares a subnet prefix with downstream switches (note that the RP switch address has to be domain-wide and therefore cannot be a link-local address).

The routable address hello option allows the PIM protocol to avoid such situations by adding a PIM hello message option that includes all the addresses on the interface on which the PIM hello message is advertised. When a PIM switch finds an upstream switch for some address, the result of RPF calculation is compared with the addresses in this option, in addition to the PIM neighbor’s address itself. Because this option includes all the possible addresses of a PIM switch on that link, it always includes the RPF calculation result if it refers to the PIM switch supporting this option.

Because of size restrictions on PIM messages and the requirement that a routable address hello option fits within a single PIM hello message, a limit of 16 addresses can be configured on the interface.

PIM IPv6 Stub Routing

The PIM stub routing feature reduces resource usage by moving routed traffic closer to the end user.

In a network using PIM stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IPv6 multicast routing and configure only the switch as a PIM stub router. The switch does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the switch. The switch uplink port cannot be used with SVIs.

You must also configure EIGRP stub routing when configuring PIM stub routing on the switch. For more information, see the EIGRPv6 Stub Routing, on page 159 section.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM assert and designated router election mechanisms are not supported on the PIM passive interfaces. Only the non-redundant access router topology is supported by the PIM stub feature. By using a non-redundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

In the figure shown below, Switch A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source. See the Configuring PIM IPv6 Stub Routing, on page 203 section for more information.
Static Mroutes

IPv6 static mroutes behave much in the same way as IPv4 static mroutes used to influence the RPF check. IPv6 static mroutes share the same database as IPv6 static routes and are implemented by extending static route support for RPF checks. Static mroutes support equal-cost multipath mroutes, and they also support unicast-only static routes.

MRIB

The Multicast Routing Information Base (MRIB) is a protocol-independent repository of multicast routing entries instantiated by multicast routing protocols (routing clients). Its main function is to provide independence between routing protocols and the Multicast Forwarding Information Base (MFIB). It also acts as a coordination and communication point among its clients.

Routing clients use the services provided by the MRIB to instantiate routing entries and retrieve changes made to routing entries by other clients. Besides routing clients, MRIB also has forwarding clients (MFIB instances) and special clients such as MLD. MFIB retrieves its forwarding entries from MRIB and notifies the MRIB of any events related to packet reception. These notifications can either be explicitly requested by routing clients or spontaneously generated by the MFIB.

Another important function of the MRIB is to allow for the coordination of multiple routing clients in establishing multicast connectivity within the same multicast session. MRIB also allows for the coordination between MLD and routing protocols.

MFIB

The MFIB is a platform-independent and routing-protocol-independent library for IPv6 software. Its main purpose is to provide a Cisco IOS platform with an interface with which to read the IPv6 multicast forwarding table and notifications when the forwarding table changes. The information provided by the MFIB has clearly defined forwarding semantics and is designed to make it easy for the platform to translate to its specific hardware or software forwarding mechanisms.

When routing or topology changes occur in the network, the IPv6 routing table is updated, and those changes are reflected in the MFIB. The MFIB maintains next-hop address information based on the information in the IPv6 routing table. Because there is a one-to-one correlation between MFIB entries and routing table entries, the MFIB contains all known routes and eliminates the need for route cache maintenance that is associated with switching paths such as fast switching and optimum switching.
MFIB

Distributed MFIB has its significance only in a stacked environment where the Master distributes the MFIB information to the other stack members. In the following section the line cards are nothing but the member switches in the stack.

MFIB (MFIB) is used to switch multicast IPv6 packets on distributed platforms. MFIB may also contain platform-specific information on replication across line cards. The basic MFIB routines that implement the core of the forwarding logic are common to all forwarding environments.

MFIB implements the following functions:

- Relays data-driven protocol events generated in the line cards to PIM.
- Provides an MFIB platform application program interface (API) to propagate MFIB changes to platform-specific code responsible for programming the hardware acceleration engine. This API also includes entry points to switch a packet in software (necessary if the packet is triggering a data-driven event) and to upload traffic statistics to the software.

The combination of MFIB and MRIB subsystems also allows the switch to have a "customized" copy of the MFIB database in each line card and to transport MFIB-related platform-specific information from the RP to the line cards.

IPv6 Multicast Process Switching and Fast Switching

A unified MFIB is used to provide both fast switching and process switching support for PIM-SM and PIM-SSM in IPv6 multicast. In process switching, the IOS daemon must examine, rewrite, and forward each packet. The packet is first received and copied into the system memory. The switch then looks up the Layer 3 network address in the routing table. The Layer 2 frame is then rewritten with the next-hop destination address and sent to the outgoing interface. The IOSd also computes the cyclic redundancy check (CRC). This switching method is the least scalable method for switching IPv6 packets.

IPv6 multicast fast switching allows switches to provide better packet forwarding performance than process switching. Information conventionally stored in a route cache is stored in several data structures for IPv6 multicast switching. The data structures provide optimized lookup for efficient packet forwarding.

In IPv6 multicast forwarding, the first packet is fast-switched if the PIM protocol logic allows it. In IPv6 multicast fast switching, the MAC encapsulation header is precomputed. IPv6 multicast fast switching uses the MFIB to make IPv6 destination prefix-based switching decisions. In addition to the MFIB, IPv6 multicast fast switching uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all MFIB entries.

The adjacency table is populated as adjacencies are discovered. Each time an adjacency entry is created (such as through ARP), a link-layer header for that adjacent node is precomputed and stored in the adjacency table. Once a route is determined, it points to a next hop and corresponding adjacency entry. It is subsequently used for encapsulation during switching of packets.

A route might have several paths to a destination prefix, such as when a switch is configured for simultaneous load balancing and redundancy. For each resolved path, a pointer is added for the adjacency corresponding to the next-hop interface for that path. This mechanism is used for load balancing across several paths.
Multiprotocol BGP for the IPv6 Multicast Address Family

The multiprotocol BGP for the IPv6 multicast address family feature provides multicast BGP extensions for IPv6 and supports the same features and functionality as IPv4 BGP. IPv6 enhancements to multicast BGP include support for an IPv6 multicast address family and network layer reachability information (NLRI) and next hop (the next switch in the path to the destination) attributes that use IPv6 addresses.

Multicast BGP is an enhanced BGP that allows the deployment of interdomain IPv6 multicast. Multiprotocol BGP carries routing information for multiple network layer protocol address families; for example, IPv6 address family and for IPv6 multicast routes. The IPv6 multicast address family contains routes used for RPF lookup by the IPv6 PIM protocol, and multicast BGP IPv6 provides for interdomain transport of the same. Users must use multiprotocol BGP for IPv6 multicast when using IPv6 multicast with BGP because the unicast BGP learned routes will not be used for IPv6 multicast.

Multicast BGP functionality is provided through a separate address family context. A subsequent address family identifier (SAFI) provides information about the type of the network layer reachability information that is carried in the attribute. Multiprotocol BGP unicast uses SAFI 1 messages, and multiprotocol BGP multicast uses SAFI 2 messages. SAFI 1 messages indicate that the routes are only usable for IP unicast, but not IP multicast. Because of this functionality, BGP routes in the IPv6 unicast RIB must be ignored in the IPv6 multicast RPF lookup.

A separate BGP routing table is maintained to configure incongruent policies and topologies (for example, IPv6 unicast and multicast) by using IPv6 multicast RPF lookup. Multicast RPF lookup is very similar to the IP unicast route lookup.

No MRIB is associated with the IPv6 multicast BGP table. However, IPv6 multicast BGP operates on the unicast IPv6 RIB when needed. Multicast BGP does not insert or update routes into the IPv6 unicast RIB.

Implementing IPv6 Multicast

Enabling IPv6 Multicast Routing

Beginning in privileged EXEC mode, follow these steps:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>ipv6 multicast-routing</td>
<td>Enables multicast routing on all IPv6-enabled interfaces and enables multicast forwarding for PIM and MLD on all enabled interfaces of the switch.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device (config)# ipv6 multicast-routing</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>
**Customizing and Verifying the MLD Protocol**

**Customizing and Verifying MLD on an Interface**

Beginning in privileged EXEC mode, follow these steps:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>(config)# interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ipv6 mld join-group [group-address] [include</td>
<td>Configures MLD reporting for a specified group and source.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config-if)# ipv6 mld join-group FF04::10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>ipv6 mld access-group access-list-name</td>
<td>Allows the user to perform IPv6 multicast receiver access control.</td>
</tr>
<tr>
<td>Example:</td>
<td>(config-if)# ipv6 access-list acc-grp-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>ipv6 mld static-group [group-address] [include</td>
<td>Statically forwards traffic for the multicast group onto a specified interface and cause the interface to behave as if a MLD joiner were present on the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>exclude] [source-address</td>
<td>source-list [acl]]</td>
</tr>
<tr>
<td></td>
<td>(config-if)# ipv6 mld static-group FF04::10</td>
<td></td>
</tr>
<tr>
<td></td>
<td>include 100::1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>ipv6 mld query-max-response-time seconds</td>
<td>Configures the maximum response time advertised in MLD queries.</td>
</tr>
<tr>
<td>Example:</td>
<td>(config-if)# ipv6 mld query-max-response-time 20</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>ipv6 mld query-timeout seconds</td>
<td>Configures the timeout value before the switch takes over as the querier for the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>(config-if)# ipv6 mld query-timeout 130</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>exit</td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Implementing MLD Group Limits

Per-interface and global MLD limits operate independently of each other. Both per-interface and global MLD limits can be configured on the same switch. The number of MLD limits, globally or per interface, is not configured by default; the limits must be configured by the user. A membership report that exceeds either the per-interface or the global state limit is ignored.

### Implementing MLD Group Limits Globally

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ipv6 mld [vrf vrf-name] state-limit number

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>(config-if) # exit</td>
<td>Displays the multicast groups that are directly connected to the switch and that were learned through MLD.</td>
</tr>
<tr>
<td><strong>Step 9</strong> show ipv6 mld groups [link-local] [group-name</td>
<td>group-address] [interface-type interface-number] [detail</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td># show ipv6 mld groups GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> show ipv6 mld groups summary</td>
<td>Displays multicast-related information about an interface.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td># show ipv6 mld groups summary</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong> show ipv6 mld interface [type number]</td>
<td>Enables debugging on MLD protocol activity.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td># show ipv6 mld interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong> debug ipv6 mld [group-name</td>
<td>group-address</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td># debug ipv6 mld</td>
<td></td>
</tr>
<tr>
<td><strong>Step 13</strong> debug ipv6 mld explicit [group-name</td>
<td>group-address]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td># debug ipv6 mld explicit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 14</strong> copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

---

IPv6

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
4. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable  
Example:  
Device# enable | Enters global configuration mode. |
| **Step 2** configure terminal  
Example:  
Device# configure terminal | Enters global configuration mode. |
| **Step 3** ipv6 mld [vrf vrf-name] state-limit number  
Example:  
Device(config)# ipv6 mld state-limit 300 | Limits the number of MLD states globally. |
| **Step 4** copy running-config startup-config | (Optional) Save your entries in the configuration file. |

**Implementing MLD Group Limits per Interface**

**SUMMARY STEPS**

1. enable  
2. configure terminal  
3. interface type number  
4. ipv6 mld limit number [except]access-list  
5. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable  
Example:  
Device# enable | Enters global configuration mode. |
| **Step 2** configure terminal  
Example:  
Device# configure terminal | Enters global configuration mode. |
### Configuring Explicit Tracking of Receivers to Track Host Behavior

The explicit tracking feature allows a switch to track the behavior of the hosts within its IPv6 network and enables the fast leave mechanism to be used with MLD version 2 host reports.

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: (config)# interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ipv6 mld explicit-tracking access-list-name</td>
<td>Enables explicit tracking of hosts.</td>
</tr>
<tr>
<td></td>
<td>Example: (config-if)# ipv6 mld explicit-tracking list1</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Resetting the MLD Traffic Counters

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>clear ipv6 mld traffic</td>
<td>Resets all MLD traffic counters.</td>
</tr>
<tr>
<td></td>
<td>Example: # clear ipv6 mld traffic</td>
<td></td>
</tr>
</tbody>
</table>
Purpose
Command or Action
Step 2 show ipv6 mld traffic
Example:
# show ipv6 mld traffic

Step 3 copy running-config startup-config

(Optional) Save your entries in the configuration file.

Clearing the MLD Interface Counters

Beginning in privileged EXEC mode, follow these steps.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 clear ipv6 mld counters interface-type</td>
<td>Clears the MLD interface counters.</td>
</tr>
</tbody>
</table>
| Example:
# clear ipv6 mld counters Ethernet1/0 |
| Step 2 copy running-config startup-config | (Optional) Save your entries in the configuration file. |

Clearing the MLD Interface Counters

Beginning in privileged EXEC mode, follow these steps.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 clear ipv6 mld counters interface-type</td>
<td>Clears the MLD interface counters.</td>
</tr>
</tbody>
</table>
| Example:
# clear ipv6 mld counters Ethernet1/0 |
| Step 2 copy running-config startup-config | (Optional) Save your entries in the configuration file. |

Configuring PIM

This section explains how to configure PIM.

Configuring PIM-SM and Displaying PIM-SM Information for a Group Range

Beginning in privileged EXEC mode, follow these steps:

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 2 ipv6 pim rp-address ipv6-address group-access-list</td>
<td>Configures the address of a PIM RP for a particular group range.</td>
</tr>
</tbody>
</table>
| Example:
(config) # ipv6 pim rp-address 2001:DB8::01:800:200E:8C6C acc-grp-1 |
| Step 3 exit | Exits global configuration mode, and returns the switch to privileged EXEC mode. |
| Example:
(config) # exit |
### Configuring PIM Options

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 pim interface</td>
<td>show ipv6 pim</td>
<td>Displays information about interfaces configured for PIM.</td>
</tr>
<tr>
<td>[state-on] [state-off]</td>
<td>interface</td>
<td></td>
</tr>
<tr>
<td>[type-number]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>show ipv6 pim</td>
<td></td>
</tr>
<tr>
<td># show ipv6 pim interface</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 5</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 pim group-map</td>
<td>show ipv6 pim</td>
<td>Displays an IPv6 multicast group mapping table.</td>
</tr>
<tr>
<td>[group-name</td>
<td>group-address</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>show ipv6 pim</td>
<td></td>
</tr>
<tr>
<td># show ipv6 pim group-map</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 6</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 pim neighbor</td>
<td>show ipv6 pim</td>
<td>Displays the PIM neighbors discovered by the Cisco IOS software.</td>
</tr>
<tr>
<td>[detail] [interface-type interface-number</td>
<td>count]</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>show ipv6 pim</td>
<td></td>
</tr>
<tr>
<td># show ipv6 pim neighbor</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 7</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 pim range-list</td>
<td>show ipv6 pim</td>
<td>Displays information about IPv6 multicast range lists.</td>
</tr>
<tr>
<td>[config] [rp-address</td>
<td>rp-name]</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>show ipv6 pim</td>
<td></td>
</tr>
<tr>
<td># show ipv6 pim range-list</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 8</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 pim tunnel</td>
<td>show ipv6 pim</td>
<td>Displays information about the PIM register encapsulation and de-encapsulation tunnels on an interface.</td>
</tr>
<tr>
<td>[interface-type interface-number]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>show ipv6 pim</td>
<td></td>
</tr>
<tr>
<td># show ipv6 pim tunnel</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 9</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug ipv6 pim [group-name</td>
<td>group-address</td>
<td>interface interface-type</td>
</tr>
<tr>
<td>Example:</td>
<td>show ipv6 pim</td>
<td></td>
</tr>
<tr>
<td># debug ipv6 pim</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 10</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy running-config startup-config</td>
<td></td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>2</td>
<td>ipv6 pim spt-threshold infinity [group-list access-list-name]</td>
<td>Configures when a PIM leaf switch joins the SPT for the specified groups.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config) # ipv6 pim spt-threshold infinity group-list acc-grp-1</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>ipv6 pim accept-register {list access-list</td>
<td>route-map map-name}</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config) # ipv6 pim accept-register route-map reg-filter</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config) # interface GigabitEthernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>ipv6 pim dr-priority value</td>
<td>Configures the DR priority on a PIM switch.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config-if) # ipv6 pim dr-priority 3</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>ipv6 pim hello-interval seconds</td>
<td>Configures the frequency of PIM hello messages on an interface.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config-if) # ipv6 pim hello-interval 45</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>ipv6 pim join-prune-interval seconds</td>
<td>Configures periodic join and prune announcement intervals for a specified interface.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config-if) # ipv6 pim join-prune-interval 75</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td>exit</td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config-if) # exit</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>ipv6 pim join-prune statistic [interface-type]</td>
<td>Displays the average join-prune aggregation for the most recently aggregated packets for each interface.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(config-if) # show ipv6 pim join-prune statistic</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Resetting the PIM Traffic Counters

If PIM malfunctions or in order to verify that the expected number of PIM packets are received and sent, the user can clear PIM traffic counters. Once the traffic counters are cleared, the user can enter the show ipv6 pim traffic command to verify that PIM is functioning correctly and that PIM packets are being received and sent correctly.

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>clear ipv6 pim traffic</td>
<td>Resets the PIM traffic counters.</td>
</tr>
<tr>
<td>Example:</td>
<td># clear ipv6 pim traffic</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>show ipv6 pim traffic</td>
<td>Displays the PIM traffic counters.</td>
</tr>
<tr>
<td>Example:</td>
<td># show ipv6 pim traffic</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

Clearing the PIM Topology Table to Reset the MRIB Connection

No configuration is necessary to use the MRIB. However, users may in certain situations want to clear the PIM topology table in order to reset the MRIB connection and verify MRIB information.

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>clear ipv6 pim topology [group-name</td>
<td>group-address]</td>
</tr>
<tr>
<td>Example:</td>
<td># clear ipv6 pim topology FF04::10</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>show ipv6 mrrib client [filter] [name {client-name</td>
<td>client-name : client-id}]</td>
</tr>
<tr>
<td>Example:</td>
<td># show ipv6 mrrib client</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>show ipv6 mrrib route {link-local</td>
<td>summary</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><code># show ipv6 mrib route</code></td>
<td>Displays PIM topology table information for a specific group or all groups.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> `show ipv6 pim topology [groupname-or-address [source-address-or-name]</td>
<td>link-local</td>
<td>route-count [detail]]`</td>
</tr>
<tr>
<td>Example: <code># show ipv6 pim topology</code></td>
<td>Enables debugging on MRIB I/O events.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>debug ipv6 mrib client</code></td>
<td>Enables debugging on MRIB proxy activity between the switch processor and line cards on distributed switch platforms.</td>
<td></td>
</tr>
<tr>
<td>Example: <code># debug ipv6 mrib client</code></td>
<td>Enables debugging on MRIB table management activity.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> <code>debug ipv6 mrib io</code></td>
<td>Displays information about MRIB routing entry-related activity.</td>
<td></td>
</tr>
<tr>
<td>Example: <code># debug ipv6 mrib io</code></td>
<td>(Optional) Save your entries in the configuration file.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> <code>debug ipv6 mrib proxy</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example: <code># debug ipv6 mrib proxy</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> `debug ipv6 mrib route [group-name</td>
<td>group-address]`</td>
<td></td>
</tr>
<tr>
<td>Example: <code># debug ipv6 mrib route</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> <code>debug ipv6 mrib table</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example: <code># debug ipv6 mrib table</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> <code>copy running-config startup-config</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Configuring PIM IPv6 Stub Routing

The PIM Stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards MLD traffic.
**PIM IPv6 Stub Routing Configuration Guidelines**

- Before configuring PIM stub routing, you must have IPv6 multicast routing configured on both the stub router and the central router. You must also have PIM mode (sparse-mode) configured on the uplink interface of the stub router.
- The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior. For more information, see the EIGRPv6 Stub Routing, on page 159 section.
- Only directly connected multicast (MLD) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- The redundant PIM stub router topology is not supported.

**Default IPv6 PIM Routing Configuration**

This table displays the default IPv6 PIM routing configuration for the Device.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multicast routing</td>
<td>Disabled on all interfaces.</td>
</tr>
<tr>
<td>PIM version</td>
<td>Version 2.</td>
</tr>
<tr>
<td>PIM mode</td>
<td>No mode is defined.</td>
</tr>
<tr>
<td>PIM stub routing</td>
<td>None configured.</td>
</tr>
<tr>
<td>PIM RP address</td>
<td>None configured.</td>
</tr>
<tr>
<td>PIM domain border</td>
<td>Disabled.</td>
</tr>
<tr>
<td>PIM multicast boundary</td>
<td>None.</td>
</tr>
<tr>
<td>Candidate BSRs</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Candidate RPs</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Shortest-path tree threshold rate</td>
<td>0 kb/s.</td>
</tr>
<tr>
<td>PIM router query message interval</td>
<td>30 seconds.</td>
</tr>
</tbody>
</table>

**Enabling IPv6 PIM Stub Routing**

**Before you begin**

PIM stub routing is disabled in IPv6 by default. Beginning in privileged EXEC mode, follow these steps to enable PIM stub routing on an interface.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
### IPv6 Multicast PIM Stub Routing

3. `ipv6 multicast pim-passive-enable`
4. `interface interface-id`
5. `ipv6 pim`
6. `ipv6 pim {bsr} | {dr-priority | value} | {hello-interval | seconds} | {join-prune-interval | seconds} | {passive}`
7. `end`

### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables IPv6 Multicast PIM routing on the switch.</td>
</tr>
<tr>
<td><code>ipv6 multicast pim-passive-enable</code></td>
<td>Enables IPv6 Multicast PIM routing on the switch.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-if)# ipv6 multicast pim-passive-enable</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode.</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td>Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# interface gigabitethernet 9/0/6</td>
</tr>
</tbody>
</table>

#### The specified interface must be one of the following:

- A routed port—A physical port that has been configured as a Layer 3 port by entering the `no switchport` interface configuration command. You will also need to enable IP PIM sparse mode on the interface, and join the interface as a statically connected member to an MLD static group.

- An SVI—A VLAN interface created by using the `interface vlan vlan-id` global configuration command. You will also need to enable IP PIM sparse mode on the VLAN, join the VLAN as a statically connected member to an MLD static group, and then enable MLD snooping on the VLAN, the MLD static group, and physical interface.

These interfaces must have IPv6 addresses assigned to them.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong> ipv6 pim</td>
<td>Enables the PIM on the interface.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 pim</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ipv6 pim {bsr}</td>
<td>Configures the various PIM stub features on the interface.</td>
</tr>
<tr>
<td></td>
<td>Enter <strong>bsr</strong> to configure BSR on a PIM switch</td>
</tr>
<tr>
<td>{dr-priority</td>
<td>value}</td>
</tr>
<tr>
<td>{hello-interval</td>
<td>seconds}</td>
</tr>
<tr>
<td>{join-prune-interval</td>
<td>seconds}</td>
</tr>
<tr>
<td>{passive}</td>
<td>Enter <strong>passive</strong> to configure the PIM in the passive mode.</td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>Returns to privileged EXEC mode.</td>

</table>

### Configuring a BSR

The tasks included here are described below.
## Configuring a BSR and Verifying BSR Information

Beginning in privileged EXEC mode, follow these steps:

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>ipv6 pim bsr candidate bsr ipv6-address [hash-mask-length] [priority priority-value]</td>
<td>Configures a switch to be a candidate BSR.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config) # ipv6 pim bsr candidate bsr 2001:DB8:3000:3000::42 124 priority 10
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>interface type number</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config) # interface GigabitEthernet 1/0/1
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>ipv6 pim bsr border</td>
<td>Specifies an interface type and number, and places the switch in interface configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config-if) # ipv6 pim bsr border
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>exit</td>
<td>Enter this command twice to exit interface configuration mode and enter privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config-if) # exit
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>show ipv6 pim bsr {election</td>
<td>rp-cache</td>
</tr>
</tbody>
</table>

**Example:**

```
(config-if) # show ipv6 pim bsr election
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

## Sending PIM RP Advertisements to the BSR

Beginning in privileged EXEC mode, follow these steps:

### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv6 pim bsr candidate rp ipv6-address [group-list access-list-name] [priority priority-value] [interval seconds]</td>
<td>Sends PIM RP advertisements to the BSR.</td>
</tr>
</tbody>
</table>

#### Example:

```
(config) # ipv6 pim bsr candidate rp 2001:DB8:3000:3000::42 priority 0
```

### Step 2

**Command or Action:**
```
interface type number
```

**Example:**
```
(config) # interface GigabitEthernet 1/0/1
```

### Step 3

**Command or Action:**
```
ipv6 pim bsr border
```

**Example:**
```
(config-if) # ipv6 pim bsr border
```

### Step 4

**Command or Action:**
```
copy running-config startup-config
```

**Example:**
```
(Optional) Save your entries in the configuration file.
```

### Configuring BSR for Use Within Scoped Zones

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
</tbody>
</table>

#### Step 1

**Command or Action:**
```
ipv6 pim bsr candidate rp ipv6-address [hash-mask-length] [priority priority-value]
```

**Example:**
```
(config) # ipv6 pim bsr candidate bsr 2001:DB8:1:1:4
```

#### Step 2

**Command or Action:**
```
ipv6 pim bsr candidate rp ipv6-address [group-list access-list-name] [priority priority-value] [interval seconds]
```

**Example:**
```
(config) # ipv6 pim bsr candidate rp 2001:DB8:1:1:1 group-list list scope 6
```

#### Step 3

**Command or Action:**
```
interface type number
```

**Example:**
```
(config) # interface GigabitEthernet 1/0/1
```

#### Step 4

**Command or Action:**
```
ipv6 pim bsr border
```

**Example:**
```
(config-if) # ipv6 pim bsr border
```
### Configuring BSR Switches to Announce Scope-to-RP Mappings

IPv6 BSR switches can be statically configured to announce scope-to-RP mappings directly instead of learning them from candidate-RP messages. A user might want to configure a BSR switch to announce scope-to-RP mappings so that an RP that does not support BSR is imported into the BSR. Enabling this feature also allows an RP positioned outside the enterprise's BSR domain to be learned by the known remote RP on the local candidate BSR switch.

Beginning in privileged EXEC mode, follow these steps:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 2 ipv6 pim bsr announced rp ipv6-address [group-list access-list-name] [priority priority-value]</td>
<td>Announces scope-to-RP mappings directly from the BSR for the specified candidate RP.</td>
</tr>
<tr>
<td>Example: (config)# ipv6 pim bsr announced rp 2001:DB8:3000::3000::42 priority 0</td>
<td></td>
</tr>
<tr>
<td>Step 3 copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Configuring SSM Mapping

When the SSM mapping feature is enabled, DNS-based SSM mapping is automatically enabled, which means that the switch will look up the source of a multicast MLD version 1 report from a DNS server.

You can use either DNS-based or static SSM mapping, depending on your switch configuration. If you choose to use static SSM mapping, you can configure multiple static SSM mappings. If multiple static SSM mappings are configured, the source addresses of all matching access lists will be used.

**Note**

To use DNS-based SSM mapping, the switch needs to find at least one correctly configured DNS server, to which the switch may be directly attached.

Beginning in privileged EXEC mode, follow these steps:
## Configuring Static Mroutes

Static multicast routes (mroutes) in IPv6 can be implemented as an extension of IPv6 static routes. You can configure your switch to use a static route for unicast routing only, to use a static multicast route for multicast RPF selection only, or to use a static route for both unicast routing and multicast RPF selection.

Beginning in privileged EXEC mode, follow these steps:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>ipv6 mld ssm-map static access-list source-address</td>
<td>Configures static SSM mappings.</td>
</tr>
<tr>
<td>(config-if) # ipv6 mld ssm-map static SSM_MAP_ACL_2 2001:DB8:1::1</td>
<td></td>
</tr>
<tr>
<td>show ipv6 mld ssm-map [source-address]</td>
<td>Displays SSM mapping information.</td>
</tr>
<tr>
<td>(config-if) # show ipv6 mld ssm-map</td>
<td></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

---

**IPv6 Procedure**

- **Step 1**: Enter global configuration mode.
  ```
  configure terminal
  ```

- **Step 2**: Enables the SSM mapping feature for groups in the configured SSM range.
  ```
  ipv6 mld ssm-map enable
  
  (config) # ipv6 mld ssm-map enable
  ```

- **Step 3**: Enables DNS-based SSM mapping.
  ```
  no ipv6 mld ssm-map query dns
  
  (config) # no ipv6 mld ssm-map query dns
  ```

- **Step 4**: Enables static SSM mappings.
  ```
  ipv6 mld ssm-map static access-list source-address
  
  (config-if) # ipv6 mld ssm-map static SSM_MAP_ACL_2 2001:DB8:1::1
  ```

- **Step 5**: Exits global configuration mode, and returns the switch to privileged EXEC mode.
  ```
  exit
  
  (config-if) # exit
  ```

- **Step 6**: Displays SSM mapping information.
  ```
  show ipv6 mld ssm-map [source-address]
  
  (config-if) # show ipv6 mld ssm-map
  ```

- **Step 7**: Copies running configuration to startup configuration.
  ```
  copy running-config startup-config
  ```

---

**Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)**
### IPv6

#### Establishing Static IPv6 Routes

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.</td>
</tr>
<tr>
<td>ipv6 route {ipv6-prefix / prefix-length ipv6-address</td>
<td>Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.</td>
</tr>
<tr>
<td>administrative-distance} [administrative-multicast-distance</td>
<td>Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.</td>
</tr>
<tr>
<td>[unicast</td>
<td>Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.</td>
</tr>
<tr>
<td>multicast] [tag tag]</td>
<td>Establishes static IPv6 routes. The example shows a static route used for both unicast routing and multicast RPF selection.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config) # ipv6 route 2001:DB8::/64 6::6 100
```

### Exit Global Configuration Mode

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>exit</td>
<td>Exits global configuration mode, and returns the switch to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
# exit
```

### Displaying the Contents of the IPv6 Multicast Routing Table

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 mroutelink-local</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>[group-name</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>group-address</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>[source-address</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>source-name]</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>[summary]</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
<tr>
<td>[count]</td>
<td>Displays the contents of the IPv6 multicast routing table.</td>
</tr>
</tbody>
</table>

**Example:**

```
# show ipv6 mroute ff07::1
```

### Displaying Active Multicast Streams on the Switch

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 mroutelink-local</td>
<td>Displays the active multicast streams on the switch.</td>
</tr>
<tr>
<td>[group-name</td>
<td>Displays the active multicast streams on the switch.</td>
</tr>
<tr>
<td>group-address</td>
<td>Displays the active multicast streams on the switch.</td>
</tr>
<tr>
<td>active [kbps]</td>
<td>Displays the active multicast streams on the switch.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config-if) # show ipv6 mroute active
```

### Checking RPF Information for a Given Unicast Host Address and Prefix

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 rpf [ipv6-prefix]</td>
<td>Checks RPF information for a given unicast host address and prefix.</td>
</tr>
</tbody>
</table>

**Example:**

```
(config-if) # show ipv6 rpf 2001::1:1:2
```

### Copying Running-Config to Startup-Config

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Save your entries in the configuration file.</td>
</tr>
</tbody>
</table>

## Using MFIB in IPv6 Multicast

Multicast forwarding is automatically enabled when IPv6 multicast routing is enabled.

### Verifying MFIB Operation in IPv6 Multicast

Beginning in privileged EXEC mode, follow these steps:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ipv6 mfib [linkscope</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>verbose</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>group-address-name</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>[ipv6-prefix / prefix-length</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>source-address-name</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>count</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>interface</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>status</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
<tr>
<td>summary]</td>
<td>Displays the forwarding entries and interfaces in the IPv6 MFIB.</td>
</tr>
</tbody>
</table>
### Resetting MFIB Traffic Counters

Beginning in privileged EXEC mode, follow these steps:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> clear ipv6 mfib counters [group-name</td>
<td>group-address</td>
</tr>
</tbody>
</table>
Prerequisites for IPv6 Client Address Learning

Before configuring IPv6 client address learning, configure the wireless clients to support IPv6.

Related Topics
Configuring RA Guard Policy (CLI), on page 219

Information About IPv6 Client Address Learning

Client Address Learning is configured on device to learn the wireless client's IPv4 and IPv6 address and clients transition state maintained by the device on an association, re-association, de-authentication and timeout.
There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLACC)
- Stateful DHCPv6
- Static Configuration

For all of these methods, the IPv6 client always sends neighbor solicitation DAD (Duplicate Address Detection) request to ensure there is no duplicate IP address on the network. The device snoops the client's NDP and DHCPv6 packets to learn about its client IP addresses.

**SLAAC Address Assignment**

The most common method for IPv6 client address assignment is Stateless Address Auto-Configuration (SLAAC). SLAAC provides simple plug-and-play connectivity where clients self-assign an address based on the IPv6 prefix. This process is achieved

Stateless Address Auto-Configuration (SLAAC) is configured as follows:

- Host sends a router solicitation message.
- Hosts waits for a Router Advertisement message.
- Hosts take the first 64 bits of the IPv6 prefix from the Router Advertisement message and combines it with the 64 bit EUI-64 address (in the case of ethernet, this is created from the MAC Address) to create a global unicast message. The host also uses the source IP address, in the IP header, of the Router Advertisement message, as its default gateway.
- Duplicate Address Detection is performed by IPv6 clients in order to ensure that random addresses that are picked do not collide with other clients.
- The choice of algorithm is up to the client and is often configurable.

The last 64 bits of the IPv6 address can be learned based on the following 2 algorithms:

- EUI-64 which is based on the MAC address of the interface, or
- Private addresses that are randomly generated.

*Figure 8: SLAAC Address Assignment*

The following Cisco IOS configuration commands from a Cisco-capable IPv6 router are used to enable SLAAC addressing and router advertisements:

```
ipv6 unicast-routing
interface Vlan20
```
Stateful DHCPv6 Address Assignment

The use of DHCPv6 is not required for IPv6 client connectivity if SLAAC is already deployed. There are two modes of operation for DHCPv6 called Stateless and Stateful.

The DHCPv6 Stateless mode is used to provide clients with additional network information that is not available in the router advertisement, but not an IPv6 address as this is already provided by SLAAC. This information can include the DNS domain name, DNS server(s), and other DHCP vendor-specific options. This interface configuration is for a Cisco IOS IPv6 router implementing stateless DHCPv6 with SLAAC enabled:

```
ipv6 unicast-routing
dhcp pool IPV6_DHCPPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
description IPV6-DHCP-Stateless
ipv6 nd other-config-flag
ipv6 dhcp server IPV6_DHCPPPOOL
ipv6 address 2001:db8:0:20::1/64
end
```

The DHCPv6 Stateful option, also known as managed mode, operates similarly to DHCPv4 in that it assigns unique addresses to each client instead of the client generating the last 64 bits of the address as in SLAAC. This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on a local Device:

```
ipv6 unicast-routing
dhcp pool IPV6_DHCPPPOOL
address prefix 2001:db8:5:10::/64
domain-name cisco.com
dns-server 2001:db8:6:6::1
interface Vlan20
```
This interface configuration is for a Cisco IOS IPv6 router implementing stateful DHCPv6 on an external DHCP server:

    ipv6 unicast-routing
domain-name cisco.com
    dns-server 2001:db8:6:6::1
    interface Vlan20
    description IPv6-DHCP-Stateful
    ip address 192.168.20.1 255.255.255.0
    ipv6 address 2001:DB8:0:20::1/64
    ipv6 nd prefix 2001:DB8:0:20::/64 no-advertise
    ipv6 nd managed-config-flag
    ipv6 nd other-config-flag
    ipv6 dhcp_relay destination 2001:DB8:0:20::2
end

Static IP Address Assignment

Statically configured address on a client.

Router Solicitation

A Router Solicitation message is issued by a host controller to facilitate local routers to transmit Router Advertisement from which it can obtain information about local routing or perform Stateless Auto-configuration. Router Advertisements are transmitted periodically and the host prompts with an immediate Router Advertisement using a Router Solicitation such as - when it boots or following a restart operation.

Related Topics

- Configuring IPv6 ND Suppress Policy (CLI), on page 225

Router Advertisement

A Router Advertisement message is issued periodically by a router or in response to a Router Solicitation message from a host. The information contained in these messages is used by hosts to perform Stateless Auto-configuration and to modify its routing table.

Related Topics

- Configuring IPv6 ND Suppress Policy (CLI), on page 225
Neighbor Discovery

IPv6 Neighbor Discovery is a set of messages and processes that determine relationships between neighboring nodes. Neighbor Discovery replaces ARP, ICMP Router Discovery, and ICMP Redirect used in IPv4.

IPv6 Neighbor Discovery inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery packets that do not comply are dropped. The neighbor binding table in the switch tracks each IPv6 address and its associated MAC address. Clients are expired from the table according to Neighbor Binding timers.

Related Topics
Configuring IPv6 ND Suppress Policy (CLI), on page 225

Neighbor Discovery Suppression

The IPv6 addresses of wireless clients are cached by the device. When the device receives an NS multicast looking for an IPv6 address, and if the target address is known to the device and belongs to one of its clients, the device will reply with an NA message on behalf of the client. The result of this process generates the equivalent of the Address Resolution Protocol (ARP) table of IPv4 but is more efficient - uses generally fewer messages.

Note
The device acts like proxy and respond with NA, only when the ipv6 nd suppress command is configured

If the device does not have the IPv6 address of a wireless client, the device will not respond with NA and forward the NS packet to the wireless side. To resolve this, an NS Multicast Forwarding knob is provided. If this knob is enabled, the device gets the NS packet for the IPv6 address that it does not have (cache miss) and forwards it to the wireless side. This packet reaches the intended wireless client and the client replies with NA.

This cache miss scenario occurs rarely, and only very few clients which do not implement complete IPv6 stack may not advertise their IPv6 address during NDP.

Related Topics
Configuring IPv6 ND Suppress Policy (CLI), on page 225

RA Guard

IPv6 clients configure IPv6 addresses and populate their router tables based on IPv6 router advertisement (RA) packets. The RA guard feature is similar to the RA guard feature of wired networks. RA guard increases the security of the IPv6 network by dropping the unwanted or rogue RA packets that come from wireless clients. If this feature is not configured, malicious IPv6 wireless clients announce themselves as the router for the network often with high priority, which would take higher precedence over legitimate IPv6 routers.

RA-Guard also examines the incoming RA’s and decides whether to switch or block them based solely on information found in the message or in the switch configuration. The information available in the frames received is useful for RA validation:

• Port on which the frame is received
• IPv6 source address
• Prefix list

The following configuration information created on the switch is available to RA-Guard to validate against the information found in the received RA frame:

• Trusted/Untrusted ports for receiving RA-guard messages
• Trusted/Untrusted IPv6 source addresses of RA-sender
• Trusted/Untrusted Prefix list and Prefix ranges
• Router Preference

RA guard occurs at the device. You can configure the device to drop RA messages at the device. All IPv6 RA messages are dropped, which protects other wireless clients and upstream wired network from malicious IPv6 clients.

//Create a policy for RA Guard//
ipv6 nd raguard policy raguard-router
trusted-port
device-role router

//Applying the RA Guard Policy on port/interface//
interface tengigabitethernet1/0/1 (Katana)
interface gigabitethernet1/0/1 (Edison)

ipv6 nd raguard attach-policy raguard-router

Applying RA Throttle Policy on VLAN (CLI), on page 222

RA Throttling

RA throttling allows the controller to enforce limits to RA packets headed toward the wireless network. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will still maintain an IPv6 client connectivity. If a client sends an RS packet, an RA is sent back to the client. This RA is allowed through the controller and unicasted to the client. This process ensures that the new clients or roaming clients are not affected by the RA throttling.

Applying RA Throttle Policy on VLAN (CLI), on page 222

Configuring IPv6 Unicast (CLI)

IPv6 unicasting must always be enabled on the switch and the controller. IPv6 unicast routing is disabled.
Before you begin

To enable the forwarding of IPv6 unicast datagrams, use the `ipv6 unicast-routing` command in global configuration mode. To disable the forwarding of IPv6 unicast datagrams, use the `no` form of this command.

### SUMMARY STEPS

1. configure terminal
2. ipv6 unicast routing

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>

<td></td>
</tr>
</tbody>
</table>
**Purpose**

Command or Action

Device (config)# interface tengigabitethernet 1/0/1

Appplies the IPv6 RA Guard feature to a specified interface.

**Step 3**

**Command or Action**

ipv6 nd raguard attach-policy raguard-router

**Example:**

Device(config-if)# ipv6 nd raguard attach-policy raguard-router

**Purpose**

Applies the IPv6 RA Guard feature to a specified interface.

**Step 4**

**Command or Action**

exit

**Example:**

Device(config-if)# exit

**Purpose**

Exits interface configuration mode.

</table>
### Applying RA Throttle Policy on VLAN (CLI)

Applying the RA Throttle policy on a VLAN. By enabling RA throttling, routers that send many RA packets can be trimmed to a minimum frequency that will still maintain an IPv6 client connectivity.

### SUMMARY STEPS

1. configure terminal
2. vlan configuration 1
3. ipv6 nd ra throttle attach-policy ra-throttler1

### RELATED TOPICS

How to Configure IPv6 Neighbor Tracking

Perform this task to provide fine tuning for the life cycle of an entry in the binding table for the IPv6 Device Tracking feature. For IPv6 device tracking to work, the binding table needs to be populated.

Note

A single IPv6 client can have multiple IPv6 addresses at any given time. When you execute the command `show ipv6 neighbor binding mac mac_address`, these addresses display the state as REACHABLE in the IPv6 neighbor binding table for that client's MAC address. If there is no control activity on these addresses for 300 seconds, they move to STALE state and become unusable by the client thereafter.

The `ipv6 neighbor tracking` command is used to send periodic probes (default time period is 300 seconds) to all IPv6 clients to ensure that the client's IPv6 address(s) do not age out and move to STALE state. These probes are sent from the switch with a source IP address of all zeros which is a Duplicate address detection (DAD) probe.

There are a few clients which do not respond to DAD probes and hence age out after 300 seconds. Follow the steps below to configure IPv6 Neighbor Tracking.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ipv6 neighbor tracking [retry-interval value]`
4. `interface vlan vlan-id`
5. `ipv6 enable`
6. `exit`
7. `vlan configuration vlan_list`
8. `ipv6 snooping [attach-policy policy_name]`
9. `end`

**Configuring IPv6 ND Suppress Policy (CLI)**

The IPv6 neighbor discovery (ND) multicast suppress feature stops as many ND multicast neighbor solicit (NS) messages as possible by dropping them (and responding to solicitations on behalf of the targets) or
converting them into unicast traffic. This feature runs on a layer 2 switch or a wireless controller and is used to reduce the amount of control traffic necessary for proper link operations.

When an address is inserted into the binding table, an address resolution request sent to a multicast address is intercepted, and the device either responds on behalf of the address owner or, at layer 2, converts the request into a unicast message and forwards it to its destination.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ipv6 nd suppress policy

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

### Configuring IPv6 on Switch (CLI)

Use this configuration example to configure IPv6 on an interface.

**Before you begin**

Enable IPv6 on the client and IPv6 support on the wired infrastructure.

### Summary Steps

1. `interface vlan 1`
2. `ip address fe80::1 link-local`
3. `ipv6 enable`
4. `end`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> interface vlan 1</td>
<td>Creates a interface and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface vlan 1</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** ip address fe80::1 link-local | Configures IPv6 address on the interface using the link-local option. |
| **Example:**                        |                                                                         |
| Device(config-if)# ip address 198.51.100.1 255.255.255.0 |                                                                         |
| Device(config-if)# ipv6 address fe80::1 link-local |                                                                         |
| Device(config-if)# ipv6 address 2001:DB8:0:1:FFFF:1234::/64 |                                                                         |

| **Step 3** ipv6 enable | (Optional) Enables IPv6 on the interface. |
| **Example:**           |                                              |
| Device(config)# ipv6 enable |                                              |

| **Step 4** end | Exits from the interface mode. |
| **Example:** |                                              |
| Device(config)# end |                                              |

### Configuring DHCP Pool (CLI)

#### SUMMARY STEPS

1. ipv6 dhcp pool Vlan21
2. address prefix 2001:DB8:0:1:FFFF:1234::/64 lifetime 300 10
3. dns-server 2001:100:0:1::1
4. domain-name example.com
5. end

## Verifying IPv6 Address Learning Configuration

This example displays the output of the `show ipv6 dhcp pool` command. This command displays the IPv6 service configuration on the device. The `vlan 21 configured pool detail` displays 6 clients that are currently using addresses from the pool.

**SUMMARY STEPS**

1. `show ipv6 dhcp pool`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> show ipv6 dhcp pool</td>
<td>Displays the IPv6 service configuration on the device.</td>
</tr>
</tbody>
</table>

**Example:**

Device show ipv6 dhcp pool
DHCPv6 pool: vlan21
Address allocation prefix: 2001:DB8::0:1:FFFF:1234::/64 valid 86400 preferred
86400 (6 in use, 0 conflicts)
DNS server: 2001:100:0:1::1
Domain name: example.com
Active clients: 6

Configuring IPv6 WLAN Security

• Prerequisites for IPv6 WLAN Security, on page 239
• Restrictions for IPv6 WLAN Security, on page 239
• Information About IPv6 WLAN Security, on page 239
• How to Configure IPv6 WLAN Security, on page 242
• Additional References, on page 258
• Feature Information for IPv6 WLAN Security, on page 259

Prerequisites for IPv6 WLAN Security

A client VLAN must be mapped to the WLAN configured on the device.

Restrictions for IPv6 WLAN Security

RADIUS Server Support

• If multiple RADIUS servers are configured for redundancy, the user database must be identical in all the servers for the backup to work properly.

Radius ACS Support

• You must configure RADIUS on both your Cisco Secure Access Control Server (ACS) and your device.
• RADIUS is supported on Cisco Secure ACS version 3.2 and later releases.

Information About IPv6 WLAN Security

Information About RADIUS

Remote Authentication Dial-In User Service (RADIUS) is a client/server protocol that provides centralized security for users attempting to gain management access to a network. It serves as a back-end database similar to Local EAP and provides authentication and accounting services.
• Authentication—The process of verifying users when they attempt to log into the device

Users must enter a valid username and password for the device to authenticate users to the RADIUS server. If multiple databases are configured, then specify the sequence in which the backend database must be tried.

• Accounting—The process of recording user actions and changes.

Whenever a user successfully executes an action, the RADIUS accounting server logs the changed attributes, the user ID of the person who made the change, the remote host where the user is logged in, the date and time when the command was executed, the authorization level of the user, and a description of the action performed and the values provided. If the RADIUS accounting server is unreachable, the users can continue their sessions uninterrupted.

User Datagram Protocol—RADIUS uses User Datagram Protocol (UDP) for its transport. It maintains a database and listens on UDP port 1812 for incoming authentication requests and UDP port 1813 for incoming accounting requests. The device, which requires access control, acts as the client and requests AAA services from the server. The traffic between the device and the server is encrypted by an algorithm defined in the protocol and a shared secret key configured on both devices.

Configures multiple RADIUS accounting and authentication servers. For example, you can have one central RADIUS authentication server but several RADIUS accounting servers in different regions. If you configure multiple servers of the same type and the first one fails or becomes unreachable, the controller automatically tries the second one, then the third one if necessary, and so on.

When RADIUS method is configured for the WLAN, the device will use the RADIUS method configured for the WLAN. When the WLAN is configured to use local EAP, the RADIUS method configured on the WLAN points to Local. The WLAN must also be configured with the name of the local EAP profile to use.

If no RADIUS method is configured in the WLAN, the device will use the default RADIUS method defined in global mode.

Information About Local EAP

Local EAP is an authentication method that allows users and wireless clients to be authenticated locally. It is designed for use in remote offices that maintain connectivity to wireless clients when the back-end system is disrupted or the external authentication server goes down. When you enable local EAP, the device serves as the authentication server and the local user database, which removes dependence on an external authentication server. Local EAP retrieves user credentials from the local user database or the LDAP back-end database to authenticate users. Local EAP supports LEAP, EAP-FAST, EAP-TLS, PEAPv0/MSCHAPv2, and PEAPv1/GTC authentication between the controller and wireless clients.

Without an EAP profile name being provided, or if a name was provided for an EAP profile that does not exist, then EAP by default allows no EAP method for local authentication.

Note

The LDAP back-end database supports these local EAP methods: EAP-TLS, EAP-FAST/GTC, and PEAPv1/GTC. LEAP, EAP-FAST/MSCHAPv2, and PEAPv0. MSCHAPv2 is supported only if the LDAP server is set up to return a clear-text password.
Device support Local EAP authentication against external LDAP databases such as Microsoft Active Directory and Novell’s eDirectory. For more information about configuring the controller for Local EAP authentication against Novell’s eDirectory, see the Configure Unified Wireless Network for Authentication Against Novell's eDirectory Database whitepaper.

Configuring a EAP Profile

SUMMARY STEPS

1. `eap profile name`  
   Example:  
   `Device(config)# eap profile wcm_eap_prof`

2. `method leap`  
   Example:  
   `Device(config-eap-profile)# method leap`

3. `method tls`  
   Example:  
   `Device(config-eap-profile)# method tls`

4. `method peap`  
   Example:  
   `Device(config-eap-profile)# method peap`

5. `method mschav2`  
   Example:  
   `Device(config-eap-profile)# method mschav2`

6. `method md5`  
   Example:  
   `Device(config-eap-profile)# method md5`

7. `method gtc`  
   Example:  
   `Device(config-eap-profile)# method gtc`

8. `method fast profile my-fast`  
   Example:  
   `Device(config-eap-profile)# method fast profile my-fast`

9. `description my_local_eap_profile`  
   Example:  
   `Device(config-eap-profile)# description my_local_eap_profile`

10. `exit`  
    Example:  
    `Device(config)# exit`

11. `eap method fast profile myFast`  
    Example:  
    `Device(config-eap-profile)# eap method fast profile myFast`

12. `authority-id [identity|information]`  
    Example:  
    `Device(config-eap-profile)# authority-id [identity|information]`

13. `local-key 0 key-name`  
    Example:  
    `Device(config-eap-profile)# local-key 0 key-name`

14. `pap-password 0 password`  
    Example:  
    `Device(config-eap-profile)# pap-password 0 password`

15. `end`

### Creating WLAN for WPA2+AES

Create a WLAN and map it to the client VLAN created for WPA2+AES.

#### SUMMARY STEPS

1. `configure terminal`
2. `wlan wpas2-aes-wlan 1 wpas2-aes-wlan`
3. `client vlan 105`
4. `local-auth wcm_eap_profile`
5. `security dot1x authentication-list default`
6. `no shutdown`
7. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>

</tbody>
</table>
### Purpose

**Command or Action**

- `local-auth wcm_eap_profile`

**Example:**

```
Device(config-wlan)#local-auth wcm_eap_profile
```

**Purpose:** Creates and sets the EAP profile on the WLAN.

### Step 4

**Command or Action**

- `security dot1x authentication-list default`

**Example:**

```
Device(config-wlan)#security dot1x authentication-list default
```

**Purpose:** Uses the default dot1x authentication list.

### Step 5

**Command or Action**

- `no shutdown`

**Example:**

```
Device(config-wlan)#no shutdown
```

**Purpose:** Enables the WLAN.

### Step 6

**Command or Action**

- `end`

**Example:**

```
Device(config)# end
```

**Purpose:** Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

### Command or Action

#### Step 6
**security dot1x authentication-list wcm-rad**

**Example:**
```
Device(config-wlan)# security dot1x authentication-list wcm-rad
```

**Purpose:** Configures the server group mapping to the WLAN for dot1x authentication.

#### Step 7
**client vlan 137**

**Example:**
```
Device(config-wlan)# client vlan 137
```

**Purpose:** Associates the VLAN to a WLAN.

#### Step 8
**no shutdown**

**Example:**
```
Device(config-wlan)# no shutdown
```

**Purpose:** Enables the WLAN.

#### Step 9
**end**

**Example:**
```
Device(config)# end
```

**Purpose:** Returns to privileged EXEC mode. Alternatively, you can also press `Ctrl-Z` to exit the global configuration mode.

### Example
```
Device# configure terminal
Device(config)# wlan ngwc_8021x 2 ngwc_8021x
Device(config-wlan)# broadcast-ssid
Device(config-wlan)# no security wpa
Device(config-wlan)# security dot1x
Device(config-wlan)# security dot1x authentication-list wcm-rad
Device(config-wlan)# client vlan 137
Device(config-wlan)# no shutdown
Device(config-wlan)# end
```

Configuring IPv6 ACL

Prerequisites for IPv6 ACL

You can filter IP Version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP Version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic when the switch is running the IP base feature set.

Restrictions for IPv6 ACL

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs.

The device supports most of the Cisco IOS-supported IPv6 ACLs with some exceptions:

- The device does not support matching on these keywords: flowlabel, routing header, and undetermined-transport.
- The device does not support reflexive ACLs (the reflect keyword).
- The device does not apply MAC-based ACLs on IPv6 frames.
- When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the device checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.
• If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the device does not allow the ACE to be added to the ACL that is currently attached to the interface

Information About IPv6 ACL

An access control list (ACL) is a set of rules used to limit access to a particular interface (for example, if you want to restrict a wireless client from pinging the management interface of the controller). ACLs are configured on the device and applied to the management interface, the AP-manager interface, any of the dynamic interfaces, or a WLAN to control data traffic to and from wireless clients or to the controller central processing unit (CPU) to control all traffic destined for the CPU.

You can also create a preauthentication ACL for web authentication. Such an ACL is used to allow certain types of traffic before authentication is complete.

IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source and destination ports.

Note

You can enable only IPv4 traffic in your network by blocking IPv6 traffic. That is, you can configure an IPv6 ACL to deny all IPv6 traffic and apply it on specific or all WLANs.

Understanding IPv6 ACLs

A switch supports two types of IPv6 ACLs:

• IPv6 router ACLs are supported on outbound or inbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. IPv6 router ACLs apply only to IPv6 packets that are routed.

• IPv6 port ACLs are supported on inbound traffic on Layer 2 interfaces only. IPv6 port ACLs are applied to all IPv6 packets entering the interface.

A switch running the IP base feature set supports only input router IPv6 ACLs. It does not support port ACLs or output IPv6 router ACLs.

Note

If you configure unsupported IPv6 ACLs, an error message appears and the configuration does not take affect.

The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.

You can apply both IPv4 and IPv6 ACLs to an interface. As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs:

• When an input router ACL and input port ACL exist in an SVI, packets received on ports to which a port ACL is applied are filtered by the port ACL. Routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.

• When an output router ACL and input port ACL exist in an SVI, packets received on the ports to
which a port ACL is applied are filtered by the port ACL. Outgoing routed IPv6 packets are filtered by the router ACL. Other packets are not filtered.

---

**Note**

If any port ACL (IPv4, IPv6, or MAC) is applied to an interface, that port ACL is used to filter packets, and any router ACLs attached to the SVI of the port VLAN are ignored.

---

### Types of ACL

#### Per User IPv6 ACL

For the per-user ACL, the full access control entries (ACE) as the text strings are configured on the ACS. The ACE is not configured on the Controller. The ACE is sent to the device in the `ACCESS-Accept` attribute and applies it directly for the client. When a wireless client roams into an foreign device, the ACEs are sent to the foreign device as an AAA attribute in the mobility Handoff message. Output direction, using per-user ACL is not supported.

#### Filter ID IPv6 ACL

For the filter-Id ACL, the full ACEs and the `acl name(filter-id)` is configured on the device and only the `filter-id` is configured on the ACS. The `filter-id` is sent to the device in the `ACCESS-Accept` attribute, and the device looks up the filter-id for the ACEs, and then applies the ACEs to the client. When the client L2 roams to the foreign device, only the filter-id is sent to the foreign device in the mobility Handoff message. Output filtered ACL, using per-user ACL is not supported. The foreign device has to configure the filter-id and ACEs beforehand.

### IPv6 ACLs and Switch Stacks

The stack master supports IPv6 ACLs in hardware and distributes the IPv6 ACLs to the stack members.

---

**Note**

For full IPv6 functionality in a switch stack, all stack members must be running the IP services feature set.

If a new switch takes over as stack master, it distributes the ACL configuration to all stack members. The member switches sync up the configuration distributed by the new stack master and flush out entries that member switches sync up the configuration distributed by the new stack master and flush out entries that are not required.

When an ACL is modified, attached to, or detached from an interface, the stack master distributes the change to all stack members.

### Configuring IPv6 ACLs

To filter IPv6 traffic, you perform these steps:
Before you begin

Before configuring IPv6 ACLs, you must select one of the dual IPv4 and IPv6 SDM templates.

SUMMARY STEPS

1. Create an IPv6 ACL, and enter IPv6 access list configuration mode.
2. Configure the IPv6 ACL to block (deny) or pass (permit) traffic.
3. Apply the IPv6 ACL to the interface where the traffic needs to be filtered.
4. Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied.

</tr>
</tbody>
</table>

Default IPv6 ACL Configuration

There are no IPv6 ACLs configured or applied.

Interaction with Other Features and Switches

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.
- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.
- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.
- If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.
How To Configure an IPv6 ACL

Creating IPv6 ACL

Beginning in privileged EXEC mode, follow these steps to create an IPv6 ACL:

**SUMMARY STEPS**

1. `configure terminal`
2. `ipv6 access-list acl_name`
3. `{deny|permit} protocol`
4. `{deny|permit} tcp`
5. `{deny|permit} udp`
6. `{deny|permit} icmp`
7. `end`
8. `show ipv6 access-list`
9. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ipv6 access-list acl_name</td>
<td>Use a name to define an IPv6 access list and enter IPv6 access-list configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>ipv6 access-list access-list-name</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> {deny</td>
<td>permit} protocol</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>{deny</td>
<td>permit} protocol</td>
</tr>
<tr>
<td>{source-ipv6-prefix/prefix-length</td>
<td>any</td>
</tr>
<tr>
<td>[operator] [port-number]]{destination-ipv6-prefix/prefix-length</td>
<td>any</td>
</tr>
<tr>
<td></td>
<td>[dscp value]</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Enter any as an abbreviation for the IPv6 prefix ::/0.</td>
<td></td>
</tr>
<tr>
<td>For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons.</td>
<td></td>
</tr>
<tr>
<td>(Optional) For operator, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range.</td>
<td></td>
</tr>
</tbody>
</table>

If the operator follows the source-ipv6-prefix/prefix-length argument, it must match the source port. If the operator follows the destination-ipv6-prefix/prefix-length argument, it must match the destination port.

| (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP. |
| (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63. |
| (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6. |
| (Optional) Enter log to cause a logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs. |
| (Optional) Enter routing to specify that IPv6 packets be routed. |
| (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295 |
| (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement. |
### Purpose

#### Command or Action

| Step 4 | {deny|permit} tcp |
|--------|------------------|
| **Example:** | {deny | permit} tcp {source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address} [ack | dscp value] [established] [fin] [log] [log-input] [neq {port | protocol}] [psh] [range {port | protocol}] [rst] [routing] [sequence value] [syn] [time-range name] [urg] |

(Optional) Define a TCP access list and the access conditions.

Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:

- **ack**—Acknowledgment bit set.
- **established**—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set.
- **fin**—Finished bit set; no more data from sender.
- **neq {port | protocol}**—Matches only packets that are not on a given port number.
- **psh**—Push function bit set.
- **range {port | protocol}**—Matches only packets in the port number range.
- **rst**—Reset bit set.
- **syn**—Synchronize bit set.
- **urg**—Urgent pointer bit set.

| Step 5 | {deny|permit} udp |
|--------|------------------|
| **Example:** | {deny | permit} udp {source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address} [ack | dscp value] [log] [log-input] [neq {port | protocol}] [psh] [range {port | protocol}] [routing] [sequence value] [time-range name] |

(Optional) Define a UDP access list and the access conditions.

Enter udp for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the operator [port] port number or name must be a UDP port number or name, and the established parameter is not valid for UDP.

| Step 6 | {deny|permit} icmp |
|--------|------------------|
| **Example:** | {deny | permit} icmp {source-ipv6-prefix/prefix-length | any | hostsource-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | hostdestination-ipv6-address} [ack | dscp value] [log] [log-input] [neq {port | protocol}] [psh] [range {port | protocol}] [routing] [sequence value] [time-range name] |

(Optional) Define an ICMP access list and the access conditions.

Enter icmp for Internet Control Message Protocol. The ICMP parameters are the same as those described for most IP protocols in Step 3a, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:

- **icmp-type**—Enter to filter by ICMP message type, a number from 0 to 255.
Applying an IPv6 to an Interface

This section describes how to apply IPv6 ACLs to network interfaces. You can apply an IPv6 ACL to outbound or inbound traffic on layer 2 and Layer 3 interfaces. You can apply IPv6 ACLs only to inbound management traffic on Layer 3 interfaces.

Beginning in privileged EXEC mode, follow these steps to control access to an interface:

SUMMARY STEPS

1. configure terminal
2. interface interface_id
3. no switchport
4. ipv6 address ipv6_address
5. ipv6 traffic-filter acl_name
6. end
7. show running-config interface tenGigabitEthernet 1/0/3
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>

</tbody>
</table>
Creating WLAN IPv6 ACL

SUMMARY STEPS

1. ipv6 traffic-filter acl acl_name
2. ipv6 traffic-filter acl web

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> ipv6 traffic-filter acl acl_name</td>
<td>Creates a named WLAN ACL.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-wlan)# ipv6 traffic-filter acl</td>
<td></td>
</tr>
<tr>
<td>&lt;acl_name&gt;</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** ipv6 traffic-filter acl web             | Creates a pre-authentication for WLAN ACL.   |
| Example:                                         |                                              |
| Device(config-wlan)# ipv6 traffic-filter acl web   |                                              |
| <acl_name-preauth>                                |                                              |

Verifying IPv6 ACL

Displaying IPv6 ACLs

You can display information about all configured access lists, all IPv6 access lists, or a specific access list by using one or more of the privileged EXEC commands.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> show access-list</td>
<td>Displays all access lists configured on the device</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show access-list</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** show ipv6 access-list acl_name         | Displays all configured IPv6 access list or the access list specified by name. |
| Example:                                         |                                              |
| Device# show ipv6 access-list [access-list-name] |                                              |
Configuration Examples for IPv6 ACL

Example: Creating IPv6 ACL

This example configures the IPv6 access list named CISCO. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny-all condition is at the end of each IPv6 access list.

Note: Logging is supported only on Layer 3 interfaces.

```
Device(config)# ipv6 access-list CISCO
Device(config-ipv6-acl)# deny tcp any any gt 5000
Device(config-ipv6-acl)# deny ::/0 lt 5000 ::/0 log
Device(config-ipv6-acl)# permit icmp any any
Device(config-ipv6-acl)# permit any any
```

Example: Applying IPv6 ACLs

This example shows how to apply the access list Cisco to outbound traffic on a Layer 3 interface.

```
Device(config)# interface TenGigabitEthernet 1/0/3
Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001::/64 eui-64
Device(config-if)# ipv6 traffic-filter CISCO out
```

Example: Displaying IPv6 ACLs

This is an example of the output from the `show access-lists` privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

```
Device #show access-lists
Extended IP access list hello
  10 permit ip any any
IPv6 access list ipv6
  permit ipv6 any any sequence 10

This is an example of the output from the show ipv6 access-lists privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.
```

```
Device# show ipv6 access-list
IPv6 access list inbound
  permit tcp any any eq bgp (8 matches) sequence 10
  permit tcp any any eq telnet (15 matches) sequence 20
  permit udp any any sequence 30

IPv6 access list outbound
  deny udp any any sequence 10
  deny tcp any any eq telnet sequence 20
```
Example: Configuring RA Throttling and NS Suppression

This task describes how to create an RA throttle policy in order to help the power-saving wireless clients from being disturbed by frequent unsolicited periodic RA's. The unsolicited multicast RA is throttled by the controller.

**Before you begin**

Enable IPv6 on the client machine.

**SUMMARY STEPS**

1. configure terminal
2. ipv6 nd ra-throttler policy Mythrottle
3. throttle-period 20
4. max-through 5
5. allow at-least 3 at-most 5
6. switch (config)# vlan configuration 100
7. ipv6 nd suppress
8. ipv6 nd ra-th attach-policy attach-policy_name
9. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>ipv6 nd ra-throttler policy Mythrottle</td>
<td>Creates a RA throttler policy called Mythrottle.</td>
</tr>
<tr>
<td>Example: Device (config)# ipv6 nd ra-throttler policy Mythrottle</td>
<td></td>
</tr>
<tr>
<td>throttle-period 20</td>
<td>Determines the time interval segment during which throttling applies.</td>
</tr>
<tr>
<td>Example: Device (config-nd-ra-throttle)# throttle-period 20</td>
<td></td>
</tr>
<tr>
<td>max-through 5</td>
<td>Determines how many initial RA's are allowed.</td>
</tr>
<tr>
<td>Example: Device (config-nd-ra-throttle)# max-through 5</td>
<td></td>
</tr>
<tr>
<td>allow at-least 3 at-most 5</td>
<td>Determines how many RA's are allowed after the initial RAs have been transmitted, until the end of the interval segment.</td>
</tr>
<tr>

</tbody>
</table>
### Purpose

#### Command or Action

**Step 3**

**device-role router**

**Example:**

Device (config-nd-raguard)# device-role [host|monitor|router|switch]
Device (config-nd-raguard)# device-role router

**Purpose:**

Defines the trusted device that can send RAs to the trusted port created above.

---

**Step 4**

**interface tenGigabitEthernet 1/0/1**

**Example:**

Device (config)# interface tenGigabitEthernet 1/0/1

**Purpose:**

Configures the interface to the trusted device.

---

**Step 5**

**ipv6 nd raguard attach-policy MyPolicy**

**Example:**

Device (config-if)# ipv6 nd raguard attach-policy MyPolicy

**Purpose:**

Configures and attaches the policy to trust the RA’s received from the port.

---

**Step 6**

**vlan configuration 19-21, 23**

**Example:**

Device (config)# vlan configuration 19-21, 23

**Purpose:**

Configures the wireless client vlans.

---

**Step 7**

**ipv6 nd suppress**

**Example:**

Device (config-vlan-config)# ipv6 nd suppress

**Purpose:**

Suppresses the ND messages over wireless.

---

**Step 8**

**ipv6 snooping**

**Example:**

Device (config-vlan-config)# ipv6 snooping

**Purpose:**

Captures IPv6 traffic.

---

**Step 9**

**ipv6 nd raguard attach-policy MyPolicy**

**Example:**

Device (config-vlan-config)# ipv6 nd raguard attach-policy MyPolicy

**Purpose:**

Attaches the RA Guard policy to the wireless client vlans.

---

**Step 10**

**ipv6 nd ra-throttler attach-policy Mythrottle**

**Example:**

Device (config-vlan-config)# ipv6 nd ra-throttler attach-policy Mythrottle

**Purpose:**

Attaches the RA throttling policy to the wireless client vlans.

---

### Example: Configuring IPv6 Neighbor Binding

#### SUMMARY STEPS

1. ipv6 neighbor binding [vlan] 19 2001::db8::25:4  interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> ipv6 neighbor binding [vlan] 19 2001:db8::25:4 interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc</td>
<td>Sets and validates the neighbor 2001:db8::25:4 only valid when transmitting on VLAN 19 through interface te1/0/3 with the source mac-address as aaa.bbb.ccc.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device (config)# ipv6 neighbor binding vlan 19 2001:db8::25:4 interface tenGigabitEthernet 1/0/3 aaa.bbb.ccc
```

CHAPTER 18

Configuring IPv6 Web Authentication

- Prerequisites for IPv6 Web Authentication, on page 277
- Restrictions for IPv6 Web Authentication, on page 277
- Information About IPv6 Web Authentication, on page 278
- How to Configure IPv6 Web Authentication, on page 279
- Verifying IPv6 Web Authentication, on page 284
- Additional References, on page 286
- Feature Information for IPv6 Web Authentication, on page 287

Prerequisites for IPv6 Web Authentication

The following configurations must be in place before you start with IPv6 Web Authentication:

- IPv6 Device Tracking.
- IPv6 DHCP Snooping.
- Disable security of type 802.1x on the wlan.
- Each WLAN must have a vlan associated to it.
- Change the default wlan setting from shutdown to no shutdown.

Related Topics
- Enabling Security on the WLAN, on page 280

Restrictions for IPv6 Web Authentication

The following restrictions are implied when using IPv6 web authentication:

Related Topics
- Enabling Security on the WLAN, on page 280
Information About IPv6 Web Authentication

Web authentication is a Layer 3 security feature and the device disallows IP traffic (except DHCP and DNS-related packets) from a particular client until it supplies a valid username and password. It is a simple authentication method without the need for a supplicant or client utility. Web authentication is typically used by customers who deploy a guest-access network. Traffic from both, HTTP and HTTPS, page is allowed to display the login page.

Note
Web authentication does not provide data encryption and is typically used as simple guest access for either a hot spot or campus atmosphere, where connectivity is always a factor.

A WLAN is configured as security weauth for web based authentication. The device supports the following types of web based authentication:

- **Web Authentication** – The client enters the credentials in a web page which is then validated by the Wlan controller.
- **Web Consent** – The Wlan controller presents a policy page with Accept/Deny buttons. Click Accept button to access the network.

Note
Maximum consecutive Web Auth sessions supported in device is 40 per second.

A Wlan is typically configured for open authentication, that is without Layer 2 authentication, when web-based authentication mechanism is used.

Web Authentication Process

The following events occur when a WLAN is configured for web authentication:

- The user opens a web browser and enters a URL address, for example, http://www.example.com. The client sends out a DNS request for this URL to get the IP address for the destination. The device bypasses the DNS request to the DNS server, which in turn responds with a DNS reply that contains the IP address of the destination www.example.com. This, in turn, is forwarded to the wireless clients.

- The client then tries to open a TCP connection with the destination IP address. It sends out a TCP SYN packet destined to the IP address of www.example.com.

- The device has rules configured for the client and cannot act as a proxy for www.example.com. It sends back a TCP SYN-ACK packet to the client with source as the IP address of www.example.com. The client sends back a TCP ACK packet in order to complete the three-way TCP handshake and the TCP connection is fully established.

- The client sends an HTTP GET packet destined to www.example.com. The device intercepts this packet and sends it for redirection handling. The HTTP application gateway prepares an HTML body and sends it back as the reply to the HTTP GET requested by the client. This HTML makes the client go to the default web-page of the device, for example, http://<Virtual-Server-IP>/login.html.

- The client closes the TCP connection with the IP address, for example, www.example.com.
• If the client wants to go to virtual IP, the client tries to open a TCP connection with the virtual IP address of the device. It sends a TCP SYN packet for virtual IP to the device.

• The device responds back with a TCP SYN-ACK and the client sends back a TCP ACK to the device in order to complete the handshake.

• The client sends an HTTP GET for /login.html destined to virtual IP in order to request for the login page.

• This request is allowed to the web server of the device, and the server responds with the default login page. The client receives the login page in the browser window where the user can log in.

<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 Web Authentication Functionality</td>
<td>Cisco IOS XE 3.2SE</td>
<td>This feature was introduced.</td>
</tr>
</tbody>
</table>
Prerequisites for IPv6 Client Mobility

To enable wireless IPv6 client connectivity, the underlying wired network must support IPv6 routing and an address assignment mechanism such as SLAAC or DHCPv6. The device must have L2 adjacency to the IPv6 router, and the VLAN needs to be tagged when the packets enter the device. APs do not require connectivity on an IPv6 network, as all traffic is encapsulated inside the IPv4 CAPWAP tunnel between the AP and device.

Restrictions For IPv6 Client Mobility

- When using the IPv6 Client Mobility, clients must support IPv6 with either static stateless auto configuration (such as Windows XP clients) or stateful DHCPv6 IP addressing (such as Windows 7 clients).
- To allow smooth operation of stateful DHCPv6 IP addressing, you must have a switch or router that supports the DHCP for IPv6 feature (such as the device) that is configured to act like a DHCPv6 server, or you need a dedicated server such as a Windows 2008 server with a built-in DHCPv6 server. Cisco Catalyst 3850 switch and Cisco Catalyst 5700 switch can act as (internal) a DHCPv6 server.

Note

To load the SDM IPv6 template in the Cisco Catalyst 3850 switch, enter the `sdm prefer dual-ipv4 and v6` default command and then reset the switch.
Information About IPv6 Client Mobility

The Device supports IPv6 mobility for IPv6-only or dual-stack nodes. The IPv6 Client Mobility is divided into:

- Link Layer and
- Network Layer

The link layer is handled by the 802.11 protocol which enables the client to roam to any AP in the same BSS (basic service set) identified by the same SSID without losing the link layer connectivity.

However, link layer mobility is not enough to make wireless client Layer 3 applications continue to work seamlessly while roaming. Cisco IOSd’s wireless mobility module uses mobility tunneling to retain seamless connectivity for the client’s Layer 3 PoP (point of presence) when the client roams across different subnets on different switches.

IPv6 is the next-generation network layer Internet protocol intended to replace IPv4 in the TCP/IP suite of protocols. This new version increases the internet global address space to accommodate users and applications that require unique global IP addresses. IPv6 incorporates 128-bit source and destination addresses, which provide significantly more addresses than the 32-bit IPv4 addresses.

To support IPv6 clients across controllers, ICMPv6 messages must be dealt with specially to ensure the IPv6 client remains on the same Layer 3 network. The device keep track of IPv6 clients by intercepting the ICMPv6 messages to provide seamless mobility and protect the network from network attacks. The NDP (neighbor discovery packets) packets are converted from multicast to unicast and delivered individually per client. This unique solution ensures that Neighbor Discovery and Router Advertisement packets are not leaked across Vlans. Clients can receive specific Neighbor Discovery and Router Advertisement packets ensuring correct IPv6 addressing and avoids unnecessary multicast traffic.

The configuration for IPv6 mobility is the same as IPv4 mobility and requires no separate software on the client side to achieve seamless roaming. The device must be part of the same mobility group. Both IPv4 and IPv6 client mobility are enabled by default.

IPv6 client mobility is used for the following:

- Retaining the client IPv6 multiple addresses in Layer-2 and Layer-3 roaming.
- IPv6 Neighbor Discovery Protocol (NDP) packet management.
- Client IPv6 addresses learning.

Using Router Advertisement

The Neighbor Discovery Protocol (NDP) operates in the link-layer and is responsible for the discovery of other nodes on the link. It determines the link-layer addresses of other nodes, finds the available routers, and maintains reachability information about the paths to other active neighbor nodes.

Router Advertisement (RA) is one of the IPv6 Neighbor Discovery Protocol (NDP) packets that is used by the hosts to discover available routers, acquire the network prefix to generate the IPv6 addresses, link MTU, and so on. The routers send RA on a regular basis, or in response to hosts Router Solicitation messages.
IPv6 wireless client mobility manages the IPv6 RA packet. The converged access device forwards the link-local all-nodes multicast RA packets to the local and roaming wireless nodes mapped on same VLAN the RA was received on.

Figure 1 illustrates the link-local all-nodes mcast RA forwarding issue in the wireless node mobility.

*Figure 1: Roaming Client Receiving Invalid RA from Router 2*

Figure 2 illustrates how a roaming client “MN” receives RA from VLAN 200 in a foreign switch and how it acquires a new IP address and breaks into L3 mobility’s point of presence.

*Figure 12: Roaming Client Receives Valid RA from Router 1*

**RA Throttling and NS suppression**

To safeguard the power-saving wireless clients from being disturbed by frequent unsolicited periodic RAs, the controller can throttle the unsolicited multicast RA.

**Related Topics**
- Verifying IPv6 Client Mobility, on page 293
- Monitoring IPv6 Client Mobility, on page 293
IPv6 Address Learning

There are three ways for IPv6 client to acquire IPv6 addresses:

- Stateless Address Auto-Configuration (SLAAC)
- Stateful DHCPv6
- Static configuration

For these methods, the IPv6 client always sends NS DAD (duplicate address detection) to ensure that there is no duplicated IP address on the network. The device snoops the clients NDP and DHCPv6 packets to learn about its client IP addresses and then updates the controllers database. The database then informs the controller for the clients new IP address.

Related Topics
- Verifying IPv6 Client Mobility, on page 293
- Monitoring IPv6 Client Mobility, on page 293

Handling Multiple IP Addresses

In the case when the new IP address is received after RUN state, whether an addition or removal, the controller updates the new IP addresses on its local database for display purposes. Essentially, the IPv6 uses the existing or same PEM state machine code flow as in IPv4. When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller will include all the available IP addresses, IPv4 and IPv6, in the API/SPI interface to the external entities.

An IPv6 client can acquire multiple IP addresses from stack for different purposes. For example, a link-local address for link local traffic, and a routable unique local or global address.

When the client is in the DHCP request state and the controller receives the first IP address notification from the database for either an IPv4 or IPv6 address, the PEM moves the client into the RUN state.

When a new IP address is received after the RUN state, either for addition or removal, the controller updates the new IP addresses on its local database for display purposes.

When the IP addresses are requested by external entities, for example, from Prime Infrastructure, the controller provides the available IP addresses, both IPv4 and IPv6, to the external entities.

Related Topics
- Verifying IPv6 Client Mobility, on page 293
- Monitoring IPv6 Client Mobility, on page 293

IPv6 Configuration

The device supports IPv6 client as seamlessly as the IPv4 clients. The administrator must manually configure the VLans to enable the IPV6, IPv6’s snooping and throttling functionality. This will enable the NDP packets to throttle between the device and its various clients.

Related Topics
- Verifying IPv6 Client Mobility, on page 293
- Monitoring IPv6 Client Mobility, on page 293
High Availability

The switch will sync with the wireless clients when the clients IP address is hard to learn. When a switchover happens, the IPv6 neighbor binding table is synced to standby state. However, the wireless client will itself disassociate and reassociate to a new active state once the switchover is complete and the neighbor binding table is updated with latest information for that client.

If, during the reassociation, the client moves to another AP then the original entry in the binding table is marked as down for sometime and will be aged-out.

For the new entries joining the switch from another AP, the new IP address is learned and notified to the controller's database.

---

**Note**

This feature is available only for the Cisco Catalyst 3850 Switch.

Pre-requisites for IPv6 Mobility

The mobility and its related infrastructure must be configured and ready for use.

Information About IPv6 Mobility

Mobility, or roaming, is a wireless LAN client's ability to maintain its association seamlessly from one access point to another securely and with as little latency as possible. This section explains how mobility works when device are included in a wireless network.

When a wireless client associates and authenticates to an access point, the access point's device places an entry for that client in its client database. This entry includes the client's MAC and IP addresses, security context and associations, quality of service (QoS) contexts, the WLAN, and the associated access point. The device uses this information to forward frames and manage traffic to and from the wireless client.

When the wireless client moves its association from one access point to another, the device simply updates the client database with the newly associated access point. If necessary, new security context and associations are established as well. The process becomes more complicated, however, when a client roams from an access point joined to one device to an access point joined to a different device. It also varies based on whether the device are operating on the same subnet.

Inter Controller Roaming

When the client associates to an access point joined to a new device, the new device exchanges mobility messages with the original device, and the client database entry is moved to the new device if sticky anchoring is disabled.
Intra Subnet Roaming with Sticky Anchoring, and Inter Subnet Roaming

Inter-subnet roaming is similar to inter-controller roaming in that the device exchange mobility messages on the client roam. However, instead of moving the client database entry to the new device, the original device marks the client with an "Anchor" entry in its own client database. The database entry is copied to the new device client database and marked with a "Foreign" entry in the new device. The roam remains transparent to the wireless client, and the client maintains its original IP address.

In inter-subnet roaming, WLANs on both anchor and foreign device need to have the same network access privileges and no source-based routing or source-based firewalls in place. Otherwise, the clients may have network connectivity issues after the handoff.

For more information on configuring mobility see, the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE, Release 3.2SE.

How to Configure IPv6 Mobility

Monitoring IPv6 Mobility

This chapter displays the mobility related IPv6 configuration. To see the mobility related configurations refer to the Cisco 5700 Wireless LAN Controller Mobility Configuration Guide, Cisco IOS XE 3.2SE.

SUMMARY STEPS

CHAPTER 21

Configuring HSRP

• Configuring HSRP, on page 305

Configuring HSRP

This chapter describes how to use Hot Standby Router Protocol (HSRP) to provide routing redundancy for routing IP traffic without being dependent on the availability of any single router.

You can also use a version of HSRP in Layer 2 mode to configure a redundant command switch to take over cluster management if the cluster command switch fails.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring HSRP

HSRP Overview

HSRP is Cisco’s standard method of providing high network availability by providing first-hop redundancy for IP hosts on an IEEE 802 LAN configured with a default gateway IP address. HSRP routes IP traffic without relying on the availability of any single router. It enables a set of router interfaces to work together to present the appearance of a single virtual router or default gateway to the hosts on a LAN. When HSRP is configured on a network or segment, it provides a virtual Media Access Control (MAC) address and an IP address that is shared among a group of configured routers. HSRP allows two or more HSRP-configured routers to use the MAC address and IP network address of a virtual router. The virtual router does not exist; it represents the common target for routers that are configured to provide backup to each other. One of the routers is selected to be the active router and another to be the standby router, which assumes control of the group MAC address and IP address should the designated active router fail.
Routers in an HSRP group can be any router interface that supports HSRP, including routed ports and switch virtual interfaces (SVIs).

Note

HSRP provides high network availability by providing redundancy for IP traffic from hosts on networks. In a group of router interfaces, the active router is the router of choice for routing packets; the standby router is the router that takes over the routing duties when an active router fails or when preset conditions are met.

HSRP is useful for hosts that do not support a router discovery protocol and cannot switch to a new router when their selected router reloads or loses power. When HSRP is configured on a network segment, it provides a virtual MAC address and an IP address that is shared among router interfaces in a group of router interfaces running HSRP. The router selected by the protocol to be the active router receives and routes packets destined for the group’s MAC address. For n routers running HSRP, there are n + 1 IP and MAC addresses assigned.

HSRP detects when the designated active router fails, and a selected standby router assumes control of the Hot Standby group’s MAC and IP addresses. A new standby router is also selected at that time. Devices running HSRP send and receive multicast UDP-based hello packets to detect router failure and to designate active and standby routers. When HSRP is configured on an interface, Internet Control Message Protocol (ICMP) redirect messages are automatically enabled for the interface.

You can configure multiple Hot Standby groups among switches and switch stacks that are operating in Layer 3 to make more use of the redundant routers. To do so, specify a group number for each Hot Standby command group you configure for an interface. For example, you might configure an interface on switch 1 as an active router and one on switch 2 as a standby router and also configure another interface on switch 2 as an active router with another interface on switch 1 as its standby router.

The following figure shows a segment of a network configured for HSRP. Each router is configured with the MAC address and IP network address of the virtual router. Instead of configuring hosts on the network with the IP address of Router A, you configure them with the IP address of the virtual router as their default router. When Host C sends packets to Host B, it sends them to the MAC address of the virtual router. If for any reason, Router A stops transferring packets, Router B responds to the virtual IP address and virtual MAC address and becomes the active router, assuming the active router duties. Host C continues to use the IP address of the virtual router to address packets destined for Host B, which Router B now receives and sends to Host B. Until Router A resumes operation, HSRP allows Router B to provide uninterrupted service to users on Host C’s segment that need to communicate with users on Host B’s segment and also continues to perform its normal function of handling packets between the Host A segment and Host B.
You can configure multiple Hot Standby groups among switches and switch stacks that are operating in Layer 3 to make more use of the redundant routers. To do so, specify a group number for each Hot Standby command group you configure for an interface. For example, you might configure an interface on switch 1 as an active router and one on switch 2 as a standby router and also configure another interface on switch 2 as an active router with another interface on switch 1 as its standby router.

**HSRP Versions**

Cisco IOS XE Release 3.3SE and later support these Hot Standby Router Protocol (HSRP) versions:

The switch supports these HSRP versions:

- **HSRPv1** - Version 1 of the HSRP, the default version of HSRP. It has these features:
  - The HSRP group number can be from 0 to 255.
  - HSRPv1 uses the multicast address 224.0.0.2 to send hello packets, which can conflict with Cisco Group Management Protocol (CGMP) leave processing. You cannot enable HSRPv1 and CGMP at the same time; they are mutually exclusive.

- **HSRPv2** - Version 2 of the HSRP has these features:
  - HSRPv2 uses the multicast address 224.0.0.102 to send hello packets. HSRPv2 and CGMP leave processing are no longer mutually exclusive, and both can be enabled at the same time.
  - HSRPv2 has a different packet format than HSRPv1.
  - The HSRP group number can be from 0 to 4095.

A switch running HSRPv1 cannot identify the physical router that sent a hello packet because the source MAC address of the router is the virtual MAC address.
HSRPv2 has a different packet format than HSRPv1. A HSRPv2 packet uses the type-length-value (TLV) format and has a 6-byte identifier field with the MAC address of the physical router that sent the packet. If an interface running HSRPv1 gets an HSRPv2 packet, the type field is ignored.

**Multiple HSRP**

The switch supports Multiple HSRP (MHSRP), an extension of HSRP that allows load sharing between two or more HSRP groups. You can configure MHSRP to achieve load-balancing and to use two or more standby groups (and paths) from a host network to a server network.

In the figure below, half the clients are configured for Router A, and half the clients are configured for Router B. Together, the configuration for Routers A and B establishes two HSRP groups. For group 1, Router A is the default active router because it has the assigned highest priority, and Router B is the standby router. For group 2, Router B is the default active router because it has the assigned highest priority, and Router A is the standby router. During normal operation, the two routers share the IP traffic load. When either router becomes unavailable, the other router becomes active and assumes the packet-transfer functions of the router that is unavailable.

---

**Note**

For MHSRP, you need to enter the `standby preempt` interface configuration command on the HSRP interfaces so that if a router fails and then comes back up, preemption restores load sharing.

---

**Figure 14: MSHRP Load Sharing**

---

**SSO HSRP**

SSO HSRP alters the behavior of HSRP when a device with redundant Route Processors (RPs) is configured for stateful switchover (SSO) redundancy mode. When an RP is active and the other RP is standby, SSO enables the standby RP to take over if the active RP fails.

With this functionality, HSRP SSO information is synchronized to the standby RP, allowing traffic that is sent using the HSRP virtual IP address to be continuously forwarded during a switchover without a loss of data or a path change. Additionally, if both RPs fail on the active HSRP device, then the standby HSRP device takes over as the active HSRP device.
The feature is enabled by default when the redundancy mode of operation is set to SSO.

**HSRP and Switch Stacks**

HSRP hello messages are generated by the stack master. If an HSRP-active stack master fails, a flap in the HSRP active state might occur. This is because HSRP hello messages are not generated while a new stack master is elected and initialized, and the standby router might become active after the stack master fails.

**Configuring HSRP for IPv6**

Switches running the IP Services and IP Base feature set support the Hot Standby Router Protocol (HSRP) for IPv6. HSRP provides routing redundancy for routing IPv6 traffic not dependent on the availability of any single router. IPv6 hosts learn of available routers through IPv6 neighbor discovery router advertisement messages. These messages are multicast periodically or are solicited by hosts.

An HSRP IPv6 group has a virtual MAC address that is derived from the HSRP group number and a virtual IPv6 link-local address that is, by default, derived from the HSRP virtual MAC address.

Periodic messages are sent for the HSRP virtual IPv6 link-local address when the HSRP group is active. These messages stop after a final one is sent when the group leaves the active state.

---

**How to Configure HSRP**

</tr>
</tbody>
</table>
**HSRP Configuration Guidelines**

- HSRPv2 and HSRPv1 are mutually exclusive. HSRPv2 is not interoperable with HSRPv1 on an interface and the reverse.

- In the procedures, the specified interface must be one of these Layer 3 interfaces:
  - Routed port: A physical port configured as a Layer 3 port by entering the `no switchport` command in interface configuration mode.
  - SVI: A VLAN interface created by using the `interface vlan vlan_id` in global configuration mode, and by default a Layer 3 interface.
  - Etherchannel port channel in Layer 3 mode: A port-channel logical interface created by using the `interface port-channel port-channel-number` in global configuration mode, and binding the Ethernet interface into the channel group.

- All Layer 3 interfaces must have IP addresses assigned to them.

- If you change the HSRP version on an interface, each HSRP group resets because it now has a new virtual MAC address.

- Only on mixed stacks of Catalyst switches:
  - HSRP for IPv4 and HSRP for IPv6 are mutually exclusive. You cannot enable both at the same time.
  - When configuring group numbers for HSRPv2 and HSRP, you must use group numbers in ranges that are multiples of 256. Valid ranges are 0 to 255, 256 to 511, 512 to 767, 3840 to 4095, and so on.

- Examples of valid and invalid group numbers:
  - If you configure groups with the numbers 2, 150, and 225, you cannot configure another group with the number 3850. It is not in the range of 0 to 255.
  - If you configure groups with the numbers 520, 600, and 700, you cannot configure another group with the number 900. It is not in the range of 512 to 767.

---

**Note**

HSRP millisecond timers are not supported.

---

**Enabling HSRP**

The `standby ip` interface configuration command activates HSRP on the configured interface. If an IP address is specified, that address is used as the designated address for the Hot Standby group. If no IP address is specified, the address is learned through the standby function. You must configure at least one Layer 3 port on the LAN with the designated address. Configuring an IP address always overrides another designated address currently in use.

When the `standby ip` command is enabled on an interface and proxy ARP is enabled, if the interface's Hot Standby state is active, proxy ARP requests are answered using the Hot Standby group MAC address. If the interface is in a different state, proxy ARP responses are suppressed.
SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `standby version { 1 | 2 }
4. `standby [group-number] ip [ip-address [secondary]]`
5. `end`
6. `show standby [interface-id [group]]`
7. `copy running-config startup-config`

<td></td>
</tr>
</tbody>
</table>

- **Optional** group-number- The group number on the interface for which HSRP is being enabled. The range is 0 to 255; the default is 0. If there is only one HSRP group, you do not need to enter a group number.
- **(Optional on all but one interface) ip-address-** The virtual IP address of the hot standby router interface. You must enter the virtual IP address for at least one of the interfaces; it can be learned on the other interfaces.
- **(Optional) secondary-** The IP address is a secondary hot standby router interface. If neither router is designated as a secondary or standby router and no priorities are set, the primary IP addresses are compared and the higher IP address is the active router, with the next highest as the standby router.
### Configuring HSRP Priority

The **standby priority**, **standby preempt**, and **standby track** interface configuration commands are all used to set characteristics for finding active and standby routers and behavior regarding when a new active router takes over.

When configuring HSRP priority, follow these guidelines:

- Assigning a priority allows you to select the active and standby routers. If preemption is enabled, the router with the highest priority becomes the active router. If priorities are equal, the current active router does not change.
- The highest number (1 to 255) represents the highest priority (most likely to become the active router).
- When setting the priority, preempt, or both, you must specify at least one keyword (**priority**, **preempt**, or both)
- The priority of the device can change dynamically if an interface is configured with the **standby track** command and another interface on the router goes down.
- The **standby track** interface configuration command ties the router hot standby priority to the availability of its interfaces and is useful for tracking interfaces that are not configured for HSRP. When a tracked interface fails, the hot standby priority on the device on which tracking has been configured decreases by 10. If an interface is not tracked, its state changes do not affect the hot standby priority of the configured device. For each interface configured for hot standby, you can configure a separate list of interfaces to be tracked.
- The **standby track interface-priority** interface configuration command specifies how much to decrement the hot standby priority when a tracked interface goes down. When the interface comes back up, the priority is incremented by the same amount.
- When multiple tracked interfaces are down and **interface-priority** values have been configured, the configured priority decrements are cumulative. If tracked interfaces that were not configured with priority values fail, the default decrement is 10, and it is noncumulative.
- When routing is first enabled for the interface, it does not have a complete routing table. If it is configured to preempt, it becomes the active router, even though it is unable to provide adequate routing services. To solve this problem, configure a delay time to allow the router to update its routing table.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP priority characteristics on an interface:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Returns to privileged EXEC mode</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch(config-if)# end</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>show standby [interface-id [group]]</td>
<td>Verifies the configuration of the standby groups.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch # show standby</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td>Switch# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. standby [group-number] priority priority
4. standby [group-number] preempt [delay [minimum seconds]] [reload seconds] [sync seconds]
5. standby [group-number] track type number [interface-priority]
6. end
7. show running-config
8. copy running-config startup-config

### Configuring HSRP Authentication and Timers

You can optionally configure an HSRP authentication string or change the hello-time interval and holdtime.

When configuring these attributes, follow these guidelines:

- The authentication string is sent unencrypted in all HSRP messages. You must configure the same authentication string on all routers and access servers on a cable to ensure interoperation. Authentication mismatch prevents a device from learning the designated Hot Standby IP address and timer values from other routers configured with HSRP.
- Routers or access servers on which standby timer values are not configured can learn timer values from the active or standby router. The timers configured on an active router always override any other timer settings.

| **Step 9** standby [group-number] preempt [delay [minimum seconds]] [reload seconds] [sync seconds] | Configures the router to preempt, which means that when the local router has a higher priority than the active router, it becomes the active router.  
- (Optional) group-number-The group number to which the command applies.  
- (Optional) delay minimum—Set to cause the local router to postpone taking over the active role for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over).  
- (Optional) delay reload—Set to cause the local router to postpone taking over the active role after a reload for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over after a reload).  
- (Optional) delay sync—Set to cause the local router to postpone taking over the active role so that IP redundancy clients can reply (either with an ok or wait reply) for the number of seconds shown. The range is 0 to 3600 seconds (1 hour); the default is 0 (no delay before taking over).  
Use the no form of the command to restore the default values. |
| **Step 10** end | Returns to privileged EXEC mode. |
| **Step 11** show running-config | Verifies the configuration of the standby groups. |
| **Step 12** copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
• All routers in a Hot Standby group should use the same timer values. Normally, the `holdtime` is greater than or equal to 3 times the `hellotime`.

Beginning in privileged EXEC mode, use one or more of these steps to configure HSRP authentication and timers on an interface:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `standby [group-number] authentication string`
4. `standby [group-number] timers hellotime holdtime`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

### Enabling HSRP Support for ICMP Redirect Messages

ICMP redirect messages are automatically enabled on interfaces configured with HSRP. ICMP is a network layer Internet protocol that provides message packets to report errors and other information relevant to IP processing. ICMP provides diagnostic functions, such as sending and directing error packets to the host. This feature filters outgoing ICMP redirect messages through HSRP, in which the next hop IP address might be changed to an HSRP virtual IP address. For more information, see the Cisco IOS IP Configuration Guide, Release 12.4.

### Configuring HSRP Groups and Clustering

When a device is participating in an HSRP standby routing and clustering is enabled, you can use the same standby group for command switch redundancy and HSRP redundancy. Use the `cluster standby-group` command to enable the same HSRP standby group to be used for command switch and routing redundancy. If you create a cluster with the same HSRP standby group name without entering the `routing-redundancy` keyword, HSRP standby routing is disabled for the group.

### Verifying HSRP

#### Verifying HSRP Configurations

From privileged EXEC mode, use this command to display HSRP settings:

```
show standby [interface-id] [group] [brief] [detail]
```

You can display HSRP information for the whole switch, for a specific interface, for an HSRP group, or for an HSRP group on an interface. You can also specify whether to display a concise overview of HSRP information or detailed HSRP information. The default display is `detail`. If there are a large number of HSRP groups, using the `show standby` command without qualifiers can result in an unwieldy display.

#### Example

```
Switch # show standby
VLAN1 - Group 1
Local state is Standby, priority 105, may preempt
Hello time 3 holdtime 10
Next hello sent in 00:00:02.182
Hot standby IP address is 172.20.128.3 configured
Active router is 172.20.128.1 expires in 00:00:09
Standby router is local
```
Configuration Examples for Configuring HSRP

Enabling HSRP: Example

This example shows how to activate HSRP for group 1 on an interface. The IP address used by the hot standby group is learned by using HSRP.

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# standby 1 ip
Switch(config-if)# end
Switch # show standby
```

Configuring HSRP Priority: Example

This example activates a port, sets an IP address and a priority of 120 (higher than the default value), and waits for 300 seconds (5 minutes) before attempting to become the active router:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
Switch(config-if)# standby ip 172.20.128.3
Switch(config-if)# standby priority 120 preempt delay 300
Switch(config-if)# end
Switch # show standby
```

Configuring MHSRP: Example

This example shows how to enable the MHSRP configuration shown in the figure *MHSRP Load Sharing*

```
Router A Configuration
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if)# no switchport
```

*Note*

This procedure is the minimum number of steps required to enable HSRP. Other configurations are optional.
Configuring HSRP Authentication and Timer: Example

This example shows how to configure word as the authentication string required to allow Hot Standby routers in group 1 to interoperate:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # ip address 10.0.0.2 255.255.255.0
Switch(config-if) # standby ip 10.0.0.3
Switch(config-if) # standby 1 preempt
Switch(config-if) # standby 2 ip 10.0.0.4
Switch(config-if) # standby 1 priority 110
Switch(config-if) # standby 2 preempt
Switch(config-if) # end
```

This example shows how to set the timers on standby group 1 with the time between hello packets at 5 seconds and the time after which a router is considered down to be 15 seconds:

```
Switch # configure terminal
Switch(config) # interface gigabitethernet1/0/1
Switch(config-if) # no switchport
Switch(config-if) # standby 1 ip
Switch(config-if) # standby 1 timers 5 15
Switch(config-if) # end
```

Configuring HSRP Groups and Clustering: Example

This example shows how to bind standby group my_hsrp to the cluster and enable the same HSRP group to be used for command switch redundancy and router redundancy. The command can only be executed on the cluster command switch. If the standby group name or number does not exist, or if the switch is a cluster member switch, an error message appears.

```
Switch # configure terminal
Switch(config) # cluster standby-group my_hsrp routing-redundancy
Switch(config-if) # end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IP Multicast Technology

Role of IP Multicast in Information Delivery

IP multicast is a bandwidth-conserving technology that reduces traffic by delivering a single stream of information simultaneously to potentially thousands of businesses and homes. Applications that take advantage of multicast include video conferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address. The sending host inserts the multicast group address into the IP destination address field of the packet and IP multicast routers and multilayer switches forward incoming IP multicast packets out all interfaces that lead to the members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

IP Multicast Routing Protocols

The software supports the following protocols to implement IP multicast routing:
Multicast Group Transmission Scheme

IP communication consists of hosts that act as senders and receivers of traffic as shown in the first figure. Senders are called sources. Traditional IP communication is accomplished by a single host source sending packets to another single host (unicast transmission) or to all hosts (broadcast transmission). IP multicast provides a third scheme, allowing a host to send packets to a subset of all hosts (multicast transmission). This subset of receiving hosts is called a multicast group. The hosts that belong to a multicast group are called group members.

Multicast is based on this group concept. A multicast group is an arbitrary number of receivers that join a group in order to receive a particular data stream. This multicast group has no physical or geographical boundaries--the hosts can be located anywhere on the Internet or on any private internetwork. Hosts that are interested in receiving data from a source to a particular group must join that group. Joining a group is accomplished by a host receiver by way of the Internet Group Management Protocol (IGMP).

- IGMP is used between hosts on a LAN and the routers (and multilayer devices) on that LAN to track the multicast groups of which hosts are members. To participate in IP multicasting, multicast hosts, routers, and multilayer devices must have the Internet Group Management Protocol (IGMP) operating.

- Protocol Independent Multicast (PIM) is used between routers so that they can track which multicast packets to forward to each other and to their directly connected LANs.

- IGMP Snooping is used for multicasting in a Layer 2 switching environment. It helps reduce the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices.

This figure shows where these protocols operate within the IP multicast environment.

Related Topics

- Configuring Basic IP Multicast Routing, on page 557
- Prerequisites for Basic IP Multicast Routing, on page 555
In a multicast environment, any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group can receive packets sent to that group. Multicast packets are delivered to a group using best-effort reliability, just like IP unicast packets.

**Unicast transmission**—One host sends and the other receives.

**Broadcast transmission**—One sender to all receivers.

**Multicast transmission**—One sender to a group of receivers.

In the next figure, the receivers (the designated multicast group) are interested in receiving the video data stream from the source. The receivers indicate their interest by sending an IGMP host report to the routers in the network. The routers are then responsible for delivering the data from the source to the receivers. The routers use Protocol Independent Multicast (PIM) to dynamically create a multicast distribution tree. The video data stream will then be delivered only to the network segments that are in the path between the source and the receivers.
IP Multicast Boundary

As shown in the figure, address scoping defines domain boundaries so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

Figure 16: Address Scoping at Boundaries

You can set up an administratively scoped boundary on an interface for multicast group addresses using the `ip multicast boundary` command with the `access-list` argument. A standard access list defines the range of addresses affected. When a boundary is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The Internet Assigned Numbers Authority (IANA) has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. They would be considered local, not globally unique.
You can configure the filter-autorp keyword to examine and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

### IP Multicast Group Addressing

A multicast group is identified by its multicast group address. Multicast packets are delivered to that multicast group address. Unlike unicast addresses that uniquely identify a single host, multicast IP addresses do not identify a particular host. To receive the data sent to a multicast address, a host must join the group that address identifies. The data is sent to the multicast address and received by all the hosts that have joined the group indicating that they wish to receive traffic sent to that group. The multicast group address is assigned to a group at the source. Network administrators who assign multicast group addresses must make sure the addresses conform to the multicast address range assignments reserved by the Internet Assigned Numbers Authority (IANA).

### IP Class D Addresses

IP multicast addresses have been assigned to the IPv4 Class D address space by IANA. The high-order four bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 to 239.255.255.255. A multicast address is chosen at the source (sender) for the receivers in a multicast group.

---

**Note**

The Class D address range is used only for the group address or destination address of IP multicast traffic. The source address for multicast datagrams is always the unicast source address.

### IP Multicast Address Scoping

The multicast address range is subdivided to provide predictable behavior for various address ranges and for address reuse within smaller domains. The table provides a summary of the multicast address ranges. A brief summary description of each range follows.

#### Table 29: Multicast Address Range Assignments

<table>
<thead>
<tr>
<th>Name</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reserved Link-Local Addresses</td>
<td>224.0.0.0 to 224.0.0.255</td>
<td>Reserved for use by network protocols on a local network segment.</td>
</tr>
<tr>
<td>Globally Scoped Addresses</td>
<td>224.0.1.0 to 238.255.255.255</td>
<td>Reserved to send multicast data between organizations and across the Internet.</td>
</tr>
<tr>
<td>Source Specific Multicast</td>
<td>232.0.0.0 to 232.255.255.255</td>
<td>Reserved for use with the SSM datagram delivery model where data is forwarded only to receivers that have explicitly joined the group.</td>
</tr>
</tbody>
</table>
Reserved Link-Local Addresses

The IANA has reserved the range 224.0.0.0 to 224.0.0.255 for use by network protocols on a local network segment. Packets with an address in this range are local in scope and are not forwarded by IP routers. Packets with link local destination addresses are typically sent with a time-to-live (TTL) value of 1 and are not forwarded by a router.

Within this range, reserved link-local addresses provide network protocol functions for which they are reserved. Network protocols use these addresses for automatic router discovery and to communicate important routing information. For example, Open Shortest Path First (OSPF) uses the IP addresses 224.0.0.5 and 224.0.0.6 to exchange link-state information.

IANA assigns single multicast address requests for network protocols or network applications out of the 224.0.1.xxx address range. Multicast routers forward these multicast addresses.

Globally Scoped Addresses

Addresses in the range 224.0.1.0 to 238.255.255.255 are called globally scoped addresses. These addresses are used to send multicast data between organizations across the Internet. Some of these addresses have been reserved by IANA for use by multicast applications. For example, the IP address 224.0.1.1 is reserved for Network Time Protocol (NTP).

Source Specific Multicast Addresses

Addresses in the range 232.0.0.0/8 are reserved for Source Specific Multicast (SSM) by IANA. In Cisco IOS software, you can use the `ip pim ssm` command to configure SSM for arbitrary IP multicast addresses also. SSM is an extension of Protocol Independent Multicast (PIM) that allows for an efficient data delivery mechanism in one-to-many communications. SSM is described in the IP Multicast Delivery Modes, on page 335 section.

GLOP Addresses

GLOP addressing (as proposed by RFC 2770, GLOP Addressing in 233/8) proposes that the 233.0.0.0/8 range be reserved for statically defined addresses by organizations that already have an AS number reserved. This practice is called GLOP addressing. The AS number of the domain is embedded into the second and third octets of the 233.0.0.0/8 address range. For example, AS 62010 is written in hexadecimal format as F23A. Separating the two octets F2 and 3A results in 242 and 58 in decimal format. These values result in a subnet of 233.242.58.0/24 that would be globally reserved for AS 62010 to use.

Limited Scope Addresses

The range 239.0.0.0 to 239.255.255.255 is reserved as administratively or limited scoped addresses for use in private multicast domains. These addresses are constrained to a local group or organization. Companies, universities, and other organizations can use limited scope addresses to have local multicast applications that will not be forwarded outside their domain. Routers typically are configured with filters to prevent multicast

<table>
<thead>
<tr>
<th>Name</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GLOP Addresses</td>
<td>233.0.0.0 to 233.255.255</td>
<td>Reserved for statically defined addresses by organizations that already have an assigned autonomous system (AS) domain number.</td>
</tr>
<tr>
<td>Limited Scope Address</td>
<td>239.0.0.0 to 239.255.255</td>
<td>Reserved as administratively or limited scope addresses for use in private multicast domains.</td>
</tr>
</tbody>
</table>
traffic in this address range from flowing outside an autonomous system (AS) or any user-defined domain. Within an AS or domain, the limited scope address range can be further subdivided so that local multicast boundaries can be defined.

**Note**
Network administrators may use multicast addresses in this range, inside a domain, without conflicting with others elsewhere in the Internet.

### Layer 2 Multicast Addresses

Historically, network interface cards (NICs) on a LAN segment could receive only packets destined for their burned-in MAC address or the broadcast MAC address. In IP multicast, several hosts need to be able to receive a single data stream with a common destination MAC address. Some means had to be devised so that multiple hosts could receive the same packet and still be able to differentiate between several multicast groups. One method to accomplish this is to map IP multicast Class D addresses directly to a MAC address. Using this method, NICs can receive packets destined to many different MAC address.

Cisco Group Management Protocol (CGMP) is used on routers connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary for those Catalyst switches that cannot distinguish between IP multicast data packets and IGMP report messages, both of which are addressed to the same group address at the MAC level.

### IP Multicast Delivery Modes

IP multicast delivery modes differ only for the receiver hosts, not for the source hosts. A source host sends IP multicast packets with its own IP address as the IP source address of the packet and a group address as the IP destination address of the packet.

### Source Specific Multicast

Source Specific Multicast (SSM) is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core network technology for the Cisco implementation of IP multicast targeted for audio and video broadcast application environments.

For the SSM delivery mode, an IP multicast receiver host must use IGMP Version 3 (IGMPv3) to subscribe to channel (S,G). By subscribing to this channel, the receiver host is indicating that it wants to receive IP multicast traffic sent by source host S to group G. The network will deliver IP multicast packets from source host S to group G to all hosts in the network that have subscribed to the channel (S, G).

SSM does not require group address allocation within the network, only within each source host. Different applications running on the same source host must use different SSM groups. Different applications running on different source hosts can arbitrarily reuse SSM group addresses without causing any excess traffic on the network.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IGMP and IGMP Snooping

Prerequisites for IGMP

• Before performing the tasks in this module, you should be familiar with the concepts explained in the "IP Multicast Routing Technology Overview" module.

• The tasks in this module assume that IP multicast has been enabled and that the Protocol Independent Multicast (PIM) interfaces have been configured using the tasks described in the "Configuring Basic IP Multicast Routing" module.
Prerequisites for IGMP Snooping

Observe these guidelines when configuring the IGMP snooping querier:

- Configure the VLAN in global configuration mode.

- Configure an IP address on the VLAN interface. When enabled, the IGMP snooping querier uses the IP address as the query source address.

- If there is no IP address configured on the VLAN interface, the IGMP snooping querier tries to use the configured global IP address for the IGMP querier. If there is no global IP address specified, the IGMP querier tries to use the VLAN device virtual interface (SVI) IP address (if one exists). If there is no SVI IP address, the device uses the first available IP address configured on the device. The first IP address available appears in the output of the `show ip interface` privileged EXEC command. The IGMP snooping querier does not generate an IGMP general query if it cannot find an available IP address on the device.

- The IGMP snooping querier supports IGMP Versions 1 and 2.

- When administratively enabled, the IGMP snooping querier moves to the nonquerier state if it detects the presence of a multicast router in the network.

- When it is administratively enabled, the IGMP snooping querier moves to the operationally disabled state under these conditions:
  - IGMP snooping is disabled in the VLAN.
  - PIM is enabled on the SVI of the corresponding VLAN.

Restrictions for IGMP and IGMP Snooping

Restrictions for Configuring IGMP

The following are the restrictions for configuring IGMP:

- The device supports IGMP Versions 1, 2, and 3.

  **Note**  
  For IGMP Version 3, only IGMP Version 3 BISS (Basic IGMPv3 Snooping Support) is supported.

- IGMP Version 3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.

- IGMPv3 can operate with both ISM and SSM. In ISM, both exclude and include mode reports are applicable. In SSM, only include mode reports are accepted by the last-hop router. Exclude mode reports are ignored.

- IGMP filtering and throttling is not supported under the WLAN.

- You cannot have a device stack containing a mix of Catalyst 3850 and Catalyst 3650 devices.
Restrictions for IGMP Snooping

The following are the restrictions for IGMP snooping:

- The device supports IGMPv3 snooping based only on the destination multicast IP address. It does not support snooping based on a source IP address or proxy report.

- IGMPv3 join and leave messages are not supported on devices running IGMP filtering or Multicast VLAN registration (MVR).

- IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

- The IGMP configurable leave time is only supported on hosts running IGMP Version 2. IGMP version 2 is the default version for the device.

The actual leave latency in the network is usually the configured leave time. However, the leave time might vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

- The IGMP throttling action restriction can be applied only to Layer 2 ports. You can use `ip igmp max-groups action replace` interface configuration command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

When the maximum group limitation is set to the default (no maximum), entering the `ip igmp max-groups action {deny | replace}` command has no effect.

If you configure the throttling action and set the maximum group limitation after an interface has added multicast entries to the forwarding table, the forwarding-table entries are either aged out or removed, depending on the throttling action.

Information About IGMP

Role of the Internet Group Management Protocol

IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Enabling PIM on an interface also enables IGMP. IGMP provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

- A querier is a network device, such as a router, that sends query messages to discover which network devices are members of a given multicast group.

- A host is a receiver, including routers, that sends report messages (in response to query messages) to inform the querier of a host membership. Hosts use IGMP messages to join and leave multicast groups.
Hosts identify group memberships by sending IGMP messages to their local multicast device. Under IGMP, devices listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

**IGMP Multicast Addresses**

IP multicast traffic uses group addresses, which are Class D IP addresses. The high-order four bits of a Class D address are 1110. Therefore, host group addresses can be in the range 224.0.0.0 to 239.255.255.255.

Multicast addresses in the range 224.0.0.0 to 224.0.0.255 are reserved for use by routing protocols and other network control traffic. The address 224.0.0.0 is guaranteed not to be assigned to any group.

IGMP packets are transmitted using IP multicast group addresses as follows:

- IGMP general queries are destined to the address 224.0.0.1 (all systems on a subnet).
- IGMP group-specific queries are destined to the group IP address for which the device is querying.
- IGMP group membership reports are destined to the group IP address for which the device is reporting.
- IGMPv2 leave-group messages are destined to the address 224.0.0.2 (all devices on a subnet).
- IGMPv3 membership reports are destined to the address 224.0.0.22; all IGMPv3-capable multicast devices must listen to this address.

**Related Topics**

- Configuring the Device as a Member of a Group (CLI), on page 350
- Example: Configuring the Device as a Member of a Multicast Group, on page 388

**IGMP Versions**

The device supports IGMP version 1, IGMP version 2, and IGMP version 3. These versions are interoperable on the device. For example, if IGMP snooping is enabled and the querier's version is IGMPv2, and the device receives an IGMPv3 report from a host, then the device can forward the IGMPv3 report to the multicast router.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

**Related Topics**

- Changing the IGMP Version (CLI), on page 353
- Restrictions for Configuring IGMP, on page 338
- Restrictions for IGMP Snooping, on page 339

**IGMP Version 1**

IGMP version 1 (IGMPv1) primarily uses a query-response model that enables the multicast router and multilayer device to find which multicast groups are active (have one or more hosts interested in a multicast group) on the local subnet. IGMPv1 has other processes that enable a host to join and leave a multicast group. For more information, see RFC 1112.

**IGMP Version 2**

IGMPv2 extends IGMP functionality by providing such features as the IGMP leave process to reduce leave latency, group-specific queries, and an explicit maximum query response time. IGMPv2 also adds the capability
for routers to elect the IGMP querier without depending on the multicast protocol to perform this task. For more information, see RFC 2236.

---

**Note**

IGMP version 2 is the default version for the device.

---

**IGMP Version 3**

The device supports IGMP version 3.

An IGMPv3 device supports Basic IGMPv3 Snooping Support (BISS), which includes support for the snooping features on IGMPv1 and IGMPv2 switches and for IGMPv3 membership report messages. BISS constrains the flooding of multicast traffic when your network includes IGMPv3 hosts. It constrains traffic to approximately the same set of ports as the IGMP snooping feature on IGMPv2 or IGMPv1 hosts.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

**IGMPv3 Host Signaling**

IGMPv3 is the third version of the IETF standards track protocol in which hosts signal membership to last-hop devices of multicast groups. IGMPv3 introduces the ability for hosts to signal group membership that allows filtering capabilities with respect to sources. A host can signal either that it wants to receive traffic from all sources sending to a group except for some specific sources (a mode called EXCLUDE) or that it wants to receive traffic only from some specific sources sending to the group (a mode called INCLUDE).

IGMPv3 can operate with both ISM and SSM. In ISM, both EXCLUDE and INCLUDE mode reports are accepted by the last-hop router. In SSM, only INCLUDE mode reports are accepted by the last-hop router.

**IGMP Versions Differences**

There are three versions of IGMP, as defined by Request for Comments (RFC) documents of the Internet Engineering Task Force (IETF). IGMPv2 improves over IGMPv1 by adding the ability for a host to signal desire to leave a multicast group and IGMPv3 improves over IGMPv2 mainly by adding the ability to listen to multicast originating from a set of source IP addresses only.

**Table 30: IGMP Versions**

<table>
<thead>
<tr>
<th>IGMP Version</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGMPv1</td>
<td>Provides the basic query-response mechanism that allows the multicast device to determine which multicast groups are active and other processes that enable hosts to join and leave a multicast group. RFC 1112 defines the IGMPv1 host extensions for IP multicasting.</td>
</tr>
<tr>
<td>IGMPv2</td>
<td>Extends IGMP, allowing such capabilities as the IGMP leave process, group-specific queries, and an explicit maximum response time field. IGMPv2 also adds the capability for devices to elect the IGMP querier without dependence on the multicast protocol to perform this task. RFC 2236 defines IGMPv2.</td>
</tr>
</tbody>
</table>
By default, enabling a PIM on an interface enables IGMPv2 on that device. IGMPv2 was designed to be as backward compatible with IGMPv1 as possible. To accomplish this backward compatibility, RFC 2236 defined special interoperability rules. If your network contains legacy IGMPv1 hosts, you should be familiar with these operability rules. For more information about IGMPv1 and IGMPv2 interoperability, see RFC 2236, Internet Group Management Protocol, Version 2.

**Devices That Run IGMPv1**

IGMPv1 devices send IGMP queries to the “all-hosts” multicast address of 224.0.0.1 to solicit multicast groups with active multicast receivers. The multicast receivers also can send IGMP reports to the device to notify it that they are interested in receiving a particular multicast stream. Hosts can send the report asynchronously or in response to the IGMP queries sent by the device. If more than one multicast receiver exists for the same multicast group, only one of these hosts sends an IGMP report message; the other hosts suppress their report messages.

In IGMPv1, there is no election of an IGMP querier. If more than one device on the segment exists, all the devices send periodic IGMP queries. IGMPv1 has no special mechanism by which the hosts can leave the group. If the hosts are no longer interested in receiving multicast packets for a particular group, they simply do not reply to the IGMP query packets sent from the device. The device continues sending query packets. If the device does not hear a response in three IGMP queries, the group times out and the device stops sending multicast packets on the segment for the group. If the host later wants to receive multicast packets after the timeout period, the host simply sends a new IGMP join to the device, and the device begins to forward the multicast packet again.

If there are multiple devices on a LAN, a designated router (DR) must be elected to avoid duplicating multicast traffic for connected hosts. PIM devices follow an election process to select a DR. The PIM device with the highest IP address becomes the DR.

The DR is responsible for the following tasks:

- Sending PIM register and PIM Join and Prune messages toward the rendezvous point (RP) to inform it about host group membership.
- Sending IGMP host-query messages.
- Sending host-query messages by default every 60 seconds in order to keep the IGMP overhead on hosts and networks very low.

**Devices That Run IGMPv2**

IGMPv2 improves the query messaging capabilities of IGMPv1.

The query and membership report messages in IGMPv2 are identical to the IGMPv1 messages with two exceptions:

- IGMPv2 query messages are broken into two categories: general queries (identical to IGMPv1 queries) and group-specific queries.
- IGMPv1 membership reports and IGMPv2 membership reports have different IGMP type codes.

IGMPv2 also enhances IGMP by providing support for the following capabilities:
• Querier election process--Provides the capability for IGMPv2 devices to elect the IGMP querier without having to rely on the multicast routing protocol to perform the process.

• Maximum Response Time field--A new field in query messages permits the IGMP querier to specify the maximum query-response time. This field permits the tuning of the query-response process to control response burstiness and to fine-tune leave latencies.

• Group-Specific Query messages--Permits the IGMP querier to perform the query operation on a specific group instead of all groups.

• Leave-Group messages--Provides hosts with a method of notifying devices on the network that they wish to leave the group.

Unlike IGMPv1, in which the DR and the IGMP querier are typically the same device, in IGMPv2 the two functions are decoupled. The DR and the IGMP querier are selected based on different criteria and may be different devices on the same subnet. The DR is the device with the highest IP address on the subnet, whereas the IGMP querier is the device with the lowest IP address.

Query messages are used to elect the IGMP querier as follows:

1. When IGMPv2 devices start, they each multicast a general query message to the all-systems group address of 224.0.0.1 with their interface address in the source IP address field of the message.

2. When an IGMPv2 device receives a general query message, the device compares the source IP address in the message with its own interface address. The device with the lowest IP address on the subnet is elected the IGMP querier.

3. All devices (excluding the querier) start the query timer, which is reset whenever a general query message is received from the IGMP querier. If the query timer expires, it is assumed that the IGMP querier has gone down, and the election process is performed again to elect a new IGMP querier.

By default, the timer is two times the query interval.

**IGMP Join and Leave Process**

**IGMP Join Process**

When a host wants to join a multicast group, the host sends one or more unsolicited membership reports for the multicast group it wants to join. The IGMP join process is the same for IGMPv1 and IGMPv2 hosts.

In IGMPv3, the join process for hosts proceeds as follows:

• When a host wants to join a group, it sends an IGMPv3 membership report to 224.0.0.22 with an empty EXCLUDE list.

• When a host wants to join a specific channel, it sends an IGMPv3 membership report to 224.0.0.22 with the address of the specific source included in the INCLUDE list.

• When a host wants to join a group excluding particular sources, it sends an IGMPv3 membership report to 224.0.0.22 excluding those sources in the EXCLUDE list.

---

**Note**

If some IGMPv3 hosts on a LAN wish to exclude a source and others wish to include the source, then the device will send traffic for the source on the LAN (that is, inclusion trumps exclusion in this situation).
IGMP Leave Process

The method that hosts use to leave a group varies depending on the version of IGMP in operation.

IGMPv1 Leave Process

There is no leave-group message in IGMPv1 to notify the devices on the subnet that a host no longer wants to receive the multicast traffic from a specific group. The host simply stops processing traffic for the multicast group and ceases responding to IGMP queries with IGMP membership reports for the group. As a result, the only way IGMPv1 devices know that there are no longer any active receivers for a particular multicast group on a subnet is when the devices stop receiving membership reports. To facilitate this process, IGMPv1 devices associate a countdown timer with an IGMP group on a subnet. When a membership report is received for the group on the subnet, the timer is reset. For IGMPv1 devices, this timeout interval is typically three times the query interval (3 minutes). This timeout interval means that the device may continue to forward multicast traffic onto the subnet for up to 3 minutes after all hosts have left the multicast group.

IGMPv2 Leave Process

IGMPv2 incorporates a leave-group message that provides the means for a host to indicate that it wishes to stop receiving multicast traffic for a specific group. When an IGMPv2 host leaves a multicast group, if it was the last host to respond to a query with a membership report for that group, it sends a leave-group message to the all-devices multicast group (224.0.0.2).

IGMPv3 Leave Process

IGMPv3 enhances the leave process by introducing the capability for a host to stop receiving traffic from a particular group, source, or channel in IGMP by including or excluding sources, groups, or channels in IGMPv3 membership reports.

IGMP Snooping

Layer 2 devices can use IGMP snooping to constrain the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. As the name implies, IGMP snooping requires the LAN device to snoop on the IGMP transmissions between the host and the router and to keep track of multicast groups and member ports. When the device receives an IGMP report from a host for a particular multicast group, the device adds the host port number to the forwarding table entry; when it receives an IGMP Leave Group message from a host, it removes the host port from the table entry. It also periodically deletes entries if it does not receive IGMP membership reports from the multicast clients.

Note

For more information on IP multicast and IGMP, see RFC 1112 and RFC 2236.

The multicast router (which could be a device with the IP services feature set on the active device) sends out periodic general queries to all VLANs. All hosts interested in this multicast traffic send join requests and are added to the forwarding table entry. The device creates one entry per VLAN in the IGMP snooping IP multicast forwarding table for each group from which it receives an IGMP join request.

The device supports IP multicast group-based bridging, instead of MAC-addressed based groups. With multicast MAC address-based groups, if an IP address being configured translates (aliases) to a previously
configured MAC address or to any reserved multicast MAC addresses (in the range 224.0.0.xxx), the command fails. Because the device uses IP multicast groups, there are no address aliasing issues.

The IP multicast groups learned through IGMP snooping are dynamic. However, you can statically configure multicast groups by using the `ip igmp snooping vlan vlan-id static ip_address interface interface-id` global configuration command. If you specify group membership for a multicast group address statically, your setting supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can consist of both user-defined and IGMP snooping-learned settings.

You can configure an IGMP snooping querier to support IGMP snooping in subnets without multicast interfaces because the multicast traffic does not need to be routed.

If a port spanning-tree, a port group, or a VLAN ID change occurs, the IGMP snooping-learned multicast groups from this port on the VLAN are deleted.

These sections describe IGMP snooping characteristics:

### Joining a Multicast Group

![Figure 17: Initial IGMP Join Message](image)

When a host connected to the device wants to join an IP multicast group and it is an IGMP version 2 client, it sends an unsolicited IGMP join message, specifying the IP multicast group to join. Alternatively, when the device receives a general query from the router, it forwards the query to all ports in the VLAN. IGMP version 1 or version 2 hosts wanting to join the multicast group respond by sending a join message to the device. The device CPU creates a multicast forwarding-table entry for the group if it is not already present. The CPU also adds the interface where the join message was received to the forwarding-table entry. The host associated with that interface receives multicast traffic for that multicast group.

<table>
<thead>
<tr>
<th>Ports</th>
<th>Type of Packet</th>
<th>Destination Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, 2</td>
<td>IGMP</td>
<td>224.1.2.3</td>
</tr>
</tbody>
</table>

Router A sends a general query to the device, which forwards the query to ports 2 through 5, all of which are members of the same VLAN. Host 1 wants to join multicast group 224.1.2.3 and multicasts an IGMP membership report (IGMP join message) to the group. The device CPU uses the information in the IGMP report to set up a forwarding-table entry that includes the port numbers connected to Host 1 and to the router.
The device hardware can distinguish IGMP information packets from other packets for the multicast group. The information in the table tells the switching engine to send frames addressed to the 224.1.2.3 multicast IP address that are not IGMP packets to the router and to the host that has joined the group.

*Figure 18: Second Host Joining a Multicast Group*

If another host (for example, Host 4) sends an unsolicited IGMP join message for the same group, the CPU receives that message and adds the port number of Host 4 to the forwarding table. Because the forwarding table directs IGMP messages only to the CPU, the message is not flooded to other ports on the device. Any known multicast traffic is forwarded to the group and not to the CPU.

- Example: Configuring the Device as a Member of a Multicast Group, on page 388

**Leaving a Multicast Group**

The router sends periodic multicast general queries, and the device forwards these queries through all ports in the VLAN. Interested hosts respond to the queries. If at least one host in the VLAN wants to receive multicast traffic, the router continues forwarding the multicast traffic to the VLAN. The device forwards multicast group traffic only to those hosts listed in the forwarding table for that IP multicast group maintained by IGMP snooping.

When hosts want to leave a multicast group, they can silently leave, or they can send a leave message. When the device receives a leave message from a host, it sends a group-specific query to learn if any other devices connected to that interface are interested in traffic for the specific multicast group. The device then updates the forwarding table for that MAC group so that only those hosts interested in receiving multicast traffic for the group are listed in the forwarding table. If the router receives no reports from a VLAN, it removes the group for the VLAN from its IGMP cache.
Immediate Leave

The device uses IGMP snooping Immediate Leave to remove from the forwarding table an interface that sends a leave message without the device sending group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original leave message. Immediate Leave ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are simultaneously in use.

Immediate Leave is only supported on IGMP version 2 hosts. IGMP version 2 is the default version for the device.

Note
You should use the Immediate Leave feature only on VLANs where a single host is connected to each port. If Immediate Leave is enabled on VLANs where more than one host is connected to a port, some hosts may be dropped inadvertently.

Related Topics
Enabling IGMP Immediate Leave (CLI), on page 373

IGMP Configurable-Leave Timer

You can configure the time that the device waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 32767 milliseconds.

Related Topics
Configuring the IGMP Leave Timer (CLI), on page 374

IGMP Report Suppression

Note
IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

The device uses IGMP report suppression to forward only one IGMP report per multicast router query to multicast devices. When IGMP report suppression is enabled (the default), the device sends the first IGMP report from all hosts for a group to all the multicast routers. The device does not send the remaining IGMP reports for the group to the multicast routers. This feature prevents duplicate reports from being sent to the multicast devices.

If the multicast router query includes requests only for IGMPv1 and IGMPv2 reports, the device forwards only the first IGMPv1 or IGMPv2 report from all hosts for a group to all the multicast routers.

If the multicast router query also includes requests for IGMPv3 reports, the device forwards all IGMPv1, IGMPv2, and IGMPv3 reports for a group to the multicast devices.

If you disable IGMP report suppression, all IGMP reports are forwarded to the multicast routers.

Related Topics
Disabling IGMP Report Suppression (CLI), on page 384
IGMP Filtering and Throttling

In some environments, for example, metropolitan or multiple-dwelling unit (MDU) installations, you might want to control the set of multicast groups to which a user on a device port can belong. You can control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan. You might also want to limit the number of multicast groups to which a user on a device port can belong.

With the IGMP filtering feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual device ports. An IGMP profile can contain one or more multicast groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a device port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing. You can also set the maximum number of IGMP groups that a Layer 2 interface can join.

IGMP filtering controls only group-specific query and membership reports, including join and leave reports. It does not control general IGMP queries. IGMP filtering has no relationship with the function that directs the forwarding of IP multicast traffic. The filtering feature operates in the same manner whether CGMP or MVR is used to forward the multicast traffic.

IGMP filtering applies only to the dynamic learning of IP multicast group addresses, not static configuration.

With the IGMP throttling feature, you can set the maximum number of IGMP groups that a Layer 2 interface can join. If the maximum number of IGMP groups is set, the IGMP snooping forwarding table contains the maximum number of entries, and the interface receives an IGMP join report, you can configure an interface to drop the IGMP report or to replace the randomly selected multicast entry with the received IGMP report.

---

**Note**

IGMPv3 join and leave messages are not supported on devices running IGMP filtering.

**Default IGMP Configuration**

How to Configure IGMP

Configuring the Device as a Member of a Group (CLI)

You can configure the device as a member of a multicast group and discover multicast reachability in a network. If all the multicast-capable routers and multilayer devices that you administer are members of a multicast group, pinging that group causes all of these devices to respond. The devices respond to ICMP echo-request packets addressed to a group of which they are members. Another example is the multicast trace-route tools provided in the software.

⚠️ **Caution**
Performing this procedure might impact the CPU performance because the CPU will receive all data traffic for the group address.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp join-group group-address
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Enables privileged EXEC mode. Enter your password if prompted.</strong></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Enters the global configuration mode.</strong></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>interface interface-id</strong></td>
</tr>

</tr>
</tbody>
</table>

**Step 4**  
`ip igmp join-group group-address`  
*Example:*  
Device(config-if)# `ip igmp join-group 225.2.2.2`  
Configures the device to join a multicast group.  
By default, no group memberships are defined.  
For `group-address`, specify the multicast IP address in dotted decimal notation.

**Step 5**  
`end`  
*Example:*  
Device(config)# `end`  
Returns to privileged EXEC mode.

**Step 6**  
`show ip igmp interface [interface-id]`  
*Example:*  
Device# `show ip igmp interface`  
Verifies your entries.

**Step 7**  
`copy running-config startup-config`  
*Example:*  
Device# `copy running-config startup-config`  
(Optional) Saves your entries in the configuration file.

---

---

**Controlling Access to IP Multicast Group (CLI)**

The device sends IGMP host-query messages to find which multicast groups have members on attached local networks. The device then forwards to these group members all packets addressed to the multicast group.  
You can place a filter on each interface to restrict the multicast groups that hosts on the subnet serviced by the interface can join.  
To limit the number of joins on the interface, configure the port for the filter which associates with the IGMP profile.  
This procedure is optional.

**SUMMARY STEPS**

1. `enable`  
2. `configure terminal`  
3. `ip igmp profile`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode. Enter your password if prompted.  
Example:  
Device> enable |
| **Step 2** | `configure terminal` | Enters the global configuration mode.  
Example:  
Device# configure terminal |
| **Step 3** | `ip igmp profile` | Enters an IGMP filter profile number from 1 to 4294967295.  
For additional information about configuring IGMP filter profiles, see Configuring IGMP Profiles (CLI), on page 361.  
Example:  
Device(config)# ip igmp profile 10  
Device(config-igmp-profile)# ? |
| **Step 4** | `permit` | Enters an IGMP profile configuration action. The following IGMP profile configuration actions are supported:  
• `deny`—Matching IP addresses are denied.  
• `exit`—Exits from the IGMP profile configuration mode.  
• `no`—Negates a command or set its defaults.  
• `permit`—Matching addresses are permitted.  
• `range`—Adds a range to the set.  
Example:  
Device(config-igmp-profile)# permit 229.9.9.0 |
| **Step 5** | `exit` | Returns to global configuration mode.  
Example:  
Device(config-igmp-profile)# exit |
### Command or Action | Purpose |
---|---|
**Step 6** | interface interface-id  
**Example:**  
Device(config)# interface gigabitethernet 1/0/1 | Specifies the interface to be configured, and enters interface configuration mode. |
**Step 7** | ip igmp filter filter_number  
**Example:**  
Device(config-if)# ip igmp filter 10 | Specifies the IGMP filter profile number.  
For additional information about applying IGMP filter profiles, see Applying IGMP Profiles (CLI), on page 363. |
**Step 8** | end  
**Example:**  
Device(config)# end | Returns to privileged EXEC mode. |
**Step 9** | show ip igmp interface [interface-id]  
**Example:**  
Device# show ip igmp interface | Verifies your entries. |
**Step 10** | copy running-config startup-config  
**Example:**  
Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Changing the IGMP Version (CLI)

By default, the switch uses IGMP Version 2, which provides features such as the IGMP query timeout and the maximum query response time.

All systems on the subnet must support the same version. The switch does not automatically detect Version 1 systems and switch to Version 1. You can mix Version 1 and Version 2 hosts on the subnet because Version 2 routers or switches always work correctly with IGMPv1 hosts.

Configure the switch for Version 1 if your hosts do not support Version 2.

This procedure is optional.

### SUMMARY STEPS

1. enable  
2. configure terminal  
3. interface interface-id
4. `ip igmp version \{1 | 2 | 3 \}`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

## DETAILED STEPS

<table>

</tbody>
</table>
Modifying the IGMP Host-Query Message Interval (CLI)

The device periodically sends IGMP host-query messages to discover which multicast groups are present on attached networks. These messages are sent to the all-hosts multicast group (224.0.0.1) with a time-to-live (TTL) of 1. The device sends host-query messages to refresh its knowledge of memberships present on the network. If, after some number of queries, the software discovers that no local hosts are members of a multicast group, the software stops forwarding multicast packets to the local network from remote origins for that group and sends a prune message upstream toward the source.

The device elects a PIM designated router (DR) for the LAN (subnet). The designated router is responsible for sending IGMP host-query messages to all hosts on the LAN. In sparse mode, the designated router also sends PIM register and PIM join messages toward the RP router. With IGMPv2, the DR is the router or multilayer device with the highest IP address. With IGMPv1, the DR is elected according to the multicast routing protocol that runs on the LAN.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp query-interval seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
 enable  
 Example:  
 Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**  
 configure terminal  
 Example: | Enters the global configuration mode. |
### Purpose

Command or Action | Purpose
--- | ---
Device# configure terminal | Specifiestheinterfaceonwhichyouwanttoenable multicast routing, and enters interface configuration mode.

**Step 3** interface *interface-id*  
Example:  
Device(config)# interface gigabitethernet 1/0/1

**Step 4** ip igmp query-interval *seconds*  
Example:  
Device(config-if)# ip igmp query-interval 75

**Step 5** end  
Example:  
Device(config)# end

**Step 6** show ip igmp interface *[interface-id]*  
Example:  
Device# show ip igmp interface

**Step 7** copy running-config startup-config  
Example:  
Device# copy running-config startup-config

### Changing the IGMP Query Timeout for IGMPv2 (CLI)

If you are using IGMPv2, you can specify the period of time before the device takes over as the querier for the interface. By default, the device waits twice the query interval period controlled by the *ip igmp query-interval* interface configuration command. After that time, if the device has received no queries, it becomes the querier.

This procedure is optional.

### SUMMARY STEPS

1. enable  
2. configure terminal  
3. interface *interface-id*
4. `ip igmp querier-timeout seconds`
5. `end`
6. `show ip igmp interface [interface-id]`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>

</table>
Changing the Maximum Query Response Time for IGMPv2 (CLI)

If you are using IGMPv2, you can change the maximum query response time advertised in IGMP queries. The maximum query response time enables the device to quickly detect that there are no more directly connected group members on a LAN. Decreasing the value enables the device to prune groups faster. This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip igmp query-max-response-time seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the interface on which you want to enable multicast routing, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip igmp query-max-response-time seconds</td>
<td>Changes the maximum query response time advertised in IGMP queries. The default is 10 seconds. The range is 1 to 25.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ip igmp</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>query-max-response-time 15</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

**Example:**

```
Device(config)# end
```

**Purpose:** Returns to privileged EXEC mode.

**Step 6**

**show ip igmp interface** `[interface-id]`

**Example:**

```
Device# show ip igmp interface
```

**Purpose:** Verifies your entries.

**Step 7**

**copy running-config startup-config**

**Example:**

```
Device# copy running-config startup-config
```

**Purpose:** (Optional) Saves your entries in the configuration file.

---

**Configuring the Device as a Statically Connected Member (CLI)**

At various times, either there is not a group member on a network segment or a host that cannot report its group membership by using IGMP. However, you may want multicast traffic to be sent to that network segment. The following commands are used to pull multicast traffic down to a network segment:

- **ip igmp join-group**—The device accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the device from fast switching.

- **ip igmp static-group**—The device does not accept the packets itself, but only forwards them. This method enables fast switching. The outgoing interface appears in the IGMP cache, but the device itself is not a member, as evidenced by lack of an L (local) flag in the multicast route entry.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface `interface-id`
4. `ip igmp static-group group-address`
5. `end`
6. `show ip igmp interface [interface-id]`
7. copy running-config startup-config
### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters the global configuration mode. |
| `configure terminal` |         |
| **Example:**      |         |
| `Device# configure terminal` |         |

| **Step 3**        | Specifies the interface on which you want to enable multicast routing, and enters interface configuration mode. |
| `interface interface-id` |         |
| **Example:**      |         |
| `Device(config)# interface gigabitethernet 1/0/1` |         |

| **Step 4**        | Configures the device as a statically connected member of a group. By default, this feature is disabled. |
| `ip igmp static-group group-address` |         |
| **Example:**      |         |
| `Device(config-if)# ip igmp static-group 239.100.100.101` |         |

| **Step 5**        | Returns to privileged EXEC mode. |
| `end`             |         |
| **Example:**      |         |
| `Device(config)# end` |         |

| **Step 6**        | Verifies your entries. |
| `show ip igmp interface [interface-id]` |         |
| **Example:**      |         |
| `Device# show ip igmp interface gigabitethernet 1/0/1` |         |

| **Step 7**        | (Optional) Saves your entries in the configuration file. |
| `copy running-config startup-config` |         |
| **Example:**      |         |
| `Device# copy running-config startup-config` |         |
Configuring IGMP Profiles (CLI)

Follow these steps to create an IGMP profile:
This task is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp profile profile number`
4. `permit | deny`
5. `range ip multicast address`
6. `end`
7. `show ip igmp profile profile number`
8. `show running-config`
9. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Assigns a number to the profile you are configuring, and enters IGMP profile configuration mode. The profile number range is 1 to 4294967295. When you are in IGMP profile configuration mode, you can create the profile by using these commands:</td>
</tr>
<tr>
<td><code>ip igmp profile profile number</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# ip igmp profile 3</code></td>
<td></td>
</tr>
</tbody>
</table>

- **deny**: Specifies that matching addresses are denied; this is the default.
- **exit**: Exits from igmp-profile configuration mode.
- **no**: Negates a command or returns to its defaults.
- **permit**: Specifies that matching addresses are permitted.
- **range**: Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with a start and an end address.
### Configuring IGMP Profiles (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 4** permit | The default is for the device to have no IGMP profiles configured.  
| deny              | **Note** To delete a profile, use the `no ip igmp profile profile number` global configuration command.  
| Example:          | (Optional) Sets the action to permit or deny access to the IP multicast address. If no action is configured, the default for the profile is to deny access. |
| `Device(config-igmp-profile)# permit` | |
| **Step 5** range | Enters the IP multicast address or range of IP multicast addresses to which access is being controlled. If entering a range, enter the low IP multicast address, a space, and the high IP multicast address. You can use the `range` command multiple times to enter multiple addresses or ranges of addresses.  
| `ip multicast address` | **Note** To delete an IP multicast address or range of IP multicast addresses, use the `no range ip multicast address` IGMP profile configuration command. |
| Example:          | |
| `Device(config-igmp-profile)# range 229.9.9.0` | |
| **Step 6** end    | Returns to privileged EXEC mode. |
| Example:          | |
| `Device(config)# end` | |
| **Step 7** show | Verifies the profile configuration. |
| `ip igmp profile profile number` | |
| Example:          | |
| `Device# show ip igmp profile 3` | |
| **Step 8** show running-config | Verifies your entries. |
| Example:          | |
| `Device# show running-config` | |
| **Step 9** copy | (Optional) Saves your entries in the configuration file. |
| `running-config startup-config` | |
| Example:          | |
| `Device# copy running-config startup-config` | |
Applying IGMP Profiles (CLI)

To control access as defined in an IGMP profile, you have to apply the profile to the appropriate interfaces. You can apply IGMP profiles only to Layer 2 access ports; you cannot apply IGMP profiles to routed ports or SVIs. You cannot apply profiles to ports that belong to an EtherChannel port group. You can apply a profile to multiple interfaces, but each interface can have only one profile applied to it.

Follow these steps to apply an IGMP profile to a switch port:

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface interface-id**
4. **ip igmp filter profile number**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies the physical interface, and enters interface configuration mode. The interface must be a Layer 2 port that does not belong to an EtherChannel port group.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip igmp filter profile number</td>
<td>Applies the specified IGMP profile to the interface. The range is 1 to 4294967295.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ip igmp filter 321</td>
<td><strong>Note</strong> To remove a profile from an interface, use the <strong>no ip igmp filter profile number</strong> interface configuration command.</td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>
Setting the Maximum Number of IGMP Groups (CLI)

Follow these steps to set the maximum number of IGMP groups that a Layer 2 interface can join:

**Before you begin**
This restriction can be applied to Layer 2 ports only; you cannot set a maximum number of IGMP groups on routed ports or SVIs. You also can use this command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `ip igmp max-groups number`
5. `end`
6. `show running-config interface interface-id`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: <code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td>Specifies the interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or a EtherChannel interface.</td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Sets the maximum number of IGMP groups that the interface can join. The range is 0 to 4294967294. The default is to have no maximum set.</td>
</tr>
<tr>
<td><strong>Step 4</strong> ip igmp max-groups number</td>
<td>The device supports a maximum number of 4096 Layer 2 IGMP groups and 2048 Layer 3 IGMP groups.</td>
</tr>
<tr>
<td><strong>Step 5</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong> show running-config interface interface-id</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 7</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### Configuring the IGMP Throttling Action (CLI)

After you set the maximum number of IGMP groups that a Layer 2 interface can join, you can configure an interface to replace the existing group with the new group for which the IGMP report was received.

Follow these steps to configure the throttling action when the maximum number of entries is in the forwarding table:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. `ip igmp max-groups action {deny | replace}
5. end
6. `show running-config interface interface-id
7. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface <code>interface-id</code></td>
<td>Specifies the physical interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or an EtherChannel interface. The interface cannot be a trunk port.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>`ip igmp max-groups action {deny</td>
<td>replace}`</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# ip igmp max-groups action replace</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>deny</strong>— Drops the report. If you configure this throttling action, the entries that were previously in the forwarding table are not removed but are aged out. After these entries are aged out and the maximum number of entries is in the forwarding table, the device drops the next IGMP report received on the interface.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>replace</strong>— Replaces the existing group with the new group for which the IGMP report was received. If you configure this throttling action, the entries that were previously in the forwarding table are removed. When the maximum number of entries is in the forwarding table, the device replaces a randomly selected entry with the received IGMP report.</td>
</tr>
</tbody>
</table>

To prevent the device from removing the forwarding-table entries, you can configure the IGMP throttling action before an interface adds entries to the forwarding table.
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>no ip igmp max-groups action</td>
<td>To return to the default action of dropping the report, use the <code>no ip igmp max-groups action</code> interface configuration command.</td>
</tr>
</tbody>
</table>

### Step 5

**Example:**

```
Device(config)# end
```

### Step 6

**Example:**

```
Device# show running-config interface gigabitethernet1/0/1
```

### Step 7

**Example:**

```
Device# copy running-config startup-config
```

### Enabling or Disabling IGMP Snooping on a VLAN Interface (CLI)

Follow these steps to enable IGMP snooping on a VLAN interface:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id`
4. `end`
5. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td>Enables IGMP snooping on the VLAN interface. The VLAN ID range is 1 to 1001 and 1006 to 4094. IGMP snooping must be globally enabled before you can enable VLAN snooping.</td>
</tr>
</tbody>
</table>

**Step 3**

**ip igmp snooping vlan vlan-id**

**Example:**

Device(config)# ip igmp snooping vlan 7

**Note** To disable IGMP snooping on a VLAN interface, use the `no ip igmp snooping vlan vlan-id` global configuration command for the specified VLAN number.

**Step 4**

**end**

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 5**

**copy running-config startup-config**

(Optional) Saves your entries in the configuration file.

Device# copy running-config startup-config

---

**Setting the Snooping Method (CLI)**

Multicast-capable router ports are added to the forwarding table for every Layer 2 multicast entry. The device learns of the ports through one of these methods:

- Snooping on IGMP queries, Protocol-Independent Multicast (PIM) packets
- Statically connecting to a multicast router port using the `ip igmp snooping mrouter` global configuration command

Beginning in privileged EXEC mode, follow these steps to alter the method in which a VLAN interface accesses a multicast router:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping vlan vlan-id mrouter interface {GigabitEthernet | Port-Channel | TenGigabitEthernet}
4. end
5. show ip igmp snooping
6. copy running-config startup-config
### DETAILED STEPS

#### Configuring a Multicast Router Port (CLI)

Perform these steps to add a multicast router port (enable a static connection to a multicast router) on the device.

**Note**

Static connections to multicast routers are supported only on device ports.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id mrouter interface interface-id`
4. `end`
5. `show ip igmp snooping mrouter [vlan vlan-id]`
6. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>

<tr>
<td><code>show ip igmp snooping mrouter [vlan vlan-id]</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# show ip igmp snooping mrouter vlan 5</code></td>
<td></td>
</tr>
</tbody>
</table>
Configuring a Host Statically to Join a Group (CLI)

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure a host on an interface.

Follow these steps to add a Layer 2 port as a member of a multicast group:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip igmp snooping vlan vlan-id static ip_address interface interface-id`
4. end
5. show ip igmp snooping groups
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip igmp snooping vlan vlan-id static ip_address interface interface-id</code></td>
<td>Statically configures a Layer 2 port as a member of a multicast group:</td>
</tr>
<tr>
<td>* <code>vlan-id</code> is the multicast group VLAN ID. The range is 1 to 1001 and 1006 to 4094.</td>
<td></td>
</tr>
<tr>
<td>* <code>ip-address</code> is the group IP address.</td>
<td></td>
</tr>
<tr>
<td>* <code>interface-id</code> is the member port. It can be a physical interface or a port channel (1 to 128).</td>
<td></td>
</tr>
</tbody>
</table>
### Enabling IGMP Immediate Leave (CLI)

When you enable IGMP Immediate Leave, the device immediately removes a port when it detects an IGMP Version 2 leave message on that port. You should use the Immediate-Leave feature only when there is a single receiver present on every port in the VLAN.

**Note**

Immediate Leave is supported only on IGMP Version 2 hosts. IGMP Version 2 is the default version for the device.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping vlan vlan-id immediate-leave`
4. `end`
5. `show ip igmp snooping vlan vlan-id`
6. `end`

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>no ip igmp snooping vlan vlan-id static mac-address interface interface-id global</code></td>
<td>To remove the Layer 2 port from the multicast group, use the no ip igmp snooping vlan vlan-id static mac-address interface interface-id global configuration command.</td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>show ip igmp snooping groups</code></td>
<td>Verifies the member port and the IP address.</td>
</tr>
<tr>
<td><strong>Step 6</strong> <code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
### Detailed Steps

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

*configure terminal*

<table>
<thead>
<tr>
<th>Example:</th>
<th><code>Device# configure terminal</code></th>
<th><strong>Purpose</strong></th>
</tr>
</thead>
</table>

**Step 3**

*ip igmp snooping vlan vlan-id immediate-leave*

<table>
<thead>
<tr>
<th>Example:</th>
<th><code>Device(config)# ip igmp snooping vlan 21 immediate-leave</code></th>
<th>Enables IGMP Immediate Leave on the VLAN interface.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong></td>
<td></td>
<td>To disable IGMP Immediate Leave on a VLAN, use the <code>no ip igmp snooping vlan vlan-id immediate-leave</code> global configuration command.</td>
</tr>
</tbody>
</table>

**Step 4**

*end*

<table>
<thead>
<tr>
<th>Example:</th>
<th><code>Device(config)# end</code></th>
<th><strong>Purpose</strong></th>
</tr>
</thead>
</table>

**Step 5**

*show ip igmp snooping vlan vlan-id*

<table>
<thead>
<tr>
<th>Example:</th>
<th><code>Device# show ip igmp snooping vlan 21</code></th>
<th>Verifies that Immediate Leave is enabled on the VLAN interface.</th>
</tr>
</thead>
</table>

**Step 6**

*end*

<table>
<thead>
<tr>
<th>Example:</th>
<th><code>Device(config)# end</code></th>
<th><strong>Purpose</strong></th>
</tr>
</thead>
</table>

Immediate Leave, on page 347

### Configuring the IGMP Leave Timer (CLI)

You can configure the leave time globally or on a per-VLAN basis. Follow these steps to enable the IGMP configurable-leave timer:
**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip igmp snooping last-member-query-interval time`
4. `ip igmp snooping vlan vlan-id last-member-query-interval time`
5. end
6. `show ip igmp snooping`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>ip igmp snooping last-member-query-interval time</code></td>
<td>Configures the IGMP leave timer globally. The range is 100 to 32767 milliseconds. The default leave time is 1000 milliseconds.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device(config)# ip igmp snooping last-member-query-interval 1000</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> To globally reset the IGMP leave timer to the default setting, use the <code>no ip igmp snooping last-member-query-interval</code> global configuration command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>ip igmp snooping vlan vlan-id last-member-query-interval time</code></td>
<td>(Optional) Configures the IGMP leave time on the VLAN interface. The range is 100 to 32767 milliseconds.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device(config)# ip igmp snooping vlan 210 last-member-query-interval 1000</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> Configuring the leave time on a VLAN overrides the globally configured timer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> To remove the configured IGMP leave-time setting from the specified VLAN, use the <code>no ip igmp snooping vlan vlan-id last-member-query-interval</code> global configuration command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring the IGMP Robustness-Variable (CLI)

Use the following procedure to configure the IGMP robustness variable on the device.

The robustness variable is the integer used by IGMP snooping during calculations for IGMP messages. The robustness variable provides fine tuning to allow for expected packet loss.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping robustness-variable count`
4. `ip igmp snooping vlan vlan-id robustness-variable count`
5. `end`
6. `show ip igmp snooping`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

Configuring TCN-Related Commands

Controlling the Multicast Flooding Time After a TCN Event (CLI)

You can configure the number of general queries by which multicast data traffic is flooded after a topology change notification (TCN) event. If you set the TCN flood query count to 1 the flooding stops after receiving 1 general query. If you set the count to 7, the flooding continues until 7 general queries are received. Groups are relearned based on the general queries received during the TCN event.

Some examples of TCN events are when the client location is changed and the receiver is on same port that was blocked but is now forwarding, and when a port goes down without sending a leave message.

Follow these steps to configure the TCN flood query count:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp snooping tcn flood query count count`
4. `end`
5. `show ip igmp snooping`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>ip igmp snooping tcn flood query count count</code></td>
<td>Specifies the number of IGMP general queries for which the multicast traffic is flooded. The range is 1 to 10. The default, the flooding query count is 2.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ip igmp snooping tcn flood query count 3</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To return to the default flooding query count, use the <code>no ip igmp snooping tcn flood query count</code> global configuration command.</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Recovering from Flood Mode (CLI)

When a topology change occurs, the spanning-tree root sends a special IGMP leave message (also known as global leave) with the group multicast address 0.0.0.0. However, you can enable the device to send the global leave message whether it is the spanning-tree root or not. When the router receives this special leave, it immediately sends general queries, which expedite the process of recovering from the flood mode during the TCN event. Leaves are always sent if the device is the spanning-tree root regardless of this configuration.

Follow these steps to enable sending of leave messages:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping tcn query solicit
4. end
5. show ip igmp snooping
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

| Step 3 | ip igmp snooping tcn query solicit |

**Example:**

```
Device(config)# ip igmp snooping tcn query solicit
```

**Purpose:** Sends an IGMP leave message (global leave) to speed the process of recovering from the flood mode caused during a TCN event. By default, query solicitation is disabled. 

**Note:** To return to the default query solicitation, use the `no ip igmp snooping tcn query solicit` global configuration command.

| Step 4 | end |

**Example:**

```
Device(config)# end
```

**Purpose:** Returns to privileged EXEC mode.

| Step 5 | show ip igmp snooping |

**Example:**

```
Device# show ip igmp snooping
```

**Purpose:** Verifies the TCN settings.

| Step 6 | copy running-config startup-config |

**Example:**

```
Device# copy running-config startup-config
```

**Purpose:** (Optional) Saves your entries in the configuration file.

### Disabling Multicast Flooding During a TCN Event (CLI)

When the device receives a TCN, multicast traffic is flooded to all the ports until 2 general queries are received. If the device has many ports with attached hosts that are subscribed to different multicast groups, this flooding might exceed the capacity of the link and cause packet loss. Follow these steps to control TCN flooding:

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. no ip igmp snooping tcn flood
5. end
6. show ip igmp snooping
7. copy running-config startup-config

### DETAILED STEPS

| Command or Action | Purpose |

| Step 1 | enable |

**Example:**

```
Device# enable
```

**Purpose:** Enables privileged EXEC mode. Enter your password if prompted.
<table>

**Configuring the IGMP Snooping Querier (CLI)**

Follow these steps to enable the IGMP snooping querier feature in a VLAN:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp snooping querier
4. ip igmp snooping querier address ip_address
5. ip igmp snooping querier query-interval interval-count
6. ip igmp snooping querier tcn query [count count | interval interval]
7. ip igmp snooping querier timer expiry timeout
8. ip igmp snooping querier version version
9. end
10. show ip igmp snooping vlan vlan-id
11. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** | enters the global configuration mode. |
| Example: | |
| Device# configure terminal | |

| **Step 3** | enables the IGMP snooping querier. |
| Example: | |
| Device(config)# ip igmp snooping querier | |

| **Step 4** | (Optional) Specifies an IP address for the IGMP snooping querier. If you do not specify an IP address, the querier tries to use the global IP address configured for the IGMP querier. |
| Example: | |
| Device(config)# ip igmp snooping querier address 172.16.24.1 | |

| **Step 5** | (Optional) Sets the interval between IGMP queriers. The range is 1 to 18000 seconds. |
| Example: | |
| Device(config)# ip igmp snooping querier query-interval 30 | |

**Note** The IGMP snooping querier does not generate an IGMP general query if it cannot find an IP address on the device.

**Disabling IGMP Report Suppression (CLI)**

Follow these steps to disable IGMP report suppression:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no ip igmp snooping report-suppression`
4. `end`
5. `show ip igmp snooping`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>

Monitoring IGMP

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

**Note**

This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 36: Commands for Displaying System and Network Statistics**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ping [group-name</td>

<td>Displays the selected VPN routing/forwarding instance by name.</td>
</tr>
</tbody>
</table>

**Monitoring IGMP Snooping Information**

You can display IGMP snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display MAC address multicast entries for a VLAN configured for IGMP snooping.
### Table 37: Commands for Displaying IGMP Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>

<td>(Optional) Enter vlan vlan-id to display information for a single VLAN.</td>
</tr>
<tr>
<td>show ip igmp snooping [vlan vlan-id</td>
<td>[ detail</td>
</tr>
<tr>
<td></td>
<td>(Optional) Enter vlan vlan-id to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td>show ip igmp snooping wireless mgid</td>
<td>Displays wireless-related events.</td>
</tr>
</tbody>
</table>
**Monitoring IGMP Filtering and Throttling Configuration**

You can display IGMP profile characteristics, and you can display the IGMP profile and maximum group configuration for all interfaces on the device or for a specified interface. You can also display the IGMP throttling configuration for all interfaces on the device or for a specified interface.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip igmp profile [profile number]</code></td>
<td>Displays the specified IGMP profile or all the IGMP profiles defined on the device.</td>
</tr>
<tr>
<td><code>show running-config [interface interface-id]</code></td>
<td>Displays the configuration of the specified interface or the configuration of all interfaces on the device, including (if configured) the maximum number of IGMP groups to which an interface can belong and the IGMP profile applied to the interface.</td>
</tr>
</tbody>
</table>

**Configuration Examples for IGMP**

**Example: Configuring the Device as a Member of a Multicast Group**

This example shows how to enable the device to join multicast group 255.2.2.2:

```
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip igmp join-group 255.2.2.2
Device(config-if)#
```

**Related Topics**
- Configuring the Device as a Member of a Group (CLI), on page 350
- Joining a Multicast Group, on page 345
- IGMP Multicast Addresses, on page 340

**Example: Controlling Access to Multicast Groups**

To limit the number of joins on the interface, configure the port for filter which associates with the IGMP profile.

```
Device# configure terminal
Device(config)# ip igmp profile 10
Device(config-igmp-profile)# ?
```

IGMP profile configuration commands:
- deny matching addresses are denied
- exit Exit from igmp profile configuration mode
- no Negate a command or set its defaults
- permit matching addresses are permitted
range add a range to the set

Device(config-igmp-profile)# range 172.16.5.1
Device(config-igmp-profile)# exit
Device(config)#
Device(config)# interface gigabitEthernet 2/0/10
Device(config-if)# ip igmp filter 10

Examples: Configuring IGMP Snooping

This example shows how to enable a static connection to a multicast router:

Device# configure terminal
Device(config)# ip igmp snooping vlan 200 mrouter interface gigabitethernet1/0/2
Device(config)# end

This example shows how to statically configure a host on a port:

Device# configure terminal
Device(config)# ip igmp snooping vlan 105 static 224.2.4.12 interface gigabitethernet1/0/1
Device(config)# end

This example shows how to enable IGMP Immediate Leave on VLAN 130:

Device# configure terminal
Device(config)# ip igmp snooping vlan 130 immediate-leave
Device(config)# end

This example shows how to set the IGMP snooping querier source address to 10.0.0.64:

Device# configure terminal
Device(config)# ip igmp snooping querier 10.0.0.64
Device(config)# end

This example shows how to set the IGMP snooping querier maximum response time to 25 seconds:

Device# configure terminal
Device(config)# ip igmp snooping querier query-interval 25
Device(config)# end

This example shows how to set the IGMP snooping querier timeout to 60 seconds:

Device# configure terminal
Device(config)# ip igmp snooping querier timer expiry 60
Device(config)# end

This example shows how to set the IGMP snooping querier feature to Version 2:

Device# configure terminal
Device(config)# no ip igmp snooping querier version 2
Example: Configuring IGMP Profiles

This example shows how to create IGMP profile 4 allowing access to the single IP multicast address and how to verify the configuration. If the action was to deny (the default), it would not appear in the `show ip igmp profile` output display.

```
Device(config)# ip igmp profile 4
Device(config-igmp-profile)# permit
Device(config-igmp-profile)# range 229.9.9.0
Device(config-igmp-profile)# end
Device# show ip igmp profile 4
IGMP Profile 4
  permit
  range 229.9.9.0 229.9.9.0
```

Example: Applying IGMP Profile

This example shows how to apply IGMP profile 4 to a port:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp filter 4
Device(config-if)# end
```

Example: Setting the Maximum Number of IGMP Groups

This example shows how to limit to 25 the number of IGMP groups that a port can join:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp max-groups 25
Device(config-if)# end
```

Example: Interface Configuration as a Routed Port

This example shows how to configure an interface on the device as a routed port. This configuration is required on the interface for several IP multicast routing configuration procedures that require running the `no switchport` command.

```
Device configure terminal
Device(config)# interface GigabitEthernet1/0/9
Device(config-if)# description interface to be use as routed port
Device(config-if)# no switchport
Device(config-if)# ip address 20.20.20.1 255.255.255.0
Device(config-if)# ip pim sparse-dense-mode
Device(config-if)# ip igmp join-group 224.1.2.3 source 15.15.15.2
Device(config-if)# end
Device# configure terminal
Device# show run interface gigabitEthernet 1/0/9
```

Current configuration : 166 bytes!
Example: Interface Configuration as an SVI

This example shows how to configure an interface on the device as an SVI. This configuration is required on the interface for several IP multicast routing configuration procedures that require running the `no switchport` command.

```
Device(config)# interface vlan 150
Device(config-if)# ip address 20.20.20.1 255.255.255.0
Device(config-if)# ip pim sparse-dense-mode
Device(config-if)# ip igmp join-group 224.1.2.3 source 15.15.15.2
Device(config-if)# end
Device# configure terminal
Device(config)# ip igmp snooping vlan 20 static 224.1.2.3
Device(config)# interface gigabitEthernet 1/0/9
Device# show run interface vlan 150
```

Current configuration : 137 bytes
!
interface Vlan150
  ip address 20.20.20.1 255.255.255.0
  ip pim sparse-dense-mode
  ip igmp static-group 224.1.2.3 source 15.15.15.2
end

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IGMP Proxy

- All devices on the IGMP UDL have the same subnet address. If all devices on the UDL cannot have the same subnet address, the upstream device must be configured with secondary addresses to match all of the subnets to which the downstream devices are attached.

- IP multicast is enabled and the PIM interfaces are configured.
Use the following guidelines when configuring PIM interfaces for IGMP proxy:

- Use PIM sparse mode (PIM-SM) when the interface is operating in a sparse-mode region and you are running static RP, bootstrap (BSR), or Auto-RP with the Auto-RP listener capability.
- Use PIM sparse-dense mode when the interface is running in a sparse-dense mode region and you are running Auto-RP without the Auto-RP listener capability.
- Use PIM dense mode (PIM-DM) when the interface is operating in dense mode and is, thus, participating in a dense-mode region.
- Use PIM-DM with the proxy-register capability when the interface is receiving source traffic from a dense-mode region that needs to reach receivers that are in a sparse-mode region.

Information about IGMP Proxy

IGMP Proxy

An IGMP proxy enables hosts in a unidirectional link routing (UDLR) environment that are not directly connected to a downstream router to join a multicast group sourced from an upstream network.

The figure below illustrates a sample topology that shows two UDLR scenarios:

- Traditional UDL routing scenario--A UDL device with directly connected receivers.
- IGMP proxy scenario--UDL device without directly connected receivers.

IGMP UDLs are needed on the upstream and downstream devices.
Scenario 1--Traditional UDLR Scenario (UDL Device with Directly Connected Receivers)

For scenario 1, no IGMP proxy mechanism is needed. In this scenario, the following sequence of events occurs:

1. User 2 sends an IGMP membership report requesting interest in group G.
2. Router B receives the IGMP membership report, adds a forwarding entry for group G on LAN B, and proxies the IGMP report to Router A, which is the UDLR upstream device.
3. The IGMP report is then proxied across the Internet link.
4. Router A receives the IGMP proxy and maintains a forwarding entry on the unidirectional link.

Scenario 2--IGMP Proxy Scenario (UDL Device without Directly Connected Receivers)

For scenario 2, the IGMP proxy mechanism is needed to enable hosts that are not directly connected to a downstream device to join a multicast group sourced from an upstream network. In this scenario, the following sequence of events occurs:

1. User 1 sends an IGMP membership report requesting interest in group G.
2. Router C sends a PIM Join message hop-by-hop to the RP (Router B).
3. Router B receives the PIM Join message and adds a forwarding entry for group G on LAN B.
4. Router B periodically checks its mroute table and proxies the IGMP membership report to its upstream UDL device across the Internet link.
5. Router A creates and maintains a forwarding entry on the unidirectional link (UDL).

In an enterprise network, it is desirable to be able to receive IP multicast traffic via satellite and forward the traffic throughout the network. With unidirectional link routing (UDLR) alone, scenario 2 would not be
possible because receiving hosts must be directly connected to the downstream device, Router B. The IGMP proxy mechanism overcomes this limitation by creating an IGMP report for (*, G) entries in the multicast forwarding table. To make this scenario functional, therefore, you must enable IGMP report forwarding of proxied (*, G) multicast static route (mroute) entries (using the `ip igmp mroute-proxy` command) and enable the mroute proxy service (using the `ip igmp proxy-service` command) on interfaces leading to PIM-enabled networks with potential members.

Because PIM messages are not forwarded upstream, each downstream network and the upstream network have a separate domain.

<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
</tbody>
</table>
| 9    | `interface` `type number` | Enters interface configuration mode for the specified interface.  
|      | **Example:**  
|      | `Device(config)# interface loopback 0` | In this example, loopback interface 0 is specified. |
| 10   | `ip igmp helper-address udl` `interface-type` `interface-number` | Configures IGMP helpering for UDLR.  
|      | **Example:**  
|      | `Device(config-if)# ip igmp helper-address udl gigabitethernet 0/0/0` | This step allows the downstream device to helper IGMP reports received from hosts to an upstream device connected to a UDL associated with the interface specified for the `interface-type` and `interface-number` arguments.  
|      |  
|      | In the example topology, IGMP helpering is configured over loopback interface 0 on the downstream device. Loopback interface 0, thus, is configured to helper IGMP reports from hosts to an upstream device connected to Gigabit Ethernet interface 0/0/0. |
| 11   | `ip igmp proxy-service` | Enables the mroute proxy service.  
|      | **Example:**  
|      | `Device(config-if)# ip igmp proxy-service` | When the mroute proxy service is enabled, the device periodically checks the static mroute table for (*, G) forwarding entries that match interfaces configured with the `ip igmp mroute-proxy` command (see Step 7) based on the IGMP query interval. Where there is a match, one IGMP report is created and received on this interface.  
|      |  
|      | **Note** The `ip igmp proxy-service` command is intended to be used with the `ip igmp helper-address (UDL)` command.  
|      |  
|      | In this example, the `ip igmp proxy-service` command is configured on loopback interface 0 to enable the forwarding of IGMP reports out the interface for all groups on interfaces registered through the `ip igmp mroute-proxy` command (see Step 7). |
| 12   | `end` | Ends the current configuration session and returns to privileged EXEC mode.  
|      | **Example:**  
|      | `Device(config-if)# end` |
| 13   | `show ip igmp interface` | (Optional) Displays multicast-related information about an interface.  
|      | **Example:**  
|      | `Device# show ip igmp interface` |
### Command or Action

**Step 14**

**Example:**

Device# show ip igmp udlr

### Purpose

(Optional) Displays UDLR information for directly connected multicast groups on interfaces that have a UDL helper address configured.

## Configuration Examples for IGMP Proxy

### Example: IGMP Proxy Configuration

The following example shows how to configure the upstream UDL device for IGMP UDLR and the downstream UDL device for IGMP UDLR with IGMP proxy support.

#### Upstream Device Configuration

```bash
interface gigabitethernet 0/0/0
  ip address 10.1.1.1 255.255.255.0
  ip pim dense-mode
!
interface gigabitethernet 1/0/0
  ip address 10.2.1.1 255.255.255.0
  ip pim dense-mode
  ip igmp unidirectional-link
!
interface gigabitethernet 2/0/0
  ip address 10.3.1.1 255.255.255.0
```

#### Downstream Device Configuration

```bash
ip pim rp-address 10.5.1.1 5
access-list 5 permit 239.0.0.0 0.255.255.255
!
interface loopback 0
  ip address 10.7.1.1 255.255.255.0
  ip pim dense-mode
  ip igmp helper-address udl ethernet 0
  ip igmp proxy-service
!
interface gigabitethernet 0/0/0
  ip address 10.2.1.2 255.255.255.0
  ip pim dense-mode
  ip igmp unidirectional-link

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Constraining IP Multicast in a Switched Ethernet Network

Before using the tasks in this module, you should be familiar with the concepts described in the “IP Multicast Technology Overview” module.
Information About IP Multicast in a Switched Ethernet Network

IP Multicast Traffic and Layer 2 Switches

The default behavior for a Layer 2 switch is to forward all multicast traffic to every port that belongs to the destination LAN on the switch. This behavior reduces the efficiency of the switch, whose purpose is to limit traffic to the ports that need to receive the data. This behavior requires a constraining mechanism to reduce unnecessary multicast traffic, which improves switch performance.

Cisco Group Management Protocol (CGMP), Router Group Management Protocol (RGMP), and IGMP snooping efficiently constrain IP multicast in a Layer 2 switching environment.

- CGMP and IGMP snooping are used on subnets that include end users or receiver clients.
- RGMP is used on routed segments that contain only routers, such as in a collapsed backbone.
- RGMP and CGMP cannot interoperate. However, Internet Group Management Protocol (IGMP) can interoperate with CGMP and RGMP snooping.

CGMP on Catalyst Switches for IP Multicast

CGMP is a Cisco-developed protocol used on device connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary for those Catalyst switches that do not distinguish between IP multicast data packets and IGMP report messages, both of which are addressed to the same group address at the MAC level. The switch can distinguish IGMP packets, but would need to use software on the switch, greatly impacting its performance.

You must configure CGMP on the multicast device and the Layer 2 switches. The result is that, with CGMP, IP multicast traffic is delivered only to those Catalyst switch ports that are attached to interested receivers. All other ports that have not explicitly requested the traffic will not receive it unless these ports are connected to a multicast router. Multicast router ports must receive every IP multicast data packet.

Using CGMP, when a host joins a multicast group, it multicasts an unsolicited IGMP membership report message to the target group. The IGMP report is passed through the switch to the router for normal IGMP processing. The router (which must have CGMP enabled on this interface) receives the IGMP report and processes it as it normally would, but also creates a CGMP Join message and sends it to the switch. The Join message includes the MAC address of the end station and the MAC address of the group it has joined.

The switch receives this CGMP Join message and then adds the port to its content-addressable memory (CAM) table for that multicast group. All subsequent traffic directed to this multicast group is then forwarded out the port for that host.

The Layer 2 switches are designed so that several destination MAC addresses could be assigned to a single physical port. This design allows switches to be connected in a hierarchy and also allows many multicast destination addresses to be forwarded out a single port.

The device port also is added to the entry for the multicast group. Multicast device must listen to all multicast traffic for every group because IGMP control messages are also sent as multicast traffic. The rest of the multicast traffic is forwarded using the CAM table with the new entries created by CGMP.

IGMP Snooping

IGMP snooping is an IP multicast constraining mechanism that runs on a Layer 2 LAN switch. IGMP snooping requires the LAN switch to examine, or “snoop,” some Layer 3 information (IGMP Join/Leave messages) in the IGMP packets sent between the hosts and the router. When the switch receives the IGMP host report from a host for a particular multicast group, the switch adds the port number of the host to the associated multicast table entry. When the switch hears the IGMP Leave group message from a host, the switch removes the table entry of the host.

Because IGMP control messages are sent as multicast packets, they are indistinguishable from multicast data at Layer 2. A switch running IGMP snooping must examine every multicast data packet to determine if it contains any pertinent IGMP control information. IGMP snooping implemented on a low-end switch with a slow CPU could have a severe performance impact when data is sent at high rates. The solution is to implement IGMP snooping on high-end switches with special application-specific integrated circuits (ASICs) that can perform the IGMP checks in hardware. CGMP is a better option for low-end switches without special hardware.

Router-Port Group Management Protocol (RGMP)

CGMP and IGMP snooping are IP multicast constraining mechanisms designed to work on routed network segments that have active receivers. They both depend on IGMP control messages that are sent between the hosts and the routers to determine which switch ports are connected to interested receivers.

Switched Ethernet backbone network segments typically consist of several routers connected to a switch without any hosts on that segment. Because routers do not generate IGMP host reports, CGMP and IGMP snooping will not be able to constrain the multicast traffic, which will be flooded to every port on the VLAN. Routers instead generate Protocol Independent Multicast (PIM) messages to Join and Prune multicast traffic flows at a Layer 3 level.

Router-Port Group Management Protocol (RGMP) is an IP multicast constraining mechanism for router-only network segments. RGMP must be enabled on the routers and on the Layer 2 switches. A multicast router indicates that it is interested in receiving a data flow by sending an RGMP Join message for a particular group. The switch then adds the appropriate port to its forwarding table for that multicast group—similar to the way it handles a CGMP Join message. IP multicast data flows will be forwarded only to the interested router ports. When the router no longer is interested in that data flow, it sends an RGMP Leave message and the switch removes the forwarding entry.

If there are any routers that are not RGMP-enabled, they will continue to receive all multicast data.

How to Constrain Multicast in a Switched Ethernet Network

Configuring Switches for IP Multicast

If you have switching in your multicast network, consult the documentation for the switch you are working with for information about how to configure IP multicast.
Configuring IGMP Snooping

No configuration is required on the router. Consult the documentation for the switch you are working with to determine how to enable IGMP snooping and follow the provided instructions.

Enabling CGMP

CGMP is a protocol used on devices connected to Catalyst switches to perform tasks similar to those performed by IGMP. CGMP is necessary because the Catalyst switch cannot distinguish between IP multicast data packets and IGMP report messages, which are both at the MAC level and are addressed to the same group address.

- CGMP should be enabled only on 802 or ATM media, or LAN emulation (LANE) over ATM.
- CGMP should be enabled only on devices connected to Catalyst switches.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip cgmp [proxy | router-only]`
5. `end`
6. `clear ip cgmp [interface-type interface-number]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface type number</td>
<td>Selects an interface that is connected to hosts on which IGMPv3 can be enabled.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# interface ethernet 1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip cgmp [proxy</td>
<td>router-only]</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ip cgmp proxy</td>
<td>- The <em>proxy</em> keyword enables the CGMP proxy function. When enabled, any device that is not CGMP-capable...</td>
</tr>
</tbody>
</table>
Enables privileged EXEC mode. Will be advertised by the proxy router. The proxy router advertises the existence of other non-CGMP-capable devices by sending a CGMP Join message with the MAC address of the non-CGMP-capable device and group address of 0000.0000.0000.

Ends the current configuration session and returns to EXEC mode.

(Optional) Clears all group entries from the caches of Catalyst switches.

Perform this task to configure IP multicast in a Layer 2 Switched Ethernet network using RGMP.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip rgmp`
5. `end`
6. `debug ip rgmp`
7. `show ip igmp interface`

**DETAILED STEPS**

### Step 1

- **Command or Action:** enable
- **Example:**

  ```
  Device> enable
  ```

Enables privileged EXEC mode.

- Enter your password if prompted.

### Step 2

- **Command or Action:** configure terminal
- **Example:**

  ```
  ```

Enters global configuration mode.

### Configuration Examples for Constraining IP Multicast in a Switched Ethernet Network

#### Example: CGMP Configuration

The following example is for a basic network environment where multicast source(s) and multicast receivers are in the same VLAN. The desired behavior is that the switch will constrain the multicast forwarding to those ports that request the multicast stream.

A 4908G-L3 router is connected to the Catalyst 4003 on port 3/1 in VLAN 50. The following configuration is applied on the GigabitEthernet1 interface. Note that there is no **ip multicast-routing** command configured because the router is not routing multicast traffic across its interfaces.
interface GigabitEthernet1
  ip address 192.168.50.11 255.255.255.0
  ip pim dense-mode
  ip cgmp

- Additional References, on page 471
- Feature History and Information for PIM, on page 473

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for PIM

- Before you begin the PIM configuration process, decide which PIM mode to use. This is based on the applications you intend to support on your network. Use the following guidelines:
  - In general, if the application is one-to-many or many-to-many in nature, then PIM-SM can be used successfully.
  - For optimal one-to-many application performance, SSM is appropriate but requires IGMP version 3 support.
- Before you configure PIM stub routing, check that you have met these conditions:
• You must have IP multicast routing configured on both the stub router and the central router. You must also have PIM mode (dense-mode, sparse-mode, or sparse-dense-mode) configured on the uplink interface of the stub router.

• You must also configure either Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing or Open Shortest Path First (OSPF) stub routing on the device.

• The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior.

Note For information about EIGRP or OSPF configurations, see the Catalyst 3850 Routing Configuration Guide, Release 3SE.

Restrictions for PIM

The following are the restrictions for configuring PIM:

• PIM is not supported when running the LAN Base feature set.

• Bidirectional PIM is not supported.

PIMv1 and PIMv2 Interoperability

To avoid misconfiguring multicast routing on your device, review the information in this section.

The Cisco PIMv2 implementation provides interoperability and transition between Version 1 and Version 2, although there might be some minor problems.

You can upgrade to PIMv2 incrementally. PIM Versions 1 and 2 can be configured on different routers and multilayer devices within one network. Internally, all routers and multilayer devices on a shared media network must run the same PIM version. Therefore, if a PIMv2 device detects a PIMv1 device, the Version 2 device downgrades itself to Version 1 until all Version 1 devices have been shut down or upgraded.

PIMv2 uses the BSR to discover and announce RP-set information for each group prefix to all the routers and multilayer devices in a PIM domain. PIMv1, together with the Auto-RP feature, can perform the same tasks as the PIMv2 BSR. However, Auto-RP is a standalone protocol, separate from PIMv1, and is a proprietary Cisco protocol. PIMv2 is a standards track protocol in the IETF.

Note We recommend that you use PIMv2. The BSR function interoperates with Auto-RP on Cisco routers and multilayer devices.

When PIMv2 devices interoperate with PIMv1 devices, Auto-RP should have already been deployed. A PIMv2 BSR that is also an Auto-RP mapping agent automatically advertises the RP elected by Auto-RP. That is, Auto-RP sets its single RP on every router or multilayer device in the group. Not all routers and devices in the domain use the PIMv2 hash function to select multiple RPs.
Dense-mode groups in a mixed PIMv1 and PIMv2 region need no special configuration; they automatically interoperate.

Sparse-mode groups in a mixed PIMv1 and PIMv2 region are possible because the Auto-RP feature in PIMv1 interoperates with the PIMv2 RP feature. Although all PIMv2 devices can also use PIMv1, we recommend that the RPs be upgraded to PIMv2. To ease the transition to PIMv2, we recommend:

- Using Auto-RP throughout the region.
- Configuring sparse-dense mode throughout the region.

If Auto-RP is not already configured in the PIMv1 regions, configure Auto-RP.

Related Topics

PIM Versions, on page 417

Restrictions for Configuring PIM Stub Routing

- The IP services image contains complete multicast routing.
- Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing.
- The redundant PIM stub router topology is not supported. Only the nonredundant access router topology is supported by the PIM stub feature.
- PIM stub routing is supported when running the IP Base and IP Services feature sets.

Related Topics

Enabling PIM Stub Routing (CLI), on page 430
PIM Stub Routing, on page 418

Restrictions for Configuring Auto-RP and BSR

Take into consideration your network configuration, and the following restrictions when configuring Auto-RP and BSR:

Restrictions for Configuring Auto-RP

The following are restrictions for configuring Auto-RP (if used in your network configuration):

- Auto-RP is not supported when running the LAN Base feature set.
- If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must manually configure an RP.
- If routed interfaces are configured in sparse mode, Auto-RP can still be used if all devices are configured with a manual RP address for the Auto-RP groups.
- If routed interfaces are configured in sparse mode and you enter the `ip pim autorp listener` global configuration command, Auto-RP can still be used even if all devices are not configured with a manual RP address for the Auto-RP groups.
Restrictions for Configuring BSR

The following are the restrictions for configuring BSR (if used in your network configuration):

• Configure the candidate BSRs as the RP-mapping agents for Auto-RP.

• For group prefixes advertised through Auto-RP, the PIMv2 BSR mechanism should not advertise a subrange of these group prefixes served by a different set of RPs. In a mixed PIMv1 and PIMv2 domain, have backup RPs serve the same group prefixes. This prevents the PIMv2 DRs from selecting a different RP from those PIMv1 DRs, due to the longest match lookup in the RP-mapping database.

Restrictions and Guidelines for Configuring Auto-RP and BSR

The following are restrictions for configuring Auto-RP and BSR (if used in your network configuration):

• If your network is all Cisco routers and multilayer devices, you can use either Auto-RP or BSR.

• If you have non-Cisco routers in your network, you must use BSR.

• If you have Cisco PIMv1 and PIMv2 routers and multilayer devices and non-Cisco routers, you must use both Auto-RP and BSR. If your network includes routers from other vendors, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 device. Ensure that no PIMv1 device is located in the path between the BSR and a non-Cisco PIMv2 device.

Note: There are two approaches to using PIMv2. You can use Version 2 exclusively in your network or migrate to Version 2 by employing a mixed PIM version environment.

• Because bootstrap messages are sent hop-by-hop, a PIMv1 device prevents these messages from reaching all routers and multilayer devices in your network. Therefore, if your network has a PIMv1 device in it and only Cisco routers and multilayer devices, it is best to use Auto-RP.

• If you have a network that includes non-Cisco routers, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 router or multilayer device. Ensure that no PIMv1 device is on the path between the BSR and a non-Cisco PIMv2 router.

• If you have non-Cisco PIMv2 routers that need to interoperate with Cisco PIMv1 routers and multilayer devices, both Auto-RP and a BSR are required. We recommend that a Cisco PIMv2 device be both the Auto-RP mapping agent and the BSR.

Information About PIM

Protocol Independent Multicast Overview

The Protocol Independent Multicast (PIM) protocol maintains the current IP multicast service mode of receiver-initiated membership. PIM is not dependent on a specific unicast routing protocol; it is IP routing protocol independent and can leverage whichever unicast routing protocols are used to populate the unicast routing table, including Enhanced Interior Gateway Routing Protocol (EIGRP), Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and static routes. PIM uses unicast routing information to perform the multicast forwarding function.

Although PIM is called a multicast routing protocol, it actually uses the unicast routing table to perform the reverse path forwarding (RPF) check function instead of building up a completely independent multicast routing table. Unlike other routing protocols, PIM does not send and receive routing updates between routers.

PIM is defined in RFC 4601, Protocol Independent Multicast - Sparse Mode (PIM-SM)

PIM can operate in dense mode or sparse mode. The router can also handle both sparse groups and dense groups at the same time (sparse-dense mode). The mode determines how the router populates its multicast routing table and how the router forwards multicast packets it receives from its directly connected LANs.

For information about PIM forwarding (interface) modes, see the following sections:

PIM Dense Mode

PIM dense mode (PIM-DM) uses a push model to flood multicast traffic to every corner of the network. This push model is a method for delivering data to the receivers without the receivers requesting the data. This method is efficient in certain deployments in which there are active receivers on every subnet in the network.

In dense mode, a router assumes that all other routers want to forward multicast packets for a group. If a router receives a multicast packet and has no directly connected members or PIM neighbors present, a prune message is sent back to the source. Subsequent multicast packets are not flooded to this router on this pruned branch.

PIM builds source-based multicast distribution trees.

PIM-DM initially floods multicast traffic throughout the network. Routers that have no downstream neighbors prune back the unwanted traffic. This process repeats every 3 minutes.

Routers accumulate state information by receiving data streams through the flood and prune mechanism. These data streams contain the source and group information so that downstream routers can build up their multicast forwarding table. PIM-DM supports only source trees—-that is, (S,G) entries—and cannot be used to build a shared distribution tree.

Note

Dense mode is not often used and its use is not recommended. For this reason it is not specified in the configuration tasks in related modules.
PIM Sparse Mode

PIM sparse mode (PIM-SM) uses a pull model to deliver multicast traffic. Only network segments with active receivers that have explicitly requested the data will receive the traffic.

Unlike dense mode interfaces, sparse mode interfaces are added to the multicast routing table only when periodic Join messages are received from downstream routers, or when a directly connected member is on the interface. When forwarding from a LAN, sparse mode operation occurs if an RP is known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense mode fashion. If the multicast traffic from a specific source is sufficient, the first hop router of the receiver may send Join messages toward the source to build a source-based distribution tree.

PIM-SM distributes information about active sources by forwarding data packets on the shared tree. Because PIM-SM uses shared trees (at least, initially), it requires the use of a rendezvous point (RP). The RP must be administratively configured in the network. See the Rendezvous Points, on page 419 section for more information.

In sparse mode, a router assumes that other routers do not want to forward multicast packets for a group, unless there is an explicit request for the traffic. When hosts join a multicast group, the directly connected routers send PIM Join messages toward the RP. The RP keeps track of multicast groups. Hosts that send multicast packets are registered with the RP by the first hop router of that host. The RP then sends Join messages toward the source. At this point, packets are forwarded on a shared distribution tree. If the multicast traffic from a specific source is sufficient, the first hop router of the host may send Join messages toward the source to build a source-based distribution tree.

Sources register with the RP and then data is forwarded down the shared tree to the receivers. The edge routers learn about a particular source when they receive data packets on the shared tree from that source through the RP. The edge router then sends PIM (S,G) Join messages toward that source. Each router along the reverse path compares the unicast routing metric of the RP address to the metric of the source address. If the metric for the source address is better, it will forward a PIM (S,G) Join message toward the source. If the metric for the RP is the same or better, then the PIM (S,G) Join message will be sent in the same direction as the RP. In this case, the shared tree and the source tree would be considered congruent.

If the shared tree is not an optimal path between the source and the receiver, the routers dynamically create a source tree and stop traffic from flowing down the shared tree. This behavior is the default behavior in software. Network administrators can force traffic to stay on the shared tree by using the `ip pim spt-threshold infinity` command.

PIM-SM scales well to a network of any size, including those with WAN links. The explicit join mechanism prevents unwanted traffic from flooding the WAN links.

Multicast Source Discovery Protocol (MSDP)

Multicast Source Discovery Protocol (MSDP) is used for inter-domain source discovery when PIM SM is used. Each PIM administrative domain has its own RP. In order for the RP in one domain to signal new sources to the RP in the other domain, MSDP is used.

When RP in a domain receives a PIM register message for a new source, with MSDP configured it sends a new source-active (SA) message to all its MSDP peers in other domains. Each intermediate MSDP peer floods this SA message away from the originating RP. The MSDP peers install this SA message in their MSDP sa-cache. If the RPs in other domains have any join requests for the group in the SA message (indicated by the presence of a (*,G) entry with non empty outgoing interface list), the domain is interested in the group, and the RP triggers an (S,G) join toward the source.
Sparse-Dense Mode

If you configure either sparse mode or dense mode on an interface, then sparseness or denseness is applied to the interface as a whole. However, some environments might require PIM to run in a single region in sparse mode for some groups and in dense mode for other groups.

An alternative to enabling only dense mode or only sparse mode is to enable sparse-dense mode. In this case, the interface is treated as dense mode if the group is in dense mode; the interface is treated in sparse mode if the group is in sparse mode. You must have an RP if the interface is in sparse-dense mode and you want to treat the group as a sparse group.

If you configure sparse-dense mode, the idea of sparseness or denseness is applied to the groups for which the router is a member.

Another benefit of sparse-dense mode is that Auto-RP information can be distributed in a dense mode; yet, multicast groups for user groups can be used in a sparse mode manner. Therefore there is no need to configure a default RP at the leaf routers.

When an interface is treated in dense mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

• Members or DVMRP neighbors are on the interface.
• There are PIM neighbors and the group has not been pruned.

When an interface is treated in sparse mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

• Members or DVMRP neighbors are on the interface.
• An explicit Join message has been received by a PIM neighbor on the interface.

PIM Versions

PIMv2 includes these improvements over PIMv1:

• A single, active rendezvous point (RP) exists per multicast group, with multiple backup RPs. This single RP compares to multiple active RPs for the same group in PIMv1.
• A bootstrap router (BSR) provides a fault-tolerant, automated RP discovery and distribution function that enables routers and multilayer devices to dynamically learn the group-to-RP mappings.
• Sparse mode and dense mode are properties of a group, as opposed to an interface.

Note

We strongly recommend using sparse-dense mode as opposed to either sparse mode or dense mode only.

• PIM join and prune messages have more flexible encoding for multiple address families.
• A more flexible hello packet format replaces the query packet to encode current and future capability options.
• Register messages sent to an RP specify whether they are sent by a border router or a designated router.
• PIM packets are no longer inside IGMP packets; they are standalone packets.
PIM Stub Routing

The PIM stub routing feature, available in all of the device software images, reduces resource usage by moving routed traffic closer to the end user.

The PIM stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards IGMP traffic.

In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IP multicast routing and configure only the device as a PIM stub router. The device does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the device. The device uplink port cannot be used with SVIs. If you need PIM for an SVI uplink port, you should upgrade to the IP Services feature set.

You must also configure EIGRP stub routing when configuring PIM stub routing on the device.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM asset and designated router election mechanisms are not supported on the PIM passive interfaces. Only the nonredundant access router topology is supported by the PIM stub feature. By using a nonredundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

*Figure 19: PIM Stub Router Configuration*

In the following figure, the Device A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source 200.1.1.3.
IGMP Helper

PIM stub routing moves routed traffic closer to the end user and reduces network traffic. You can also reduce traffic by configuring a stub router (switch) with the IGMP helper feature.

You can configure a stub router (switch) with the `ip igmp helper-address ip-address` interface configuration command to enable the switch to send reports to the next-hop interface. Hosts that are not directly connected to a downstream router can then join a multicast group sourced from an upstream network. The IGMP packets from a host wanting to join a multicast stream are forwarded upstream to the next-hop device when this feature is configured. When the upstream central router receives the helper IGMP reports or leaves, it adds or removes the interfaces from its outgoing interface list for that group.

Rendezvous Points

A rendezvous point (RP) is a role that a device performs when operating in Protocol Independent Multicast (PIM) Sparse Mode (SM). An RP is required only in networks running PIM SM. In the PIM-SM model, only network segments with active receivers that have explicitly requested multicast data will be forwarded the traffic. This method of delivering multicast data is in contrast to PIM Dense Mode (PIM DM). In PIM DM, multicast traffic is initially flooded to all segments of the network. Routers that have no downstream neighbors or directly connected receivers prune back the unwanted traffic.

An RP acts as the meeting place for sources and receivers of multicast data. In a PIM-SM network, sources must send their traffic to the RP. This traffic is then forwarded to receivers down a shared distribution tree. By default, when the first hop device of the receiver learns about the source, it will send a Join message directly to the source, creating a source-based distribution tree from the source to the receiver. This source tree does not include the RP unless the RP is located within the shortest path between the source and receiver.

In most cases, the placement of the RP in the network is not a complex decision. By default, the RP is needed only to start new sessions with sources and receivers. Consequently, the RP experiences little overhead from traffic flow or processing. In PIM version 2, the RP performs less processing than in PIM version 1 because sources must only periodically register with the RP to create state.
Auto-RP

In the first version of PIM-SM, all leaf routers (routers directly connected to sources or receivers) were required to be manually configured with the IP address of the RP. This type of configuration is also known as static RP configuration. Configuring static RPs is relatively easy in a small network, but it can be laborious in a large, complex network.

Following the introduction of PIM-SM version 1, Cisco implemented a version of PIM-SM with the Auto-RP feature. Auto-RP automates the distribution of group-to-RP mappings in a PIM network. Auto-RP has the following benefits:

- Configuring the use of multiple RPs within a network to serve different groups is easy.
- Auto-RP allows load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Auto-RP avoids inconsistent, manual RP configurations that can cause connectivity problems.

Multiple RPs can be used to serve different group ranges or serve as backups to each other. For Auto-RP to work, a router must be designated as an RP-mapping agent, which receives the RP-announcement messages from the RPs and arbitrates conflicts. The RP-mapping agent then sends the consistent group-to-RP mappings to all other routers. Thus, all routers automatically discover which RP to use for the groups they support.

If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must statically configure an RP.

If router interfaces are configured in sparse mode, Auto-RP can still be used if all routers are configured with a static RP address for the Auto-RP groups.

To make Auto-RP work, a router must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other routers by dense mode flooding. Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP. One advantage of Auto-RP is that any change to the RP designation must be configured only on the routers that are RPs and not on the leaf routers. Another advantage of Auto-RP is that it offers the ability to scope the RP address within a domain. Scoping can be achieved by defining the time-to-live (TTL) value allowed for the Auto-RP advertisements.

Each method for configuring an RP has its own strengths, weaknesses, and level of complexity. In conventional IP multicast network scenarios, we recommend using Auto-RP to configure RPs because it is easy to configure, well-tested, and stable. The alternative ways to configure an RP are static RP, Auto-RP, and bootstrap router.

Related Topics

- Setting Up Auto-RP in a New Internetwork (CLI), on page 434
The Role of Auto-RP in a PIM Network

Auto-RP automates the distribution of group-to-rendezvous point (RP) mappings in a PIM network. To make Auto-RP work, a device must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other devices by way of dense mode flooding.

Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP.

The mapping agent receives announcements of intention to become the RP from Candidate-RPs. The mapping agent then announces the winner of the RP election. This announcement is made independently of the decisions by the other mapping agents.

Multicast Boundaries

Administratively-scoped boundaries can be used to limit the forwarding of multicast traffic outside of a domain or subdomain. This approach uses a special range of multicast addresses, called administratively-scoped addresses, as the boundary mechanism. If you configure an administratively-scoped boundary on a routed interface, multicast traffic whose multicast group addresses fall in this range cannot enter or exit this interface, which provides a firewall for multicast traffic in this address range.

Multicast boundaries and TTL thresholds control the scoping of multicast domains; however, TTL thresholds are not supported by the device. You should use multicast boundaries instead of TTL thresholds to limit the forwarding of multicast traffic outside of a domain or a subdomain.

Figure 20: Administratively-Scoped Boundaries

The following figure shows that Company XYZ has an administratively-scoped boundary set for the multicast address range 239.0.0.0/8 on all routed interfaces at the perimeter of its network. This boundary prevents any multicast traffic in the range 239.0.0.0 through 239.255.255.255 from entering or leaving the network. Similarly, the engineering and marketing departments have an administratively-scoped boundary of 239.128.0.0/16 around the perimeter of their networks. This boundary prevents multicast traffic in the range of 239.128.0.0 through 239.128.255.255 from entering or leaving their respective networks.
You can define an administratively-scoped boundary on a routed interface for multicast group addresses. A standard access list defines the range of addresses affected. When a boundary is defined, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The IANA has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively-scoped addresses. This range of addresses can then be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

You can configure the `filter-autorp` keyword to examine and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

**Sparse-Dense Mode for Auto-RP**

A prerequisite of Auto-RP is that all interfaces must be configured in sparse-dense mode using the `ip pim sparse-dense-mode` interface configuration command. An interface configured in sparse-dense mode is treated in either sparse mode or dense mode of operation, depending on which mode the multicast group operates. If a multicast group has a known RP, the interface is treated in sparse mode. If a group has no known RP, by default the interface is treated in dense mode and data will be flooded over this interface. (You can prevent dense-mode fallback; see the module “Configuring Basic IP Multicast.”)

To successfully implement Auto-RP and prevent any groups other than 224.0.1.39 and 224.0.1.40 from operating in dense mode, we recommend configuring a "sink RP" (also known as “RP of last resort”). A sink RP is a statically configured RP that may or may not actually exist in the network. Configuring a sink RP does not interfere with Auto-RP operation because, by default, Auto-RP messages supersede static RP configurations. We recommend configuring a sink RP for all possible multicast groups in your network, because it is possible for an unknown or unexpected source to become active. If no RP is configured to limit source registration, the group may revert to dense mode operation and be flooded with data.

**Auto-RP Benefits**

Auto-RP uses IP multicast to automate the distribution of group-to-RP mappings to all Cisco routers and multilayer devices in a PIM network. Auto-RP has these benefits:

- Easy to use multiple RPs within a network to serve different group ranges.
- Provides load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Avoids inconsistent, manual RP configurations on every router and multilayer device in a PIM network, which can cause connectivity problems.
Benefits of Auto-RP in a PIM Network

- Auto-RP allows any change to the RP designation to be configured only on the devices that are RPs, not on the leaf routers.
- Auto-RP offers the ability to scope the RP address within a domain.

PIMv2 Bootstrap Router

PIMv2 Bootstrap Router (BSR) is another method to distribute group-to-RP mapping information to all PIM routers and multilayer devices in the network. It eliminates the need to manually configure RP information in every router and device in the network. However, instead of using IP multicast to distribute group-to-RP mapping information, BSR uses hop-by-hop flooding of special BSR messages to distribute the mapping information.

The BSR is elected from a set of candidate routers and devices in the domain that have been configured to function as BSRs. The election mechanism is similar to the root-bridge election mechanism used in bridged LANs. The BSR election is based on the BSR priority of the device contained in the BSR messages that are sent hop-by-hop through the network. Each BSR device examines the message and forwards out all interfaces only the message that has either a higher BSR priority than its BSR priority or the same BSR priority, but with a higher BSR IP address. Using this method, the BSR is elected.

The elected BSR sends BSR messages with a TTL of 1. Neighboring PIMv2 routers or multilayer devices receive the BSR message and multicast it out all other interfaces (except the one on which it was received) with a TTL of 1. In this way, BSR messages travel hop-by-hop throughout the PIM domain. Because BSR messages contain the IP address of the current BSR, the flooding mechanism enables candidate RPs to automatically learn which device is the elected BSR.

Candidate RPs send candidate RP advertisements showing the group range for which they are responsible to the BSR, which stores this information in its local candidate-RP cache. The BSR periodically advertises the contents of this cache in BSR messages to all other PIM devices in the domain. These messages travel hop-by-hop through the network to all routers and devices, which store the RP information in the BSR message in their local RP cache. The routers and devices select the same RP for a given group because they all use a common RP hashing algorithm.

PIM Domain Border

As IP multicast becomes more widespread, the chance of one PIMv2 domain bordering another PIMv2 domain increases. Because two domains probably do not share the same set of RPs, BSR, candidate RPs, and candidate BSRs, you need to constrain PIMv2 BSR messages from flowing into or out of the domain. Allowing messages to leak across the domain borders could adversely affect the normal BSR election mechanism and elect a single BSR across all bordering domains and comingle candidate RP advertisements, resulting in the election of RPs in the wrong domain.

Multicast Forwarding

Forwarding of multicast traffic is accomplished by multicast-capable routers. These routers create distribution trees that control the path that IP multicast traffic takes through the network in order to deliver traffic to all receivers.

Multicast traffic flows from the source to the multicast group over a distribution tree that connects all of the sources to all of the receivers in the group. This tree may be shared by all sources (a shared tree) or a separate distribution tree can be built for each source (a source tree). The shared tree may be one-way or bidirectional.

Before describing the structure of source and shared trees, it is helpful to explain the notations that are used in multicast routing tables. These notations include the following:

- \((S,G)\) = (unicast source for the multicast group G, multicast group G)
- \((*,G)\) = (any source for the multicast group G, multicast group G)

The notation of \((S,G)\), pronounced “S comma G,” enumerates a shortest path tree where S is the IP address of the source and G is the multicast group address.

Shared trees are \((*,G)\) and the source trees are \((S,G)\) and always routed at the sources.

Multicast Distribution Source Tree

The simplest form of a multicast distribution tree is a source tree. A source tree has its root at the source host and has branches forming a spanning tree through the network to the receivers. Because this tree uses the shortest path through the network, it is also referred to as a shortest path tree (SPT).

The figure shows an example of an SPT for group 224.1.1.1 rooted at the source, Host A, and connecting two receivers, Hosts B and C.

Using standard notation, the SPT for the example shown in the figure would be \((192.168.1.1, 224.1.1.1)\).

The \((S,G)\) notation implies that a separate SPT exists for each individual source sending to each group—which is correct.
Multicast Distribution Shared Tree

Unlike source trees that have their root at the source, shared trees use a single common root placed at some chosen point in the network. This shared root is called a rendezvous point (RP).

The following figure shows a shared tree for the group 224.2.2.2 with the root located at Router D. This shared tree is unidirectional. Source traffic is sent towards the RP on a source tree. The traffic is then forwarded down the shared tree from the RP to reach all of the receivers (unless the receiver is located between the source and the RP, in which case it will be serviced directly).

**Figure 21: Shared Tree**

In this example, multicast traffic from the sources, Hosts A and D, travels to the root (Router D) and then down the shared tree to the two receivers, Hosts B and C. Because all sources in the multicast group use a common shared tree, a wildcard notation written as (*, G), pronounced “star comma G,” represents the tree. In this case, * means all sources, and G represents the multicast group. Therefore, the shared tree shown in the figure would be written as (*, 224.2.2.2).

Both source trees and shared trees are loop-free. Messages are replicated only where the tree branches. Members of multicast groups can join or leave at any time; therefore the distribution trees must be dynamically updated. When all the active receivers on a particular branch stop requesting the traffic for a particular multicast group, the routers prune that branch from the distribution tree and stop forwarding traffic down that branch. If one receiver on that branch becomes active and requests the multicast traffic, the router will dynamically modify the distribution tree and start forwarding traffic again.

**Source Tree Advantage**

Source trees have the advantage of creating the optimal path between the source and the receivers. This advantage guarantees the minimum amount of network latency for forwarding multicast traffic. However, this optimization comes at a cost. The routers must maintain path information for each source. In a network that has thousands of sources and thousands of groups, this overhead can quickly become a resource issue on the routers. Memory consumption from the size of the multicast routing table is a factor that network designers must take into consideration.
Shared Tree Advantage

Shared trees have the advantage of requiring the minimum amount of state in each router. This advantage lowers the overall memory requirements for a network that only allows shared trees. The disadvantage of shared trees is that under certain circumstances the paths between the source and receivers might not be the optimal paths, which might introduce some latency in packet delivery. For example, in the figure above the shortest path between Host A (source) and Host B (a receiver) would be Router A and Router C. Because we are using Router D as the root for a shared tree, the traffic must traverse Routers A, B, D and then C. Network designers must carefully consider the placement of the rendezvous point (RP) when implementing a shared tree-only environment.

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination address and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)—which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is described in the following section.

PIM Shared Tree and Source Tree

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

**Figure 22: Shared Tree and Source Tree (Shortest-Path Tree)**

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

![Shared Tree Diagram](image)

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree.
or source tree. By default, the software devices to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.
4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.
5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.
6. By default, reception of the first data packet prompts Router C to send a join message toward the source.
7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.
8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the `ip pim spt-threshold` global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

Delivering the Use of PIM Shortest-Path Tree (CLI), on page 454

**Reverse Path Forwarding**

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination network and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.
In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)—which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is an algorithm used for forwarding multicast datagrams.

Protocol Independent Multicast (PIM) uses the unicast routing information to create a distribution tree along the reverse path from the receivers towards the source. The multicast routers then forward packets along the distribution tree from the source to the receivers. RPF is a key concept in multicast forwarding. It enables routers to correctly forward multicast traffic down the distribution tree. RPF makes use of the existing unicast routing table to determine the upstream and downstream neighbors. A router will forward a multicast packet only if it is received on the upstream interface. This RPF check helps to guarantee that the distribution tree will be loop-free.

**RPF Check**

When a multicast packet arrives at a router, the router performs an RPF check on the packet. If the RPF check succeeds, the packet is forwarded. Otherwise, it is dropped.

For traffic flowing down a source tree, the RPF check procedure works as follows:

1. The router looks up the source address in the unicast routing table to determine if the packet has arrived on the interface that is on the reverse path back to the source.

2. If the packet has arrived on the interface leading back to the source, the RPF check succeeds and the packet is forwarded out the interfaces present in the outgoing interface list of a multicast routing table entry.

3. If the RPF check in Step 2 fails, the packet is dropped.

The figure shows an example of an unsuccessful RPF check.

*Figure 23: RPF Check Fails*

As the figure illustrates, a multicast packet from source 151.10.3.21 is received on serial interface 0 (S0). A check of the unicast route table shows that S1 is the interface this router would use to forward unicast data to 151.10.3.21. Because the packet has arrived on interface S0, the packet is discarded.

The figure shows an example of a successful RPF check.
In this example, the multicast packet has arrived on interface S1. The router refers to the unicast routing table and finds that S1 is the correct interface. The RPF check passes, and the packet is forwarded.

PIM uses both source trees and RP-rooted shared trees to forward datagrams. The RPF check is performed differently for each:

- If a PIM router or multilayer device has a source-tree state (that is, an (S, G) entry is present in the multicast routing table), it performs the RPF check against the IP address of the source of the multicast packet.
- If a PIM router or multilayer device has a shared-tree state (and no explicit source-tree state), it performs the RPF check on the RP address (which is known when members join the group).

DVMRP and dense-mode PIM use only source trees and use RPF.

**Note**

DVMRP is not supported on the device.

Sparse-mode PIM uses the RPF lookup function to decide where it needs to send joins and prunes:

- \((S, G)\) joins (which are source-tree states) are sent toward the source.
- \((*,G)\) joins (which are shared-tree states) are sent toward the RP.

## Default PIM Routing Configuration

This table displays the default PIM routing configuration for the device.

| 4    | `ip pim passive`  
**Example:**  

Device(config-if)# ip pim passive | Configures the PIM stub feature on the interface. |
| 5    | `end`  
**Example:**  

Device(config)# end | Returns to privileged EXEC mode. |
| 6    | `show ip pim interface`  
**Example:**  

Device# show ip pim interface | (Optional) Displays the PIM stub that is enabled on each interface. |
| 7    | `show ip igmp groups detail`  
**Example:**  

Device# show ip igmp groups detail | (Optional) Displays the interested clients that have joined the specific multicast source group. |
| 8    | `show ip mrout`  
**Example:**  

Device# show ip mrout | (Optional) Displays the IP multicast routing table. |
| 9    | `show running-config`  
**Example:**  

Device# show running-config | Verifies your entries. |
| 10   | `copy running-config startup-config`  
**Example:**  

Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
Configuring a Rendezvous Point

You must have a rendezvous point (RP), if the interface is in sparse-dense mode and if you want to handle the group as a sparse group. You can use these methods:

- By manually assigning an RP to multicast groups.
- As a standalone, Cisco-proprietary protocol separate from PIMv1, which includes:
  - Setting up Auto-RP in a new internetwork
  - Adding Auto-RP to an existing sparse-mode cloud
  - Preventing join messages to false RPs
  - Filtering incoming RP announcement messages

- By using a standards track protocol in the Internet Engineering Task Force (IETF), which includes configuring PIMv2 BSR.

**Note**
You can use Auto-RP, BSR, or a combination of both, depending on the PIM version that you are running and the types of routers in your network. For information about working with different PIM versions in your network, see **PIMv1 and PIMv2 Interoperability**, on page 412.

**Related Topics**
- **Configuring the Candidate RPs (CLI)**, on page 447
- **Rendezvous Points**, on page 419

**Manually Assigning an RP to Multicast Groups (CLI)**

If the rendezvous point (RP) for a group is learned through a dynamic mechanism (such as Auto-RP or BSR), you need not perform this task for that RP.

Senders of multicast traffic announce their existence through register messages received from the source first-hop router (designated router) and forwarded to the RP. Receivers of multicast packets use RPs to join a multicast group by using explicit join messages.

**Note**
RPs are not members of the multicast group; they serve as a *meeting place* for multicast sources and group members.

You can configure a single RP for multiple groups defined by an access list. If there is no RP configured for a group, the multilayer device responds to the group as dense and uses the dense-mode PIM techniques.
This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip pim rp-address ip-address [access-list-number] [override]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>ip pim rp-address ip-address [access-list-number] [override]</code></td>
<td>Configures the address of a PIM RP. By default, no PIM RP address is configured. You must configure the IP address of RPs on all routers and multilayer devices (including the RP).</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# ip pim rp-address 10.1.1.20 override</code></td>
<td></td>
</tr>
</tbody>
</table>

**Note**
If there is no RP configured for a group, the device treats the group as dense, using the dense-mode PIM techniques.

A PIM device can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain. The access list conditions specify for which groups the device is an RP.

- For `ip-address`, enter the unicast address of the RP in dotted-decimal notation.
- (Optional) For `access-list-number`, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.
- (Optional) The **override** keyword indicates that if there is a conflict between the RP configured with this command and one learned by Auto-RP or BSR, the RP configured with this command prevails.

### Setting Up Auto-RP in a New Internetwork (CLI)

If you are setting up Auto-RP in a new internetwork, you do not need a default RP because you configure all the interfaces for sparse-dense mode.
Omit Step 3 in the following procedure, if you want to configure a PIM router as the RP for the local group.

### SUMMARY STEPS

1. `enable`
2. `show running-config`
3. `configure terminal`
4. `ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds`
5. `access-list access-list-number {deny | permit} source [source-wildcard]`
6. `ip pim send-rp-discovery scope ttl`
7. `end`
8. `show running-config`
9. `show ip pim rp mapping`
10. `show ip pim rp`
11. `copy running-config startup-config`

**Adding Auto-RP to an Existing Sparse-Mode Cloud (CLI)**

This section contains suggestions for the initial deployment of Auto-RP into an existing sparse-mode cloud to minimize disruption of the existing multicast infrastructure.

This procedure is optional.

**SUMMARY STEPS**

1. enable
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode. Enter your password if prompted.  
**Example:**  
Device> enable |
| **Step 2** show running-config | Verifies that a default RP is already configured on all PIM devices and the RP in the sparse-mode network. It was previously configured with the `ip pim rp-address` global configuration command.  
**Note** This step is not required for spare-dense-mode environments.  
The selected RP should have good connectivity and be available across the network. Use this RP for the global groups (for example, 224.x.x.x and other global groups). Do not reconfigure the group address range that this RP serves. RPs dynamically discovered through Auto-RP take precedence over statically configured RPs. Assume that it is desirable to use a second RP for the local groups.  
**Example:**  
Device# show running-config |
| **Step 3** configure terminal | Enters the global configuration mode.  
**Example:**  
Device# configure terminal |
| **Step 4** `ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds` | Configures another PIM device to be the candidate RP for local groups.  
**Example:**  
Device(config)# ip pim send-rp-announce gigabitethernet 1/0/5 scope 20 group-list 10 interval 120  
**• For `interface-id`, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs.**  
**• For `scope ttl`, specify the time-to-live value in hops. Enter a hop count that is high enough so that the**
RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255.

- For **group-list access-list-number**, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups.

- For **interval seconds**, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383.

| Step 5 | access-list access-list-number {deny | permit} source [source-wildcard] |

**Example:**

Device(config)# access-list 10
permit 224.0.0.0 15.255.255.255

Creates a standard access list, repeating the command as many times as necessary.

- For **access-list-number**, enter the access list number specified in Step 3.

- The **deny** keyword denies access if the conditions are matched.

- The **permit** keyword permits access if the conditions are matched.

- For **source**, enter the multicast group address range for which the RP should be used.

- (Optional) For **source-wildcard**, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

Recall that the access list is always terminated by an implicit deny statement for everything.

| Step 6 | ip pim send-rp-discovery scope ttl |

**Example:**

Device(config)# ip pim send-rp-discovery scope 50

Finds a device whose connectivity is not likely to be interrupted, and assigns it the role of RP-mapping agent.

For **scope ttl**, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255.

**Note** To remove the device as the RP-mapping agent, use the **no ip pim send-rp-discovery** global configuration command.

| Step 7 | end |

**Example:**

Returns to privileged EXEC mode.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Step 8**  
**show running-config**  
**Example:**  
Device# show running-config  

Verifies your entries.

**Step 9**  
**show ip pim rp mapping**  
**Example:**  
Device# show ip pim rp mapping  

Displays active RPs that are cached with associated multicast routing entries.

**Step 10**  
**show ip pim rp**  
**Example:**  
Device# show ip pim rp  

Displays the information cached in the routing table.

**Step 11**  
**copy running-config startup-config**  
**Example:**  
Device# copy running-config startup-config  

(Optional) Saves your entries in the configuration file.

**Related Topics**  
Sparse-Dense Mode for Auto-RP, on page 422

**Preventing Join Messages to False RPs (CLI)**

Determine whether the `ip pim accept-rp` command was previously configured throughout the network by using the `show running-config` privileged EXEC command. If the `ip pim accept-rp` command is not configured on any device, this problem can be addressed later. In those routers or multilayer devices already configured with the `ip pim accept-rp` command, you must enter the command again to accept the newly advertised RP.

To accept all RPs advertised with Auto-RP and reject all other RPs by default, use the `ip pim accept-rp auto-rp` global configuration command.

This procedure is optional.

**Related Topics**  
Example: Preventing Join Messages to False RPs, on page 470

**Filtering Incoming RP Announcement Messages (CLI)**

You can add configuration commands to the mapping agents to prevent a maliciously configured router from masquerading as a candidate RP and causing problems.

This procedure is optional.
SUMMARY STEPS

1. enable
2. configure terminal
3. `ip pim rp-announce-filter rp-list access-list-number group-list access-list-number`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

### Configuring PIMv2 BSR

The process for configuring PIMv2 BSR may involve the following optional tasks:

- Defining the PIM domain border
- Defining the IP multicast boundary
- Configuring candidate BSRs
- Configuring candidate RPs

---

**Command or Action**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Create an access list that specifies from which routers and multilayer devices the mapping agent accepts candidate RP announcements (rp-list ACL).</td>
<td></td>
</tr>
<tr>
<td>• Create an access list that specifies the range of multicast groups from which to accept or deny (group-list ACL).</td>
<td></td>
</tr>
<tr>
<td>• For source, enter the multicast group address range for which the RP should be used.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</td>
<td></td>
</tr>
<tr>
<td>The access list is always terminated by an implicit deny statement for everything.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 6**

**Example:**

Device# show running-config

Verifies your entries.

**Step 7**

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

**Related Topics**

Example: Filtering Incoming RP Announcement Messages, on page 470
Defining the PIM Domain Border (CLI)

Perform the following steps to configure the PIM domain border. This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip pim bsr-border
5. end
6. show running-config
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

Configuring the Candidate RPs (CLI)

You can configure one or more candidate RPs. Similar to BSRs, the RPs should also have good connectivity to other devices and be in the backbone portion of the network. An RP can serve the entire IP multicast address space or a portion of it. Candidate RPs send candidate RP advertisements to the BSR.

This procedure is optional.
Before you begin

When deciding which devices should be RPs, consider these options:

- In a network of Cisco routers and multilayer devices where only Auto-RP is used, any device can be configured as an RP.

- In a network that includes only Cisco PIMv2 routers and multilayer devices and with routers from other vendors, any device can be used as an RP.

- In a network of Cisco PIMv1 routers, Cisco PIMv2 routers, and routers from other vendors, configure only Cisco PIMv2 routers and multilayer devices as RPs.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip pim rp-candidate interface-id [group-list access-list-number]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. end
6. show running-config
7. copy running-config startup-config

**DETAILED STEPS**

<table>

| Step 4 | `access-list access-list-number {deny | permit} source [source-wildcard]` | Creates a standard access list, repeating the command as many times as necessary. |
|---------|-------------------------------------------------------------|-----------------------------------------------|
| Example: | | For `group-list access-list-number`, enter an IP standard access list number from 1 to 99. If no group-list is specified, the device is a candidate RP for all groups. |
### Command or Action

**Example:**

```plaintext
Device(config)# access-list 10 permit 239.0.0.0/24
0.255.255.255
```

**Purpose**

- For `access-list-number`, enter the access list number specified in Step 2.
- The `deny` keyword denies access if the conditions are matched. The `permit` keyword permits access if the conditions are matched.
- For `source`, enter the number of the network or host from which the packet is being sent.
- (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

The access list is always terminated by an implicit deny statement for everything.

**Step 5**

**Example:**

```plaintext
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 6**

**Example:**

```plaintext
Device# show running-config
```

Verifies your entries.

**Step 7**

**Example:**

```plaintext
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

## Configuring Sparse Mode with Auto-RP(CLI)

### Before you begin

- An interface configured in sparse-dense mode is treated in either sparse mode or dense mode of operation, depending on the mode in which the multicast group operates. You must decide how to configure your interfaces.
• All access lists that are needed when Auto-RP is configured should be configured prior to beginning the configuration task.

Note

• If a group has no known RP and the interface is configured to be sparse-dense mode, the interface is treated as if it were in dense mode, and data is flooded over the interface. To avoid this data flooding, configure the Auto-RP listener and then configure the interface as sparse mode.

• When configuring Auto-RP, you must either configure the Auto-RP listener feature (Step 5) and specify sparse mode (Step 7) or specify sparse-dense mode (Step 8).

• When you configure sparse-dense mode, dense mode failover may result in a network dense-mode flood. To avoid this condition, use PIM sparse mode with the Auto-RP listener feature.

Follow this procedure to configure auto-rendezvous point (Auto-RP). Auto-RP can also be optionally used with anycast RP.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast-routing [distributed]`
4. Either perform Steps 5 through 7 or perform Steps 6 and 8.
5. `ip pim autorp listener`
6. `interface type number`
7. `ip pim sparse-mode`
8. `ip pim sparse-dense-mode`
9. `exit`
10. Repeat Steps 1 through 9 on all PIM interfaces.
11. `ip pim send-rp-announce {interface-type interface-number | ip-address} scope ttl-value [group-list access-list] [interval seconds] [bidir]`
12. `ip pim send-rp-discovery {interface-type interface-number} scope ttl-value [interval seconds]`
13. `ip pim rp-announce-filter rp-list access-list group-list access-list`
14. `no ip pim dm-fallback`
15. `interface type number`
16. `ip multicast boundary access-list [filter-autorp]`
17. `end`
18. `show ip pim autorp`
19. `show ip pim rp [mapping] [rp-address]`
20. `show ip igmp groups [group-name | group-address| interface-type interface-number] [detail]`
21. `show ip mroute [group-address | group-name] [source-address | source-name] [interface-type interface-number] [summary] [count] [active kbps]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td><code>Example:</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>Enters global configuration mode.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

configure terminal  
Example:  
Device# configure terminal

Enables IP multicast routing.  
- Use the *distributed* keyword to enabled Multicast Distributed Switching.

**Step 3**

ip multicast-routing [distributed]  
Example:  
Device(config)# ip multicast-routing

Either perform Steps 5 through 7 or perform Steps 6 and 8.

**Step 4**

ip pim autorp listener  
Example:  
Device(config)# ip pim autorp listener

Causes IP multicast traffic for the two Auto-RP groups 224.0.1.39 and 224.0.1.40 to be PIM dense mode flooded across interfaces operating in PIM sparse mode.  
- Skip this step if you are configuring sparse-dense mode in Step 8.

**Step 5**

interface type number  
Example:  
Device(config)# interface Gigabitethernet 1/0/0

Selects an interface that is connected to hosts on which PIM can be enabled.

**Step 7**

ip pim sparse-mode  
Example:  
Device(config-if)# ip pim sparse-mode

Enables PIM sparse mode on an interface. When configuring Auto-RP in sparse mode, you must also configure the Auto-RP listener in the next step.  
- Skip this step if you are configuring sparse-dense mode in Step 8.

**Step 8**

ip pim sparse-dense-mode  
Example:  
Device(config-if)# ip pim sparse-dense-mode

Enables PIM sparse-dense mode on an interface.  
- Skip this step if you configured sparse mode in Step 7.

**Step 9**

exit  
Example:  
Device(config-if)# exit

Exits interface configuration mode and returns to global configuration mode.

**Step 10**

Repeat Steps 1 through 9 on all PIM interfaces.

**Step 11**

ip pim send-rp-announce {interface-type interface-number | ip-address} scope ttl-value [group-list access-list] [interval seconds] [bidir]

Sends RP announcements out all PIM-enabled interfaces.  
- Perform this step on the RP device only.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Example:**      | • Use the `interface-type` and `interface-number` arguments to define which IP address is to be used as the RP address.  
• Use the `ip-address` argument to specify a directly connected IP address as the RP address.  

### Note
If the `ip-address` argument is configured for this command, the RP-announce message will be sourced by the interface to which this IP address is connected (that is, the source address in the IP header of the RP-announce message is the IP address of that interface).  

• This example shows that the interface is enabled with a maximum of 31 hops. The IP address by which the device wants to be identified as RP is the IP address associated with loopback interface 0. Access list 5 describes the groups for which this device serves as RP. |

---

| Step 12 | **ip pim send-rp-discovery** `[interface-type interface-number] scope ttl-value [interval seconds]` | Configures the device to be an RP mapping agent.  
• Perform this step on RP mapping agent devices or on combined RP/RP mapping agent devices.  

### Note
Auto-RP allows the RP function to run separately on one device and the RP mapping agent to run on one or multiple devices. It is possible to deploy the RP and the RP mapping agent on a combined RP/RP mapping agent device.  

• Use the optional `interface-type` and `interface-number` arguments to define which IP address is to be used as the source address of the RP mapping agent.  

• Use the `scope` keyword and `ttl-value` argument to specify the Time-to-Live (TTL) value in the IP header of Auto-RP discovery messages.  

• Use the optional `interval` keyword and `seconds` argument to specify the interval at which Auto-RP discovery messages are sent. |
### Command or Action

<table>
<thead>
<tr>
<th>Step 13</th>
<th>ip pim rp-announce-filter rp-list access-list group-list access-list</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ip pim rp-announce-filter rp-list 1 group-list 2</td>
</tr>
</tbody>
</table>

### Purpose

**Note** Lowering the interval at which Auto-RP discovery messages are sent from the default value of 60 seconds results in more frequent floodings of the group-to-RP mappings. In some network environments, the disadvantages of lowering the interval (more control packet overhead) may outweigh the advantages (more frequent group-to-RP mapping updates).

- The example shows limiting the Auto-RP discovery messages to 31 hops on loopback interface 1.

#### Step 14

**no ip pim dm-fallback**

**Example:**

Device(config)# no ip pim dm-fallback

(Optional) Prevents PIM dense mode fallback.

- Skip this step if all interfaces have been configured to operate in PIM sparse mode.

**Note** The `no ip pim dm-fallback` command behavior is enabled by default if all the interfaces are configured to operate in PIM sparse mode (using the `ip pim sparse-mode` command).

#### Step 15

**interface type number**

**Example:**

Device(config)# interface gigabitethernet 1/0/0

Selects an interface that is connected to hosts on which PIM can be enabled.

#### Step 16

**ip multicast boundary access-list [filter-autorp]**

**Example:**

Device(config-if)# ip multicast boundary 10 filter-autorp

Configures an administratively scoped boundary.

- Perform this step on the interfaces that are boundaries to other devices.
- The access list is not shown in this task.
- An access list entry that uses the `deny` keyword creates a multicast boundary for packets that match that entry.

#### Step 17

**end**

**Example:**

Device(config-if)# end

Returns to global configuration mode.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 18</strong> show ip pim autorp</td>
<td>(Optional) Displays the Auto-RP information.</td>
</tr>
<tr>
<td>Example: Device# show ip pim autorp</td>
<td></td>
</tr>
<tr>
<td><strong>Step 19</strong> show ip pim rp [mapping] [rp-address]</td>
<td>(Optional) Displays RPs known in the network and shows how the device learned about each RP.</td>
</tr>
<tr>
<td>Example: Device# show ip pim rp mapping</td>
<td></td>
</tr>
<tr>
<td><strong>Step 20</strong> show ip igmp groups [group-name</td>
<td>group-address</td>
</tr>
<tr>
<td>Example: Device# show ip igmp groups</td>
<td>• A receiver must be active on the network at the time that this command is issued in order for receiver information to be present on the resulting display.</td>
</tr>
<tr>
<td><strong>Step 21</strong> show ip mroute [group-address</td>
<td>group-name</td>
</tr>
<tr>
<td>Example: Device# show ip mroute cbone-audio</td>
<td></td>
</tr>
</tbody>
</table>

### Delaying the Use of PIM Shortest-Path Tree (CLI)

Perform these steps to configure a traffic rate threshold that must be reached before multicast routing is switched from the source tree to the shortest-path tree.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. access-list access-list-number {deny | permit} source [source-wildcard]
4. ip pim spt-threshold {kbps | infinity} [group-list access-list-number]
5. end
6. show running-config
7. copy running-config startup-config

---

**IP Multicast Routing**

[Page Dimensions: 612.0x792.0]
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable | Enables privileged EXEC mode. Enter your password if prompted.  
Example:  
Device> enable |
| **Step 2** | configure terminal | Enters global configuration mode.  
Example:  
Device# configure terminal |
| **Step 3** | access-list access-list-number {deny | permit} source [source-wildcard] | Creates a standard access list.  
- For access-list-number, the range is 1 to 99.  
- The deny keyword denies access if the conditions are matched.  
- The permit keyword permits access if the conditions are matched.  
- For source, specify the multicast group to which the threshold will apply.  
- (Optional) For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
The access list is always terminated by an implicit deny statement for everything.  
Example:  
Device(config)# access-list 16 permit 225.0.0.0 0.255.255.255 |
| **Step 4** | ip pim spt-threshold {kbps | infinity} [group-list access-list-number] | Specifies the threshold that must be reached before moving to shortest-path tree (spt).  
- For kbps, specify the traffic rate in kilobits per second. The default is 0 kbps.  
  **Note**  
  Because of device hardware limitations, 0 kbps is the only valid entry even though the range is 0 to 4294967.  
- Specify infinity if you want all sources for the specified group to use the shared tree, never switching to the source tree.  
- (Optional) For group-list access-list-number, specify the access list created in Step 2. If the value is 0 or if the group list is not used, the threshold applies to all groups.  
Example:  
Device(config)# ip pim spt-threshold infinity group-list 16 |
### Modifying the PIM Router-Query Message Interval (CLI)

PIM routers and multilayer devices send PIM router-query messages to find which device will be the designated router (DR) for each LAN segment (subnet). The DR is responsible for sending IGMP host-query messages to all hosts on the directly connected LAN.

With PIM DM operation, the DR has meaning only if IGMPv1 is in use. IGMPv1 does not have an IGMP querier election process, so the elected DR functions as the IGMP querier. With PIM-SM operation, the DR is the device that is directly connected to the multicast source. It sends PIM register messages to notify the RP that multicast traffic from a source needs to be forwarded down the shared tree. In this case, the DR is the device with the highest IP address.

This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. ip pim query-interval seconds
5. end
6. show ip igmp interface [interface-id]
7. copy running-config startup-config

---

Verifying PIM Operations

Verifying IP Multicast Operation in a PIM-SM or a PIM-SSM Network

When you verify the operation of IP multicast in a PIM-SM network environment or in an PIM-SSM network environment, a useful approach is to begin the verification process on the last hop router, and then continue the verification process on the routers along the SPT until the first hop router has been reached. The goal of the verification is to ensure that IP multicast traffic is being routed properly through an IP multicast network.

Perform the following optional tasks to verify IP multicast operation in a PIM-SM or a PIM-SSM network. The steps in these tasks help to locate a faulty hop when sources and receivers are not operating as expected.

Note: If packets are not reaching their expected destinations, you might want consider disabling IP multicast fast switching, which would place the router in process switching mode. If packets begin reaching their proper destinations after IP multicast fast switching has been disabled, then the issue most likely was related to IP multicast fast switching.

Verifying IP Multicast on the First Hop Router

Enter these commands on the first hop router to verify IP multicast operations on the first hop router:

**SUMMARY STEPS**

1. enable
2. show ip mroute [group-address]
3. show ip mroute active [kb/s]

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong> show ip mroute [group-address]</td>
<td>Confirms that the F flag has been set for mroutes on the first hop router.</td>
</tr>
<tr>
<td>Device# show ip mroute 239.1.2.3 (*, 239.1.2.3), 00:18:10/stopped, RP 172.16.0.1, flags: SPF</td>
<td></td>
</tr>
<tr>
<td>Incoming interface: Serial1/0, RPF nbr 172.31.200.2</td>
<td></td>
</tr>
<tr>
<td>Outgoing interface list: Null</td>
<td></td>
</tr>
<tr>
<td>(10.0.0.1, 239.1.2.3), 00:18:10/00:03:22, flags: FT</td>
<td></td>
</tr>
</tbody>
</table>
Verifying IP Multicast on Routers Along the SPT

Enter these commands on routers along the SPT to verify IP multicast operations on routers along the SPT in a PIM-SM or PIM-SSM network:

**SUMMARY STEPS**

1. enable
2. show ip mroute [group-address]
3. show ip mroute active

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| enable
| Example: Device> enable |
| Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
| show ip mroute [group-address]
| Example: Device# show ip mroute 239.1.2.3 (*) 239.1.2.3 00:17:56/00:03:02 RP 172.16.0.1 flags: S |
| Confirms the RPF neighbor towards the source for a particular group or groups. |
Verifying IP Multicast Operation on the Last Hop Router

Enter these commands on the last hop router to verify IP multicast operations on the last hop router:

**SUMMARY STEPS**

1. `enable`
2. `show ip igmp groups`
3. `show ip pim rp mapping`
4. `show ip mroute`
5. `show ip interface [type number]`
6. `show ip mfib`
7. `show ip pim interface count`
8. `show ip mroute count`
9. `show ip mroute active [kb/s]`

Note:

By default, the output of the `show ip mroute` command with the `active` keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the `kb/s` argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device> enable
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td><code>show ip igmp groups</code></td>
<td>Verifies IGMP memberships on the last hop router. This information will confirm the multicast groups with receivers that are directly connected to the last hop router and that are learned through IGMP.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device# show ip igmp groups
IGMP Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
239.1.2.3 GigabitEthernet1/0/0 00:05:14 00:02:14 10.1.0.6
224.0.1.39 GigabitEthernet0/0/0 00:09:11 00:02:08 172.31.100.1
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td><code>show ip pim rp mapping</code></td>
<td>Confirms that the group-to-RP mappings are being populated correctly on the last hop router.</td>
</tr>
</tbody>
</table>

**Note** Ignore this step if you are verifying a last hop router in a PIM-SSM network. The `show ip pim rp mapping` command does not work with routers in a PIM-SSM network because PIM-SSM does not use RPs. In addition, if configured correctly, PIM-SSM groups do not appear in the output of the `show ip pim rp mapping` command. |

**Example:**
```
Device# show ip pim rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4
    RP 172.16.0.1 (?), v2v1
        Info source: 172.16.0.1 (?), elected via Auto-RP
        Uptime: 00:09:11, expires: 00:02:47
```

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td><code>show ip mroute</code></td>
<td>Verifies that the mroute table is being populated properly on the last hop router.</td>
</tr>
</tbody>
</table>

**Example:**
```
Device# show ip mroute
(*, 239.1.2.3), 00:05:14/00:03:04, RP 172.16.0.1, flags: SJC
    Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1
    Outgoing interface list:
        GigabitEthernet1/0, Forward/Sparse-Dense,
        00:05:10/00:03:04

(10.0.0.1, 239.1.2.3), 00:02:49/00:03:29, flags: T
    Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1
    Outgoing interface list:
        GigabitEthernet1/0, Forward/Sparse-Dense,
        00:02:49/00:03:04

(*, 224.0.1.39), 00:10:05/stopped, RP 0.0.0.0, flags: DC
    Incoming interface: Null, RPF nbr 0.0.0.0
    Outgoing interface list:
        GigabitEthernet1/0, Forward/Sparse-Dense,
```

**IP Multicast Routing**

**Verifying IP Multicast Operation on the Last Hop Router**
### Step 5

**show ip interface [type number]**

**Example:**

```
Device# show ip interface GigabitEthernet 0/0/0
GigabitEthernet0/0 is up, line protocol is up
Internet address is 172.31.100.2/24
Broadcast address is 255.255.255.255
Address determined by setup command
MTU is 1500 bytes
Helper address is not set
Directed broadcast forwarding is disabled
Multicast reserved groups joined: 224.0.0.1
                          224.0.0.22 224.0.0.13
                          224.0.0.5 224.0.0.6
Outgoing access list is not set
Inbound access list is not set
Proxy ARP is enabled
Local Proxy ARP is disabled
Security level is default
Split horizon is enabled
ICMP redirects are always sent
ICMP unreachables are always sent
ICMP mask replies are never sent
IP fast switching is enabled
IP fast switching on the same interface is disabled
IP Flow switching is disabled
IP CEF switching is disabled
IP multicast fast switching is enabled
IP multicast distributed fast switching is disabled
IP route-cache flags are Fast
Router Discovery is disabled
IP output packet accounting is disabled
IP access violation accounting is disabled
TCP/IP header compression is disabled
RTP/IP header compression is disabled
Policy routing is disabled
Network address translation is disabled
WCCP Redirect outbound is disabled
WCCP Redirect inbound is disabled
WCCP Redirect exclude is disabled
BGP Policy Mapping is disabled
```

**Note**: Using the **no ip mroute-cache** interface command disables IP multicast fast-switching. When IP multicast fast switching is disabled, packets are forwarded through the process-switched path.

### Step 6

**show ip mfib**

**Example:**

```
Device# show ip mfib
```

**Purpose**: Displays the forwarding entries and interfaces in the IP Multicast Forwarding Information Base (MFIB).
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 7** | **show ip pim interface count**  
**Example:**  
Device# show ip pim interface count  
State: * - Fast Switched, D - Distributed Fast Switched  
H - Hardware Switching Enabled  
Address Interface FS  
Mpackets In/Out  
172.31.100.2 GigabitEthernet0/0/0 *  
4122/0  
10.1.0.1 GigabitEthernet1/0/0 *  
0/3193 | Confirms that multicast traffic is being forwarded on the last hop router. |
| **Step 8** | **show ip mroute count**  
**Example:**  
Device# show ip mroute count  
IP Multicast Statistics  
6 routes using 4008 bytes of memory  
3 groups, 1.00 average sources per group  
Forwarding Counts: Pkt Count/Pkts per second/Avg Pkt Size/Kilobits per second  
Other counts: Total/RPF failed/Other drops (OIF-null, rate-limit etc)  
Group: 239.1.2.3, Source count: 1, Packets forwarded: 3165, Packets received: 3165  
RP-tree: Forwarding: 0/0/0/0, Other: 0/0/0  
Source: 10.0.0.1/32, Forwarding: 3165/20/28/4, Other: 0/0/0  
Group: 224.0.1.39, Source count: 1, Packets forwarded: 21, Packets received: 120  
Source: 172.16.0.1/32, Forwarding: 21/1/48/0, Other: 120/0/99  
Group: 224.0.1.40, Source count: 1, Packets forwarded: 10, Packets received: 10  
Source: 172.16.0.1/32, Forwarding: 10/1/48/0, Other: 10/0/0 | Confirms that multicast traffic is being forwarded on the last hop router. |
| **Step 9** | **show ip mroute active [kb/s]**  
**Example:**  
Device# show ip mroute active  
Active IP Multicast Sources - sending >= 4 kbps | Displays information about active multicast sources sending traffic to groups on the last hop router. The output of this command provides information about the multicast packet rate for active sources. |
Using PIM-Enabled Routers to Test IP Multicast Reachability

If all the PIM-enabled routers and access servers that you administer are members of a multicast group, pinging that group causes all routers to respond, which can be a useful administrative and debugging tool.

To use PIM-enabled routers to test IP multicast reachability, perform the following tasks:

**Configuring Routers to Respond to Multicast Pings**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip igmp join-group group-address`
5. Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network.
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface type number</td>
<td>Enters interface configuration mode.</td>
</tr>
</tbody>
</table>
### Command or Action

**Example:**

Device(config)# interface gigabitethernet 1/0/0

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>For the type and number arguments, specify an interface that is directly connected to hosts or is facing hosts.</td>
</tr>
</tbody>
</table>

**Step 4**  
*ip igmp join-group group-address*

**Example:**

Device(config-if)# ip igmp join-group 225.2.2.2

(Optional) Configures an interface on the router to join the specified group.

For the purpose of this task, configure the same group address for the `group-address` argument on all interfaces on the router participating in the multicast network.

**Note**  
With this method, the router accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the router from fast switching.

**Step 5**

Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network.

**Step 6**

*end*

**Example:**

Device(config-if)# end

Ends the current configuration session and returns to privileged EXEC mode.

---

### Pinging Routers Configured to Respond to Multicast Pings

on a router to initiate a ping test to the routers configured to respond to multicast pings. This task is used to test IP multicast reachability in a network.

**SUMMARY STEPS**

1. enable
2. ping group-address

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

**Example:**

Device> enable

**Step 2** ping group-address

**Example:**

Device# ping 225.2.2.2

Pings an IP multicast group address.  
A successful response indicates that the group address is functioning.
## Monitoring and Troubleshooting PIM

### Monitoring PIM Information

Use the privileged EXEC commands in the following table to monitor your PIM configurations.

**Table 40: PIM Monitoring Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip pim all-vrfs tunnel [tunnel tunnel_number</td>
<td>verbose]`</td>
</tr>
<tr>
<td><code>show ip pim autorp</code></td>
<td>Displays global auto-RP information.</td>
</tr>
<tr>
<td><code>show ip pim boundary</code></td>
<td>Displays information about mroutes filtered by administratively scoped IPv4 multicast boundaries configured on an interface.</td>
</tr>
<tr>
<td><code>show ip pim interface</code></td>
<td>Displays information about interfaces configured for Protocol Independent Multicast (PIM).</td>
</tr>
<tr>
<td><code>show ip pim neighbor</code></td>
<td>Displays the PIM neighbor information.</td>
</tr>
<tr>
<td>`show ip pim rp [group-name</td>
<td>group-address]`</td>
</tr>
<tr>
<td>`show ip pim tunnel [tunnel</td>
<td>verbose]`</td>
</tr>
<tr>
<td>`show ip pim vrf { word { all-vrfs</td>
<td>autorp</td>
</tr>
<tr>
<td><code>show ip igmp groups detail</code></td>
<td>Displays the interested clients that have joined the specific multicast source group.</td>
</tr>
</tbody>
</table>
Monitoring the RP Mapping and BSR Information

Use the privileged EXEC mode in the following table to verify the consistency of group-to-RP mappings:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ip pim rp [ hostname or IP address</td>
<td>Displays all available RP mappings and metrics. This tells you how the device learns of the RP (through the BSR or the Auto-RP mechanism).</td>
</tr>
<tr>
<td>mapping [ hostname or IP address</td>
<td>(Optional) For the <code>hostname</code>, specify the IP name of the group about which to display RPs.</td>
</tr>
<tr>
<td>elected</td>
<td>(Optional) For the <code>IP address</code>, specify the IP address of the group about which to display RPs.</td>
</tr>
<tr>
<td>in-use ]</td>
<td>(Optional) Use the <code>mapping</code> keyword to display all group-to-RP mappings of which the Cisco device is aware (either configured or learned from Auto-RP).</td>
</tr>
<tr>
<td>metric [ hostname or IP address ] ]</td>
<td>(Optional) Use the <code>metric</code> keyword to display the RP RPF metric.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip pim rp-hash group</code></td>
<td>Displays the RP that was selected for the specified group. That is, on a PIMv2 router or multilayer device, confirms that the same RP is the one that a PIMv1 system chooses. For <code>group</code>, enter the group address for which to display RP information.</td>
</tr>
</tbody>
</table>

Use the privileged EXEC commands in the following table to monitor BSR information:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip pim bsr</code></td>
<td>Displays information about the elected BSR.</td>
</tr>
<tr>
<td><code>show ip pim bsr-router</code></td>
<td>Displays information about the BSRv2.</td>
</tr>
</tbody>
</table>

Troubleshooting PIMv1 and PIMv2 Interoperability Problems

When debugging interoperability problems between PIMv1 and PIMv2, check these in the order shown:

1. Verify RP mapping with the `show ip pim rp-hash` privileged EXEC command, making sure that all systems agree on the same RP for the same group.

2. Verify interoperability between different versions of DRs and RPs. Make sure that the RPs are interacting with the DRs properly (by responding with register-stops and forwarding decapsulated data packets from registers).

Configuration Examples for PIM

Example: Enabling PIM Stub Routing

In this example, IP multicast routing is enabled, Switch A PIM uplink port 25 is configured as a routed uplink port with spare-dense-mode enabled. PIM stub routing is enabled on the VLAN 100 interfaces and on Gigabit Ethernet port 20.

```
Device(config)# ip multicast-routing distributed
Device(config)# interface GigabitEthernet3/0/25
Device(config-if)# no switchport
Device(config-if)# ip address 3.1.1.2 255.255.255.0
Device(config-if)# ip pim sparse-dense-mode
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# no switchport
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# end
```

Example: Configuring Auto-RP

This example shows how to send RP announcements out all PIM-enabled interfaces for a maximum of 31 hops. The IP address of port 1 is the RP. Access list 5 describes the group for which this device serves as RP:

```
Device(config)# ip pim send-rp-announce gigabitethernet1/0/1 scope 31 group-list 5
Device(config)# access-list 5 permit 224.0.0.0 15.255.255.255
```

Related Topics

Setting Up Auto-RP in a New Internetwork (CLI), on page 434
Auto-RP, on page 420

Example: Sparse Mode with Auto-RP

The following example configures sparse mode with Auto-RP:

```
ip multicast-routing
ip pim autorp listener
ip pim send-rp-announce Loopback0 scope 16 group-list 1
ip pim send-rp-discovery Loopback1 scope 16
no ip pim dm-fallback
access-list 1 permit 239.254.2.0 0.0.0.255
access-list 1 permit 239.254.3.0 0.0.0.255
.
.
access-list 10 permit 224.0.1.39
access-list 10 permit 224.0.1.40
access-list 10 permit 239.254.2.0 0.0.0.255
access-list 10 permit 239.254.3.0 0.0.0.255
```

Related Topics

Setting Up Auto-RP in a New Internetwork (CLI), on page 434
Auto-RP, on page 420

Example: Defining the IP Multicast Boundary to Deny Auto-RP Information

This example shows a portion of an IP multicast boundary configuration that denies Auto-RP information:

```
Device(config)# access-list 1 deny 224.0.1.39
```
Example: Filtering Incoming RP Announcement Messages

This example shows a sample configuration on an Auto-RP mapping agent that is used to prevent candidate RP announcements from being accepted from unauthorized candidate RPs:

```
Device(config)# ip pim rp-announce-filter rp-list 10 group-list 20
Device(config)# access-list 10 permit host 172.16.5.1
Device(config)# access-list 10 permit host 172.16.2.1
Device(config)# access-list 20 deny 239.0.0.0 0.0.255.255
Device(config)# access-list 20 permit 224.0.0.0 15.255.255.255
```

The mapping agent accepts candidate RP announcements from only two devices, 172.16.5.1 and 172.16.2.1. The mapping agent accepts candidate RP announcements from these two devices only for multicast groups that fall in the group range of 224.0.0.0 to 239.255.255.255. The mapping agent does not accept candidate RP announcements from any other devices in the network. Furthermore, the mapping agent does not accept candidate RP announcements from 172.16.5.1 or 172.16.2.1 if the announcements are for any groups in the 239.0.0.0 through 239.255.255.255 range. This range is the administratively scoped address range.

Related Topics

Filtering Incoming RP Announcement Messages (CLI), on page 440

Example: Preventing Join Messages to False RPs

If all interfaces are in sparse mode, use a default-configured RP to support the two well-known groups 224.0.1.39 and 224.0.1.40. Auto-RP uses these two well-known groups to collect and distribute RP-mapping information. When this is the case and the `ip pim accept-rp auto-rp` command is configured, another `ip pim accept-rp` command accepting the RP must be configured as follows:

```
Device(config)# ip pim accept-rp 172.10.20.1 1
Device(config)# access-list 1 permit 224.0.1.39
Device(config)# access-list 1 permit 224.0.1.40
```

Related Topics

Preventing Join Messages to False RPs (CLI), on page 440

Example: Configuring Candidate BSRs

This example shows how to configure a candidate BSR, which uses the IP address 172.21.24.18 on a port as the advertised BSR address, uses 30 bits as the hash-mask-length, and has a priority of 10.

```
Device(config)# interface gigabitethernet1/0/2
```
Example: Configuring Candidate RPs

This example shows how to configure the device to advertise itself as a candidate RP to the BSR in its PIM domain. Standard access list number 4 specifies the group prefix associated with the RP that has the address identified by a port. That RP is responsible for the groups with the prefix 239.

Device(config)# ip pim rp-candidate gigabitethernet1/0/2 group-list 4
Device(config)# access-list 4 permit 239.0.0.0 0.255.255.255

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About PIM MIB Extension for IP Multicast

PIM MIB Extensions for SNMP Traps for IP Multicast

Protocol Independent Multicast (PIM) is an IP multicast routing protocol used for routing multicast data packets to multicast groups. RFC 2934 defines the PIM MIB for IPv4, which describes managed objects that enable users to remotely monitor and configure PIM using Simple Network Management Protocol (SNMP).

PIM MIB extensions introduce the following new classes of PIM notifications:

- neighbor-change--This notification results from the following conditions:
  - A router’s PIM interface is disabled or enabled (using the `ip pim` command in interface configuration mode)
  - A router’s PIM neighbor adjacency expires (defined in RFC 2934)

- rp-mapping-change--This notification results from a change in the rendezvous point (RP) mapping information due to either Auto-RP messages or bootstrap router (BSR) messages.
Benefits of PIM MIB Extensions

PIM MIB extensions:
- Allow users to identify changes in the multicast topology of their network by detecting changes in the RP mapping.
- Provide traps to monitor the PIM protocol on PIM-enabled interfaces.
- Help users identify routing issues when multicast neighbor adjacencies expire on a multicast interface.
- Enable users to monitor RP configuration errors (for example, errors due to flapping in dynamic RP allocation protocols like Auto-RP).

How to Configure PIM MIB Extension for IP Multicast

Enabling PIM MIB Extensions for IP Multicast

Perform this task to enable PIM MIB extensions for IP multicast.

**Note**
- The pimInterfaceVersion object was removed from RFC 2934 and, therefore, is no longer supported in software.
- The following MIB tables are not supported in Cisco software:
  - `pimIpMRouteTable`
  - `pimIpMRouteNextHopTable`

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `snmp-server enable traps pim [neighbor-change | rp-mapping-change | invalid-pim-message]`
4. `snmp-server host host-address [traps | informs] community-string pim`
## DETAILED STEPS

<table>

Configuration Examples for PIM MIB Extensions

Example Enabling PIM MIB Extensions for IP Multicast

The following example shows how to configure a router to generate notifications indicating that a PIM interface of the router has been enabled. The first line configures PIM traps to be sent as SNMP v2c traps to the host with IP address 10.0.0.1. The second line configures the router to send the neighbor-change class of trap notification to the host.

```
snmp-server host 10.0.0.1 traps version 2c public pim
snmp-server enable traps pim neighbor-change
interface ethernet0/0
ip pim sparse-dense-mode
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Using MSDP to Interconnect Multiple PIM-SM Domains

Benefits of Using MSDP to Interconnect Multiple PIM-SM Domains

- Allows a rendezvous point (RP) to dynamically discover active sources outside of its domain.
- Introduces a more manageable approach for building multicast distribution trees between multiple domains.
MSDP is a mechanism to connect multiple PIM-SM domains. The purpose of MSDP is to discover multicast sources in other PIM domains. The main advantage of MSDP is that it reduces the complexity of interconnecting multiple PIM-SM domains by allowing PIM-SM domains to use an interdomain source tree (rather than a common shared tree). When MSDP is configured in a network, RPs exchange source information with RPs in other domains. An RP can join the interdomain source tree for sources that are sending to groups for which it has receivers. The RP can do that because it is the root of the shared tree within its domain, which has branches to all points in the domain where there are active receivers. When a last-hop device learns of a new source outside the PIM-SM domain (through the arrival of a multicast packet from the source down the shared tree), it then can send a join toward the source and join the interdomain source tree.

---

**Note**

If the RP either has no shared tree for a particular group or a shared tree whose outgoing interface list is null, it does not send a join to the source in another domain.

When MSDP is enabled, an RP in a PIM-SM domain maintains MSDP peering relationships with MSDP-enabled devices in other domains. This peering relationship occurs over a TCP connection, where primarily a list of sources sending to multicast groups is exchanged. MSDP uses TCP (port 639) for its peering connections. As with BGP, using point-to-point TCP peering means that each peer must be explicitly configured. The TCP connections between RPs, moreover, are achieved by the underlying routing system. The receiving RP uses the source lists to establish a source path. If the multicast sources are of interest to a domain that has receivers, multicast data is delivered over the normal, source-tree building mechanism provided by PIM-SM. MSDP is also used to announce sources sending to a group. These announcements must originate at the RP of the domain.

The figure illustrates MSDP operating between two MSDP peers. PIM uses MSDP as the standard mechanism to register a source with the RP of a domain.
When MSDP is implemented, the following sequence of events occurs:

1. When a PIM designated device (DR) registers a source with its RP as illustrated in the figure, the RP sends a Source-Active (SA) message to all of its MSDP peers.

**Note**

1. The SA message identifies the source address, the group that the source is sending to, and the address or the originator ID of the RP, if configured.
2. Each MSDP peer that receives the SA message floods the SA message to all of its peers downstream from the originator. In some cases (such as the case with the RPs in PIM-SM domains B and C in the figure), an RP may receive a copy of an SA message from more than one MSDP peer. To prevent looping, the RP consults the BGP next-hop database to determine the next hop toward the originator of the SA message. If both MBGP and unicast BGP are configured, MBGP is checked first, and then unicast BGP. That next-hop neighbor is the RPF-peer for the originator. SA messages that are received from the originator on any interface other than the interface to the RPF peer are dropped. The SA message flooding process, therefore, is referred to as peer-RPF flooding. Because of the peer-RPF flooding mechanism, BGP or MBGP must be running in conjunction with MSDP.
1. When an RP receives an SA message, it checks to see whether there are any members of the advertised groups in its domain by checking to see whether there are interfaces on the group’s (*, G) outgoing interface list. If there are no group members, the RP does nothing. If there are group members, the RP sends an (S, G) join toward the source. As a result, a branch of the interdomain source tree is constructed across autonomous system boundaries to the RP. As multicast packets arrive at the RP, they are then forwarded down its own shared tree to the group members in the RP’s domain. The members’ DRs then have the option of joining the rendezvous point tree (RPT) to the source using standard PIM-SM procedures.

2. The originating RP continues to send periodic SA messages for the (S, G) state every 60 seconds for as long as the source is sending packets to the group. When an RP receives an SA message, it caches the SA message. Suppose, for example, that an RP receives an SA message for (172.16.5.4, 228.1.2.3) from originating RP 10.5.4.3. The RP consults its mroute table and finds that there are no active members for group 228.1.2.3, so it passes the SA message to its peers downstream of 10.5.4.3. If a host in the domain then sends a join to the RP for group 228.1.2.3, the RP adds the interface toward the host to the outgoing interface list of its (*, 224.1.2.3) entry. Because the RP caches SA messages, the device will have an entry for (172.16.5.4, 228.1.2.3) and can join the source tree as soon as a host requests a join.

**Note**

In all current and supported software releases, caching of MSDP SA messages is mandatory and cannot be manually enabled or disabled. By default, when an MSDP peer is configured, the `ip multicast cache-sa-state` command will automatically be added to the running configuration.

**MSDP Message Types**

There are four basic MSDP message types, each encoded in their own Type, Length, and Value (TLV) data format.

**SA Messages**

SA messages are used to advertise active sources in a domain. In addition, these SA messages may contain the initial multicast data packet that was sent by the source.

SA messages contain the IP address of the originating RP and one or more (S, G) pairs being advertised. In addition, the SA message may contain an encapsulated data packet.

**Note**

For more information about SA messages, see the SA Message Origination Receipt and Processing, on page 485 section.

**SA Request Messages**

SA request messages are used to request a list of active sources for a specific group. These messages are sent to an MSDP SA cache that maintains a list of active (S, G) pairs in its SA cache. Join latency can be reduced by using SA request messages to request the list of active sources for a group instead of having to wait up to 60 seconds for all active sources in the group to be readvertised by originating RPs.
SA Response Messages

SA response messages are sent by the MSDP peer in response to an SA request message. SA response messages contain the IP address of the originating RP and one or more (S, G) pairs of the active sources in the originating RP’s domain that are stored in the cache.

Keepalive Messages

Keepalive messages are sent every 60 seconds in order to keep the MSDP session active. If no keepalive messages or SA messages are received for 75 seconds, the MSDP session is reset.

SA Message Origination Receipt and Processing

The section describes SA message origination, receipt, and processing in detail.

SA Message Origination

SA messages are triggered by an RP (assuming MSDP is configured) when any new source goes active within a local PIM-SM domain. A local source is a source that is directly connected to the RP or is the first-hop DR that has registered with it. An RP originates SA messages only for local sources in its PIM-SM domain; that is, for local sources that register with it.

Note

A local source is denoted by the A flag being set in the (S, G) mroute entry on the RP (which can be viewed in the output of the `show ip mroute` command). This flag indicates that the source is a candidate for advertisement by the RP to other MSDP peers.

When a source is in the local PIM-SM domain, it causes the creation of (S, G) state in the RP. New sources are detected by the RP either by the receipt of a register message or the arrival of the first (S, G) packet from a directly connected source. The initial multicast packet sent by the source (either encapsulated in the register message or received from a directly connected source) is encapsulated in the initial SA message.

SA Message Receipt

SA messages are only accepted from the MSDP RPF peer that is in the best path back toward the originator. The same SA message arriving from other MSDP peers must be ignored or SA loops can occur. Deterministically selecting the MSDP RPF peer for an arriving SA message requires knowledge of the MSDP topology. However, MSDP does not distribute topology information in the form of routing updates. MSDP infers this information by using (M)BGP routing data as the best approximation of the MSDP topology for the SA RPF check mechanism. An MSDP topology, therefore, must follow the same general topology as the BGP peer topology. Besides a few exceptions (such as default MSDP peers and MSDP peers in MSDP mesh groups), MSDP peers, in general should also be (M)BGP peers.

How RPF Check Rules Are Applied to SA Messages

The rules that apply to RPF checks for SA messages are dependent on the BGP peerings between the MSDP peers:

- Rule 1: Applied when the sending MSDP peer is also an interior (M)BGP peer.
- Rule 2: Applied when the sending MSDP peer is also an exterior (M)BGP peer.
• Rule 3: Applied when the sending MSDP peer is not an (M)BGP peer.

RPF checks are not performed in the following cases:
• If the sending MSDP peer is the only MSDP peer, which would be the case if only a single MSDP peer or a default MSDP peer is configured.
• If the sending MSDP peer is a member of a mesh group.
• If the sending MSDP peer address is the RP address contained in the SA message.

How the Software Determines the Rule to Apply to RPF Checks

The software uses the following logic to determine which RPF rule to apply to RPF checks:
• Find the (M)BGP neighbor that has the same IP address as the sending MSDP peer.
  • If the matching (M)BGP neighbor is an internal BGP (iBGP) peer, apply Rule 1.
  • If the matching (M)BGP neighbor is an external BGP (eBGP) peer, apply Rule 2.
  • If no match is found, apply Rule 3.

The implication of the RPF check rule selection is as follows: The IP address used to configure an MSDP peer on a device must match the IP address used to configure the (M)BGP peer on the same device.

Rule 1 of RPF Checking of SA Messages in MSDP

Rule 1 of RPF checking in MSDP is applied when the sending MSDP peer is also an i(M)BGP peer. When Rule 1 is applied, the RPF check proceeds as follows:

1. The peer searches the BGP Multicast Routing Information Base (MRIB) for the best path to the RP that originated the SA message. If a path is not found in the MRIB, the peer then searches the Unicast Routing Information Base (URIB). If a path is still not found, the RPF check fails.

2. If the previous search succeeds (that is, the best path is found), the peer then determines the address of the BGP neighbor for this best path, which will be the address of the BGP neighbor that sent the peer the path in BGP update messages.

Note
The BGP neighbor address is not the same as the next-hop address in the path. Because i(M)BGP peers do not update the next-hop attribute of a path, the next-hop address usually is not the same as the address of the BGP peer that sent us the path.

Note
The BGP neighbor address is not necessarily the same as the BGP ID of the peer that sent the peer the path.

1. If the IP address of the sending MSDP peer is the same as the BGP neighbor address (that is, the address of the BGP peer that sent the peer the path), then the RPF check succeeds; otherwise it fails.

Implications of Rule 1 of RPF Checking on MSDP

The MSDP topology must mirror the (M)BGP topology. In general, wherever there is an i(M)BGP peer connection between two devices, an MSDP peer connection should be configured. More specifically, the IP
address of the far-end MSDP peer connection must be the same as the far-end i(M)BGP peer connection. The addresses must be the same because the BGP topology between i(M)BGP peers inside an autonomous system is not described by the AS path. If it were always the case that i(M)BGP peers updated the next-hop address in the path when sending an update to another i(M)BGP peer, then the peer could rely on the next-hop address to describe the i(M)BGP topology (and hence the MSDP topology). However, because the default behavior for i(M)BGP peers is to not update the next-hop address, the peer cannot rely on the next-hop address to describe the i(M)BGP topology (MSDP topology). Instead, the i(M)BGP peer uses the address of the i(M)BGP peer that sent the path to describe the i(M)BGP topology (MSDP topology) inside the autonomous system.

Care should be taken when configuring the MSDP peer addresses to make sure that the same address is used for both i(M)BGP and MSDP peer addresses.

**Rule 2 of RPF Checking of SA Messages in MSDP**

Rule 2 of RPF checking in MSDP is applied when the sending MSDP peer is also an e(M)BGP peer. When Rule 2 is applied, the RPF check proceeds as follows:

1. The peer searches the BGP MRIB for the best path to the RP that originated the SA message. If a path is not found in the MRIB, the peer then searches the URIB. If a path is still not found, the RPF check fails.
2. If the previous search succeeds (that is, the best path is found), the peer then examines the path. If the first autonomous system in the best path to the RP is the same as the autonomous system of the e(M)BGP peer (which is also the sending MSDP peer), then the RPF check succeeds; otherwise it fails.

**Implications of Rule 2 of RPF Checking on MSDP**

The MSDP topology must mirror the (M)BGP topology. In general, wherever there is an e(M)BGP peer connection between two devices, an MSDP peer connection should be configured. As opposed to Rule 1, the IP address of the far-end MSDP peer connection does not have to be the same as the far-end e(M)BGP peer connection. The reason that the addresses do not have to be identical is that BGP topology between two e(M)BGP peers is not described by the AS path.

**Rule 3 of RPF Checking of SA Messages in MSDP**

Rule 3 of RPF checking is applied when the sending MSDP peer is not a (M)BGP peer at all. When Rule 3 is applied, the RPF check proceeds as follows:

1. The peer searches the BGP MRIB for the best path to the RP that originated the SA message. If a path is not found in the MRIB, the peer then searches the URIB. If a path is still not found, the RPF check fails.
2. If the previous search succeeds (that is, the best path to the RP that originated the SA message is found), the peer then searches the BGP MRIB for the best path to the MSDP peer that sent the SA message. If a path is not found in the MRIB, the peer then searches the URIB. If a path is still not found, the RPF check fails.
SA Message Processing

The following steps are taken by an MSDP peer whenever it processes an SA message:

1. Using the group address G of the (S, G) pair in the SA message, the peer locates the associated (*, G) entry in the mroute table. If the (*, G) entry is found and its outgoing interface list is not null, then there are active receivers in the PIM-SM domain for the source advertised in the SA message.

2. The MSDP peer then creates an (S, G) entry for the advertised source.

3. If the (S, G) entry did not already exist, the MSDP peer immediately triggers an (S, G) join toward the source in order to join the source tree.

4. The peer then floods the SA message to all other MSDP peers with the exception of:
   - The MSDP peer from which the SA message was received.
   - Any MSDP peers that are in the same MSDP mesh group as this device (if the peer is a member of a mesh group).

Note: SA messages are stored locally in the device’s SA cache.

MSDP Peers

Like BGP, MSDP establishes neighbor relationships with other MSDP peers. MSDP peers connect using TCP port 639. The lower IP address peer takes the active role of opening the TCP connection. The higher IP address peer waits in LISTEN state for the other to make the connection. MSDP peers send keepalive messages every 60 seconds. The arrival of data performs the same function as the keepalive message and keeps the session from timing out. If no keepalive messages or data is received for 75 seconds, the TCP connection is reset.

MSDP MD5 Password Authentication

The MSDP MD5 password authentication feature is an enhancement to support Message Digest 5 (MD5) signature protection on a TCP connection between two MSDP peers. This feature provides added security by protecting MSDP against the threat of spoofed TCP segments being introduced into the TCP connection stream.

Related Topics
- Configuring MSDP MD5 Password Authentication Between MSDP Peers, on page 497
- Example: Configuring MSDP MD5 Password Authentication, on page 517

How MSDP MD5 Password Authentication Works

Developed in accordance with RFC 2385, the MSDP MD5 password authentication feature is used to verify each segment sent on the TCP connection between MSDP peers. The `ip msdp password peer` command is used to enable MD5 authentication for TCP connections between two MSDP peers. When MD5 authentication
is enabled between two MSDP peers, each segment sent on the TCP connection between the peers is verified. MD5 authentication must be configured with the same password on both MSDP peers; otherwise, the connection between them will not be made. Configuring MD5 authentication causes the Cisco IOS software to generate and verify the MD5 digest of every segment sent on the TCP connection.

Benefits of MSDP MD5 Password Authentication

- Protects MSDP against the threat of spoofed TCP segments being introduced into the TCP connection stream.
- Uses the industry-standard MD5 algorithm for improved reliability and security.

SA Message Limits

The `ip msdp sa-limit` command is used to limit the overall number of SA messages that a device can accept from specified MSDP peers. When the `ip msdp sa-limit` command is configured, the device maintains a per-peer count of SA messages stored in the SA cache and will ignore new messages from a peer if the configured SA message limit for that peer has been reached.

The `ip msdp sa-limit` command was introduced as a means to protect an MSDP-enabled device from denial of service (DoS) attacks. We recommended that you configure SA message limits for all MSDP peerings on the device. An appropriately low SA limit should be configured on peerings with a stub MSDP region (for example, a peer that may have some further downstream peers but that will not act as a transit for SA messages across the rest of the Internet). A high SA limit should be configured for all MSDP peerings that act as transits for SA messages across the Internet.

MSDP Keepalive and Hold-Time Intervals

The `ip msdp keepalive` command is used to adjust the interval at which an MSDP peer will send keepalive messages and the interval at which the MSDP peer will wait for keepalive messages from other peers before declaring them down.

Once an MSDP peer session is established, each side of the connection sends a keepalive message and sets a keepalive timer. If the keepalive timer expires, the local MSDP peer sends a keepalive message and restarts its keepalive timer; this interval is referred to as the keepalive interval. The `keepalive-interval` argument is used to adjust the interval for which keepalive messages will be sent. The keepalive timer is set to the value specified for the `keepalive-interval` argument when the peer comes up. The keepalive timer is reset to the value of the `keepalive-interval` argument whenever an MSDP keepalive message is sent to the peer and reset when the timer expires. The keepalive timer is deleted when an MSDP peer session is closed. By default, the keepalive timer is set to 60 seconds.

Note

The value specified for the `keepalive-interval` argument must be less than the value specified for the `holdtime-interval` argument and must be at least one second.

The hold-time timer is initialized to the value of the `hold-time-interval` argument whenever an MSDP peering connection is established, and is reset to the value of the `hold-time-interval` argument whenever an MSDP keepalive message is received. The hold-time timer is deleted whenever an MSDP peering connection is closed. By default, the hold-time interval is set to 75 seconds.
Use the `hold-time-interval` argument to adjust the interval at which the MSDP peer will wait for keepalive messages from other peers before declaring them down.

**MSDP Connection-Retry Interval**

You can adjust the interval at which all MSDP peers will wait after peering sessions are reset before attempting to reestablish the peering sessions. This interval is referred to as the connection-retry interval. By default, MSDP peers will wait 30 seconds after the session is reset before attempting to reestablish sessions with other peers. The modified configured connection-retry interval applies to all MSDP peering sessions on the device.

**Default MSDP Peers**

A stub autonomous system also might want to have MSDP peerings with more than one RP for the sake of redundancy. For example, SA messages cannot just be accepted from multiple default peers, because there is no RPF check mechanism. Instead, SA messages are accepted from only one peer. If that peer fails, SA messages are then accepted from the other peer. The underlying assumption here, of course, is that both default peers are sending the same SA messages.

The figure illustrates a scenario where default MSDP peers might be used. In the figure, a customer that owns Device B is connected to the Internet through two Internet service providers (ISPs), one that owns Device A and the other that owns Device C. They are not running BGP or MBGP between them. In order for the customer to learn about sources in the ISP domain or in other domains, Device B identifies Device A as its default MSDP peer. Device B advertises SA messages to both Device A and Device C, but accepts SA messages either from Device A only or Device C only. If Device A is the first default peer in the configuration, it will be used if it is up and running. Only if Device A is not running will Device B accept SA messages from Device C.

The ISP will also likely use a prefix list to define which prefixes it will accept from the customer device. The customer will define multiple default peers, each having one or more prefixes associated with it.

The customer has two ISPs to use. The customer defines both ISPs as default peers. As long as the first default peer identified in the configuration is up and running, it will be the default peer and the customer will accept all SA messages it receives from that peer.
Figure 26: Default MSDP Peer Scenario

Device B advertises SAs to Device A and Device C, but uses only Device A or Device C to accept SA messages. If Device A is first in the configuration, it will be used if it is up and running. Only when Device A is not running will Device B accept SAs from Device C. This is the behavior without a prefix list.

If you specify a prefix list, the peer will be a default peer only for the prefixes in the list. You can have multiple active default peers when you have a prefix list associated with each. When you do not have any prefix lists, you can configure multiple default peers, but only the first one is the active default peer as long as the device has connectivity to this peer and the peer is alive. If the first configured peer goes down or the connectivity to this peer goes down, the second configured peer becomes the active default, and so on.

MSDP Mesh Groups

An MSDP mesh group is a group of MSDP speakers that have fully meshed MSDP connectivity between one another. In other words, each of the MSDP peers in the group must have an MSDP peering relationship (MSDP connection) to every other MSDP peer in the group. When an MSDP mesh group is configured between a group of MSDP peers, SA message flooding is reduced. Because when an MSDP peer in the group receives an SA message from another MSDP peer in the group, it assumes that this SA message was sent to all the other MSDP peers in the group. As a result, it is not necessary for the receiving MSDP peer to flood the SA message to the other MSDP peers in the group.

Related Topics

Configuring an MSDP Mesh Group, on page 503
Example: Configuring MSDP Mesh Groups, on page 520

Benefits of MSDP Mesh Groups

• Optimizes SA flooding--MSDP mesh groups are particularly useful for optimizing SA flooding when two or more peers are in a group.
• Reduces the amount of SA traffic across the Internet--When MSDP mesh groups are used, SA messages are not flooded to other mesh group peers.

• Eliminates RPF checks on arriving SA messages--When an MSDP mesh group is configured, SA messages are always accepted from mesh group peers.

SA Origination Filters

By default, an RP that is configured to run MSDP will originate SA messages for all local sources for which it is the RP. Local sources that register with an RP, therefore, will be advertised in SA messages, which in some cases is not desirable. For example, if sources inside a PIM-SM domain are using private addresses (for example, network 10.0.0.0/8), you should configure an SA origination filter to restrict those addresses from being advertised to other MSDP peers across the Internet.

To control what sources are advertised in SA messages, you can configure SA origination filters on an RP. By creating SA origination filters, you can control the sources advertised in SA messages as follows:

• You can configure an RP to prevent the device from advertising local sources in SA messages. The device will still forward SA messages from other MSDP peers in the normal fashion; it will just not originate any SA messages for local sources.

• You can configure the device to only originate SA messages for local sources sending to specific groups that match (S, G) pairs defined in the extended access list. All other local sources will not be advertised in SA messages.

• You can configure the device to only originate SA messages for local sources sending to specific groups that match AS paths defined in an AS-path access list. All other local sources will not be advertised in SA messages.

• You can configure the device to only originate SA messages for local sources that match the criteria defined in the route map. All other local sources will not be advertised in SA messages.

• You configure an SA origination filter that includes an extended access list, an AS-path access list, and route map, or a combination thereof. In this case, all conditions must be true before any local sources are advertised in SA messages.

Use of Outgoing Filter Lists in MSDP

By default, an MSDP-enabled device forwards all SA messages it receives to all of its MSDP peers. However, you can prevent SA messages from being forwarded to MSDP peers by creating outgoing filter lists. Outgoing filter lists apply to all SA messages, whether locally originated or received from another MSDP peer, whereas SA origination filters apply only to locally originated SA messages. For more information about enabling a filter for MSDP SA messages originated by the local device, see the Controlling SA Messages Originated by an RP for Local Sources, on page 504 section.

By creating an outgoing filter list, you can control the SA messages that a device forwards to a peer as follows:

• You can filter all outgoing SA messages forwarded to a specified MSDP peer by configuring the device to stop forwarding its SA messages to the MSDP peer.

• You can filter a subset of outgoing SA messages forwarded to a specified MSDP peer based on (S, G) pairs defined in an extended access list by configuring the device to only forward SA messages to the
MSDP peer that match the (S, G) pairs permitted in an extended access list. The forwarding of all other SA messages to the MSDP peer will be stopped.

- You can filter a subset of outgoing SA messages forwarded to a specified MSDP peer based on match criteria defined in a route map by configuring the device to only forward SA messages that match the criteria defined in the route map. The forwarding of all other SA messages to the MSDP peer will be stopped.

- You can filter a subset of outgoing SA messages from a specified peer based on the announcing RP address contained in the SA message by configuring the device to filter outgoing SA messages based on their origin, even after an SA message has been transmitted across one or more MSDP peers. The forwarding of all other SA messages to the MSDP peer will be stopped.

- You can configure an outgoing filter list that includes an extended access list, a route map, and either an RP access list or an RP route map. In this case, all conditions must be true for the MSDP peer to forward the outgoing SA message.

⚠️ Caution
Arbitrary filtering of SA messages can result in downstream MSDP peers being starved of SA messages for legitimate active sources. Care, therefore, should be taken when using these sorts of filters. Normally, outgoing filter lists are used only to reject undesirable sources, such as sources using private addresses.

## Use of Incoming Filter Lists in MSDP

By default, an MSDP-enabled device receives all SA messages sent to it from its MSDP peers. However, you can control the source information that a device receives from its MSDP peers by creating incoming filter lists.

By creating incoming filter lists, you can control the incoming SA messages that a device receives from its peers as follows:

- You can filter all incoming SA messages from a specified MSDP peer by configuring the device to ignore all SA messages sent to it from the specified MSDP peer.

- You can filter a subset of incoming SA messages from a specified peer based on (S, G) pairs defined in an extended access list by configuring the device to only receive SA messages from the MSDP peer that match the (S, G) pairs defined in the extended access list. All other incoming SA messages from the MSDP peer will be ignored.

- You can filter a subset of incoming SA request messages from a specified peer based on match criteria defined in a route map by configuring the device to only receive SA messages that match the criteria defined in the route map. All other incoming SA messages from the MSDP peer will be ignored.

- You can filter a subset of incoming SA messages from a specified peer based on both (S, G) pairs defined in an extended access list and on match criteria defined in a route map by configuring the device to only receive incoming SA messages that both match the (S, G) pairs defined in the extended access list and match the criteria defined in the route map. All other incoming SA messages from the MSDP peer will be ignored.

- You can filter a subset of incoming SA messages from a specified peer based on the announcing RP address contained in the SA message by configuring the device to filter incoming SA messages based on their origin, even after the SA message may have already been transmitted across one or more MSDP peers.
You can configure an incoming filter list that includes an extended access list, a route map, and either an RP access list or an RP route map. In this case, all conditions must be true for the MSDP peer to receive the incoming SA message.

---

**Caution**

Arbitrary filtering of SA messages can result in downstream MSDP peers being starved of SA messages for legitimate active sources. Care, therefore, should be taken when using these sorts of filters. Normally, incoming filter lists are used only to reject undesirable sources, such as sources using private addresses.

---

### TTL Thresholds in MSDP

The time-to-live (TTL) value provides a means to limit the number of hops a packet can take before being dropped. The `ip multicast ttl-threshold` command is used to specify a TTL for data-encapsulated SA messages sent to specified MSDP peers. By default, multicast data packets in SA messages are sent to an MSDP peer, provided the TTL value of the packet is greater than 0, which is standard TTL behavior.

In general, a TTL-threshold problem can be introduced by the encapsulation of a source’s initial multicast packet in an SA message. Because the multicast packet is encapsulated inside of the unicast SA message (whose TTL is 255), its TTL is not decremented as the SA message travels to the MSDP peer. Furthermore, the total number of hops that the SA message traverses can be drastically different than a normal multicast packet because multicast and unicast traffic may follow completely different paths to the MSDP peer and hence the remote PIM-SM domain. As a result, encapsulated packets can end up violating TTL thresholds. The solution to this problem is to configure a TTL threshold that is associated with any multicast packet that is encapsulated in an SA message sent to a particular MSDP peer using the `ip multicast ttl-threshold` command. The `ip msdp ttl-threshold` command prevents any multicast packet whose TTL in the IP header is less than the TTL value specified for the `ttl-value` argument from being encapsulated in SA messages sent to that peer.

---

### SA Request Messages

You can configure a noncaching device to send SA request messages to one or more specified MSDP peers. If an noncaching RP has an MSDP peer that is caching SAs, you can reduce the join latency for a noncaching peer by enabling the noncaching peer to send SA request messages. When a host requests a join to a particular group, the noncaching RP sends an SA request message to its caching peers. If a peer has cached source information for the group in question, it sends the information to the requesting RP with an SA response message. The requesting RP uses the information in the SA response but does not forward the message to any other peers. If a noncaching RP receives an SA request, it sends an error message back to the requestor.

---

**Note**

In all current and supported software releases, caching of MSDP SA messages is mandatory and cannot be manually enabled or disabled. By default, when an MSDP peer is configured, the configured commands are automatically added to the running configuration.

---

### SA Request Filters

By default, a device honors all outgoing SA request messages from its MSDP peers; that is, it sends cached source information to requesting MSDP peers in SA response messages. You can control the outgoing SA
request messages that a device will honor from specified peers by creating an SA request filter. An SA request filter controls the outgoing SA requests that the device will honor from MSDP peers as follows:

• You can filter all SA request messages from a specified peer by configuring the device to ignore all SA requests from the specified MSDP peer.

• You can filter a subset of SA request messages from a specified peer based on groups defined in a standard access list by configuring the device to honor only SA request messages from the MSDP peer that match the groups defined in a standard access list. SA request messages from the specified peer for other groups will be ignored.

How to Use MSDP to Interconnect Multiple PIM-SM Domains

The first task is required; all other tasks are optional.

Configuring an MSDP Peer

Note
By enabling an MSDP peer, you implicitly enable MSDP.

Before you begin

• IP multicast routing must be enabled and PIM-SM must be configured.

• With the exception of a single MSDP peer, default MSDP peer, and MSDP mesh group scenarios, all MSDP peers must be configured to run BGP prior to being configured for MSDP.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip msdp peer {peer-name|peer-address} [connect-source type number] [remote-as as-number]
4. ip msdp description {peer-name|peer-address} text
5. end

### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Enables MSDP and configures an MSDP peer as specified by the DNS name or IP address.</td>
</tr>
</tbody>
</table>

#### Step 3

**ip msdp peer** `{peer-name|peer-address} [connect-source type number] [remote-as as-number]`

**Example:**

Device(config)# ip msdp peer 192.168.1.2 connect-source loopback0

**Note**

The device that is selected to be configured as an MSDP peer is also usually a BGP neighbor. If it is not, see the Configuring a Default MSDP Peer, on page 502 section or the Configuring an MSDP Mesh Group, on page 503 section.

- If you specify the `connect-source` keyword, the primary address of the specified local interface `type` and `number` values are used as the source IP address for the TCP connection. The `connect-source` keyword is recommended, especially for MSDP peers on a border that peer with a device inside of a remote domain.

#### Step 4

**ip msdp description** `{peer-name|peer-address} text`

**Example:**

Device(config)# ip msdp description 192.168.1.2 router at customer a

(Optional) Configures a description for a specified peer to make it easier to identify in a configuration or in `show` command output.

#### Step 5

**end**

**Example:**

Device(config)# end

Exits global configuration mode and returns to privileged EXEC mode.

## Shutting Down an MSDP Peer

Perform this optional task to shut down an MSDP peer.

If you are configuring several MSDP peers and you do not want any of the peers to go active until you have finished configuring all of them, you can shut down each peer, configure each peer, and later bring each peer up. You might also want to shut down an MSDP session without losing the configuration for that MSDP peer.

**Note**

When an MSDP peer is shut down, the TCP connection is terminated and not restarted until the peer is brought back up using the `no ip msdp shutdown` command (for the specified peer).
**Before you begin**

MSDP is running and the MSDP peers must be configured.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip msdp shutdown {peer-name | peer-address}`
4. Repeat Step 3 to shut down additional MSDP peers.
5. `end`

**DETAILED STEPS**

Troubleshooting Tips

If a device has a password configured for an MSDP peer but the MSDP peer does not, a message such as the following will appear on the console while the devices attempt to establish an MSDP session between them:

%TCP-6-BADAUTH: No MD5 digest from [peer's IP address]:11003 to [local router's IP address]:179

Similarly, if the two devices have different passwords configured, a message such as the following will appear on the console:

%TCP-6-BADAUTH: Invalid MD5 digest from [peer's IP address]:11004 to [local router's IP address]:179

The `debug ip tcp transactions` command is used to display information on significant TCP transactions such as state changes, retransmissions, and duplicate packets. In the context of monitoring or troubleshooting MSDP MD5 password authentication, use the `debug ip tcp transactions` command to verify that the MD5 password is enabled and that the keepalive message is received by the MSDP peer.

Preventing DoS Attacks by Limiting the Number of SA Messages Allowed in the SA Cache from Specified MSDP Peers

Perform this optional (but highly recommended) task to limit the overall number of SA messages that the device can accept from specified MSDP peers. Performing this task protects an MSDP-enabled device from distributed denial-of-service (DoS) attacks.

Note

We recommend that you perform this task for all MSDP peerings on the device.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip msdp sa-limit {peer-address | peer-name} sa-limit
4. Repeat Step 3 to configure SA limits for additional MSDP peers.
5. exit
6. show ip msdp count [as-number]
7. show ip msdp peer {peer-address | peer-name}
8. show ip msdp summary

DETAILED STEPS

<table>

<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### Adjusting the MSDP Keepalive and Hold-Time Intervals

Perform this optional task to adjust the interval at which an MSDP peer will send keepalive messages and the interval at which the MSDP peer will wait for keepalive messages from other peers before declaring them down. By default, it may take as long as 75 seconds for an MSDP peer to detect that a peering session with another MSDP peer has gone down. In network environments with redundant MSDP peers, decreasing the hold-time interval can expedite the reconvergence time of MSDP peers in the event that an MSDP peer fails.

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td><code>configure terminal</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>3</td>
<td>`ip msdp sa-limit {peer-address</td>
<td>peer-name} sa-limit`&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ip msdp sa-limit 192.168.10.1 100</td>
</tr>
<tr>
<td>4</td>
<td>Repeat Step 3 to configure SA limits for additional MSDP peers.</td>
<td>--</td>
</tr>
<tr>
<td>5</td>
<td><code>exit</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# exit</td>
<td>Exits global configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>6</td>
<td><code>show ip msdp count [as-number]</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# show ip msdp count</td>
<td>(Optional) Displays the number of sources and groups originated in MSDP SA messages and the number of SA messages from an MSDP peer in the SA cache.</td>
</tr>
<tr>
<td>7</td>
<td>`show ip msdp peer {peer-address</td>
<td>peer-name}`&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# show ip msdp peer</td>
</tr>
<tr>
<td>8</td>
<td><code>show ip msdp summary</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# show ip msdp summary</td>
<td>(Optional) Displays MSDP peer status.&lt;br&gt;&lt;br&gt;<strong>Note</strong> The output of this command displays a per-peer “SA Count” field that displays the number of SAs stored in the cache.</td>
</tr>
</tbody>
</table>
We recommend that you do not change the command defaults for the `ip msdp keepalive` command, because the command defaults are in accordance with RFC 3618, _Multicast Source Discovery Protocol_. If your network environment requires that you modify the defaults, you must configure the same time values for the `keepalive-interval` and `hold-time-interval` arguments on both ends of the MSDP peering session.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip msdp keepalive {peer-address | peer-name} keepalive-interval hold-time-interval`
4. Repeat Step 3 to adjust the keepalive message interval for additional MSDP peers.
5. `exit`

**DETAILED STEPS**

</tbody>
</table>

**Adjusting the MSDP Connection-Retry Interval**

Perform this optional task to adjust the interval at which MSDP peers will wait after peering sessions are reset before attempting to reestablish the peering sessions. In network environments where fast recovery of SA messages is required, such as in trading floor network environments, you may want to decrease the connection-retry interval to a time value less than the default value of 30 seconds.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip msdp timer connection-retry-interval`
4. `exit`

### DETAILED STEPS

<table>
<thead>
<tr>

**Using TTL Thresholds to Limit the Multicast Data Sent in SA Messages**

Perform this optional task to establish a time to live (TTL) threshold to limit the multicast data sent in SA messages.

**SUMMARY STEPS**

1. \texttt{enable}
2. \texttt{configure terminal}
3. \texttt{ip msdp ttl-threshold} \{peer-address | peer-name\} \texttt{ttl-value}
4. \texttt{exit}
### Requesting Source Information from MSDP Peers

Perform this optional task to enable a device to request source information from MSDP peers.

**Note**  
Because SA caching is enabled by default and cannot be explicitly enabled or disabled in earlier Cisco software releases, performing this task is seldom needed.

### SUMMARY STEPS

1. **enable**  
2. **configure terminal**  
3. **ip msdp sa-request** `{peer-address | peer-name}`  
4. Repeat Step 3 to specify that the device send SA request messages to additional MSDP caching peers.  
5. **exit**

</table>
Including a Bordering PIM Dense Mode Region in MSDP

Perform this optional task to configure a border device to send SA messages for sources active in a PIM dense mode (PIM-DM) region.

You can have a device that borders a PIM-SM region and a PIM-DM region. By default, sources in the PIM-DM domain are not included in MSDP. You can configure this border device to send SA messages for sources active in the PIM-DM domain. If you do so, it is very important to also configure the `ip msdp redistribute` command to control what local sources from the PIM-DM domain are advertised. Not configuring this command can result in the (S, G) state remaining long after a source in the PIM-DM domain has stopped sending. For configuration information, see the Controlling SA Messages Originated by an RP for Local Sources, on page 504 section.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip msdp border sa-address type number`
4. `exit`

**DETAILED STEPS**

<table>

### Configuring an Originating Address Other Than the RP Address

Perform this optional task to allow an MSDP speaker that originates an SA message to use the IP address of its interface as the RP address in the SA message.

You can also change the originator ID for any one of the following reasons:

- If you configure multiple devices in an MSDP mesh group for Anycast RP.
- If you have a device that borders a PIM-SM domain and a PIM-DM domain. If a device borders a PIM-SM domain and a PIM-DM domain and you want to advertise active sources within the PIM-DM domain, configure the RP address in SA messages to be the address of the originating device’s interface.

**Before you begin**

MSDP is enabled and the MSDP peers are configured. For more information about configuring MSDP peers, see the Configuring an MSDP Peer, on page 495 section.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip msdp originator-id type number`
4. `exit`

### DETAILED STEPS

<table>

### Monitoring MSDP

Perform this optional task to monitor MSDP SA messages, peers, state, and peer status.

### SUMMARY STEPS

1. enable
2. debug ip msdp [peer-address | peer-name] [detail] [routes]
3. debug ip msdp resets
4. show ip msdp count [as-number]
5. show ip msdp peer [peer-address | peer-name]
6. show ip msdp sa-cache [group-address | source-address | group-name | source-name] [as-number]
7. show ip msdp summary

### DETAILED STEPS

#### Step 1 enable

**Example:**

```bash
Device# enable
```

Enables privileged EXEC mode.
+ Enter your password if prompted.

#### Step 2 debug ip msdp [peer-address | peer-name] [detail] [routes]

Use this command to debug MSDP activity.

Use the optional `peer-address` or `peer-name` argument to specify for which peer debug events are logged.

The following is sample output from the `debug ip msdp` command:
Example:

Device# debug ip mssdp
MSDP debugging is on
Device#
MSDP: 224.150.44.254: Received 1388-byte message from peer
MSDP: 224.150.44.254: SA TLV, len: 1388, ec: 115, RP: 172.31.3.92
MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.92, used EMBGP peer
MSDP: 224.150.44.250: Forward 1388-byte SA to peer
MSDP: 224.150.44.254: Received 1028-byte message from peer
MSDP: 224.150.44.254: SA TLV, len: 1028, ec: 85, RP: 172.31.3.92
MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.92, used EMBGP peer
MSDP: 224.150.44.250: Forward 1028-byte SA to peer
MSDP: 224.150.44.254: Received 1388-byte message from peer
MSDP: 224.150.44.254: SA TLV, len: 1388, ec: 115, RP: 172.31.3.111
MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.111, used EMBGP peer
MSDP: 224.150.44.250: Forward 1388-byte SA to peer
MSDP: 224.150.44.254: Received 56-byte message from peer
MSDP: 224.150.44.254: SA TLV, len: 56, ec: 4, RP: 192.168.76.241
MSDP: 224.150.44.250: Peer RPF check passed for 192.168.76.241, used EMBGP peer
MSDP: 224.150.44.254: Forward 56-byte SA to peer
MSDP: 224.150.44.254: Received 116-byte message from peer
MSDP: 224.150.44.254: SA TLV, len: 116, ec: 9, RP: 172.31.3.111
MSDP: 224.150.44.254: Peer RPF check passed for 172.31.3.111, used EMBGP peer
MSDP: 224.150.44.250: Forward 116-byte SA to peer
MSDP: 224.150.44.254: Received 32-byte message from peer
MSDP: 224.150.44.254: SA TLV, len: 32, ec: 2, RP: 172.31.3.78
MSDP: 224.150.44.250: Peer RPF check passed for 172.31.3.78, used EMBGP peer
MSDP: 224.150.44.254: Forward 32-byte SA to peer

Step 3  debug ip mssdp resets
Use this command to debug MSDP peer reset reasons.

Example:

Device# debug ip mssdp resets

Step 4  show ip mssdp count [as-number]
Use this command to display the number of sources and groups originated in MSDP SA messages and the number of SA messages from an MSDP peer in the SA cache. The `ip mssdp cache-sa-state` command must be configured for this command to produce any output.

The following is sample output from the `show ip mssdp count` command:

Example:

Device# show ip mssdp count
SA State per Peer Counters, <Peer>: <# SA learned>
  192.168.4.4: 8
SA State per ASN Counters, <asn>: <# sources>/<# groups>
  Total entries: 8
  ? : 8/8

Step 5  show ip mssdp peer [peer-address | peer-name]
Use this command to display detailed information about MSDP peers.

Use the optional `peer-address` or `peer-name` argument to display information about a particular peer.

The following is sample output from the `show ip mssdp peer` command:
Example:

Device# show ip msdp peer 192.168.4.4
MSDP Peer 192.168.4.4 (?), AS 64512 (configured AS)
Connection status:
  State: Up, Resets: 0, Connection source: Loopback0 (2.2.2.2)
  Uptime(Downtime): 00:07:55, Messages sent/received: 8/18
  Output messages discarded: 0
  Connection and counters cleared 00:08:55 ago
SA Filtering:
  Input (S,G) filter: none, route-map: none
  Input RP filter: none, route-map: none
  Output (S,G) filter: none, route-map: none
  Output RP filter: none, route-map: none
SA-Requests:
  Input filter: none
  Peer ttl threshold: 0
  SAs learned from this peer: 8
  Input queue size: 0, Output queue size: 0
  MD5 signature protection on MSDP TCP connection: not enabled

Step 6 show ip msdp sa-cache [group-address | source-address | group-name | source-name] [as-number]

Use this command to display the (S, G) state learned from MSDP peers.
The following is sample output from the show ip msdp sa-cache command:

Example:

Device# show ip msdp sa-cache
MSDP Source-Active Cache - 8 entries
  (10.44.44.5, 239.232.1.0), RP 192.168.4.4, BGP/AS 64512, 00:01:20/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.1), RP 192.168.4.4, BGP/AS 64512, 00:01:20/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.2), RP 192.168.4.4, BGP/AS 64512, 00:01:19/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.3), RP 192.168.4.4, BGP/AS 64512, 00:01:19/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.4), RP 192.168.4.4, BGP/AS 64512, 00:01:19/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.5), RP 192.168.4.4, BGP/AS 64512, 00:01:19/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.6), RP 192.168.4.4, BGP/AS 64512, 00:01:19/00:05:32, Peer 192.168.4.4
  (10.44.44.5, 239.232.1.7), RP 192.168.4.4, BGP/AS 64512, 00:01:19/00:05:32, Peer 192.168.4.4

Step 7 show ip msdp summary

Use this command to display MSDP peer status.
The following is sample output from the show ip msdp summary command:

Example:

Device# show ip msdp summary
MSDP Peer Status Summary
Peer Address  AS  State  Uptime/  Reset SA  Peer Name
        Downtime Count Count
192.168.4.4  4  Up  00:08:05  0  8  ?

Clearing MSDP Connections Statistics and SA Cache Entries

Perform this optional task to clear MSDP connections, statistics, and SA cache entries.
SUMMARY STEPS

1. enable
2. clear ip msdp peer [peer-address | peer-name]
3. clear ip msdp statistics [peer-address | peer-name]
4. clear ip msdp sa-cache [group-address]

DETAILED STEPS

</table>

Enabling SNMP Monitoring of MSDP

Perform this optional task to enable Simple Network Management Protocol (SNMP) monitoring of MSDP.

Before you begin

- SNMP and MSDP is configured on your devices.
- In each PIM-SM domain there should be a device that is configured as the MSDP speaker. This device must have SNMP and the MSDP MIB enabled.
**Note**
- All MSDP-MIB objects are implemented as read-only.
- The Requests table is not supported in Cisco’s implementation of the MSDP MIB.
- The msdpEstablished notification is not supported in Cisco’s implementation of the MSDP MIB.

**SUMMARY STEPS**

1. `enable`
2. `snmp-server enable traps msdp`
3. `snmp-server host host [traps | informs] [version {1 | 2c | 3 [auth | priv | noauth]}] community-string [udp-port port-number] msdp`
4. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>

<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>2.</td>
<td><code>snmp-server enable traps msdp</code></td>
<td>Enables the sending of MSDP notifications for use with SNMP.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td><code>Device# snmp-server enable traps msdp</code></td>
</tr>
<tr>
<td>3.</td>
<td>`snmp-server host host [traps</td>
<td>informs] [version {1</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td><code>Device# snmp-server host examplehost msdp</code></td>
</tr>
<tr>
<td>4.</td>
<td><code>exit</code></td>
<td>Exits global configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td><code>Device(config)# exit</code></td>
</tr>
</tbody>
</table>

**Troubleshooting Tips**

You can compare the results of MSDP MIB notifications to the output from the software by using the `show ip msdp summary` and `show ip msdp peer` commands on the appropriate device. You can also compare the results of these commands to the results from SNMP Get operations. You can verify SA cache table entries using the `show ip msdp sa-cache` command. Additional troubleshooting information, such as the local address of the connection, the local port, and the remote port, can be obtained using the output from the `debug ip msdp` command.
Configuration Examples for Using MSDP to Interconnect Multiple PIM-SM Domains

Example: Configuring an MSDP Peer

The following example shows how to establish MSDP peering connections between three MSDP peers:

**Device A**

```
! interface Loopback 0
  ip address 10.220.8.1 255.255.255.255
! ip msdp peer 10.220.16.1 connect-source Loopback0
ip msdp peer 10.220.32.1 connect-source Loopback0
!
```

**Device B**

```
! interface Loopback 0
  ip address 10.220.16.1 255.255.255.255
! ip msdp peer 10.220.8.1 connect connect-source Loopback0
ip msdp peer 10.220.32.1 connect connect-source Loopback0
!
```

**Device C**

```
! interface Loopback 0
  ip address 10.220.32.1 255.255.255.255
! ip msdp peer 10.220.8.1 connect 10.220.8.1 connect-source Loopback0
ip msdp peer 10.220.16.1 connect 10.220.16.1 connect-source Loopback0
!
```

Example: Configuring MSDP MD5 Password Authentication

The following example shows how to enable MD5 password authentication for TCP connections between two MSDP peers:
Example: Configuring a Default MSDP Peer

The figure illustrates a scenario where default MSDP peers might be used. In the figure, a customer that owns Device B is connected to the internet through two ISPs, one that owns Device A and the other that owns Device C. They are not running (M)BGP between them. In order for the customer to learn about sources in the ISP domain or in other domains, Device B identifies Device A as its default MSDP peer. Device B advertises SA messages to both Device A and Device C, but accepts SA messages either from Device A only or Device C only. If Device A is the first default peer in the configuration, it will be used if it is up and running. Only if Device A is not running will Device B accept SA messages from Device C.

The ISP will also likely use a prefix list to define which prefixes it will accept from the customer device. The customer will define multiple default peers, each having one or more prefixes associated with it.

The customer has two ISPs to use. The customer defines both ISPs as default peers. As long as the first default peer identified in the configuration is up and running, it will be the default peer and the customer will accept all SA messages it receives from that peer.
Device B advertises SAs to Device A and Device C, but uses only Device A or Device C to accept SA messages. If Device A is first in the configuration file, it will be used if it is up and running. Only when Device A is not running will Device B accept SAs from Device C. This is the behavior without a prefix list.

If you specify a prefix list, the peer will be a default peer only for the prefixes in the list. You can have multiple active default peers when you have a prefix list associated with each. When you do not have any prefix lists, you can configure multiple default peers, but only the first one is the active default peer as long as the device has connectivity to this peer and the peer is alive. If the first configured peer goes down or the connectivity to this peer goes down, the second configured peer becomes the active default, and so on.

The following example shows a partial configuration of Device A and Device C in the figure. Each of these ISPs may have more than one customer using default peering, like the customer in the figure. In that case, they may have similar configurations. That is, they will only accept SAs from a default peer if the SA is permitted by the corresponding prefix list.

**Device A Configuration**

```plaintext
ip msdp default-peer 10.1.1.1
ip msdp default-peer 10.1.1.1 prefix-list site-b ge 32
ip prefix-list site-b permit 10.0.0.0/8
```

**Device C Configuration**

```plaintext
ip msdp default-peer 10.1.1.1 prefix-list site-b ge 32
ip prefix-list site-b permit 10.0.0.0/8
```

Example: Configuring MSDP Mesh Groups

The following example shows how to configure three devices to be fully meshed members of an MSDP mesh group:

**Device A Configuration**

```plaintext
ip msdp peer 10.2.2.2
ip msdp peer 10.3.3.3
ip msdp mesh-group test-mesh-group 10.2.2.2
ip msdp mesh-group test-mesh-group 10.3.3.3
```

**Device B Configuration**

```plaintext
ip msdp peer 10.1.1.1
ip msdp peer 10.3.3.3
ip msdp mesh-group test-mesh-group 10.1.1.1
ip msdp mesh-group test-mesh-group 10.3.3.3
```

**Device C Configuration**

```plaintext
ip msdp peer 10.1.1.1
ip msdp peer 10.2.2.2
ip msdp mesh-group test-mesh-group 10.1.1.1
ip msdp mesh-group test-mesh-group 10.2.2.2
```

Configuring Wireless Multicast

- Finding Feature Information, on page 523
- Prerequisites for Configuring Wireless Multicast, on page 523
- Restrictions for Configuring Wireless Multicast, on page 523
- Information About Wireless Multicast, on page 524
- How to Configure Wireless Multicast, on page 528
- Monitoring Wireless Multicast, on page 536
- Where to Go Next for Wireless Multicast, on page 537

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Wireless Multicast

- The IP multicast routing must be enabled and the PIM version and PIM mode must be configured. The default routes should be available in the device. After performing these tasks, the device can then forward multicast packets and can populate its multicast routing table.

- To participate in IP multicasting, the multicast hosts, routers, and multilayer switches must have IGMP operating.

- When enabling multicast mode on the, a CAPWAP multicast group address should also be configured. Access points listen to the CAPWAP multicast group using IGMP.

Restrictions for Configuring Wireless Multicast

The following are the restrictions for configuring IP multicast routing:
Restrictions for IPv6 Snooping

The IPv6 snooping feature is not supported on Etherchannel ports.

Restrictions for IPv6 RA Guard

- The IPv6 RA Guard feature does not offer protection in environments where IPv6 traffic is tunneled.
- This feature is supported only in hardware when the ternary content addressable memory (TCAM) is programmed.
- This feature can be configured on a switch port interface in the ingress direction.
- This feature supports host mode and router mode.
- This feature is supported only in the ingress direction; it is not supported in the egress direction.
- This feature is not supported on EtherChannel and EtherChannel port members.
- This feature is not supported on trunk ports with merge mode.
- This feature is supported on auxiliary VLANs and private VLANs (PVLANs). In the case of PVLANs, primary VLAN features are inherited and merged with port features.
- Packets dropped by the IPv6 RA Guard feature can be spanned.

- If the `platform ipv6 acl icmp optimize neighbor-discovery` command is configured, the IPv6 RA Guard feature cannot be configured and an error message will be displayed. This command adds default global Internet Control Message Protocol (ICMP) entries that will override the RA guard ICMP entries.

Information About Wireless Multicast

If the network supports packet multicasting, the multicast method that the device uses can be configured. The device performs multicasting in two modes:

- Unicast mode—The device unicasts every multicast packet to every access point associated to the device. This mode is inefficient but might be required on networks that do not support multicasting.
- Multicast mode—The device sends multicast packets to a CAPWAP multicast group. This method reduces overhead on the device processor and shifts the work of packet replication to the network, which is much more efficient than the unicast method.

When the multicast mode is enabled and the device receives a multicast packet from the wired LAN, the device encapsulates the packet using CAPWAP and forwards the packet to the CAPWAP multicast group address. The device always uses the management VLAN for sending multicast packets. Access points in the
multicast group receive the packet and forward it to all the BSSIDs mapped to the VLAN on which clients receive multicast traffic.

The device supports all the capabilities of v1 including Multicast Listener Discovery (MLD) v1 snooping but the v2 and v3 capabilities are limited. This feature keeps track of and delivers IPv6 multicast flows to the clients that request them. To support IPv6 multicast, global multicast mode should be enabled.

Internet Group Management Protocol (IGMP) snooping is introduced to better direct multicast packets. When this feature is enabled, the device snooping gathers IGMP reports from the clients, processes them, creates unique multicast group IDs (MGIDs) based on the Layer 3 multicast address and the VLAN number, and sends the IGMP reports to the IGMP querier. The device then updates the access point MGID table on the access point with the client MAC address. When the device receives multicast traffic for a particular multicast group, it forwards it to all the access points, but only those access points that have active clients listening or subscribed to that multicast group send multicast traffic on that particular WLAN. IP packets are forwarded with an MGID that is unique for an ingress VLAN and the destination multicast group. Layer 2 multicast packets are forwarded with an MGID that is unique for the ingress VLAN.

MGID is a 14-bit value filled in the 16-bit reserved field of wireless information in CAPWAP header. The remaining 2 bits should be set to zero.

Information About Multicast Optimization

Multicast used to be based on the group of the multicast addresses and the VLAN as one entity, MGID. With the VLAN group, duplicate packets might increase. Using the VLAN group feature, every client listens to the multicast stream on a different VLAN. As a result, the device creates different MGIDs for each multicast address and VLAN. Therefore, in a worst case situation, the upstream router sends one copy for each VLAN, which results in as many copies as the number of VLANs in the group. Because the WLAN remains the same for all clients, multiple copies of the multicast packet are sent over the wireless network. To suppress the duplication of a multicast stream on the wireless medium between the device and the access points, the multicast optimization feature can be used.

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the device can be configured as a multicast VLAN where multicast groups are registered. The clients are allowed to listen to a multicast stream on the multicast VLAN. The MGID is generated using the multicast VLAN and multicast IP addresses. If multiple clients on different VLANs of the same VLAN are listening to a single multicast IP address, a single MGID is generated. The device makes sure that all multicast streams from the clients on this VLAN group always go out on the multicast VLAN to ensure that the upstream router has one entry for all the VLANs of the VLAN group. Only one multicast stream hits the VLAN group even if the clients are on different VLANs. Therefore, the multicast packets that are sent out over the network is just one stream.

IPv6 Global Policies

IPv6 global policies provide storage and access policy database services. IPv6 ND inspection and IPv6 RA guard are IPv6 global policies features. Every time an ND inspection or RA guard is configured globally, the
policy attributes are stored in the software policy database. The policy is then applied to an interface, and the software policy database entry is updated to include this interface to which the policy is applied.

**IPv6 RA Guard**

The IPv6 RA Guard feature provides support for allowing the network administrator to block or reject unwanted or rogue RA guard messages that arrive at the network device platform. RAs are used by devices to announce themselves on the link. The IPv6 RA Guard feature analyzes these RAs and filters out RAs that are sent by unauthorized devices. In host mode, all RA and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 (L2) device with the information found in the received RA frame. Once the L2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.

**Information About IPv6 Snooping**

**IPv6 Neighbor Discovery Inspection**

The IPv6 Neighbor Discovery Inspection, or IPv6 "snooping," feature bundles several Layer 2 IPv6 first-hop security features, including IPv6 Address Glean and IPv6 Device Tracking. IPv6 neighbor discovery (ND) inspection operates at Layer 2, or between Layer 2 and Layer 3, and provides IPv6 features with security and scalability. This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables and analyzes ND messages in order to build a trusted binding table. IPv6 ND messages that do not have valid bindings are dropped. An ND message is considered trustworthy if its IPv6-to-MAC mapping is verifiable.

When IPv6 ND inspection is configured on a target (which varies depending on platform target support and may include device ports, switch ports, Layer 2 interfaces, Layer 3 interfaces, and VLANs), capture instructions are downloaded to the hardware to redirect the ND protocol and Dynamic Host Configuration Protocol (DHCP) for IPv6 traffic up to the switch integrated security features (SISF) infrastructure in the routing device. For ND traffic, messages such as NS, NA, RS, RA, and REDIRECT are directed to SISF. For DHCP, UDP messages sourced from port 546 or 547 are redirected.

IPv6 ND inspection registers its "capture rules" to the classifier, which aggregates all rules from all features on a given target and installs the corresponding ACL down into the platform-dependent modules. Upon receiving redirected traffic, the classifier calls all entry points from any registered feature (for the target on which the traffic is being received), including the IPv6 ND inspection entry point. This entry point is the last to be called, so any decision (such as drop) made by another feature supersedes the IPv6 ND inspection decision.

**IPv6 ND Inspection**

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables. IPv6 ND inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery messages that do not have valid bindings are dropped. A neighbor discovery message is considered trustworthy if its IPv6-to-MAC mapping is verifiable.

This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.
IPv6 Device Tracking

IPv6 device tracking provides IPv6 host liveness tracking so that a neighbor table can be immediately updated when an IPv6 host disappears.

IPv6 First-Hop Security Binding Table

The IPv6 First-Hop Security Binding Table recovery mechanism feature enables the binding table to recover in the event of a device reboot. A database table of IPv6 neighbors connected to the device is created from information sources such as ND snooping. This database, or binding, table is used by various IPv6 guard features to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors to prevent spoofing and redirect attacks.

This mechanism enables the binding table to recover in the event of a device reboot. The recovery mechanism will block any data traffic sourced from an unknown source; that is, a source not already specified in the binding table and previously learned through ND or DHCP gleaning. This feature recovers the missing binding table entries when the resolution for a destination address fails in the destination guard. When a failure occurs, a binding table entry is recovered by querying the DHCP server or the destination host, depending on the configuration.

Recovery Protocols and Prefix Lists

The IPv6 First-Hop Security Binding Table Recovery Mechanism feature introduces the capability to provide a prefix list that is matched before the recovery is attempted for both DHCP and NDP.

If an address does not match the prefix list associated with the protocol, then the recovery of the binding table entry will not be attempted with that protocol. The prefix list should correspond to the prefixes that are valid for address assignment in the Layer 2 domain using the protocol. The default is that there is no prefix list, in which case the recovery is attempted for all addresses. The command to associate a prefix list to a protocol is `protocol {dhcp | ndp} [prefix-list prefix-list-name].`

IPv6 Address Glean

IPv6 address glean is the foundation for many other IPv6 features that depend on an accurate binding table. It inspects ND and DHCP messages on a link to glean addresses, and then populates the binding table with these addresses. This feature also enforces address ownership and limits the number of addresses any given node is allowed to claim.

The following figure shows how IPv6 address glean works.

<td>Displays all (Source, Group and VLAN) lists and the corresponding MGID value.</td>
</tr>
<tr>
<td><code>show wireless multicast [source source] group group vlan vlanid</code></td>
<td>Displays details of the given (S,G,V) and shows all of the clients associated with it and their MC2UC status.</td>
</tr>
<tr>
<td><code>show ip igmp snooping wireless mcast-spi-count</code></td>
<td>Displays statistics of the number of multicast SPIs per MGID sent between IOS and the Wireless Controller Module.</td>
</tr>
<tr>
<td><code>show ip igmp snooping wireless mgid</code></td>
<td>Displays the MGID mappings.</td>
</tr>
<tr>
<td><code>show ip igmp snooping igmpv2-tracking</code></td>
<td>Displays the client-to-SGV mappings and SGV-to-client mappings.</td>
</tr>
<tr>
<td><code>show ip igmp snooping querier vlan vlanid</code></td>
<td>Displays IGMP querier information for the specified VLAN.</td>
</tr>
<tr>
<td><code>show ip igmp snooping querier detail</code></td>
<td>Displays detailed IGMP querier information of all the VLANs.</td>
</tr>
<tr>
<td><code>show ipv6 mld snooping querier vlan vlanid</code></td>
<td>Displays MLD querier information for the specified VLAN.</td>
</tr>
<tr>
<td><code>show ipv6 mld snooping wireless mgid</code></td>
<td>Displays MGIDs for IPv6 multicast group.</td>
</tr>
</tbody>
</table>

---

**Step 6**

**no shutdown**

*Example:*

```
Device(config-wlan)# no shutdown
```

Enables the disabled WLAN.

**Step 7**

**end**

*Example:*

```
Device(config)# end
```

Exits the configuration mode. Alternatively, press **Ctrl-Z** to exit the configuration mode.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring SSM

The following are the prerequisites for configuring source-specific multicast (SSM) and SSM mapping:

- Before you configure SSM mapping, you must perform the following tasks:
  - Enable IP multicast routing.
  - Enable PIM sparse mode.
  - Configure SSM.

- Before you configure static SSM mapping, you must configure access control lists (ACLs) that define the group ranges to be mapped to source addresses.
Before you can configure and use SSM mapping with DNS lookups, you need to add records to a running DNS server. If you do not already have a DNS server running, you need to install one.

Note
You can use a product such as Cisco Network Registrar to add records to a running DNS server.

Restrictions for Configuring SSM

The following are the restrictions for configuring SSM:

• To run SSM with IGMPv3, SSM must be supported in the Cisco IOS router, the host where the application is running, and the application itself.

• Existing applications in a network predating SSM will not work within the SSM range unless they are modified to support (S, G) channel subscriptions. Therefore, enabling SSM in a network may cause problems for existing applications if they use addresses within the designated SSM range.

• IGMP Snooping—IGMPv3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.

• Address management is still necessary to some degree when SSM is used with Layer 2 switching mechanisms. Cisco Group Management Protocol (CGMP), IGMP snooping, or Router-Port Group Management Protocol (RGMP) support only group-specific filtering, not (S, G) channel-specific filtering. If different receivers in a switched network request different (S, G) channels sharing the same group, they do not benefit from these existing mechanisms. Instead, both receivers receive all (S, G) channel traffic and filter out the unwanted traffic on input. Because SSM can re-use the group addresses in the SSM range for many independent applications, this situation can lead to decreased traffic filtering in a switched network. For this reason, it is important to use random IP addresses from the SSM range for an application to minimize the chance for re-use of a single address within the SSM range between different applications. For example, an application service providing a set of television channels should, even with SSM, use a different group for each television (S, G) channel. This setup guarantees that multiple receivers to different channels within the same application service never experience traffic aliasing in networks that include Layer 2 devices.

• In PIM-SSM, the last hop router will continue to periodically send (S, G) join messages if appropriate (S, G) subscriptions are on the interfaces. Therefore, as long as receivers send (S, G) subscriptions, the shortest path tree (SPT) state from the receivers to the source will be maintained, even if the source is not sending traffic for longer periods of time (or even never).

The opposite situation occurs with PIM-SM, where (S, G) state is maintained only if the source is sending traffic and receivers are joining the group. If a source stops sending traffic for more than 3 minutes in PIM-SM, the (S, G) state is deleted and only reestablished after packets from the source arrive again through the RPT (rendezvous point tree). Because no mechanism in PIM-SSM notifies a receiver that a source is active, the network must maintain the (S, G) state in PIM-SSM as long as receivers are requesting receipt of that channel.

The following are the restrictions for configuring SSM mapping:

• The SSM Mapping feature does not share the benefit of full SSM. SSM mapping takes a group G join from a host and identifies this group with an application associated with one or more sources, therefore,
it can only support one such application per group G. Nevertheless, full SSM applications may still share the same group also used in SSM mapping.

- Enable IGMPv3 with care on the last hop router when you rely solely on SSM mapping as a transition solution for full SSM. When you enable both SSM mapping and IGMPv3 and the hosts already support IGMPv3 (but not SSM), the hosts send IGMPv3 group reports. SSM mapping does not support these IGMPv3 group reports, and the router does not correctly associate sources with these reports.

### Information About SSM

The source-specific multicast (SSM) feature is an extension of IP multicast in which datagram traffic is forwarded to receivers from only those multicast sources that the receivers have explicitly joined. For multicast groups configured for SSM, only SSM distribution trees (no shared trees) are created.

This section describes how to configure source-specific multicast (SSM). For a complete description of the SSM commands in this section, refer to the IP Multicast Command Reference. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

### SSM Components Overview

SSM is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core networking technology for the Cisco implementation of IP multicast solutions targeted for audio and video broadcast application environments. The device supports the following components that support SSM implementation:

- Protocol independent multicast source-specific mode (PIM-SSM)

  PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM sparse mode (PIM-SM).

- Internet Group Management Protocol version 3 (IGMPv3)

### SSM and Internet Standard Multicast (ISM)

The current IP multicast infrastructure in the Internet and many enterprise intranets is based on the PIM-SM protocol and Multicast Source Discovery Protocol (MSDP). These protocols have the limitations of the Internet Standard Multicast (ISM) service model. For example, with ISM, the network must maintain knowledge about which hosts in the network are actively sending multicast traffic.

The ISM service consists of the delivery of IP datagrams from any source to a group of receivers called the multicast host group. The datagram traffic for the multicast host group consists of datagrams with an arbitrary IP unicast source address (S) and the multicast group address (G) as the IP destination address. Systems receive this traffic by becoming members of the host group. Membership in a host group simply requires signaling the host group through IGMP version 1, 2, or 3.

In SSM, delivery of datagrams is based on (S, G) channels. In both SSM and ISM, no signaling is required to become a source. However, in SSM, receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources. In other words, receivers can receive traffic only from (S, G) channels to which they are subscribed, whereas in ISM, receivers need not know the IP addresses of sources from which they receive their traffic. The proposed standard approach for channel subscription signaling uses IGMP and includes modes membership reports, which are supported only in IGMP version 3.
SSM IP Address Range

SSM can coexist with the ISM service by applying the SSM delivery model to a configured subset of the IP multicast group address range. Cisco IOS software allows SSM configuration for the IP multicast address range of 224.0.0.0 through 239.255.255.255. When an SSM range is defined, existing IP multicast receiver applications do not receive any traffic when they try to use an address in the SSM range (unless the application is modified to use an explicit (S, G) channel subscription).

SSM Operations

An established network, in which IP multicast service is based on PIM-SM, can support SSM services. SSM can also be deployed alone in a network without the full range of protocols required for interdomain PIM-SM (for example, MSDP, Auto-RP, or bootstrap router [BSR]) if only SSM service is needed.

If SSM is deployed in a network already configured for PIM-SM, only the last-hop routers support SSM. Routers that are not directly connected to receivers do not require support for SSM. In general, these not-last-hop routers must only run PIM-SM in the SSM range and might need additional access control configuration to suppress MSDP signalling, registering, or PIM-SM shared tree operations from occurring within the SSM range.

Use the `ip pim ssm` global configuration command to configure the SSM range and to enable SSM. This configuration has the following effects:

- For groups within the SSM range, (S, G) channel subscriptions are accepted through IGMPv3 include-mode membership reports.

- PIM operations within the SSM range of addresses change to PIM-SSM, a mode derived from PIM-SM. In this mode, only PIM (S, G) join and prune messages are generated by the router, and no (S, G) rendezvous point tree (RPT) or (*, G) RPT messages are generated. Incoming messages related to RPT operations are ignored or rejected, and incoming PIM register messages are immediately answered with register-stop messages. PIM-SSM is backward-compatible with PIM-SM unless a router is a last-hop router. Therefore, routers that are not last-hop routers can run PIM-SM for SSM groups (for example, if they do not yet support SSM).

- No MSDP source-active (SA) messages within the SSM range are accepted, generated, or forwarded.

SSM Mapping

In a typical set-top box (STB) deployment, each TV channel uses one separate IP multicast group and has one active server host sending the TV channel. A single server can send multiple TV channels, but each to a different group. In this network environment, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the report addresses the well-known TV server for the TV channel associated with the multicast group.

When SSM mapping is configured, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the router translates this report into one or more channel memberships for the well-known sources associated with this group.

When the router receives an IGMPv1 or IGMPv2 membership report for a group, the router uses SSM mapping to determine one or more source IP addresses for the group. SSM mapping then translates the membership report as an IGMPv3 report and continues as if it had received an IGMPv3 report. The router then sends PIM joins and continues to be joined to these groups as long as it continues to receive the IGMPv1 or IGMPv2 membership reports, and the SSM mapping for the group remains the same.
SSM mapping enables the last hop router to determine the source addresses either by a statically configured table on the router or through a DNS server. When the statically configured table or the DNS mapping changes, the router leaves the current sources associated with the joined groups.

**Static SSM Mapping**

With static SSM mapping, you can configure the last hop router to use a static map to determine the sources that are sending to groups. Static SSM mapping requires that you configure ACLs to define group ranges. After configuring the ACLs to define group ranges, you can then map the groups permitted by those ACLs to sources by using the `ip igmp ssm-map static` global configuration command.

You can configure static SSM mapping in smaller networks when a DNS is not needed or to locally override DNS mappings. When configured, static SSM mappings take precedence over DNS mappings.

**Related Topics**

Configuring Static Traffic Forwarding with SSM Mapping (CLI), on page 549

**DNS-Based SSM Mapping**

You can use DNS-based SSM mapping to configure the last hop router to perform a reverse DNS lookup to determine sources sending to groups. When DNS-based SSM mapping is configured, the router constructs a domain name that includes the group address and performs a reverse lookup into the DNS. The router looks up IP address resource records and uses them as the source addresses associated with this group. SSM mapping supports up to 20 sources for each group. The router joins all sources configured for a group.

**Figure 29: DNS-Based SSM Mapping**

The following figure displays DNS-based SSM mapping.

The SSM mapping mechanism that enables the last hop router to join multiple sources for a group can provide source redundancy for a TV broadcast. In this context, the last hop router provides redundancy using SSM mapping to simultaneously join two video sources for the same TV channel. However, to prevent the last hop
router from duplicating the video traffic, the video sources must use a server-side switchover mechanism. One video source is active, and the other backup video source is passive. The passive source waits until an active source failure is detected before sending the video traffic for the TV channel. Thus, the server-side switchover mechanism ensures that only one of the servers is actively sending video traffic for the TV channel.

To look up one or more source addresses for a group that includes G1, G2, G3, and G4, you must configure these DNS records on the DNS server:

\[
\begin{align*}
G4.G3.G2.G1 & \text{ [multicast-domain] [timeout] IN A source-address-1} \\
& \text{ IN A source-address-2} \\
& \text{ IN A source-address-n}
\end{align*}
\]

See your DNS server documentation for more information about configuring DNS resource records.

### How to Configure SSM

For a complete description of the source-specific multicast (SSM) commands in this section, see the *IP Multicast Command Reference, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

### Configuring SSM (CLI)

Follow these steps to configure SSM:

This procedure is optional.

**Before you begin**

If you want to use an access list to define the Source Specific Multicast (SSM) range, configure the access list before you reference the access list in the `ip pim ssm` command.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip pim ssm [default | range access-list]`
4. `interface type number`
5. `ip pim {sparse-mode | sparse-dense-mode}`
6. `ip igmp version 3`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`
### DETAILED STEPS

Purpose

Command or Action

Device# show running-config

Step 9

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

Configuring Source Specific Multicast Mapping

The Source Specific Multicast (SSM) mapping feature supports SSM transition when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. You can use SSM mapping to leverage SSM for video delivery to legacy STBs that do not support IGMPv3 or for applications that do not use the IGMPv3 host stack.

Configuring Static SSM Mapping (CLI)

Follow these steps to configure static SSM Mapping:

For additional information on SSM mapping, see the IP Multicast CG Library, Cisco IOS XE Release 3SE (Catalyst 3850 Switches).

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip igmp ssm-map enable
4. no ip igmp ssm-map query dns
5. ip igmp ssm-map static access-list source-address
6. end
7. show running-config
8. copy running-config startup-config

</table>
Configuring DNS-Based SSM Mapping (CLI)

To configure DNS-based SSM mapping, you need to create a DNS server zone or add records to an existing zone. If the routers that are using DNS-based SSM mapping are also using DNS for other purposes, you should use a normally configured DNS server. If DNS-based SSM mapping is the only DNS implementation being used on the router, you can configure a false DNS setup with an empty root zone or a root zone that points back to itself.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp ssm-map enable
4. ip igmp ssm-map query dns
5. ip domain multicast domain-prefix
6. ip name-server server-address1 [server-address2...server-address6]
7. Repeat Step 6 to configure additional DNS servers for redundancy, if required.
8. end
9. show running-config
10. copy running-config startup-config

DETAILED STEPS

### Command or Action

| Step 4 | `ip igmp ssm-map query dns`  
| Purpose | (Optional) Enables DNS-based SSM mapping.  
| Example |  
| | Device(config)# `ip igmp ssm-map query dns`  
| Note | Use this command to reenable DNS-based SSM mapping if DNS-based SSM mapping is disabled.  

| Step 5 | `ip domain multicast domain-prefix`  
| Purpose | (Optional) Changes the domain prefix used for DNS-based SSM mapping.  
| Example |  
| | Device(config)# `ip domain multicast ssm-map.cisco.com`  
| Note | By default, the software uses the ip-addr.arpa domain prefix.  

| Step 6 | `ip name-server server-address1 [server-address2...server-address6]`  
| Purpose | Specifies the address of one or more name servers to use for name and address resolution.  
| Example |  
| | Device(config)# `ip name-server 10.48.81.21`  

| Step 7 | Repeat Step 6 to configure additional DNS servers for redundancy, if required.  

| Step 8 | `end`  
| Purpose | Returns to privileged EXEC mode.  
| Example |  
| | Device(config)# `end`  

| Step 9 | `show running-config`  
| Purpose | Verifies your entries.  
| Example |  
| | Device# `show running-config`  

| Step 10 | `copy running-config startup-config`  
| Purpose | (Optional) Saves your entries in the configuration file.  
| Example |  
| | Device# `copy running-config startup-config`

- Additional References, on page 571
- Feature History and Information for IP Multicast, on page 573

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Basic IP Multicast Routing

The following are the prerequisites for configuring basic IP multicast routing:

- To use this feature, the device or must be running the IP services feature set. The IP Services image contains complete multicast routing.

- You must configure the PIM version and the PIM mode in order to perform IP multicast routing. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting. You can configure an interface to be in the PIM dense mode, sparse mode, or sparse-dense mode.

- Enabling PIM on an interface also enables IGMP operation on that interface. (To participate in IP multicasting, the multicast hosts, routers, and multilayer device must have IGMP operating.)
If you enable PIM on multiple interfaces, when most of these interfaces are not on the outgoing interface list, and IGMP snooping is disabled, the outgoing interface might not be able to sustain line rate for multicast traffic because of the extra replication.

Related Topics
- Configuring Basic IP Multicast Routing, on page 557
- Information About Basic IP Multicast Routing, on page 556
- IP Multicast Routing Protocols, on page 329

Restrictions for Basic IP Multicast Routing

The following are the restrictions for IP multicast routing:

- IP multicast routing is not supported on switches running the LAN base feature set.
- High-availability support for Layer 3 multicast routing is not supported.
- You cannot have a device stack containing a mix of Catalyst 3850 and Catalyst 3650 devices.

Information About Basic IP Multicast Routing

IP multicasting is an efficient way to use network resources, especially for bandwidth-intensive services such as audio and video. IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address.

The sending host inserts the multicast group address into the IP destination address field of the packet, and IP multicast routers and multilayer devices forward incoming IP multicast packets out all interfaces that lead to members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

Note
For complete syntax and usage information for the commands used in this chapter, see the IP Multicast Command Reference, Cisco IOS XE Release 3SE (Catalyst 3850 Switches). For information on configuring the Multicast Source Discovery Protocol (MSDP), see the Catalyst 3850 Routing Configuration Guide.

Multicast Forwarding Information Base Overview

The device uses the Multicast Forwarding Information Base (MFIB) architecture and the Multicast Routing Information Base (MRIB) for IP multicast.

The MFIB architecture provides both modularity and separation between the multicast control plane (Protocol Independent Multicast [PIM] and Internet Group Management Protocol [IGMP]) and the multicast forwarding plane (MFIB). This architecture is used in Cisco IOS IPv6 multicast implementations.
MFIB itself is a multicast routing protocol independent forwarding engine; that is, it does not depend on PIM or any other multicast routing protocol. It is responsible for:

- Forwarding multicast packets
- Registering with the MRIB to learn the entry and interface flags set by the control plane
- Handling data-driven events that must be sent to the control plane
- Maintaining counts, rates, and bytes of received, dropped, and forwarded multicast packets

The MRIB is the communication channel between MRIB clients. Examples of MRIB clients are PIM, IGMP, the multicast routing (mroute) table, and the MFIB.

How to Configure Basic IP Multicast Routing

Configuring Basic IP Multicast Routing

By default, multicast routing is disabled, and there is no default mode setting.
This procedure is required.

**Before you begin**

You must configure the PIM version and the PIM mode. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting.

In populating the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream devices or when there is a directly connected member on the interface. When forwarding from a LAN, sparse-mode operation occurs if there is an RP known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver’s first-hop router might send join messages toward the source to build a source-based distribution tree.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip multicast-routing
4. interface interface-id
5. ip pim {dense-mode | sparse-mode | sparse-dense-mode}
6. end
7. show running-config
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>

<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt;.enable</td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 | configure terminal | Enters the global configuration mode. |
| Example: | device# configure terminal | |

| Step 3 | ip multicast-routing | Enables IP multicast routing. |
| Example: | device(config)# ip multicast-routing | IP multicast routing is supported with Multicast Forwarding Information Base (MFIB) and Multicast Routing Information Base (MRIB). |

| Step 4 | interface interface-id | Specifies the Layer 3 interface on which you want to enable multicast routing, and enters interface configuration mode. |
| Example: | | The specified interface must be one of the following:
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td>• A routed port—A physical port that has been configured as a Layer 3 port by entering the <code>no switchport</code> interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see Example: Interface Configuration as a Routed Port, on page 390</td>
</tr>
<tr>
<td></td>
<td>• An SVI—A VLAN interface created by using the <code>interface vlan vlan-id</code> global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see Example: Interface Configuration as an SVI, on page 391</td>
</tr>
<tr>
<td>These interfaces must have IP addresses assigned to them.</td>
<td></td>
</tr>
</tbody>
</table>

### Step 5

Configuring IP Multicast Forwarding (CLI)

You can use the following procedure to configure IPv4 Multicast Forwarding Information Base (MFIB) interrupt-level IP multicast forwarding of incoming packets or outgoing packets on the device.

### Note
After you have enabled IP multicast routing by using the `ip multicast-routing` command, IPv4 multicast forwarding is enabled. Because IPv4 multicast forwarding is enabled by default, you can use the `no` form of the `ip mfib` command to disable IPv4 multicast forwarding.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. ip mfib
4. exit
5. show running-config
6. copy running-config startup-config

### Configuring a Static Multicast Route (mroute) (CLI)

You can use the following procedure to configure static mroutes. Static mroutes are similar to unicast static routes but differ in the following ways:

- Static mroutes are used to calculate RPF information, not to forward traffic.
- Static mroutes cannot be redistributed.

Static mroutes are strictly local to the device on which they are defined. Because Protocol Independent Multicast (PIM) does not have its own routing protocol, there is no mechanism to distribute static mroutes throughout the network. Consequently, the administration of static mroutes tends to be more complicated than the administration of unicast static routes.

When static mroutes are configured, they are stored on the device in a separate table referred to as the static mroute table. When configured, the `ip mroute` command enters a static mroute into the static mroute table for the source address or source address range specified for the source-address and mask arguments. Sources that match the source address or that fall in the source address range specified for the source-address argument will RPF to either the interface associated with the IP address specified for the `rpf-address` argument or the local interface on the device specified for the `interface-type` and `interface-number` arguments. If an IP address is specified for the `rpf-address` argument, a recursive lookup is done from the unicast routing table on this address to find the directly connected neighbor.
If there are multiple static mroutes configured, the device performs a longest-match lookup of the mroute table. When the mroute with the longest match (of the source-address) is found, the search terminates and the information in the matching static mroute is used. The order in which the static mroutes are configured is not important.

The administrative distance of an mroute may be specified for the optional distance argument. If a value is not specified for the distance argument, the distance of the mroute defaults to zero. If the static mroute has the same distance as another RPF source, the static mroute will take precedence. There are only two exceptions to this rule: directly connected routes and the default unicast route.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip mroute \[vrf vrf-name\] source-address mask \{ fallback-lookup \{global | vrf vrf-name \} [ protocol ] \{rpf-address | interface-type interface-number\}\} [distance]
4. exit
5. show running-config
6. copy running-config startup-config

### Configuring Optional IP Multicast Routing Features

#### Defining the IP Multicast Boundary (CLI)

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information. This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `access-list access-list-number deny source [source-wildcard]`
4. `interface interface-id`
5. `ip multicast boundary access-list-number`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

**DETAILED STEPS**

### Limiting How Long an sdr Cache Entry Exists (CLI)

By default, entries are never deleted from the sdr cache. You can limit how long the entry remains active so that if a source stops advertising SAP information, old advertisements are not unnecessarily kept. This procedure is optional.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip sap cache-timeout minutes`
4. `end`
5. `show running-config`
6. `show ip sap`
7. `copy running-config startup-config`

**Monitoring and Maintaining Basic IP Multicast Routing**

**Clearing Caches, Tables, and Databases**

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure are or suspected to be invalid.
You can use any of the privileged EXEC commands in the following table to clear IP multicast caches, tables, and databases.

**Table 47: Commands for Clearing Caches, Tables, and Databases**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear igmp group {group [hostname</td>
<td>IP address]</td>

<tr>
<td>clear ip mfib {counters [group</td>
<td>source]</td>
</tr>
<tr>
<td>clear ip mrm {status-report [source]}</td>
<td>IP multicast routing clear commands.</td>
</tr>
<tr>
<td>clear ip mroute {*</td>
<td>[hostname</td>
</tr>
<tr>
<td>clear ip msdp {peer</td>
<td>sa-cache</td>
</tr>
<tr>
<td>clear ip multicast {limit</td>
<td>redundancy statistics}</td>
</tr>
<tr>
<td>clear ip pim {df [int</td>
<td>rp rp address]</td>
</tr>
<tr>
<td>clear ip sap [group-address</td>
<td>“session-name”]</td>
</tr>
</tbody>
</table>

**Displaying System and Network Statistics**

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

---

**Note**
This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 48: Commands for Displaying System and Network Statistics**

<table>
<thead>
<tr>

<td>Display bootstrap router information (version 2).</td>
</tr>
<tr>
<td>show ip pim interface [type number] [count</td>
<td>detail</td>
</tr>
<tr>
<td>show ip pim neighbor [type number]</td>
<td>Lists the PIM neighbors discovered by the device. This command is available in all software images.</td>
</tr>
</tbody>
</table>
Purpose

Command | Purpose
--- | ---
show ip pim mdt [ bgp ] | Displays multicast tunnel information.
show ip pim rp [group-name | group-address] | Displays the RP routers associated with a sparse-mode multicast group. This command is available in all software images.
show ip pim rp-hash [group-name | group-address] | Displays the RP to be chosen based upon the group selected.
show ip pim tunnel [ tunnel | verbose ] | Displays the registered tunnels.
show ip pim vrf name | Displays VPN routing and forwarding instances.
show ip rpf {source-address | name} | Displays how the device is doing Reverse-Path Forwarding (that is, from the unicast routing table, DVMRP routing table, or static mroutes).

Command parameters include:

- *Host name or IP address*—IP name or group address.
- *Select*—Group-based VRF select information.
- *vrf*—Selects VPN Routing/Forwarding instance.

Command parameters include:

- *A.B.C.D*—IP group address.
- *WORD*—Session name (in double quotes).
- *detail*—Session details.

Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing

You can use the privileged EXEC commands in the following table to monitor IP multicast routers, packets, and paths.

Table 48: Commands for Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>mrinfo { [hostname</td>
<td>address]</td>
</tr>
<tr>
<td>mstat { [hostname</td>
<td>address]</td>
</tr>
</tbody>
</table>
### Command

| mtrace { [hostname | address] | vrf } |
|------------------|
| Traces the path from a source to a destination branch for a multicast distribution tree for a given group. |

### Configuration Examples for IP Multicast Routing

#### Example: Configuring an IP Multicast Boundary

This example shows how to set up a boundary for all administratively-scoped addresses:

```
Device(config)# access-list 1 deny 239.0.0.0 0.255.255.255
Device(config)# access-list 1 permit 224.0.0.0 15.255.255.255
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip multicast boundary 1
```

#### Related Topics

- IP Multicast Boundary, on page 332
- Multicast Group Transmission Scheme, on page 330

#### Example: Responding to mrinfo Requests

The software answers mrinfo requests sent by mrouted systems and Cisco routers and multilayer devices. The software returns information about neighbors through DVMRP tunnels and all the routed interfaces. This information includes the metric (always set to 1), the configured TTL threshold, the status of the interface, and various flags. You can also use the mrinfo privileged EXEC command to query the router or device itself, as in this example:

```
Device# mrinfo
171.69.214.27  (mm1-7kd.cisco.com)  [version cisco 11.1]  [flags: PMS]:
171.69.214.27  ->  171.69.214.26  (mm1-r7kb.cisco.com)  [1/0/pim/querier]
171.69.214.27  ->  171.69.214.25  (mm1-45a.cisco.com)  [1/0/pim/querier]
171.69.214.33  ->  171.69.214.34  (mm1-45c.cisco.com)  [1/0/pim]
171.69.214.137  ->  0.0.0.0  [1/0/pim/querier/down/leaf]
171.69.214.203  ->  0.0.0.0  [1/0/pim/querier/down/leaf]
171.69.214.18  ->  171.69.214.20  (mm1-45e.cisco.com)  [1/0/pim]
171.69.214.18  ->  171.69.214.19  (mm1-45c.cisco.com)  [1/0/pim]
171.69.214.18  ->  171.69.214.17  (mm1-45a.cisco.com)  [1/0/pim]
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring the Service Discovery Gateway

The following are restrictions for configuring the Service Discovery Gateway:

- The Service Discovery Gateway does not support topologies with multiple hops. All network segments must be connected directly to it. The Service Discovery Gateway can learn services from all connected segments to build its cache and respond to requests acting as a proxy.

- The use of third-party mDNS servers or applications are not supported with this feature.
Information about the Service Discovery Gateway and mDNS

mDNS

mDNS was defined to achieve zero configuration, with zero configuration being defined as providing the following features:

- **Addressing**—Allocating IP addresses to hosts
- **Naming**—Using names to refer to hosts instead of IP addresses
- **Service discovery**—Finding services automatically on the network

With mDNS, network users no longer have to assign IP addresses, assign host names, or type in names to access services on the network. Users only need to ask to see what network services are available, and choose from a list.

With mDNS, **addressing** is accomplished through the use of DHCP/DHCPv6 or IPv4 and IPv6 Link Local scoped addresses. The benefit of zero-configuration occurs when no infrastructure services such as DHCP or DNS are present and self-assigned link-local addressing can be used. The client can then select a random IPv4 address in the link-local range (169.254.0.0/24) or use its IPv6 link-local address (FE80::/10) for communication.

With mDNS, **naming** (name-to-address translation on a local network using mDNS) queries are sent over the local network using link-local scoped IP multicast. Because these DNS queries are sent to a multicast address (IPv4 address 224.0.0.251 or IPv6 address FF02::FB), no single DNS server with global knowledge is required to answer the queries. When a service or device sees a query for any service it is aware of, it provides a DNS response with the information from its cache.

With mDNS, **service discovery** is accomplished by browsing. An mDNS query is sent out for a given service type and domain, and any device that is aware of matching services replies with service information. The result is a list of available services for the user to choose from.

The mDNS protocol (mDNS-RFC), together with DNS Service Discovery (DNS-SD-RFC) achieves the zero-configuration addressing, naming, and service discovery.

mDNS-SD

Multicast DNS Service Discovery (mDNS-SD) uses DNS protocol semantics and multicast over well-known multicast addresses to achieve zero configuration service discovery. DNS packets are sent to and received on port 5353 using a multicast address of 224.0.0.251 and its IPv6 equivalent FF02::FB.

Because mDNS uses a link-local multicast address, its scope is limited to a single physical or logical LAN. If the networking reach needs to be extended to a distributed campus or to a wide-area environment consisting of many different networking technologies, mDNS gateway is implemented. An mDNS gateway provides a transport for mDNS packets across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain to another.

mDNS-SD Considerations for Wireless Clients

- mDNS packets can be sent out of Layer 3 interfaces that might not have an IP address.
- Packets with mDNS multicast IP and multicast MAC are sent on a multicast CAPWAP tunnel, if multicast-multicast mode is enabled. A multicast CAPWAP tunnel is a special CAPWAP tunnel used...
for reducing the number of copies of multicast packet that are required to be generated for each AP CAPWAP tunnel. Sending packets on the multicast CAPWAP tunnel requires the outer IP header to be destined to the multicast CAPWAP tunnel’s address, which all APs are subscribed to.

- All mDNS packet handling is done at a foreign switch for roamed clients. A foreign switch is the new switch that a roamed wireless client is actually attached to, which is called the point of attachment.

**Service Discovery Gateway**

The Service Discovery Gateway feature enables multicast Domain Name System (mDNS) to operate across Layer 3 boundaries (different subnets). An mDNS gateway provides transport for service discovery across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain (subnet) to another. Prior to implementation of this feature, mDNS was limited in scope to within a subnet because of the use of link-local scoped multicast addresses. This feature enhances Bring Your Own Device (BYOD).

**mDNS Gateway and Subnets**

You need to enable an mDNS gateway for service discovery to operate across subnets. You can enable mDNS gateway for a device or for an interface.

---

**Note**

You need to configure service routing globally before configuring at the interface level.

After the device or interface is enabled, you can redistribute service discovery information across subnets. You can create service policies and apply filters on either incoming service discovery information (called IN-bound filtering) or outgoing service discovery information (called OUT-bound filtering).

---

**Note**

If redistribution is enabled globally, global configuration is given higher priority than interface configuration.

---

**Figure 30: Sample Networking Scenario**

For example, if the mDNS gateway functionality is enabled on the router in this figure, then service information can be sent from one subnet to another and vice-versa. For example, the printer and fax service information being advertised in the network with IP address 192.0.2.6 are redistributed to the network with IP address 198.51.100.4. The printer and fax service information in the network with IP address 192.0.2.6 is learned by...
mDNS-enabled hosts and devices in the other network.

Filtering

After configuring the mDNS gateway and subnets, you can filter services that you want to redistribute. While creating a service list, the `permit` or `deny` command options are used:

- The `permit` command option allows you to permit or transport specific service list information.
- The `deny` option allows you to deny service list information that is available to be transported to other subnets.

You need to include a sequence number when using the `permit` or `deny` command option. The same service list name can be associated with multiple sequence numbers and each sequence number will be mapped to a rule.

- **Note**

  If no filters are configured, then the default action is to deny service list information to be transported through the device or interface.

  Query is another option provided when creating service lists. You can create queries using a service list. If you want to browse for a service, then active queries can be used. This function is helpful to keep the records refreshed in the cache.

- **Note**

  Active queries can only be used globally and cannot be used at the interface level.

  A service end-point (such as a printer or fax) sends unsolicited announcements when a service starts up. After that, it sends unsolicited announcements whenever a network change event occurs (such as an interface coming up or going down). The device always respond to queries.
After creating a service list and using the `permit` or `deny` command options, you can filter using match statements (commands) based on service-instance, service-type, or message-type (announcement or query).

## How to Configure the Service Discovery Gateway

### Configuring the Service List (CLI)

This procedure describes how to create a service list, apply a filter for the service list, and configure parameters for the service list name.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `service-list mdns-sd service-list-name {deny sequence-number | permit sequence-number | query}`
4. `match message-type {announcement | any | query}`
5. `match service-instance { LINE }`
6. `match service-type {LINE }`
7. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
**Purpose**

Enters mDNS service discovery service list mode. In this mode, you can:

- Create a service list and apply a filter on the service list according to the `permit` or `deny` option applied to the sequence number.
- Create a service list and associate a query for the service list name if the `query` option is used.

**Note**

The sequence number sets the priority of the rule. A rule with a lower sequence number is selected first and the service announcement or query is allowed or denied accordingly. You define the sequence number as per your network requirements.

**Step 3**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`service-list mdns-sd service-list-name {deny sequence-number</td>
<td>permit sequence-number</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# service-list mdns-sd sl1 permit 3</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# service-list mdns-sd sl4 query</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`match message-type {announcement</td>
<td>any</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-mdns-sd-sl)# match message-type announcement</code></td>
<td></td>
</tr>
</tbody>
</table>

These commands configure the parameters for the service list name that is created in step 2.

If the `match message-type` is an announcement, then the service list rule only allows service advertisements or announcements for the device. If the `match message-type` is a query, then only a query from the client for a certain service in the network is allowed.

Multiple service maps of the same name with different sequence numbers can be created and the evaluation of the filters will be ordered on the sequence number. Service lists are an ordered sequence of individual statements, each one has a permit or deny result. Evaluation of service list consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is stopped once the first statement match is found and an action permit/deny associated with the statement match is performed. The default action after scanning through the entire list is to deny.

**Note**

You cannot use the `match` command if you have used the `query` option in the previous step. The `match` command can be used only for the `permit` or `deny` option.
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 5</td>
<td><code>match service-instance { LINE }</code></td>
<td>(Optional) Sets the service instance to match. This command configures the parameters for the service list name that is created in step 2.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-mdns-sd-sl)# # match service-instance</td>
<td></td>
</tr>
<tr>
<td></td>
<td>servInst 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: You cannot use the <code>match</code> command if you have used the <code>query</code> option in the previous step. The <code>match</code> command can be used only for the <code>permit</code> or <code>deny</code> option.</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td><code>match service-type {LINE }</code></td>
<td>(Optional) Sets the value of the mDNS service type string to match. This command configures the parameters for the service list name that is created in step 2.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-mdns-sd-sl)# match service-type</td>
<td></td>
</tr>
<tr>
<td></td>
<td>_ipp._tcp</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: You cannot use the <code>match</code> command if you have used the <code>query</code> option in the previous step. The <code>match</code> command can be used only for the <code>permit</code> or <code>deny</code> option.</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-mdns-sd-sl)# end</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

Proceed to enable the mDNS gateway and redistribution of services.

### Enabling mDNS Gateway and Redistributing Services (CLI)

After enabling mDNS gateway for a device, you can apply filters (apply IN-bound filtering or OUT-bound filtering) and active queries by using `service-policy` and `service-policy-query` commands, respectively. You can redistribute services and service announcements using the `redistribute mdns-sd` command, and set some part of the system memory for cache using the `cache-memory-max` command.

**Note**

By default, mDNS gateway is disabled on all interfaces.

### SUMMARY STEPS

1. `enable`
2. configure terminal
3. service-routing mdns-sd
4. service-policy service-policy-name \{IN | OUT\}
5. redistribute mdns-sd
6. cache-memory-max cache-config-percentage
7. service-policy-query service-list-query-name service-list-query-periodicity
8. exit
9. wireless multicast
10. no wireless mdns-bridging
11. end

```
Device(config)# service-routing mdns-sd
Device(config-mdns)# Redistribute mdns-sd if-name
```
Example: Disable Bridging of mDNS Packets to Wireless Clients

The following example displays how to disable bridging of mDNS packets to wireless clients.

Device(config)# wireless multicast
Device(config)# no wireless mdns-bridging

Example: Creating a Service-List, Applying a Filter and Configuring Parameters

The following example shows the creation of a service-list sl1. The permit command option is being applied on sequence number 3 and all services with message-type announcement are filtered and available for transport across various subnets associated with the device.

Device# configure terminal
Device(config)# service-list mdns-sd sl1 permit 3
Device(config-mdns-sd-sl1)# match message-type announcement
Device(config-mdns-sd)# exit

Example: Enabling mDNS Gateway and Redistributing Services

The following example shows how to enable an mDNS gateway for a device and enable redistribution of services across subnets. IN-bound filtering is applied on the service-list serv-pol1. Twenty percent of system memory is made available for cache and service-list-query periodicity is configured at 100 seconds.

Device# configure terminal
Device# service-routing mdns-sd
Device(config-mdns-sd)# service-policy serv-pol1 IN
Device(config-mdns-sd)# redistribute mdns-sd
Device(config-mdns-sd)# cache-memory-max 20
Device(config-mdns-sd)# service-policy-query sl-query1 100
Device(config-mdns-sd)# exit
Example: Global mDNS Configuration

The following example displays how to globally configure mDNS.

```
Device# configure terminal
Device(config)# service-list mdns-sd mypermit-all permit 10
Device(config-mdns-sd-s1)# exit
Device(config)# service-list mdns-sd querier query
Device(config-mdns-sd-s1)# service-type _dns._udp
Device(config-mdns-sd-s1)# end
Device# configure terminal
Device(config)# service-routing mdns-sd
Device(config-mdns)# service-policy mypermit-all IN
Device(config-mdns)# service-policy mypermit-all OUT
```

Example: Interface mDNS Configuration

The following example displays how to configure mDNS for an interface.

```
Device(config)# interface Vlan136
Device(config-if)# description *** Mgmt VLAN ***
Device(config-if)# ip address 9.7.136.10 255.255.255.0
Device(config-if)# ip helper-address 9.1.0.100
Device(config-if)# service-routing mdns-sd
Device(config-if-mdns-sd)# service-policy mypermit-all IN
Device(config-if-mdns-sd)# service-policy mypermit-all OUT
Device(config-if-mdns-sd)# service-policy-query querier 60
```

Where to Go Next for Configuring Services Discovery Gateway

You can configure the following:

- IGMP
• Wireless Multicast
• PIM
• SSM
• IP Multicast Routing

Prerequisites for Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

• You must have PIM sparse mode running in your network.

• If you plan to use a group list to control to which groups the shortest-path tree (SPT) threshold applies, you must have configured your access list before performing the task.

Information About Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

PIM Registering Process

IP multicast sources do not use a signaling mechanism to announce their presence. Sources just send their data into the attached network, as opposed to receivers that use Internet Group Management Protocol (IGMP) to announce their presence. If a source sends traffic to a multicast group configured in PIM sparse mode (PIM-SM), the Designated Router (DR) leading toward the source must inform the rendezvous point (RP) about the presence of this source. If the RP has downstream receivers that want to receive the multicast traffic (natively) from this source and has not joined the shortest path leading toward the source, then the DR must
send the traffic from the source to the RP. The PIM registering process, which is individually run for each \((S, G)\) entry, accomplishes these tasks between the DR and RP.

The registering process begins when a DR creates a new \((S, G)\) state. The DR encapsulates all the data packets that match the \((S, G)\) state into PIM register messages and unicasts those register messages to the RP.

If an RP has downstream receivers that want to receive register messages from a new source, the RP can either continue to receive the register messages through the DR or join the shortest path leading toward the source. By default, the RP will join the shortest path, because delivery of native multicast traffic provides the highest throughput. Upon receipt of the first packet that arrives natively through the shortest path, the RP will send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

Once a routing entry is established for a source, a periodic reregistering takes place between the DR and RP. One minute before the multicast routing table state times out, the DR will send one dataless register message to the RP each second that the source is active until the DR receives a register-stop message from the RP. This action restarts the timeout time of the multicast routing table entry, typically resulting in one reregistering exchange every 2 minutes. Reregistering is necessary to maintain state, to recover from lost state, and to keep track of sources on the RP. It will take place independently of the RP joining the shortest path.

**PIM Version 1 Compatibility**

If an RP is running PIM Version 1, it will not understand dataless register messages. In this case, the DR will not send dataless register messages to the RP. Instead, approximately every 3 minutes after receipt of a register-stop message from the RP, the DR encapsulates the incoming data packets from the source into register messages and sends them to the RP. The DR continues to send register messages until it receives another register-stop message from the RP. The same behavior occurs if the DR is running PIM Version 1.

When a DR running PIM Version 1 encapsulates data packets into register messages for a specific \((S, G)\) entry, the entry is process-switched, not fast-switched or hardware-switched. On platforms that support these faster paths, the PIM registering process for an RP or DR running PIM Version 1 may lead to periodic out-of-order packet delivery. For this reason, we recommend upgrading your network from PIM Version 1 to PIM Version 2.

**PIM Designated Router**

Devices configured for IP multicast send PIM hello messages to determine which device will be the designated router (DR) for each LAN segment (subnet). The hello messages contain the device’s IP address, and the device with the highest IP address becomes the DR.

The DR sends Internet Group Management Protocol (IGMP) host query messages to all hosts on the directly connected LAN. When operating in sparse mode, the DR sends source registration messages to the rendezvous point (RP).

By default, multicast devices send PIM router query messages every 30 seconds. By enabling a device to send PIM hello messages more often, the device can discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently. It is appropriate to make this change only on redundant devices on the edge of the network.
PIM Sparse-Mode Register Messages

Dataless register messages are sent at a rate of one message per second. Continuous high rates of register messages might occur if a DR is registering bursty sources (sources with high data rates) and if the RP is not running PIM Version 2.

By default, PIM sparse-mode register messages are sent without limiting their rate. Limiting the rate of register messages will limit the load on the DR and RP, at the expense of dropping those register messages that exceed the set limit. Receivers may experience data packet loss within the first second in which packets are sent from bursty sources.

Preventing Use of Shortest-Path Tree to Reduce Memory Requirement

Understanding PIM shared tree and source tree will help you understand how preventing the use of the shortest-path tree can reduce memory requirements.

PIM Shared Tree and Source Tree

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

Figure 31: Shared Tree and Source Tree (Shortest-Path Tree)

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software device to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.

2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.

4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.

5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.

6. By default, reception of the first data packet prompts Router C to send a join message toward the source.

7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.

8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the `ip pim spt-threshold` global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

- Delaying the Use of PIM Shortest-Path Tree (CLI), on page 454

**Benefit of Preventing or Delaying the Use of the Shortest-Path Tree**

The switch from shared to source tree happens upon the arrival of the first data packet at the last hop device (Router C in PIM Shared Tree and Source Tree, on page 426). This switch occurs because the `ip pim spt-threshold` command controls that timing, and its default setting is 0 kbps.

The shortest-path tree requires more memory than the shared tree, but reduces delay. You might want to prevent or delay its use to reduce memory requirements. Instead of allowing the leaf device to move to the shortest-path tree immediately, you can prevent use of the SPT or specify that the traffic must first reach a threshold.

You can configure when a PIM leaf device should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the device triggers a PIM Join message toward the source to construct a source tree (shortest-path tree). If the `infinity` keyword is specified, all sources for the specified group use the shared tree, never switching to the source tree.
How to Optimize PIM Sparse Mode in a Large IP Multicast Deployment

Optimizing PIM Sparse Mode in a Large Deployment

Consider performing this task if your deployment of IP multicast is large.

Steps 3, 5, and 6 in this task are independent of each other and are therefore considered optional. Any one of these steps will help optimize PIM sparse mode. If you are going to perform Step 5 or 6, you must perform Step 4. Step 6 applies only to a designated router; changing the PIM query interval is only appropriate on redundant routers on the edge of the PIM domain.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip pim register-rate-limit rate
4. ip pim spt-threshold {kbps|infinity}[group-list access-list]
5. interface type number
6. ip pim query-interval period [msec]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip pim register-rate-limit rate</td>
<td>(Optional) Sets a limit on the maximum number of PIM sparse mode register messages sent per second for each (S, G) routing entry.</td>
</tr>
<tr>
<td>Example: Router(config)# ip pim register-rate-limit 10</td>
<td>• Use this command to limit the number of register messages that the designated router (DR) will allow for each (S, G) entry.</td>
</tr>
<tr>
<td></td>
<td>• By default, there is no maximum rate set.</td>
</tr>
<tr>
<td></td>
<td>• Configuring this command will limit the load on the DR and RP at the expense of dropping those register messages that exceed the set limit.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• Receivers may experience data packet loss within the first second in which register messages are sent from bursty sources.</td>
<td>(Optional) Specifies the threshold that must be reached before moving to the shortest-path tree.</td>
</tr>
<tr>
<td>Step 4  ip pim spt-threshold {kbps</td>
<td>infinity} [group-list access-list]</td>
</tr>
<tr>
<td>Example: Router(config)# ip pim spt-threshold infinity group-list 5</td>
<td>• Specifying the infinity keyword causes the router never to move to the shortest-path tree; it remains on the shared tree. This keyword applies to a multicast environment of “many-to-many” communication.</td>
</tr>
<tr>
<td></td>
<td>• The group list is a standard access list that controls which groups the SPT threshold applies to. If a value of 0 is specified or the group list is not used, the threshold applies to all groups.</td>
</tr>
<tr>
<td></td>
<td>• In the example, group-list 5 is already configured to permit the multicast groups 239.254.2.0 and 239.254.3.0: access-list 5 permit 239.254.2.0 0.0.0.255 access-list 5 permit 239.254.3.0 0.0.0.255</td>
</tr>
<tr>
<td>Step 5  interface type number</td>
<td>Configures an interface.</td>
</tr>
<tr>
<td>Example: Router(config)# interface ethernet 0</td>
<td>• If you do not want to change the default values of the PIM SPT threshold or the PIM query interval, do not perform this step; you are done with this task.</td>
</tr>
<tr>
<td>Step 6  ip pim query-interval period [msec]</td>
<td>(Optional) Configures the frequency at which multicast routers send PIM router query messages.</td>
</tr>
<tr>
<td>Example: Router(config-if)# ip pim query-interval 1</td>
<td>• Perform this step only on redundant routers on the edge of a PIM domain.</td>
</tr>
<tr>
<td></td>
<td>• The default query interval is 30 seconds.</td>
</tr>
<tr>
<td></td>
<td>• The period argument is in seconds unless the msec keyword is specified.</td>
</tr>
<tr>
<td></td>
<td>• Set the query interval to a smaller number of seconds for faster convergence, but keep in mind the trade-off between faster convergence and higher CPU and bandwidth usage.</td>
</tr>
</tbody>
</table>
Configuration Examples for Optimizing PIM Sparse Mode in a Large Multicast Deployment

Optimizing PIM Sparse Mode in a Large IP Multicast Deployment Example

The following example shows how to:

- Set the query interval to 1 second for faster convergence.
- Configure the router to never move to the SPT but to remain on the shared tree.
- Set a limit of 10 PIM sparse mode register messages sent per second for each (S, G) routing entry.

```plaintext
interface ethernet 0
  ip pim query-interval 1
  ...
  ip pim spt-threshold infinity
  ip pim register-rate-limit 10
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Multicast Subsecond Convergence

Service providers must have a multicast-enabled core in order to use the Cisco Multicast Subsecond Convergence feature.

Restrictions for Multicast Subsecond Convergence

Devices that use the subsecond designated router (DR) failover enhancement must be able to process hello interval information arriving in milliseconds. Devices that are congested or do not have enough CPU cycles to process the hello interval can assume that the Protocol Independent Multicast (PIM) neighbor is disconnected, although this may not be the case.
Information About Multicast Subsecond Convergence

Benefits of Multicast Subsecond Convergence

- The scalability components improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content).
- New algorithms and processes (such as aggregated join messages, which deliver up to 1000 individual messages in a single packet) reduce the time to reach convergence by a factor of 10.
- Multicast subsecond convergence improves service availability for large multicast networks.
- Multicast users such as financial services firms and brokerages receive better quality of service (QoS), because multicast functionality is restored in a fraction of the time previously required.

Multicast Subsecond Convergence Scalability Enhancements

The Multicast Subsecond Convergence feature provides scalability enhancements that improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content). Scalability enhancements in this release include the following:

- Improved Internet Group Management Protocol (IGMP) and PIM state maintenance through new timer management techniques
- Improved scaling of the Multicast Source Discovery Protocol (MSDP) Source-Active (SA) cache

The scalability enhancements provide the following benefits:

- Increased potential PIM multicast route (mroute), IGMP, and MSDP SA cache state capacity
- Decreased CPU usage

PIM Router Query Messages

Multicast subsecond convergence allows you to send PIM router query messages (PIM hellos) every few milliseconds. The PIM hello message is used to locate neighboring PIM devices. Before the introduction of this feature, the device could send the PIM hellos only every few seconds. By enabling a device to send PIM hello messages more often, this feature allows the device to discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently.

Reverse Path Forwarding

Unicast Reverse Path Forwarding (RPF) helps to mitigate problems caused by the introduction of malformed or forged IP source addresses into a network by discarding IP packets that lack a verifiable IP source address.
Malformed or forged source addresses can indicate denial-of-service (DoS) attacks based on source IP address spoofing.

RPF uses access control lists (ACLs) in determining whether to drop or forward data packets that have malformed or forged IP source addresses. An option in the ACL commands allows system administrators to log information about dropped or forwarded packets. Logging information about forged packets can help in uncovering information about possible network attacks.

Per-interface statistics can help system administrators quickly discover the interface serving as the entry point for an attack on the network.

### RPF Checks

PIM is designed to forward IP multicast traffic using the standard unicast routing table. PIM uses the unicast routing table to decide if the source of the IP multicast packet has arrived on the optimal path from the source. This process, the RPF check, is protocol-independent because it is based on the contents of the unicast routing table and not on any particular routing protocol.

**Related Topics**
- [Modifying the Periodic RPF Check Interval](#), on page 600
- [Example Modifying the Periodic RPF Check Interval](#), on page 603

### Triggered RPF Checks

Multicast subsecond convergence provides the ability to trigger a check of RPF changes for mroute states. This check is triggered by unicast routing changes. By performing a triggered RPF check, users can set the periodic RPF check to a relatively high value (for example, 10 seconds) and still fail over quickly.

The triggered RPF check enhancement reduces the time needed for service to be restored after disruption, such as for single service events (for example, in a situation with one source and one receiver) or as the service scales along any parameter (for example, many sources, many receivers, and many interfaces). This enhancement decreases in time-to-converge PIM (mroute), IGMP, and MSDP (SA cache) states.

### RPF Failover

In an unstable unicast routing environment that uses triggered RPF checks, the environment could be constantly triggering RPF checks, which places a burden on the resources of the device. To avoid this problem, use the `ip multicast rpf backoff` command to prevent a second triggered RPF check from occurring for the length of time configured. That is, the PIM “backs off” from another triggered RPF check for a minimum amount of milliseconds as configured by the user.

If the backoff period expires without further routing table changes, PIM then scans for routing changes and accordingly establishes multicast RPF changes. However, if more routing changes occur during the backoff period, PIM doubles the backoff period to avoid overloading the device with PIM RPF changes while the routing table is still converging.

**Related Topics**
- [Configuring PIM RPF Failover Intervals](#), on page 601
- [Example Configuring PIM RPF Failover Intervals](#), on page 604
### Topology Changes and Multicast Routing Recovery

The Multicast Subsecond Convergence feature set enhances both enterprise and service provider network backbones by providing almost instantaneous recovery of multicast paths after unicast routing recovery. Because PIM relies on the unicast routing table to calculate its RPF when a change in the network topology occurs, unicast protocols first need to calculate options for the best paths for traffic, and then multicast can determine the best path.

Multicast subsecond convergence allows multicast protocol calculations to finish almost immediately after the unicast calculations are completed. As a result, multicast traffic forwarding is restored substantially faster after a topology change.

### How to Configure Multicast Subsecond Convergence

#### Modifying the Periodic RPF Check Interval

Perform this optional task to modify the intervals at which periodic RPF checks occur.

> **Note**
> Cisco recommends that you do not change the default values for the `ip rpf interval` command. The default values allow subsecond RPF failover. The default interval at which periodic RPF checks occur is 10 seconds.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast rpf interval seconds [list access-list | route-map route-map]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

<tr>
<td><code>Device(config)# ip multicast rpf interval 10</code></td>
<td></td>
</tr>
</tbody>
</table>
Configuring PIM RPF Failover Intervals

Perform this optional task to configure the intervals at which PIM RPF failover will be triggered by changes in the routing tables.

**Note**
Cisco recommends that you do not modify the default values for the `ip multicast rpf backoff` command. The default values allow subsecond RPF failover.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast rpf backoff minimum maximum [disable]`

**DETAILED STEPS**

### Verifying Multicast Subsecond Convergence Configurations

Perform this task to display detailed information about and to verify information regarding the Multicast Subsecond Convergence feature.

### SUMMARY STEPS

1. enable
2. show ip pim interface type number
3. show ip pim neighbor
**DETAILED STEPS**

**Step 1** enable
Example:

```
Device> enable
```
Enables privileged EXEC mode.
- Enter your password if prompted.

**Step 2** show ip pim interface type number
Use this command to display information about interfaces configured for PIM.
The following is sample output from the `show ip pim interface` command:

Example:

```
Device# show ip pim interface GigabitEthernet 1/0/0
```

<table>
<thead>
<tr>
<th>Address</th>
<th>Interface</th>
<th>Ver/ Nbr</th>
<th>Query</th>
<th>DR</th>
<th>DR</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.16.1.4</td>
<td>GigabitEthernet1/0/0</td>
<td>v2/S</td>
<td>1</td>
<td>100 ms</td>
<td>1</td>
</tr>
</tbody>
</table>

**Step 3** show ip pim neighbor
Use this command to display the PIM neighbors discovered by the Cisco IOS XE software.
The following is sample output from the `show ip pim neighbor` command:

Example:

```
Device# show ip pim neighbor
```

<table>
<thead>
<tr>
<th>Neighbor Address</th>
<th>Interface</th>
<th>Uptime/Expires</th>
<th>Ver</th>
<th>DR</th>
<th>Prio/Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.16.1.3</td>
<td>GigabitEthernet1/0/0</td>
<td>00:03:41/250 msec</td>
<td>v2</td>
<td>1</td>
<td>/ S</td>
</tr>
</tbody>
</table>

**Configuration Examples for Multicast Subsecond Convergence**

**Example Modifying the Periodic RPF Check Interval**

In the following example, the `ip multicast rpf interval` has been set to 10 seconds. This command does not show up in `show running-config` output unless the interval value has been configured to be the nondefault value.

```
!
ip multicast-routing
ip multicast rpf interval 10
.
.
interface Ethernet0/0
  ip address 172.16.2.1 255.255.255.0
```
Example Configuring PIM RPF Failover Intervals

In the following example, the `ip multicast rpf backoff` command has been configured with a minimum backoff interval value of 100 and a maximum backoff interval value of 2500. This command does not show up in `show running-config` command output unless the interval value has been configured to be the nondefault value.

```plaintext
! ip multicast-routing
!
!
ip multicast rpf backoff 100 2500
!
interface Ethernet0/0
  ip address 172.16.2.1 255.255.255.0
!
!
ip pim sparse-mode
!
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IP Multicast Load Splitting across Equal-Cost Paths

IP multicast is enabled on the device using the tasks described in the “Configuring Basic IP Multicast” module of the IP Multicast: PIM Configuration Guide.
Information About IP Multicast Load Splitting across Equal-Cost Paths

Load Splitting Versus Load Balancing

Load splitting and load balancing are not the same. Load splitting provides a means to randomly distribute (*, G) and (S, G) traffic streams across multiple equal-cost reverse path forwarding (RPF) paths, which does not necessarily result in a balanced IP multicast traffic load on those equal-cost RPF paths. By randomly distributing (*, G) and (S, G) traffic streams, the methods used for load splitting IP multicast traffic attempt to distribute an equal amount of traffic flows on each of the available RPF paths not by counting the flows, but, rather, by making a pseudorandom decision. These methods are collectively referred to as equal-cost multipath (ECMP) multicast load splitting methods and result in better load-sharing in networks where there are many traffic streams that utilize approximately the same amount of bandwidth.

If there are just a few (S, G) or (*, G) states flowing across a set of equal-cost links, the chance that they are well balanced is quite low. To overcome this limitation, precalculated source addresses—for (S, G) states or rendezvous point (RP) addresses for (*, G) states, can be used to achieve a reasonable form of load balancing. This limitation applies equally to the per-flow load splitting in Cisco Express Forwarding (CEF) or with EtherChannels: As long as there are only a few flows, those methods of load splitting will not result in good load distribution without some form of manual engineering.

Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist

By default, for Protocol Independent Multicast sparse mode (PIM-SM), Source Specific Multicast (PIM-SSM), bidirectional PIM (bidir-PIM), and PIM dense mode (PIM-DM) groups, if multiple equal-cost paths are available, Reverse Path Forwarding (RPF) for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address. This method is referred to as the highest PIM neighbor behavior. This behavior is in accordance with RFC 2362 for PIM-SM, but also applies to PIM-SSM, PIM-DM, and bidir-PIM.

The figure illustrates a sample topology that is used in this section to explain the default behavior for IP multicast when multiple equal-cost paths exist.

Figure 32: Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist

In the figure, two sources, S1 and S2, are sending traffic to IPv4 multicast groups, G1 and G2. Either PIM-SM, PIM-SSM, or PIM-DM can be used in this topology. If PIM-SM is used, assume that the default of 0 for the `ip pim spt-threshold` command is being used on Device 2, that an Interior Gateway Protocol (IGP) is being
run, and that the output of the `show ip route` command for S1 and for S2 (when entered on Device 2) displays serial interface 0 and serial interface 1 on Device 1 as equal-cost next-hop PIM neighbors of Device 2.

Without further configuration, IPv4 multicast traffic in the topology illustrated in the figure would always flow across one serial interface (either serial interface 0 or serial interface 1), depending on which interface has the higher IP address. For example, suppose that the IP addresses configured on serial interface 0 and serial interface 1 on Device 1 are 10.1.1.1 and 10.1.2.1, respectively. Given that scenario, in the case of PIM-SM and PIM-SSM, Device 2 would always send PIM join messages towards 10.1.2.1 and would always receive IPv4 multicast traffic on serial interface 1 for all sources and groups shown in the figure. In the case of PIM-DM, Device 2 would always receive IP multicast traffic on serial Interface 1, only that in this case, PIM join messages are not used in PIM-DM; instead Device 2 would prune the IP multicast traffic across serial interface 0 and would receive it through serial interface 1 because that interface has the higher IP address on Device 1.

IPv4 RPF lookups are performed by intermediate multicast device to determine the RPF interface and RPF neighbor for IPv4 (*,G) and (S, G) multicast routes (trees). An RPF lookup consists of RPF route-selection and route-path-selection. RPF route-selection operates solely on the IP unicast address to identify the root of the multicast tree. For (*, G) routes (PIM-SM and Bidir-PIM), the root of the multicast tree is the RP address for the group G; for (S, G) trees (PIM-SM, PIM-SSM and PIM-DM), the root of the multicast tree is the source S. RPF route-selection finds the best route towards the RP or source in the routing information base (RIB), and, if configured (or available), the Distance Vector Multicast Routing Protocol (DVMRP) routing table, the Multiprotocol Border Gateway Protocol (MBGP) routing table or configured static mroute. If the resulting route has only one available path, then the RPF lookup is complete, and the next-hop device and interface of the route become the RPF neighbor and RPF interface of this multicast tree. If the route has more than one path available, then route-path-selection is used to determine which path to choose.

For IP multicast, the following route-path-selection methods are available:

---

**Note**

All methods but the default method of route-path-selection available in IP multicast enable some form of ECMP multicast load splitting.

- **Highest PIM neighbor**—This is the default method; thus, no configuration is required. If multiple equal-cost paths are available, RPF for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address; as a result, without configuration, ECMP multicast load splitting is disabled by default.

- **ECMP multicast load splitting method based on source address**—You can configure ECMP multicast load splitting using the `ip multicast multipath` command. Entering this form of the `ip multicast multipath` command enables ECMP multicast load splitting based on source address using the S-hash algorithm. For more information, see the ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm, on page 610 section.

- **ECMP multicast load splitting method based on source and group address**—You can configure ECMP multicast load splitting using the `ip multicast multipath` command with the `s-g-hash` and `basic` keywords. Entering this form of the `ip multicast multipath` command enables ECMP multicast load splitting based on source and group address using the basic S-G-hash algorithm. For more information, see the ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm, on page 610 section.

- **ECMP multicast load splitting method based on source, group, and next-hop address**—You can configure ECMP multicast load splitting using the `ip multicast multipath` command with the `s-g-hash` and `next-hop-based` keywords. Entering this form of the command enables ECMP multicast load splitting based on source, group, and next-hop address using the next-hop-based S-G-hash algorithm. For more
The default behavior (the highest PIM neighbor behavior) does not result in any form of ECMP load-splitting in IP multicast, but instead selects the PIM neighbor that has the highest IP address among the next-hop PIM neighbors for the available paths. A next hop is considered to be a PIM neighbor when it displays in the output of the `show ip pim neighbor` command, which is the case when PIM hello messages have been received from it and have not timed out. If none of the available next hops are PIM neighbors, then simply the next hop with the highest IP address is chosen.

### Methods to Load Split IP Multicast Traffic

In general, the following methods are available to load split IP multicast traffic:

- You can enable ECMP multicast load splitting based on source address, based on source and group address, or based on source, group, and next-hop address. After the equal-cost paths are recognized, ECMP multicast load splitting operates on a per (S, G) basis, rather than a per packet basis as in unicast traffic.
- Alternative methods to load split IP multicast are to consolidate two or more equal-cost paths into a generic routing encapsulation (GRE) tunnel and allow the unicast routing protocol to perform the load splitting, or to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, Multilink PPP (MLPPP) link bundles, or Multilink Frame Relay (FR.16) link bundles.

### Overview of ECMP Multicast Load Splitting

By default, ECMP multicast load splitting of IPv4 multicast traffic is disabled. ECMP multicast load splitting can be enabled using the `ip multicast multipath` command.

### ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm

ECMP multicast load splitting traffic based on source address uses the S-hash algorithm, enabling the RPF interface for each (*, G) or (S, G) state to be selected among the available equal-cost paths, depending on the RPF address to which the state resolves. For an (S, G) state, the RPF address is the source address of the state; for a (*, G) state, the RPF address is the address of the RP associated with the group address of the state.

When ECMP multicast load splitting based on source address is configured, multicast traffic for different states can be received across more than just one of the equal-cost interfaces. The method applied by IPv4 multicast is quite similar in principle to the default per-flow load splitting in IPv4 CEF or the load splitting used with Fast and Gigabit EtherChannels. This method of ECMP multicast load splitting, however, is subject to polarization.

### ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm

ECMP multicast load splitting based on source and group address uses a simple hash, referred to as the basic S-G-hash algorithm, which is based on source and group address. The basic S-G-hash algorithm is predictable.
because no randomization is used in coming up with the hash value. The S-G-hash mechanism, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device this hash is being calculated on.

Note

The basic S-G-hash algorithm ignores bidir-PIM groups.

Predictability As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The method used by ECMP multicast load splitting in IPv4 multicast allows for consistent load splitting in a network where the same number of equal-cost paths are present in multiple places in a topology. If an RP address or source addresses are calculated once to have flows split across N paths, then they will be split across those N paths in the same way in all places in the topology. Consistent load splitting allows for predictability, which, in turn, enables load splitting of IPv4 multicast traffic to be manually engineered.

Polarization As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The hash mechanism used in IPv4 multicast to load split multicast traffic by source address or by source and group address is subject to a problem usually referred to as polarization. A by-product of ECMP multicast load splitting based on source address or on source and group address, polarization is a problem that prevents routers in some topologies from effectively utilizing all available paths for load splitting.

The figure illustrates a sample topology that is used in this section to explain the problem of polarization when configuring ECMP multicast load splitting based on source address or on source and group address.

*Figure 33: Polarization Topology*

In the topology illustrated in the figure, notice that Router 7 has two equal-cost paths towards the sources, S1 to S10, through Router 5 and Router 6. For this topology, suppose that ECMP multicast load splitting is enabled with the `ip multicast multipath` command on all routers in the topology. In that scenario, Router 7 would apply equal-cost load splitting to the 10 (S, G) states. The problem of polarization in this scenario would affect Router 7 because that router would end up choosing serial interface 0 on Router 5 for sources S1 to S5 and serial interface 1 on Router 6 for sources S6 to S10. The problem of polarization, furthermore, would also affect Router 5 and Router 6 in this topology. Router 5 has two equal-cost paths for S1 to S5 through serial interface 0 on Router 1 and serial interface 1 on Router 2. Because Router 5 would apply the
same hash algorithm to select which of the two paths to use, it would end up using just one of these two upstream paths for sources S1 to S5; that is, either all the traffic would flow across Router 1 and Router 5 or across Router 2 and Router 5. It would be impossible in this topology to utilize Router 1 and Router 5 and Router 2 and Router 5 for load splitting. Likewise, the polarization problem would apply to Router 3 and Router 6 and Router 4 and Router 6; that is, it would be impossible in this topology to utilize both Router 3 and Router 6 and Router 4 and Router 6 for load splitting.

**ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address**

Configuring ECMP multicast load splitting based on source, group, and next-hop address enables a more complex hash, the next-hop-based S-G-hash algorithm, which is based on source, group, and next-hop address. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

---

**Note**

The next-hop-based S-G-hash algorithm in IPv4 multicast is the same algorithm used in IPv6 ECMP multicast load splitting, which, in turn, utilizes the same hash function used for PIM-SM bootstrap device (BSR).

The next-hop-based hash mechanism does not produce polarization and also maintains better RPF stability when paths fail. These benefits come at the cost that the source or RP IP addresses cannot be used to reliably predict and engineer the outcome of load splitting when the next-hop-based S-G-hash algorithm is used. Because many customer networks have implemented equal-cost multipath topologies, the manual engineering of load splitting, thus, is not a requirement in many cases. Rather, it is more of a requirement that the default behavior of IP multicast be similar to IP unicast; that is, it is expected that IP multicast use multiple equal-cost paths on a best-effort basis. Load splitting for IPv4 multicast, therefore, could not be enabled by default because of the anomaly of polarization.

---

**Note**

Load splitting for CEF unicast also uses a method that does not exhibit polarization and likewise cannot be used to predict the results of load splitting or engineer the outcome of load splitting.

The next-hop-based hash function avoids polarization because it introduces the actual next-hop IP address of PIM neighbors into the calculation, so the hash results are different for each device, and in effect, there is no problem of polarization. In addition to avoiding polarization, this hash mechanism also increases stability of the RPF paths chosen in the face of path failures. Consider a device with four equal-cost paths and a large number of states that are load split across these paths. Suppose that one of these paths fails, leaving only three available paths. With the hash mechanism used by the polarizing hash mechanisms (the hash mechanism used by the S-hash and basic S-G-hash algorithms), the RPF paths of all states would likely reconverge and thus change between those three paths, especially those paths that were already using one of those three paths. These states, therefore, may unnecessarily change their RPF interface and next-hop neighbor. This problem exists simply because the chosen path is determined by taking the total number of paths available into consideration by the algorithm, so once a path changes, the RPF selection for all states is subject to change too. For the next-hop-based hash mechanism, only the states that were using the changed path for RPF would need to reconverge onto one of the three remaining paths. The states that were already using one of those paths would not change. If the fourth path came back up, the states that initially used it would immediately reconverge back to that path without affecting the other states.
Thenext-hop-based S-G-hash algorithm ignores bidir-PIM groups.

**Effect of ECMP Multicast Load Splitting on PIM Neighbor Query and Hello Messages for RPF Path Selection**

If load splitting of IP multicast traffic over ECMP is *not* enabled and there are multiple equal-cost paths towards an RP or a source, IPv4 multicast will first elect the highest IP address PIM neighbor. A PIM neighbor is a device from which PIM hello (or PIMv1 query) messages are received. For example, consider a device that has two equal-cost paths learned by an IGP or configured through two static routes. The next hops of these two paths are 10.1.1.1 and 10.1.2.1. If both of these next-hop devices send PIM hello messages, then 10.1.2.1 would be selected as the highest IP address PIM neighbor. If only 10.1.1.1 sends PIM hello messages, then 10.1.1.1 would be selected. If neither of these devices sends PIM hello messages, then 10.1.2.1 would be selected. This deference to PIM hello messages allows the construction of certain types of dynamic failover scenarios with only static multicast routes (mroutes); it is otherwise not very useful.

**Note**

For more information about configuring static mroutes, see the Configuring Multiple Static Mroutes in Cisco IOS configuration note on the Cisco IOS IP multicast FTP site, which is available at:

When load splitting of IP multicast traffic over ECMP is enabled, the presence of PIM hello message from neighbors is not considered; that is, the chosen RPF neighbor does not depend on whether or not PIM hello messages are received from that neighbor--it only depends on the presence or absence of an equal-cost route entry.

**Effect of ECMP Multicast Loading Splitting on Assert Processing in PIM-DM and DF Election in Bidir-PIM**

The `ip multicast multipath` command only changes the RPF selection on the downstream device; it does not have an effect on designated forwarder (DF) election in bidir-PIM or the assert processing on upstream devices in PIM-DM.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on assert processing in PIM-DM and DF election in bidir-PIM.
In the figure, Device 2 has two equal-cost paths to S1 and S2 and the RP addresses on Device 1. Both paths are across Gigabit Ethernet interface 1/0/0: one path towards Device 3 and one path towards Device 4. For PIM-SM and PIM-SSM (*, G) and (S, G) RPF selection, there is no difference in the behavior of Device 2 in this topology versus Device 2 in the topology illustrated in the figure. There is, however, a difference when using PIM-DM or bidir-PIM.

If PIM-DM is used in the topology illustrated in the figure, Device 3 and Device 4 would start flooding traffic for the states onto Gigabit Ethernet interface 1/0/0 and would use the PIM assert process to elect one device among them to forward the traffic and to avoid traffic duplication. As both Device 3 and Device 4 would have the same route cost, the device with the higher IP address on Gigabit Ethernet interface 1/0/0 would always win the assert process. As a result, if PIM-DM is used in this topology, traffic would not be load split across Device 3 and Device 4.

If bidir-PIM is used in the topology illustrated in the figure, a process called DF election would take place between Device 2, Device 3, and Device 4 on Gigabit Ethernet interface 1/0/0. The process of DF election would elect one device for each RP to forward traffic across Gigabit Ethernet interface 1/0/0 for any groups using that particular RP, based on the device with the highest IP address configured for that interface. Even if multiple RPs are used (for example one for G1 and another one for G2), the DF election for those RPs would always be won by the device that has the higher IP address configured on Gigabit Ethernet interface 1/0/0 (either Device 3 or Device 4 in this topology). The election rules used for DF election are virtually the same as the election rules used for the PIM assert process, only the protocol mechanisms to negotiate them are more refined for DF election (in order to return the results more expeditiously). As a result, when bidir-PIM is used in this topology, load splitting would always occur across Gigabit Ethernet interface 1/0/0.

The reason that ECMP multicast load splitting does influence the RPF selection but not the assert process in PIM-DM or DF election in bidir-PIM is because both the assert process and DF election are cooperative processes that need to be implemented consistently between participating devices. Changing them would require some form of protocol change that would also need to be agreed upon by the participating devices. RPF selection is a purely device local policy and, thus, can be enabled or disabled without protocol changes individually on each device.

For PIM-DM and bidir-PIM, configuring ECMP multicast load splitting with the `ip multicast multipath` command is only effective in topologies where the equal-cost paths are not upstream PIM neighbors on the same LAN, but rather neighbors on different LANs or point-to-point links.

**Effect of ECMP Multicast Load Splitting on the PIM Assert Process in PIM-SM and PIM-SSM**

There are also cases where ECMP multicast load splitting with the `ip multicast multipath` command can become ineffective due to the PIM assert process taking over, even when using PIM-SM with (*, G) or (S, G) forwarding or PIM-SSM with (S, G) forwarding.
The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on the PIM assert process in PIM-SM and PIM-SSM.

**Figure 35: ECMP Multicast Load Splitting and the PIM Assert Process in PIM-SM and PIM-SSM**

In the topology illustrated in the figure, if both Device 2 and Device 5 are Cisco devices and are consistently configured for ECMP multicast load splitting with the `ip multicast multipath` command, then load splitting would continue to work as expected; that is, both devices would have Device 3 and Device 4 as equal-cost next hops and would sort the list of equal-cost paths in the same way (by IP address). When applying the multipath hash function, for each (S, G) or (*, G) state, they would choose the same RPF neighbor (either Device 3 or Device 4) and send their PIM joins to this neighbor.

If Device 5 and Device 2 are inconsistently configured with the `ip multicast multipath` command, or if Device 5 is a third-party device, then Device 2 and Device 5 may choose different RPF neighbors for some (*, G) or (S, G) states. For example, Device 2 could choose Device 3 for a particular (S, G) state or Device 5 could choose Device 4 for a particular (S, G) state. In this scenario, Device 3 and Device 4 would both start to forward traffic for that state onto Gigabit Ethernet interface 1/0/0, see each other’s forwarded traffic, and--to avoid traffic duplication--start the assert process. As a result, for that (S, G) state, the device with the higher IP address for Gigabit Ethernet interface 1/0/0 would forward the traffic. However, both Device 2 and Device 5 would be tracking the winner of the assert election and would send their PIM joins for that state to this assert winner, even if this assert winner is not the same device as the one that they calculated in their RPF selection. For PIM-SM and PIM-SSM, therefore, the operation of ECMP multicast load splitting can only be guaranteed when all downstream devices on a LAN are consistently configured Cisco devices.

**ECMP Multicast Load Splitting and Reconvergence When Unicast Routing Changes**

When unicast routing changes, all IP multicast routing states reconverge immediately based on the available unicast routing information. Specifically, if one path goes down, the remaining paths reconverge immediately, and if the path comes up again, multicast forwarding will subsequently reconverge to the same RPF paths that were used before the path failed. Reconvergence occurs whether load splitting of IP multicast traffic over ECMP is configured or not.

**Use of BGP with ECMP Multicast Load Splitting**

ECMP multicast load splitting works with RPF information learned through BGP in the same way as with RPF information learned from other protocols: It chooses one path out of the multiple paths installed by the protocol. The main difference with BGP is that it only installs a single path, by default. For example, when a BGP speaker learns two identical external BGP (eBGP) paths for a prefix, it will choose the path with the lowest device ID as the best path. The best path is then installed in the IP routing table. If BGP multipath support is enabled and the eBGP paths are learned from the same neighboring AS, instead of picking the single best path, BGP installs multiple paths in the IP routing table. By default, BGP will install only one path to the IP routing table.
To leverage ECMP multicast load splitting for BGP learned prefixes, you must enable BGP multipath. Once configured, when BGP installs the remote next-hop information, RPF lookups will execute recursively to find the best next hop towards that BGP next hop (as in unicast). If for example there is only a single BGP path for a given prefix, but there are two IGP paths to reach that BGP next hop, then multicast RPF will correctly load split between the two different IGP paths.

Use of ECMP Multicast Load Splitting with Static Mroutes

If it is not possible to use an IGP to install equal cost routes for certain sources or RPs, static routes can be configured to specify the equal-cost paths for load splitting. You cannot use static mroutes to configure equal-cost paths because the software does not support the configuration of one static mroute per prefix. There are some workarounds for this limitation using recursive route lookups but the workarounds cannot be applied to equal-cost multipath routing.

Use of ECMP Multicast Load Splitting with Static Mroutes

If it is not possible to use an IGP to install equal cost routes for certain sources or RPs, static routes can be configured to specify the equal-cost paths for load splitting. You cannot use static mroutes to configure equal-cost paths because the software does not support the configuration of one static mroute per prefix. There are some workarounds for this limitation using recursive route lookups but the workarounds cannot be applied to equal-cost multipath routing.

Note
For more information about configuring static mroutes, see the Configuring Multiple Static Mroutes in Cisco IOS configuration note on the Cisco IOS IP multicast FTP site at ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt.

You can specify only static mroutes for equal-cost multipaths in IPv4 multicast; however, those static mroutes would only apply to multicast, or you can specify that the equal-cost multipaths apply to both unicast and multicast routing. In IPv6 multicast, there is no such restriction. Equal-cost multipath mroutes can be configured for static IPv6 mroutes that apply to only unicast routing, only multicast routing, or both unicast and multicast routing.

Alternative Methods of Load Splitting IP Multicast Traffic

Load splitting of IP multicast traffic can also be achieved by consolidating multiple parallel links into a single tunnel over which the multicast traffic is then routed. This method of load splitting is more complex to configure than ECMP multicast load splitting. One such case where configuring load splitting across equal-cost paths using GRE links can be beneficial is the case where the total number of (S, G) or (*, G) states is so small and the bandwidth carried by each state so variable that even the manual engineering of the source or RP addresses cannot guarantee the appropriate load splitting of the traffic.

Note
With the availability of ECMP multicast load splitting, tunnels typically only need to be used if per-packet load sharing is required.

IP multicast traffic can also be used to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, MLPPP link bundles or Multilink Frame Relay (FRF.16) bundles. GRE or other type of tunnels can also constitute such forms of Layer 2 link bundles. Before using such an Layer 2 mechanism, it is necessary to understand how unicast and multicast traffic is load split.

Before load splitting IP multicast traffic across equal-cost paths over a tunnel, you must configure CEF per-packet load balancing or else the GRE packets will not be load balanced per packet.
How to Load Split IP Multicast Traffic over ECMP

Enabling ECMP Multicast Load Splitting

Perform the following tasks to load split IP multicast traffic across multiple equal-cost paths, based on source address.

If two or more equal-cost paths from a source are available, unicast traffic will be load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the RPF neighbor. According to PIM specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.

Configuring load splitting with the `ip multicast multipath` command causes the system to load split multicast traffic across multiple equal-cost paths based on source address using the S-hash algorithm. When the `ip multicast multipath` command is configured and multiple equal-cost paths exist, the path in which multicast traffic will travel is selected based on the source IP address. Multicast traffic from different sources will be load split across the different equal-cost paths. Load splitting will not occur across equal-cost paths for multicast traffic from the same source sent to different multicast groups.

The `ip multicast multipath` command load splits the traffic and does not load balance the traffic. Traffic from a source will use only one path, even if the traffic far out weighs traffic from other sources.

Prerequisites for IP Multicast Load Splitting - ECMP

- You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.

- You must have multiple paths available to the RP to configure ECMP multicast load splitting.

Note: Use the `show ip route` command with either the IP address of the source for the `ip-address` argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

- When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.

- Before configuring ECMP multicast load splitting, it is best practice to use the `show ip rpf` command to validate whether sources can take advantage of IP multicast multipath capabilities.

- BGP does not install multiple equal-cost paths by default. Use the `maximum-paths` command to configure multipath (for example in BGP). For more information, see the Use of BGP with ECMP Multicast Load Splitting, on page 615 section.
Restrictions

- If two or more equal-cost paths from a source are available, unicast traffic will be load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the RPF neighbor. According to PIM specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.

- The `ip multicast multipath` command does not support configurations in which the same PIM neighbor IP address is reachable through multiple equal-cost paths. This situation typically occurs if unnumbered interfaces are used. Use different IP addresses for all interfaces when configuring the `ip multicast multipath` command.

- The `ip multicast multipath` command load splits the traffic and does not load balance the traffic. Traffic from a source will use only one path, even if the traffic far outweighs traffic from other sources.

Enabling ECMP Multicast Load Splitting Based on Source Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source address (using the S-hash algorithm) to take advantage of multiple paths through the network. The S-hash algorithm is predictable because no randomization is used in calculating the hash value. The S-hash algorithm, however, is subject to polarization because for a given source, the same hash is always picked irrespective of the device on which the hash is being calculated.

Note

Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

Before you begin

- You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.

- You must have multiple paths available to the RP to configure ECMP multicast load splitting.

Note

Use the `show ip route` command with either the IP address of the source for the `ip-address` argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

- When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.

- Before configuring ECMP multicast load splitting, it is best practice to use the `show ip rpf` command to validate whether sources can take advantage of IP multicast multipath capabilities.

- BGP does not install multiple equal-cost paths by default. Use the `maximum-paths` command to configure multipath (for example in BGP). For more information, see the Use of BGP with ECMP Multicast Load Splitting, on page 615 section.
SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast multipath
4. Repeat step 3 on all the devices in a redundant topology.
5. exit
6. show ip rpf source-address [group-address]
7. show ip route ip-address

| **Step 6**  
  show ip rpf  source-address [group-address]  
  Example:  
  Device# show ip rpf 10.1.1.2 | (Optional) Displays the information that IP multicast routing uses to perform the RPF check.  
  • Use this command to verify RPF selection so as to ensure that IP multicast traffic is being properly load split. |
| **Step 7**  
  show ip route  ip-address  
  Example:  
  Device# show ip route 10.1.1.2 | (Optional) Displays the current state of the IP routing table.  
  • Use this command to verify that there are multiple paths available to a source or RP for ECMP multicast load splitting.  
  • For the ip-address argument, enter the IP address of a source to validate that there are multiple paths available to the source (for shortest path trees) or the IP address of an RP to validate that there are multiple paths available to the RP (for shared trees). |

**Related Topics**

ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm, on page 610  
Example Enabling ECMP Multicast Load Splitting Based on Source Address, on page 624

**Enabling ECMP Multicast Load Splitting Based on Source and Group Address**

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source and group address (using the basic S-G-hash algorithm) to take advantage of multiple paths through the network. The basic S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. The basic S-G-hash algorithm, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device on which the hash is being calculated.

The basic S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than the the S-hash algorithm. Using the basic S-G-hash algorithm for load splitting, in particular, enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

**Note**

Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

**SUMMARY STEPS**

1.  enable  
2.  configure terminal  
3.  ip multicast multipath s-g-hash basic  
4.  Repeat Step 3 on all the devices in a redundant topology.  
5.  exit
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  **enable**  
  **Example:**
  Device> enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Step 2**
  **configure terminal**  
  **Example:**
  Device# configure terminal | Enters global configuration mode. |
| **Step 3**
  **ip multicast multipath s-g-hash basic**  
  **Example:**
  Device(config)# ip multicast multipath s-g-hash basic | Enables ECMP multicast load splitting based on source and group address using the basic S-G-hash algorithm.  
  • Because this command changes the way an RPF neighbor is selected, it must be configured consistently on all devices in a redundant topology to avoid looping. |
| **Step 4**
  **Repeat Step 3 on all the devices in a redundant topology.** | -- |
| **Step 5**
  **exit**  
  **Example:**
  Device(config)# exit | Exits global configuration mode and returns to privileged EXEC mode. |
| **Step 6**
  **show ip rpf source-address [group-address]**  
  **Example:**
  Device# show ip rpf 10.1.1.2 | (Optional) Displays the information that IP multicast routing uses to perform the RPF check.  
  • Use this command to verify RPF selection so as to ensure that IP multicast traffic is being properly load split. |
| **Step 7**
  **show ip route ip-address**  
  **Example:**
  Device# show ip route 10.1.1.2 | (Optional) Displays the current state of the IP routing table.  
  • Use this command to verify that there multiple paths available to a source or RP for ECMP multicast load splitting.  
  • For the *ip-address* argument, enter the IP address of a source to validate that there are multiple paths available to the source (for shortest path trees) or the IP address of an RP to validate that there are multiple paths available to the RP (for shared trees). |
Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source, group, and next-hop address (using the next-hop-based S-G-hash algorithm) to take advantage of multiple paths through the network. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

The next-hop-based S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than S-hash algorithm and eliminates the polarization problem. Using the next-hop-based S-G-hash algorithm for ECMP multicast load splitting enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast multipath s-g-hash next-hop-based`
4. Repeat Steps 1 through 3 on all the routers in a redundant topology.
5. `end`
6. `show ip rpf source-address [group-address]`
7. `show ip route ip-address`

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SSM Channel Based Filtering for Multicast Boundaries

IP multicast is enabled on the device using the tasks described in the "Configuring Basic IP Multicast" module of the IP Multicast: PIM Configuration Guide.
Information About the SSM Channel Based Filtering for Multicast Boundaries Feature

Rules for Multicast Boundaries

The SSM Channel Based Filtering for Multicast Boundaries feature expands the `ip multicast boundary` command for control plane filtering support. More than one `ip multicast boundary` command can be applied to an interface.

The following rules govern the `ip multicast boundary` command:

- One instance of the in and out keywords can be configured on an interface.
- The in and out keywords can be used for standard or extended access lists.
- Only standard access lists are permitted with the use of the `filter-autorp` keyword or no keyword.
- A maximum of three instances of a command will be allowed on an interface: one instance of in, one instance of out, and one instance of `filter-autorp` or no keyword.
- When multiple instances of the command are used, the filtering will be cumulative. If a boundary statement with no keyword exists with a boundary statement with the in keyword, both access lists will be applied on the in direction and a match on either one will be sufficient.
- All instances of the command apply to both control and data plane traffic.
- Protocol information on the extended access list is parsed to allow reuse and filtering for consistency. An (S,G) operation will be filtered by an extended access list under all conditions stated above for keywords if the access list filters (S,G) traffic for all protocols.

- Additional References, on page 637
- Feature History and Information for PIM Dense Mode State Refresh, on page 638

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisite for PIM Dense Mode State Refresh

- You must have PIM dense mode enabled on an interface before configuring the PIM Dense Mode State Refresh feature.

Restrictions on PIM Dense Mode State Refresh

- All routers in a PIM dense mode network must run a software release that supports the PIM Dense Mode State Refresh feature to process and forward state refresh control messages.
• The origination interval for the state refresh control message must be the same for all PIM routers on the same LAN. Specifically, the same origination interval must be configured on each router interface that is directly connected to the LAN.

**Information About PIM Dense Mode State Refresh**

**PIM Dense Mode State Refresh Overview**

The PIM Dense Mode State Refresh feature is an extension of the PIM Version 2 multicast routing architecture.

PIM dense mode builds source-based multicast distribution trees that operate on a flood and prune principle. Multicast packets from a source are flooded to all areas of a PIM dense mode network. PIM routers that receive multicast packets and have no directly connected multicast group members or PIM neighbors send a prune message back up the source-based distribution tree toward the source of the packets. As a result, subsequent multicast packets are not flooded to pruned branches of the distribution tree. However, the pruned state in PIM dense mode times out approximately every 3 minutes and the entire PIM dense mode network is reflooded with multicast packets and prune messages. This reflooding of unwanted traffic throughout the PIM dense mode network consumes network bandwidth.

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out by periodically forwarding a control message down the source-based distribution tree. The control message refreshes the prune state on the outgoing interfaces of each router in the distribution tree.

**Related Topics**

- Configuring PIM Dense Mode State Refresh, on page 634
- Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example, on page 636
- Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example, on page 637

**Benefits of PIM Dense Mode State Refresh**

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out, which saves network bandwidth by greatly reducing the reflooding of unwanted multicast traffic to pruned branches of the PIM dense mode network. This feature also enables PIM routers in a PIM dense mode multicast network to recognize topology changes (sources joining or leaving a multicast group) before the default 3-minute state refresh timeout period.

**How to Configure PIM Dense Mode State Refresh**

**Configuring PIM Dense Mode State Refresh**

There are no configuration tasks for enabling the PIM Dense Mode State Refresh feature. By default, all PIM routers that are running a Cisco IOS XE software release that supports the PIM Dense Mode State Refresh feature automatically process and forward state refresh control messages.
To disable the processing and forwarding of state refresh control messages on a PIM router, use the `ip pim state-refresh disable` global configuration command. To enable state refresh again if it has been disabled, use the `no ip pim state-refresh disable` global configuration command.

The origination of state refresh control messages is disabled by default. To configure the origination of the control messages on a PIM router, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# interface type number</code></td>
<td>Specifies an interface and places the router in interface configuration mode.</td>
</tr>
<tr>
<td><code>Router(config-if)# ip pim state-refresh origination-interval [interval]</code></td>
<td>Configures the origination of the PIM Dense Mode State Refresh control message. Optionally, you can configure the number of seconds between control messages by using the <code>interval</code> argument. The default interval is 60 seconds. The interval range is 1 second to 100 seconds.</td>
</tr>
</tbody>
</table>

**Related Topics**
- PIM Dense Mode State Refresh Overview, on page 634
- Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example, on page 636
- Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example, on page 637

**Verifying PIM Dense Mode State Refresh Configuration**

Use the `show ip pim interface [type number] detail` and the `show ip pim neighbor [interface]` commands to verify that the PIM Dense Mode State Refresh feature is configured correctly. The following output of the `show ip pim interface [type number] detail` command indicates that processing, forwarding, and origination of state refresh control messages is enabled.

```
Router# show ip pim interface fastethernet 0/1/0 detail
FastEthernet0/1/0 is up, line protocol is up
    Internet address is 172.16.8.1/24
    Multicast switching:process
    Multicast packets in/out:0/0
    Multicast boundary:not set
    Multicast TTL threshold:0
    PIM:enabled
    PIM version:2, mode:dense
    PIM DR:172.16.8.1 (this system)
    PIM neighbor count:0
    PIM Hello/Query interval:30 seconds
    PIM State-Refresh processing:enabled
    PIM State-Refresh origination:enabled, interval:60 seconds
    PIM NBMA mode:disabled
    PIM ATM multipoint signalling:disabled
    PIM domain border:disabled
    Multicast Tagswitching:disabled
```

The `S` in the Mode field of the following `show ip pim neighbor [interface]` command output indicates that the neighbor has the PIM Dense Mode State Refresh feature configured.

```
Router# show ip pim neighbor
PIM Neighbor Table
```
Monitoring and Maintaining PIM DM State Refresh

Following are the PIM Dense Mode State Refresh control messages that are sent and received by a PIM router after the `debug ip pim` privileged EXEC command is configured for multicast group 239.0.0.1:

```
Router# debug ip pim 239.0.0.1
*Mar 1 00:25:10.416:PIM:Originating refresh message for (172.16.8.3,239.0.0.1)
*Mar 1 00:25:10.416:PIM:Send SR on GigabitEthernet1/1/0 for (172.16.8.3,239.0.0.1) TTL=9
```

The following output from the `show ip mroute` command displays the resulting prune timer changes for GigabitEthernet interface1/0/0 and multicast group 239.0.0.1. (The following output assumes that the `debug ip pim` privileged EXEC command has already been configured on the router.) In the first output from the `show ip mroute` command, the prune timer reads 00:02:06. The debug messages indicate that a PIM Dense Mode State Refresh control message is received and sent on Ethernet interface 1/0, and that other PIM Dense Mode State Refresh routers were discovered. In the second output from the `show ip mroute` command, the prune timer has been reset to 00:02:55.

```
Router# show ip mroute 239.0.0.1
(172.16.8.3, 239.0.0.1), 00:09:50/00:02:06, flags:PT
  Incoming interface:GigabitEthernet1/1/0, RPF nbr 172.16.5.2
  Outgoing interface list:
    GigabitEthernet1/0/0, Prune/Dense, 00:09:43/00:02:06
Router# *Mar 1 00:32:06.657:PIM:SR on iif from 172.16.5.2 orig 172.16.8.1 for (172.16.8.3,239.0.0.1)
*Mar 1 00:32:06.661: flags:prune-indicator
*Mar 1 00:32:06.661: PIM:Cached metric is [0/0]
*Mar 1 00:32:06.661:PIM:Keep RPF nbr 172.16.5.2
*Mar 1 00:32:06.661:PIM:Send SR on Ethernet1/0 for (172.16.8.3,239.0.0.1) TTL=8
*Mar 1 00:32:06.661: flags:prune-indicator
Router# show ip mroute 239.0.0.1
(172.16.8.3, 239.0.0.1), 00:10:01/00:02:55, flags:PT
  Incoming interface:GigabitEthernet1/1/0, RPF nbr 172.16.5.2
  Outgoing interface list:
    GigabitEthernet1/0/0, Prune/Dense, 00:09:55/00:02:55
```

Configuration Examples for PIM Dense Mode State Refresh

Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is originating, processing, and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 0/1/0 every 60 seconds:

```
ip multicast-routing distributed
interface FastEthernet0/1/0
```
ip address 172.16.8.1 255.255.255.0
ip pim state-refresh origination-interval 60
ip pim dense-mode

Related Topics

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IGMP State Limit

- IP multicast is enabled and the Protocol Independent Multicast (PIM) interfaces are configured using the tasks described in the "Configuring Basic IP Multicast" module of the IP Multicast: PIM Configuration Guide.
- ALL ACLs must be configured. For information, see the see the "Creating an IP Access List and Applying It to an Interface " module of the Security Configuration Guide: Access Control Lists guide.

Restrictions for IGMP State Limit

You can configure only one global limit per device and one limit per interface.
Information About IGMP State Limit

IGMP State Limit

The IGMP State Limit feature allows for the configuration of IGMP state limiters, which impose limits on mroute states resulting from IGMP membership reports (IGMP joins) on a global or per interface basis. Membership reports exceeding the configured limits are not entered into the IGMP cache. This feature can be used to prevent DoS attacks or to provide a multicast CAC mechanism in network environments where all the multicast flows roughly utilize the same amount of bandwidth.

Note

IGMP state limiters impose limits on the number of mroute states resulting from IGMP, IGMP v3 lite, and URL Rendezvous Directory (URD) membership reports on a global or per interface basis.

Configuring IGMP State Limiters Example, on page 643

IGMP State Limit Feature Design

• Configuring IGMP state limiters in global configuration mode specifies a global limit on the number of IGMP membership reports that can be cached.

• Configuring IGMP state limiters in interface configuration mode specifies a limit on the number of IGMP membership reports on a per interface basis.

• Use ACLs to prevent groups or channels from being counted against the interface limit. A standard or an extended ACL can be specified. A standard ACL can be used to define the (*, G) state to be excluded from the limit on an interface. An extended ACLs can be used to define the (S, G) state to be excluded from the limit on an interface. An extended ACL also can be used to define the (*, G) state to be excluded from the limit on an interface, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.

• You can only configure one global limit per device and one limit per interface.

Mechanics of IGMP State Limiters

The mechanics of IGMP state limiters are as follows:

• Each time a router receives an IGMP membership report for a particular group or channel, the Cisco IOS software checks to see if either the limit for the global IGMP state limiter or the limit for the per interface IGMP state limiter has been reached.

• If only a global IGMP state limiter has been configured and the limit has not been reached, IGMP membership reports are honored. When the configured limit has been reached, subsequent IGMP membership reports are then ignored (dropped) and a warning message in one of the following formats is generated:
• %IGMP-6-IGMP_GROUP_LIMIT: IGMP limit exceeded for <group (*, group address)> on <interface type number> by host <ip address>

• %IGMP-6-IGMP_CHANNEL_LIMIT: IGMP limit exceeded for <channel (source address, group address)> on <interface type number> by host <ip address>

• If only per interface IGMP state limiters are configured, then each limit is only counted against the interface on which it was configured.

• If both a global IGMP state limiter and per interface IGMP state limiters are configured, the limits configured for the per interface IGMP state limiters are still enforced but are constrained by the global limit.

How to Configure IGMP State Limit

Configuring IGMP State Limiters

Note
IGMP state limiters impose limits on the number of mroutestate resulting from IGMP, IGMP v3lite, and URD membership reports on a global or per interface basis.

Configuring Global IGMP State Limiters

Perform this optional task to configure one global IGMP state limiter per device.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp limit number
4. end
5. show ip igmp groups

DETAILED STEPS

</tbody>
</table>
Purpose

Command or Action | Purpose
---|---
Device# configure terminal | Configures a global limit on the number of mroutestates resulting from IGMP membership reports (IGMP joins).

**Step 3**

ip igmp limit *number*

Example:

Device(config)# ip igmp limit 150

**Step 4**

deend

Example:

Device(config-if)# end

**Step 5**

show ip igmp groups

Example:

Device# show ip igmp groups

(Optional) Displays the multicast groups with receivers that are directly connected to the device and that were learned through IGMP.

### Configuration examples for IGMP State Limit

#### Configuring IGMP State Limiters Example

The following example shows how to configure IGMP state limiters to provide multicast CAC in a network environment where all the multicast flows roughly utilize the same amount of bandwidth.

This example uses the topology illustrated in the figure.
In this example, a service provider is offering 300 Standard Definition (SD) TV channels. Each SD channel utilizes approximately 4 Mbps.

The service provider must provision the Gigabit Ethernet interfaces on the PE router connected to the Digital Subscriber Line Access Multiplexers (DSLAMs) as follows: 50% of the link’s bandwidth (500 Mbps) must be available to subscribers of the Internet, voice, and video on demand (VoD) service offerings while the remaining 50% (500 Mbps) of the link’s bandwidth must be available to subscribers of the SD channel offerings.

Because each SD channel utilizes the same amount of bandwidth (4 Mbps), per interface IGMP state limiters can be used to provide the necessary CAC to provision the services being offered by the service provider. To determine the required CAC needed per interface, the total number of channels is divided by 4 (because each channel utilizes 4 Mbps of bandwidth). The required CAC needed per interface, therefore, is as follows:

\[
\frac{500\text{Mbps}}{4\text{Mbps}} = 125 \text{ mroutes}
\]

Once the required CAC is determined, the service provider uses the results to configure the per IGMP state limiters required to provision the Gigabit Ethernet interfaces on the PE router. Based on the network’s CAC requirements, the service provider must limit the SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 125. Configuring a per interface IGMP state limit of 125 for the SD channels provisions the interface for 500 Mbps of bandwidth, the 50% of the link’s bandwidth that must always be available (but never exceeded) for the SD channel offerings.

The following configuration shows how the service provider uses a per interface mroute state limiter to provision interface Gigabit Ethernet 0/0/0 for the SD channels and Internet, Voice, and VoD services being offered to subscribers:

```
interface GigabitEthernet0/0/0
description --- Interface towards the DSLAM ---
.
.
ip igmp limit 125
```

• Feature Information for STP, on page 674

Restrictions for STP

• An attempt to configure a device as the root device fails if the value necessary to be the root device is less than 1.

• If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected devices running older software.

• The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About Spanning Tree Protocol

Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Devices might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.
The STP uses a spanning-tree algorithm to select one device of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

- Root—A forwarding port elected for the spanning-tree topology
- Designated—A forwarding port elected for every switched LAN segment
- Alternate—A blocked port providing an alternate path to the root bridge in the spanning tree
- Backup—A blocked port in a loopback configuration

The device that has all of its ports as the designated role or as the backup role is the root device. The device that has at least one of its ports in the designated role is called the designated device.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Devices send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The devices do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending device and its ports, including device and MAC addresses, device priority, port priority, and path cost. Spanning tree uses this information to elect the root device and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a device are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

**Note**

By default, the device sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the `[no] keepalive` interface configuration command with no keywords.

### Spanning-Tree Topology and BPDUs

The stable, active spanning-tree topology of a switched network is controlled by these elements:

- The unique bridge ID (device priority and MAC address) associated with each VLAN on each device. In a device stack, all devices use the same bridge ID for a given spanning-tree instance.
- The spanning-tree path cost to the root device.
- The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the devices in a network are powered up, each functions as the root device. Each device sends a configuration BPDU through all of its ports. The BPDUs communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the device that the sending device identifies as the root device
- The spanning-tree path cost to the root
- The bridge ID of the sending device
- Message age
• The identifier of the sending interface
• Values for the hello, forward delay, and max-age protocol timers

When a device receives a configuration BPDU that contains *superior* information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the device, the device also forwards it with an updated message to all attached LANs for which it is the designated device.

If a device receives a configuration BPDU that contains *inferior* information to that currently stored for that port, it discards the BPDU. If the device is a designated device for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:

• One device in the network is elected as the root device (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.

  For each VLAN, the device with the highest device priority (the lowest numerical priority value) is elected as the root device. If all devices are configured with the default priority (32768), the device with the lowest MAC address in the VLAN becomes the root device. The device priority value occupies the most significant bits of the bridge ID, as shown in the following figure.

• A root port is selected for each device (except the root device). This port provides the best path (lowest cost) when the device forwards packets to the root device.

When selecting the root port on a device stack, spanning tree follows this sequence:

• Selects the lowest root bridge ID
• Selects the lowest path cost to the root device
• Selects the lowest designated bridge ID
• Selects the lowest designated path cost
• Selects the lowest port ID

• Only one outgoing port on the stack root device is selected as the root port. The remaining devices in the stack become its designated devices (Device 2 and Device 3) as shown in the following figure.

• The shortest distance to the root device is calculated for each device based on the path cost.

• A designated device for each LAN segment is selected. The designated device incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
One stack member is elected as the stack root device. The stack root device contains the outgoing root port (Device 1).

All paths that are not needed to reach the root device from anywhere in the switched network are placed in the spanning-tree blocking mode.

**Bridge ID, Device Priority, and Extended System ID**

The IEEE 802.1D standard requires that each device has an unique bridge identifier (bridge ID), which controls the selection of the root device. Because each VLAN is considered as a different logical bridge with PVST+ and Rapid PVST+, the same device must have a different bridge ID for each configured VLAN. Each VLAN on the device has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the device priority, and the remaining 6 bytes are derived from the device MAC address.

The device supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the device priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for the device, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.
The 2 bytes previously used for the device priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

### Table 51: Device Priority Value and Extended System ID

<table>
<thead>
<tr>
<th>Priority Value</th>
<th>Extended System ID (Set Equal to the VLAN ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 15</td>
<td>Bit 14</td>
</tr>
<tr>
<td>32768</td>
<td>16384</td>
</tr>
</tbody>
</table>

Spanning tree uses the extended system ID, the device priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the device stack appears as a single device to the rest of the network, all devices in the stack use the same bridge ID for a given spanning tree. If the stack master fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack master.

Support for the extended system ID affects how you manually configure the root device, the secondary root device, and the device priority of a VLAN. For example, when you change the device priority value, you change the probability that the device will be elected as the root device. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root device for the specified VLAN has a device priority lower than 24576, the device sets its own priority for the specified VLAN to 4096 less than the lowest device priority. 4096 is the value of the least-significant bit of a 4-bit device priority value as shown in the table.

### Port Priority Versus Path Cost

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your device is a member of a device stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see Related Topics.

### Spanning-Tree Interface States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface
transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

Each Layer 2 interface on a device using spanning tree exists in one of these states:

- **Blocking**—The interface does not participate in frame forwarding.
- **Listening**—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.
- **Learning**—The interface prepares to participate in frame forwarding.
- **Forwarding**—The interface forwards frames.
- **Disabled**—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:

- From initialization to blocking
- From blocking to listening or to disabled
- From listening to learning or to disabled
- From learning to forwarding or to disabled
- From forwarding to disabled

Figure 38: Spanning-Tree Interface States

An interface moves through the states.

When you power up the device, spanning tree is enabled by default, and every interface in the device, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:
1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.

2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.

3. In the learning state, the interface continues to block frame forwarding as the device learns end-station location information for the forwarding database.

4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

**Blocking State**

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each device interface. A device initially functions as the root until it exchanges BPDUs with other devices. This exchange establishes which device in the network is the root or root device. If there is only one device in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after device initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

**Listening State**

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

**Learning State**

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs
Forwarding State

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface
- Forwards frames switched from another interface
- Learns addresses
- Receives BPDUs

Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Does not receive BPDUs

How a Device or Port Becomes the Root Device or Root Port

If all devices in a network are enabled with default spanning-tree settings, the device with the lowest MAC address becomes the root device.

*Figure 39: Spanning-Tree Topology*

Device A is elected as the root device because the device priority of all the devices is set to the default (32768) and Device A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Device A might not be the ideal root device. By increasing the priority (lowering the numerical value) of the ideal device so that it becomes the root device, you force a spanning-tree recalculation to form a new topology with the ideal device as the root.

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.
For example, assume that one port on Device B is a Gigabit Ethernet link and that another port on Device B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.

**Spanning Tree and Redundant Connectivity**

You can create a redundant backbone with spanning tree by connecting two device interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds are the same, the port priority and port ID are added together, and spanning tree disables the link with the highest value.

You can also create redundant links between devices by using EtherChannel groups.

**Spanning-Tree Address Management**

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C2000000 to 0x0180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each device in the stack receives but does not forward packets destined for addresses between 0x0180C2000000 and 0x0180C20000F.

If spanning tree is enabled, the CPU on the device or on each device in the stack receives packets destined for 0x0180C2000000 and 0x0180C2000010. If spanning tree is disabled, the device or each device in the stack forwards those packets as unknown multicast addresses.

**Accelerated Aging to Retain Connectivity**

The default for aging dynamic addresses is 5 minutes, the default setting of the `mac address-table aging-time` global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (`spanning-tree vlan vlan-id forward-time seconds` global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the device accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be
subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the device.

### Spanning-Tree Modes and Protocols

The device supports these spanning-tree modes and protocols:

- **PVST+**—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. The PVST+ runs on each VLAN on the device up to the maximum supported, ensuring that each has a loop-free path through the network.

  The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root device. This root device propagates the spanning-tree information associated with that VLAN to all other devices in the network. Because each device has the same information about the network, this process ensures that the network topology is maintained.

  Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to reprovision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

- **Rapid PVST+**—This spanning-tree mode is the same as PVST+ except that it uses a rapid convergence based on the IEEE 802.1w standard. Beginning from the 15.2(4)E release, the default mode of STP is Rapid PVST+. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

  Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to reprovision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

- **MSTP**—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a device stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

### Supported Spanning-Tree Instances

In PVST+ or Rapid PVST+ mode, the device or device stack supports up to 128 spanning-tree instances.

In MSTP mode, the device or device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

- [Default MSTP Configuration](#), on page 691

### Spanning-Tree Interoperability and Backward Compatibility

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ device cannot connect to multiple MST regions.

When a network contains devices running Rapid PVST+ and devices running PVST+, we recommend that the Rapid PVST+ devices and PVST+ devices be configured for different spanning-tree instances. In the
Rapid PVST+ spanning-tree instances, the root device must be a Rapid PVST+ device. In the PVST+ instances, the root device must be a PVST+ device. The PVST+ devices should be at the edge of the network.

All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

### STP and IEEE 802.1Q Trunks

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for all VLANs allowed on the trunks. However, in a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for each VLAN allowed on the trunks.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the device uses it instead of PVST+. The device combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.

Rapid PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

### Spanning Tree and Device Stacks

When the device stack is operating in PVST+ or Rapid PVST+ mode:

- A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

- When a new device joins the stack, it sets its bridge ID to the active switch bridge ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root.

- When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.
• If the device stack is the spanning-tree root and the active switch fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.

• If a neighboring device external to the device stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a device in the active topology.

• If a new device external to the device stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a device in the network.

**Note**

Beginning from the 15.2(4)E release, the default mode of STP is Rapid PVST+. 
How to Configure Spanning-Tree Features

Changing the Spanning-Tree Mode (CLI)

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the device runs the Rapid PVST+ protocol.

If you want to enable a mode that is different from the default mode, this procedure is required.

SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree mode {pvst | mst | rapid-pvst}
4. interface interface-id
5. spanning-tree link-type point-to-point
6. end
7. clear spanning-tree detected-protocols

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

<td></td>
</tr>
</tbody>
</table>
### Disabling Spanning Tree (CLI)

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

⚠️ Caution

When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. no spanning-tree vlan *vlan-id*
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
Configuring the Root Device (CLI)

To configure a device as the root for the specified VLAN, use the `spanning-tree vlan vlan-id root` global configuration command to modify the device priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the device priority of the root devices for each VLAN. Because of the extended system ID support, the device sets its own priority for the specified VLAN to 24576 if this value will cause this device to become the root for the specified VLAN.

Use the `diameter` keyword to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the `hello` keyword to override the automatically calculated hello time.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree vlan vlan-id root primary [diameter net-diameter]`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>For <code>vlan-id</code>, the range is 1 to 4094.</td>
</tr>
<tr>
<td><code>no spanning-tree vlan vlan-id</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# no spanning-tree vlan 300</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a Secondary Root Device (CLI)

When you configure a device as the secondary root, the device priority is modified from the default value (32768) to 28672. With this priority, the device is likely to become the root device for the specified VLAN if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768, and therefore, are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the `spanning-tree vlan vlan-id root primary` global configuration command.

This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. spanning-tree vlan vlan-id root secondary [diameter net-diameter
4. end

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 spanning-tree vlan vlan-id root primary [diameter net-diameter</td>
<td>Configures a device to become the root for the specified VLAN.</td>
</tr>
<tr>
<td>Example: Device(config)# spanning-tree vlan 20-24 root primary diameter 4</td>
<td>• For <code>vlan-id</code>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For <code>diameter net-diameter</code>, specify the maximum number of devices between any two end stations. The range is 2 to 7.</td>
</tr>
<tr>
<td>Step 4 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

---

**What to do next**

After configuring the device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the `spanning-tree vlan vlan-id hello-time`, `spanning-tree vlan vlan-id forward-time`, and the `spanning-tree vlan vlan-id max-age` global configuration commands.
## DETAILED STEPS

## Configuring Port Priority (CLI)

*Note*

If your device is a member of a device stack, you must use the `spanning-tree [vlan vlan-id] cost cost` interface configuration command instead of the `spanning-tree [vlan vlan-id] port-priority priority` interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

## SUMMARY STEPS

1. `enable`
2. configure terminal  
3. interface interface-id  
4. spanning-tree port-priority priority  
5. spanning-tree vlan vlan-id port-priority priority  
6. end

**DETAILED STEPS**

<table>
<thead>
<tr>

<td><code>spanning-tree vlan vlan-id cost cost</code></td>
<td>Configures the cost for a VLAN.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.

- For `vlan-id`, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.
- For `cost`, the range is 1 to 200000000; the default value is derived from the media speed of the interface.

### Step 6

**Example:**

```
Device(config-if)# end
```

This procedure is optional.

### Configuring the Device Priority of a VLAN (CLI)

You can configure the device priority and make it more likely that a standalone device or a device in the stack will be chosen as the root device.

#### Note

Exercise care when using this command. For most situations, we recommend that you use the `spanning-tree vlan vlan-id root primary` and the `spanning-tree vlan vlan-id root secondary` global configuration commands to modify the device priority.

The `show spanning-tree interface interface-id` privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the `show running-config` privileged EXEC command to confirm the configuration.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config-if)# spanning-tree vlan 10,12-15,20 cost 300</code></td>
<td>If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>Returns to privileged EXEC mode.</strong></td>
</tr>
</tbody>
</table>

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree vlan vlan-id priority priority`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Step 1 enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### Configuring the Hello Time (CLI)

The hello time is the time interval between configuration messages generated and sent by the root device. This procedure is optional.

#### SUMMARY STEPS

1. `enable`
2. `spanning-tree vlan vlan-id hello-time seconds`
3. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>spanning-tree vlan vlan-id hello-time seconds</code></td>
<td>Configures the VLAN's hello time.</td>
</tr>
</tbody>
</table>

- For `vlan-id`, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.
- For `hello-time`, the range is 0 to 61440 in increments of 4096; the default is 2 seconds. The lower the number, the more likely the device will be chosen as the root device.

Valid priority values are 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. All other values are rejected.
Configuring the Forwarding-Delay Time for a VLAN (CLI)

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree vlan vlan-id forward-time seconds
4. end

### DETAILED STEPS

<table>
<thead>

<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> spanning-tree vlan vlan-id max-age seconds</td>
<td>Configures the maximum-aging time of a VLAN. The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

---

**Example:**

**Step 3**

```
Device(config)# spanning-tree vlan 20,25
forward-time 18
```
### Configuring the Transmit Hold-Count (CLI)

You can configure the BPDU burst size by changing the transmit hold count value.

**Note**
Changing this parameter to a higher value can have a significant impact on CPU utilization, especially in Rapid PVST+ mode. Lowering this value can slow down convergence in certain scenarios. We recommend that you maintain the default setting.

This procedure is optional.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree transmit hold-count value`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td>Example:</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

Configure the number of BPDUs that can be sent before pausing for 1 second.

For *value*, the range is 1 to 20; the default is 6.

### Example

**Step 3**

configure terminal

```
Device(config)# spanning-tree transmit hold-count 6
```

**Step 4**

```
Device(config)# end
```

Returns to privileged EXEC mode.

---

### Monitoring Spanning-Tree Status

**Table 54: Commands for Displaying Spanning-Tree Status**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>show spanning-tree active</strong></td>
<td>Displays spanning-tree information on active interfaces only.</td>
</tr>
<tr>
<td><strong>show spanning-tree detail</strong></td>
<td>Displays a detailed summary of interface information.</td>
</tr>
<tr>
<td><strong>show spanning-tree vlan vlan-id</strong></td>
<td>Displays spanning-tree information for the specified VLAN.</td>
</tr>
<tr>
<td><strong>show spanning-tree interface interface-id</strong></td>
<td>Displays spanning-tree information for the specified interface.</td>
</tr>
<tr>
<td><strong>show spanning-tree interface interface-id portfast</strong></td>
<td>Displays spanning-tree portfast information for the specified interface.</td>
</tr>
<tr>
<td><strong>show spanning-tree summary [totals]</strong></td>
<td>Displays a summary of interface states or displays the total lines of the STP state section.</td>
</tr>
</tbody>
</table>

To clear spanning-tree counters, use the **clear spanning-tree [interface interface-id]** privileged EXEC command.

• Feature Information for MSTP, on page 710

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for MSTP

• For two or more devices to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

• For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.

• For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a device stack by manually configuring the path cost.

• For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the internal spanning tree (IST) master of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST regions must contain the CST root, and all of the other MST regions must have a better path to the root CST.
contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the devices in the clouds.

Restrictions for MSTP

- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
- The device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.
- PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)
- All stack members must run the same version of spanning tree (all PVST+, Rapid PVST+, or MSTP).
- VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each device within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.
- Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.
- A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.
- After configuring a device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the spanning-tree mst hello-time, spanning-tree mst forward-time, and the spanning-tree mst max-age global configuration commands.

Information About MSTP

MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing, and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

Note

The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment.

When the device is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.

Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same device ID.

MSTP Configuration Guidelines

- When you enable MST by using the `spanning-tree mode mst` global configuration command, RSTP is automatically enabled.
- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.
- When the device is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

<table>
<thead>
<tr>
<th>Speed</th>
<th>Path Cost Value</th>

<td>200,000</td>
</tr>
<tr>
<td>1 Gb/s</td>
<td>20,000</td>
</tr>
</tbody>
</table>
### Root Switch

The device maintains a spanning-tree instance for the group of VLANs mapped to it. A device ID, consisting of the device priority and the device MAC address, is associated with each instance. For a group of VLANs, the device with the lowest device ID becomes the root device.

When you configure a device as the root, you modify the device priority from the default value (32768) to a significantly lower value so that the device becomes the root device for the specified spanning-tree instance. When you enter this command, the device checks the device priorities of the root devices. Because of the extended system ID support, the device sets its own priority for the specified instance to 24576 if this value will cause this device to become the root for the specified spanning-tree instance.

If any root device for the specified instance has a device priority lower than 24576, the device sets its own priority to 4096 less than the lowest device priority. (4096 is the value of the least-significant bit of a 4-bit device priority value. For more information, select "Bridge ID, Device Priority, and Extended System ID" link in Related Topics.

If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected switches running older software.

The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Use the **diameter** keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

**Multiple Spanning-Tree Regions**

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each device belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the device for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the “Specifying the MST Region Configuration and Enabling MSTP” link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

**IST, CIST, and CST**

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- An internal spanning tree (IST), which is the spanning tree that runs in an MST region.
  
  Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

  The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because the MSTP BPU carries information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

  All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root device ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

  An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- A common and internal spanning tree (CIST), which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.
The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

**Operations Within an MST Region**

The IST connects all the MSTP switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the IST master before the implementation of the IEEE 802.1s standard). It is the device within the region with the lowest device ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MSTP switches at the boundary of the region is selected as the CIST regional root.

When an MSTP device initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The device also initializes all of its MST instances and claims to be the root for all of them. If the device receives superior MST root information (lower device ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

**Related Topics**

Illustration of MST Regions, on page 681

**Operations Between MST Regions**

If there are multiple regions or legacy IEEE 802.1D devices within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP devices in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP devices in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual device to adjacent STP devices and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring devices and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPDU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, device priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.

MSTP devices use Version 3 RSTP BPDU or IEEE 802.1D STP BPDU to communicate with legacy IEEE 802.1D devices. MSTP devices use MSTP BPDU to communicate with MSTP devices.

Illustration of MST Regions, on page 681
IEEE 802.1s Terminology

Some MST naming conventions used in Cisco’s prestandard implementation have been changed to identify some internal or regional parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root device for the unique instance that spans the whole network, the CIST.
- The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single device for the CIST. The CIST external root path cost is the root path cost calculated between these virtual devices and devices that do not belong to any region.
- The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest device to the CIST root in the region. The CIST regional root acts as a root device for the IST.
- The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

Illustration of MST Regions

This figure displays three MST regions and a legacy IEEE 802.1D device (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.
Hop Count

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the `spanning-tree mst max-hops` global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root device of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a device receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDUs it generates. When the count reaches zero, the device discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.
Boundary Ports

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both devices and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

Note

If there is a legacy STP device on the segment, messages are always considered external.

The other change from the Cisco prestandard implementation is that the CIST regional root device ID field is now inserted where an RSTP or legacy IEEE 802.1Q device has the sender device ID. The whole region performs like a single virtual device by sending a consistent sender device ID to neighboring devices. In this example, device C would receive a BPDU with the same consistent sender device ID of root, whether or not A or B is designated for the segment.

IEEE 802.1s Implementation

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

Port Role Naming Change

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco’s implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special master role.
• The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the `show` commands identify a port as boundary in the `type` column of the output.

### Interoperation Between Legacy and Standard Devices

Because automatic detection of prestandard devices can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard device, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a device receives a prestandard BPDU on a port that has not been configured for prestandard BPDU transmission.

**Figure 42: Standard and Prestandard Device Interoperation**

Assume that A is a standard device and B a prestandard device, both configured to be in the same region. A is the root device for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPDU, AY cannot detect that a prestandard device is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology changes.

We recommend that you minimize the interaction between standard and prestandard MST implementations.

### Detecting Unidirectional Link Failure

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.
Figure 43: Detecting Unidirectional Link Failure

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Device A is the root device, and its BPDUs are lost on the link leading to device B. RSTP and MST BPDU s include the role and state of the sending port. With this information, device A can detect that device B does not react to the superior BPDU s it sends and that device B is the designated, not root device. As a result, device A blocks (or keeps blocking) its port, which prevents the bridging loop.

MSTP and Device Stacks

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

The active switch is the stack root when the stack is the root of the network and no root selection has been made within the stack.

If the device stack is the spanning-tree root and the active switch fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.

If a device that does not support MSTP is added to a device stack that does support MSTP or the reverse, the device is put into a version mismatch state. If possible, the device is automatically upgraded or downgraded to the same version of software that is running on the device stack.

Interoperability with IEEE 802.1D STP

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDU s on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDU s because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device might also continue to assign a boundary role to a port when the device to which this device is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring devices), use the clear spanning-tree detected-protocols privileged EXEC command.

If all the legacy devices on the link are RSTP devices, they can process MSTP BPDU s as if they are RSTP BPDU s. Therefore, MSTP devices send either a Version 0 configuration and TCN BPDU s or Version 3 MSTP BPDU s on a boundary port. A boundary port connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.
RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).

Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the device with the highest device priority (lowest numerical priority value) as the root device. The RSTP then assigns one of these port roles to individual ports:

- **Root port**—Provides the best path (lowest cost) when the device forwards packets to the root device.
- **Designated port**—Connects to the designated device, which incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
- **Alternate port**—Offers an alternate path toward the root device to that provided by the current root port.
- **Backup port**—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a device has two or more connections to a shared LAN segment.
- **Disabled port**—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

<table>
<thead>
<tr>
<th>Operational Status</th>

</tbody>
</table>

To be consistent with Cisco STP implementations, this guide defines the port state as *blocking* instead of *discarding*. Designated ports start in the listening state.
Rapid Convergence

The RSTP provides for rapid recovery of connectivity following the failure of a device, a device port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

- **Edge ports**—If you configure a port as an edge port on an RSTP device by using the `spanning-tree portfast` interface configuration command, the edge port immediately transitions to the forwarding state. An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.

- **Root ports**—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.

- **Point-to-point links**—If you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

**Figure 44: Proposal and Agreement Handshaking for Rapid Convergence**

Device A is connected to Device B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Device A is a smaller numerical value than the priority of Device B. Device A sends a proposal message (a configuration BPDU with the proposal flag set) to Device B, proposing itself as the designated device.

After receiving the proposal message, Device B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Device B’s agreement message, Device A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Device B blocked all of its nonedge ports and because there is a point-to-point link between Devices A and B.

When Device C is connected to Device B, a similar set of handshaking messages are exchanged. Device C selects the port connected to Device B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more device joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a device stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the device is in MST mode.

The device learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the `spanning-tree link-type` interface configuration command.
Synchronization of Port Roles

When the device receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The device is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the device is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

*Figure 45: Sequence of Events During Rapid Convergence*

After ensuring that all of the ports are synchronized, the device sends an agreement message to the designated device corresponding to its root port. When the devices connected by a point-to-point link are in agreement...
about their port roles, the RSTP immediately transitions the port states to forwarding.

**Bridge Protocol Data Unit Format and Processing**

The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

The sending device sets the proposal flag in the RSTP BPDU to propose itself as the designated device on that LAN. The port role in the proposal message is always set to the designated port.
The sending device sets the agreement flag in the RSTP BPDU to accept the previous proposal. The port role in the agreement message is always set to the root port.

The RSTP does not have a separate topology change notification (TCN) BPDU. It uses the topology change (TC) flag to show the topology changes. However, for interoperability with IEEE 802.1D devices, the RSTP device processes and generates TCN BPDUs.

The learning and forwarding flags are set according to the state of the sending port.

**Processing Superior BPDU Information**

If a port receives superior root information (lower device ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDU received is an RSTP BPDU with the proposal flag set, the device sends an agreement message after all of the other ports are synchronized. If the BPDU is an IEEE 802.1D BPDU, the device does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

**Processing Inferior BPDU Information**

If a designated port receives an inferior BPDU (such as a higher device ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.

**Topology Changes**

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- **Detection**—Unlike IEEE 802.1D in which any transition between the blocking and the forwarding state causes a topology change, only transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP device detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.

- **Notification**—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP device processes and generates TCN BPDUs.

- **Acknowledgement**—When an RSTP device receives a TCN message on a designated port from an IEEE 802.1D device, it replies with an IEEE 802.1D configuration BPDU with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D device and a configuration BPDU with the TCA bit set is received, the TC-while timer is reset.

  This behavior is only required to support IEEE 802.1D devices. The RSTP BPDUs never have the TCA bit set.

- **Propagation**—When an RSTP device receives a TC message from another device through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding
the port on which it is received). The device starts the TC-while timer for all such ports and flushes the information learned on them.

- Protocol migration—For backward compatibility with IEEE 802.1D devices, RSTP selectively sends IEEE 802.1D configuration BPDU s and TCN BPDU s on a per-port basis.

When a port is initialized, the migrate-delay timer is started (specifies the minimum time during which RSTP BPDU s are sent), and RSTP BPDU s are sent. While this timer is active, the device processes all BPDU s received on that port and ignores the protocol type.

If the device receives an IEEE 802.1D BPDU after the port migration-delay timer has expired, it assumes that it is connected to an IEEE 802.1D device and starts using only IEEE 802.1D BPDU s. However, if the RSTP device is using IEEE 802.1D BPDU s on a port and receives an RSTP BPDU after the timer has expired, it restarts the timer and starts using RSTP BPDU s on that port.

**Protocol Migration Process**

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDU s on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDU s because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device also might continue to assign a boundary role to a port when the device to which it is connected has joined the region.

How to Configure MSTP Features

Specifying the MST Region Configuration and Enabling MSTP (CLI)

For two or more switches to be in the same MST region, they must have the same VLAN-to-instance mapping, the same configuration revision number, and the same name.

A region can have one member or multiple members with the same MST configuration; each member must be capable of processing RSTP BPDUs. There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mst configuration`
4. `instance instance-id vlan vlan-range`
5. `name name`
6. `revision version`
7. `show pending`
8. `exit`
9. `spanning-tree mode mst`
10. `end`

Related Topics
Root Switch, on page 678
Specifying the MST Region Configuration and Enabling MSTP (CLI), on page 692
Configuring a Secondary Root Device (CLI)

When you configure a device with the extended system ID support as the secondary root, the device priority is modified from the default value (32768) to 28672. The device is then likely to become the root device for the specified instance if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768 and therefore are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the `spanning-tree mst instance-id root primary` global configuration command.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree mst instance-id root secondary`
4. `end`

### Configuring Port Priority (CLI)

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

**Note**

If the device is a member of a device stack, you must use the `spanning-tree mst [instance-id] cost cost` interface configuration command instead of the `spanning-tree mst [instance-id] port-priority priority` interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree mst instance-id port-priority priority`
5. `end`

### Configuring the Device Priority (CLI)

Changing the priority of a device makes it more likely to be chosen as the root device whether it is a standalone device or a device in the stack.

#### Note

Exercise care when using this command. For normal network configurations, we recommend that you use the `spanning-tree mst instance-id root primary` and the `spanning-tree mst instance-id root secondary` global configuration commands to specify a device as the root or secondary root device. You should modify the device priority only in circumstances where these commands do not work.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

### Specifying the Link Type to Ensure Rapid Transitions (CLI)

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote device running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.
SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree link-type point-to-point
5. end

Designating the Neighbor Type (CLI)

A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.
You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the `show` commands, even if the port is in STP compatibility mode.

This procedure is optional.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree mst pre-standard`
5. `end`

Restarting the Protocol Migration Process (CLI)

This procedure restarts the protocol migration process and forces renegotiation with neighboring devices. It reverts the device to MST mode. It is needed when the device no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Follow these steps to restart the protocol migration process (force the renegotiation with neighboring devices) on the device.

Before you begin
A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

If you want to use the interface version of the command, you must also know the MST interface used. This example uses GigabitEthernet1/0/1 as the interface because that was the interface set up by the instructions listed under Related Topics.

SUMMARY STEPS

1. `enable`
2. Enter one of the following commands:
   - `clear spanning-tree detected-protocols`
   - `clear spanning-tree detected-protocols interface interface-id`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable  
Example:  
Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | Enter one of the following commands:  
- `clear spanning-tree detected-protocols`
- `clear spanning-tree detected-protocols interface interface-id`
Example:  
Device# clear spanning-tree detected-protocols  
or
Device# clear spanning-tree detected-protocols interface GigabitEthernet1/0/1 | The device reverts to the MSTP mode, and the protocol migration process restarts. |
What to do next

This procedure may need to be repeated if the device receives more legacy IEEE 802.1D configuration BPDUs (BPDUs with the protocol version set to 0).

Information About Optional Spanning-Tree Features

PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

*Figure 46: PortFast-Enabled Interfaces*

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to converge.

Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.
BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast edge-enabled ports, spanning tree shuts down ports that are in a PortFast edge-operational state if any BPDU is received on them. In a valid configuration, PortFast edge-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast edge-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast edge feature, and the port receives a BPDU, it is put in the error-disabled state.

The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.

BPDU Filtering

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast edge-enabled interfaces at the global level keeps those interfaces that are in a PortFast edge-operational state from sending or receiving BPDUs. The interfaces still send a few BPDUs at link-up before the switch begins to filter outbound BPDUs. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDUs. If a BPDU is received on a PortFast edge-enabled interface, the interface loses its PortFast edge-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast edge feature keeps the interface from sending or receiving BPDUs.

Caution

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature for the entire switch or for an interface.
UplinkFast

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one redundant link that spanning tree blocks to prevent loops.

If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.

When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

Note

UplinkFast is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.
This topology has no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in a blocking state.

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked interface on Switch C and transitions it to the forwarding state without going through the listening and learning states. This change takes approximately 1 to 5 seconds.

- Events That Cause Fast Convergence, on page 716

**Cross-Stack UplinkFast**

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see Related Topics.
How Cross-Stack UplinkFast Works

Cross-Stack UplinkFast (CSUF) ensures that one link in the stack is elected as the path to the root.

*Figure 50: Cross-Stack UplinkFast Topology*

The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.

When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.
Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate (2 * forward-delay time + max-age time).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

**Related Topics**
- Enabling UplinkFast for Use with Redundant Links (CLI), on page 725
- Events That Cause Fast Convergence, on page 716

### Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur.

Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.
  
  If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.

- The failed link, which connects the stack root to the spanning-tree root, recovers.

- A network reconfiguration causes a new stack-root switch to be selected.

- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

**Note**
The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.

- The stack-root switch, which was powered off or failed, is powered on.

- A new switch, which might become the stack root, is added to the stack.

BackboneFast

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches. BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDU from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDU for the maximum aging time (default is 20 seconds).

The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.
This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B is in the blocking state.

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDU’s to Switch C, identifying itself as the root. When Switch C receives the inferior BPDU’s from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is set. BackboneFast reconfigures the topology to account for the failure of link L1.

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDU’s did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDU’s that indicate it is the root switch. However, the other switches ignore these inferior
BPDUs, and the new switch learns that Switch B is the designated switch to Switch A, the root switch.

**EtherChannel Guard**

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel, but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.

**Related Topics**
- Enabling EtherChannel Guard (CLI), on page 729

**Root Guard**

*Figure 54: Root Guard in a Service-Provider Network*

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer’s network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer’s switch from becoming the root switch or being in the path to the root.
If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer’s switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

Caution
Misuse of the root guard feature can cause a loss of connectivity.

Related Topics
Enabling Root Guard (CLI), on page 730

Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in MST mode, BPDUs are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.
How to Configure Optional Spanning-Tree Features

Enabling PortFast (CLI)

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution

Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. spanning-tree portfast [trunk]
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
Enabling BPDU Guard (CLI)

You can enable the BPDU guard feature if your switch is running PVST+, Rapid PVST+, or MSTP.

⚠️ Caution

Configure PortFast edge only on ports that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree portfast edge bpdu guard default
4. interface interface-id
5. spanning-tree portfast edge
6. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Globally enables BPDU guard. By default, BPDU guard is disabled.</td>
</tr>
<tr>
<td><code>spanning-tree portfast edge bpduguard default</code></td>

<td>Device(config-if)# end</td>
</tr>
</tbody>
</table>

**What to do next**

To prevent the port from shutting down, you can use the `errdisable detect cause bpduguard shutdown vlan` global configuration command to shut down just the offending VLAN on the port where the violation occurred.

You also can use the `spanning-tree bpduguard enable` interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put it in the error-disabled state.

**Related Topics**

- BPDUGuard, on page 712
Enabling BPDU Filtering (CLI)

You can also use the `spanning-tree bpdutfilter enable` interface configuration command to enable BPDU filtering on any interface without also enabling the PortFast edge feature. This command prevents the interface from sending or receiving BPDUs.

**Caution**

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

**Caution**

Configure PortFast edge only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree portfast edge bpdutfilter default
4. interface `interface-id`
5. spanning-tree portfast edge
6. end

**DETAILED STEPS**

  `end`
  
  **Example:**
  
  `Device(config-if)# end`
  
  Returns to privileged EXEC mode. |

**Related Topics**

- [BPDU Filtering], on page 712

### Enabling UplinkFast for Use with Redundant Links (CLI)

**Note**

When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable UplinkFast and CSUF.

**Before you begin**

UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the `no spanning-tree vlan vlan-id priority` global configuration command.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `spanning-tree uplinkfast [max-update-rate pkts-per-second]`
4. `end`
## Enabling UplinkFast for Use with Redundant Links (CLI)

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable  
Example:  
Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2** | configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| **Step 3** | spanning-tree uplinkfast [max-update-rate pkts-per-second]  
Example:  
Device(config)# spanning-tree uplinkfast max-update-rate 200 | Enables UplinkFast.  
(Optional) For pkts-per-second, the range is 0 to 32000 packets per second; the default is 150.  
If you set the rate to 0, station-learning frames are not generated, and the spanning-tree topology converges more slowly after a loss of connectivity.  
When you enter this command, CSUF also is enabled on all nonstack port interfaces. |
| **Step 4** | end  
Example:  
Device(config)# end | Returns to privileged EXEC mode. |

When UplinkFast is enabled, the switch priority of all VLANs is set to 49152. If you change the path cost to a value less than 3000 and you enable UplinkFast or UplinkFast is already enabled, the path cost of all interfaces and VLAN trunks is increased by 3000 (if you change the path cost to 3000 or above, the path cost is not altered). The changes to the switch priority and the path cost reduce the chance that a switch will become the root switch.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you enable the UplinkFast feature using these instructions, CSUF is automatically globally enabled on nonstack port interfaces.

**Related Topics**

- Events That Cause Fast Convergence, on page 716
Disabling UplinkFast (CLI)

This procedure is optional.

Follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

**Before you begin**

UplinkFast must be enabled.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no spanning-tree uplinkfast`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Disables UplinkFast and CSUF on the switch and all of its VLANs.</td>
</tr>
<tr>
<td><code>no spanning-tree uplinkfast</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# no spanning-tree uplinkfast</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you disable the UplinkFast feature using these instructions, CSUF is automatically globally disabled on nonstack port interfaces.
Enabling BackboneFast (CLI)

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable BackboneFast on the switch.

**Before you begin**

If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree backbonefast
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
<tr>
<td>Device(config)# spanning-tree backbonefast</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Related Topics**

| BackboneFast, on page 717 |
Enabling EtherChannel Guard (CLI)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable EtherChannel Guard on the device.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. spanning-tree etherchannel guard misconfig
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>spanning-tree etherchannel guard misconfig</td>
</tr>
<tr>
<td>Example:</td>
<td>Enables EtherChannel guard.</td>
</tr>
<tr>
<td>Device(config)# spanning-tree etherchannel guard misconfig</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

You can use the `show interfaces status err-disabled` privileged EXEC command to show which device ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the `show etherchannel summary` privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the `shutdown` and `no shutdown` interface configuration commands on the port-channel interfaces that were misconfigured.
Enabling Root Guard (CLI)

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.

Note
You cannot enable both root guard and loop guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.
This procedure is optional.
Follow these steps to enable root guard on the switch.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `spanning-tree guard root`
5. `end`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Specifies an interface to configure, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> spanning-tree guard root</td>
<td>Enables root guard on the interface.</td>
</tr>
</tbody>
</table>
Enabling Loop Guard (CLI)

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

**Note**

You cannot enable both loop guard and root guard at the same time.

You can enable this feature if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional. Follow these steps to enable loop guard on the device.

**SUMMARY STEPS**

1. Enter one of the following commands:
   - `show spanning-tree active`
   - `show spanning-tree mst`

2. `configure terminal`

3. `spanning-tree loopguard default`

4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Verifies which interfaces are alternate or root ports.</td>
</tr>
<tr>
<td>Enter one of the following commands:</td>
<td></td>
</tr>
<tr>
<td>- <code>show spanning-tree active</code></td>
<td></td>
</tr>
<tr>
<td>- <code>show spanning-tree mst</code></td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

Device# `show spanning-tree active`

or

Device# `show spanning-tree mst`
## Purpose

**Command or Action**

Device# show spanning-tree mst

### Step 2

**configure terminal**

- Feature Information for EtherChannels, on page 774

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for EtherChannels

The following are restrictions for EtherChannels:

- All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.
- Layer 3 EtherChannels are not supported if running the LAN Base license feature set.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
Information About EtherChannels

EtherChannel Overview

EtherChannel provides fault-tolerant high-speed links between switches, routers, and servers. You can use the EtherChannel to increase the bandwidth between the wiring closets and the data center, and you can deploy it anywhere in the network where bottlenecks are likely to occur. EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention.

An EtherChannel consists of individual Ethernet links bundled into a single logical link.

Figure 55: Typical EtherChannel Configuration

![EtherChannel Diagram]

The EtherChannel provides full-duplex bandwidth up to 8 Gb/s (Gigabit EtherChannel) or 80 Gb/s (10-Gigabit EtherChannel) between your switch and another switch or host.

Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The number of EtherChannels is limited to 128.

The LAN Base feature set supports up to 24 EtherChannels.

All ports in each EtherChannel must be configured as either Layer 2 or Layer 3 ports. The EtherChannel Layer 3 ports are made up of routed ports. Routed ports are physical ports configured to be in Layer 3 mode by using the `no switchport` interface configuration command. For more information, see the Configuring Interface Characteristics chapter.

Related Topics

- Configuring Layer 2 EtherChannels (CLI), on page 751
- EtherChannel Configuration Guidelines, on page 748
- Default EtherChannel Configuration, on page 747
- Layer 2 EtherChannel Configuration Guidelines, on page 749
EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as would any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.

- When you configure an EtherChannel in the on mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the on mode; otherwise, packet loss can occur.

Related Topics

Configuring Layer 2 EtherChannels (CLI), on page 751
EtherChannel Configuration Guidelines, on page 748
Default EtherChannel Configuration, on page 747
Layer 2 EtherChannel Configuration Guidelines, on page 749

EtherChannel on Devices

You can create an EtherChannel on a device, on a single device in the stack, or on multiple devices in the stack (known as cross-stack EtherChannel).

Figure 56: Single-Switch EtherChannel
EtherChannel Link Failover

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

Related Topics
- Configuring Layer 2 EtherChannels (CLI), on page 751
- EtherChannel Configuration Guidelines, on page 748
- Default EtherChannel Configuration, on page 747
- Layer 2 EtherChannel Configuration Guidelines, on page 749

Channel Groups and Port-Channel Interfaces

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.

Figure 58: Relationship of Physical Ports, Channel Group and Port-Channel Interface

The channel-group command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 128. This port-channel interface number corresponds to the one specified with the channel-group interface configuration command.
• With Layer 2 ports, use the `channel-group` interface configuration command to dynamically create the port-channel interface.

  You also can use the `interface port-channel port-channel-number` global configuration command to manually create the port-channel interface, but then you must use the `channel-group channel-group-number` command to bind the logical interface to a physical port. The `channel-group-number` can be the same as the `port-channel-number`, or you can use a new number. If you use a new number, the `channel-group` command dynamically creates a new port channel.

• With Layer 3 ports, you should manually create the logical interface by using the `interface port-channel` global configuration command followed by the `no switchport` interface configuration command. You then manually assign an interface to the EtherChannel by using the `channel-group` interface configuration command.

• With Layer 3 ports, use the `no switchport` interface command to configure the interface as a Layer 3 interface, and then use the `channel-group` interface configuration command to dynamically create the port-channel interface.

**Port Aggregation Protocol**

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco devices and on those devices licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP can be enabled on cross-stack EtherChannels.

By using PAgP, the device or device stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single device in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed,
duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single device port.

**PAgP Modes**

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

**Table 61: EtherChannel PAgP Modes**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets.</td>
</tr>
<tr>
<td>desirable</td>
<td>Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel).</td>
</tr>
</tbody>
</table>

Switch ports exchange PAgP packets only with partner ports configured in the **auto** or **desirable** modes. Ports configured in the **on** mode do not exchange PAgP packets.

Both the **auto** and **desirable** modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the **desirable** mode can form an EtherChannel with another port that is in the **desirable** or **auto** mode.
- A port in the **auto** mode can form an EtherChannel with another port in the **desirable** mode.

A port in the **auto** mode cannot form an EtherChannel with another port that is also in the **auto** mode because neither port starts PAgP negotiation.

**Silent Mode**

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the **non-silent** keyword. If you do not specify **non-silent** with the **auto** or **desirable** mode, silent mode is assumed.

Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever...
becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

## PAgP Learn Method and Priority

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.

When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.

PAgP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the `pagp port-priority` interface configuration command. The higher the priority, the more likely that the port will be selected.

---

**Note**

The device supports address learning only on aggregate ports even though the `physical-port` keyword is provided in the CLI. The `pagp learn-method` command and the `pagp port-priority` command have no effect on the device hardware, but they are required for PAgP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the device is a physical learner, we recommend that you configure the device as a physical-port learner by using the `pagp learn-method physical-port` interface configuration command. Set the load-distribution method based on the source MAC address by using the `port-channel load-balance src-mac` global configuration command. The device then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the `pagp learn-method` command in this situation.

Layer 2 EtherChannel Configuration Guidelines, on page 749

PAgP Interaction with Other Features

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAgP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created (through the `interface port-channel` global configuration command).

PAgP sends and receives PAgP PDUs only from ports that are up and have PAgP enabled for the auto or desirable mode.

Link Aggregation Control Protocol

The LACP is defined in IEEE 802.3ad and enables Cisco devices to manage Ethernet channels between devices that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the device or device stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single device port.

LACP Modes

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.</td>
</tr>
<tr>
<td>passive</td>
<td>Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets.</td>
</tr>
</tbody>
</table>

Both the active and passive LACP modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the active mode can form an EtherChannel with another port that is in the active or passive mode.
- A port in the passive mode cannot form an EtherChannel with another port that is also in the passive mode because neither port starts LACP negotiation.
LACP and Link Redundancy

LACP port-channel operation, bandwidth availability, and link redundancy can be further refined with the LACP port-channel min-links and the LACP max-bundle features.

The LACP port-channel min-links feature:

- Configures the minimum number of ports that must be linked up and bundled in the LACP port channel.
- Prevents a low-bandwidth LACP port channel from becoming active.
- Causes an LACP port channel to become inactive if there are too few active members ports to supply the required minimum bandwidth.

The LACP max-bundle feature:

- Defines an upper limit on the number of bundled ports in an LACP port channel.
- Allows hot-standby ports with fewer bundled ports. For example, in an LACP port channel with five ports, you can specify a max-bundle of three, and the two remaining ports are designated as hot-standby ports.

- Configuring the LACP Max Bundle Feature (CLI), on page 760
- Configuring LACP Hot-Standby Ports: Example, on page 772
- Configuring the LACP Port Channel Min-Links Feature (CLI), on page 762

LACP Interaction with Other Features

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created through the interface port-channel global configuration command.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

EtherChannel On Mode

EtherChannel on mode can be used to manually configure an EtherChannel. The on mode forces a port to join an EtherChannel without negotiations. The on mode can be useful if the remote device does not support PAgP or LACP. In the on mode, a usable EtherChannel exists only when the devices at both ends of the link are configured in the on mode.
Ports that are configured in the on mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the on mode.

⚠️ Caution

You should use care when using the on mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

## Load-Balancing and Forwarding Methods

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the device.

You configure the load-balancing and forwarding method by using the `port-channel load-balance` and the `port-channel load-balance extended` global configuration commands.

## MAC Address Forwarding

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host’s MAC address of the incoming packet. Therefore, packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular device. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

- EtherChannel Configuration Guidelines, on page 748
- Layer 2 EtherChannel Configuration Guidelines, on page 749
- Default EtherChannel Configuration, on page 747
Layer 3 EtherChannel Configuration Guidelines, on page 750

**IP Address Forwarding**

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel. Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular device. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

**Load-Balancing Advantages**

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the device in the network and the kind of traffic that needs to be load-distributed.

*Figure 59: Load Distribution and Forwarding Methods*

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the device EtherChannel ensures that the device uses all available bandwidth to the router. The router is configured for destination-based forwarding because
the large number of workstations ensures that the traffic is evenly distributed from the router EtherChannel.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

EtherChannel and Device Stacks

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active device removes the failed stack member device ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a device is added to an existing stack, the new device receives the running configuration from the active device and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAgP or LACP configuration on a winning device stack is not affected, but the PAgP or LACP configuration on the losing device stack is lost after the stack reboots.

Device Stack and PAgP

With PAgP, if the active device fails or leaves the stack, the standby device becomes the new active device. A spanning-tree reconvergence is not triggered unless there is a change in the EtherChannel bandwidth. The new active device synchronizes the configuration of the stack members to that of the active device. The PAgP
configuration is not affected after an active device change unless the EtherChannel has ports residing on the old active device.

**Device Stacks and LACP**

With LACP, the system ID uses the stack MAC address from the active device. When an active device fails or leaves the stack and the standby device becomes the new active device change, the LACP system ID is unchanged. By default, the LACP configuration is not affected after the active device changes.

**Default EtherChannel Configuration**

The default EtherChannel configuration is described in this table.

**Table 63: Default EtherChannel Configuration**

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

- Do not try to configure more than 128 EtherChannels on the device or device stack.
- Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
- Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
- Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
- Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the `shutdown` interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.
- When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:
  - Allowed-VLAN list
  - Spanning-tree path cost for each VLAN
  - Spanning-tree port priority for each VLAN
  - Spanning-tree Port Fast setting
- Do not configure a port to be a member of more than one EtherChannel group.
- Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same device or on different devices in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.
- Do not configure a secure port as part of an EtherChannel or the reverse.
- Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.
• If EtherChannels are configured on device interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a device by using the `dot1x system-auth-control` global configuration command.

• If cross-stack EtherChannel is configured and the device stack partitions, loops and forwarding issues can occur.

Layer 2 EtherChannel Configuration Guidelines

When configuring Layer 2 EtherChannels, follow these guidelines:

• Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.

• An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAgP is set to the `auto` or `desirable` mode.

• Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

Auto-LAG

The auto-LAG feature provides the ability to auto create EtherChannels on ports connected to a switch. By default, auto-LAG is disabled globally and is enabled on all port interfaces. The auto-LAG applies to a switch only when it is enabled globally.

On enabling auto-LAG globally, the following scenarios are possible:

- All port interfaces participate in creation of auto EtherChannels provided the partner port interfaces have EtherChannel configured on them. For more information, see the "The supported auto-LAG configurations between the actor and partner devices" table below.
- Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.
- When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:
Table 64: The supported auto-LAG configurations between the actor and partner devices

<table>
<thead>
<tr>
<th>Actor/Partner</th>
<th>Active</th>
<th>Passive</th>
<th>Auto</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Passive</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Auto</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels.

You cannot add any configurations in an existing auto created EtherChannel. To add, you should first convert it into a manual EtherChannel by executing the `port-channel<channel-number> persistent`.

Note

Auto-LAG uses the LACP protocol to create auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

Auto-LAG Configuration Guidelines

Follow these guidelines when configuring the auto-LAG feature.

- When auto-LAG is enabled globally and on the port interface, and if you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.

- A port interface will not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.

- When auto-LAG is enabled and auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.

- The auto-LAG is supported only on Layer 2 EtherChannel. It is not supported on Layer 3 interface and Layer 3 EtherChannel.

- The auto-LAG is supported on cross-stack EtherChannel.

How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

Configuring Layer 2 EtherChannels (CLI)

You configure Layer 2 EtherChannels by assigning ports to a channel group with the `channel-group` interface configuration command. This command automatically creates the port-channel logical interface.
**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `switchport mode {access | trunk}`
4. `switchport access vlan vlan-id`
5. `channel-group channel-group-number mode {auto [non-silent] | desirable [non-silent] | on } | { active | passive}`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| **Step 2** interface interface-id  
Example:  
Device(config)# interface gigabitethernet2/0/1 | Specifies a physical port, and enters interface configuration mode.  
Valid interfaces are physical ports.  
For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group.  
For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode. |
| **Step 3** switchport mode {access | trunk}  
Example:  
Device(config-if)# switchport mode access | Assigns all ports as static-access ports in the same VLAN, or configure them as trunks.  
If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094. |
| **Step 4** switchport access vlan vlan-id  
Example:  
Device(config-if)# switchport access vlan 22 | (Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094. |
| **Step 5** channel-group channel-group-number mode {auto [non-silent] | desirable [non-silent] | on } | { active | passive}  
Example:  
Device(config-if)# channel-group 5 mode auto | Assigns the port to a channel group, and specifies the PAgP or the LACP mode.  
For *channel-group-number*, the range is 1 to 128.  
For *mode*, select one of these keywords:  
  - **auto** — Enables PAgP only if a PAgP device is detected.  
    It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives |
but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **desirable** — Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **on** — Forces the port to channel without PAgP or LACP. In the **on** mode, an EtherChannel exists only when a port group in the **on** mode is connected to another port group in the **on** mode.

- **non-silent** — (Optional) If your device is connected to a partner that is PAgP-capable, configures the device port for nonsilent operation when the port is in the **auto** or **desirable** mode. If you do not specify **non-silent**, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

- **active** — Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.

- **passive** — Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.

**Step 6**

**Example:**

```
Device(config-if)# end
```

Returns to privileged EXEC mode.

Configuring Layer 3 EtherChannels (CLI)

Follow these steps to assign an Ethernet port to a Layer 3 EtherChannel. This procedure is required.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. no ip address
5. no switchport
6. channel-group channel-group-number mode { auto [ non-silent ] | desirable [ non-silent ] | on } | { active | passive }
7. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 configure terminal | Enters global configuration mode. |
| Example:                  |         |
| Device# configure terminal|         |

| Step 3 interface interface-id | Specifies a physical port, and enters interface configuration mode. Valid interfaces include physical ports. For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group. For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode. |
| Example:                      |         |
| Device(config)# interface gigabitethernet 1/0/2 |         |

| Step 4 no ip address | Ensures that there is no IP address assigned to the physical port. |
| Example:             |         |
### Command or Action

| Device(config-if)# no ip address |

### Step 5

**no switchport**

**Example:**

Device(config-if)# no switchport

### Purpose

Puts the port into Layer 3 mode.

### Step 6

**channel-group channel-group-number mode { auto [ non-silent ] | desirable [ non-silent ] | on | { active | passive }**

**Example:**

Device(config-if)# channel-group 5 mode auto

Assigns the port to a channel group, and specifies the PAgP or the LACP mode.

**For mode**, select one of these keywords:

- **auto**—Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **desirable**—Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.

- **on**—Forces the port to channel without PAgP or LACP. In the on mode, an EtherChannel exists only when a port group in the on mode is connected to another port group in the on mode.

- **non-silent**—(Optional) If your device is connected to a partner that is PAgP capable, configures the device port for nonsilent operation when the port is in the auto or desirable mode. If you do not specify non-silent, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

- **active**—Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.

- **passive**—Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.
Configuring EtherChannel Load-Balancing (CLI)

You can configure EtherChannel load-balancing to use one of several different forwarding methods. This task is optional.

**SUMMARY STEPS**

1. **configure terminal**
2. **port-channel load-balance**
   ```
   [ dst-ip | dst-mac | dst-mixed-ip-port | dst-port | extended
   [ dst-ip | dst-mac | dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port
   ```
3. **end**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
| **port-channel load-balance**
   ```
   [ dst-ip | dst-mac | dst-mixed-ip-port | dst-port | extended
   [ dst-ip | dst-mac | dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port
   ```
| **Example:** |  |
| Device(config)# port-channel load-balance src-mac |  |
## Configuring EtherChannel Extended Load-Balancing (CLI)

Configure EtherChannel extended load-balancing when you want to use a combination of load-balancing methods.

This task is optional.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ipv6-label</code></td>
<td>Specifies the IPv6 flow label.</td>
</tr>
<tr>
<td><code>l3,proto</code></td>
<td>Specifies the Layer 3 protocol.</td>
</tr>
<tr>
<td><code>src-dst-ip</code></td>
<td>Specifies the source and destination host IP address.</td>
</tr>
<tr>
<td><code>src-dst-mac</code></td>
<td>Specifies the source and destination host MAC address.</td>
</tr>
<tr>
<td><code>src-dst-mixed-ip-port</code></td>
<td>Specifies the source and destination host IP address and TCP/UDP port.</td>
</tr>
<tr>
<td><code>src-dst-port</code></td>
<td>Specifies the source and destination TCP/UDP port.</td>
</tr>
<tr>
<td><code>src-ip</code></td>
<td>Specifies the source host IP address.</td>
</tr>
<tr>
<td><code>src-mac</code></td>
<td>Specifies the source MAC address of the incoming packet.</td>
</tr>
<tr>
<td><code>src-mixed-ip-port</code></td>
<td>Specifies the source host IP address and TCP/UDP port.</td>
</tr>
<tr>
<td><code>src-port</code></td>
<td>Specifies the source TCP/UDP port.</td>
</tr>
</tbody>
</table>

### Step 3

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.
### SUMMARY STEPS

1. configure terminal
2. port-channel load-balance extended [ dst-ip | dst-mac dst-port | ipv6-label | l3proto | src-ip | src-mac | src-port ]
3. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> port-channel load-balance extended [ dst-ip</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# port-channel load-balance extended dst-ip dst-mac src-ip</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring the PAgP Learn Method and Priority (CLI)

This task is optional.

### SUMMARY STEPS

1. configure terminal
2. `interface interface-id`
3. `pagp learn-method physical-port`
4. `pagp port-priority priority`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  ```configure terminal```  
  **Example:**  
  `Device# configure terminal` | Enters global configuration mode. |
| **Step 2**
  ```interface interface-id```  
  **Example:**  
  `Device(config)# interface gigabitethernet 1/0/2` | Specifies the port for transmission, and enters interface configuration mode. |
| **Step 3**
  ```pagp learn-method physical-port```  
  **Example:**  
  `Device(config-if)# pagp learn-method physical port` | Selects the PAgP learning method. By default, aggregate-port learning is selected, which means the device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives. Selects physical-port to connect with another device that is a physical learner. Make sure to configure the port-channel load-balance global configuration command to src-mac. The learning method must be configured the same at both ends of the link. |
| **Step 4**
  ```pagp port-priority priority```  
  **Example:**  
  `Device(config-if)# pagp port-priority 200` | Assigns a priority so that the selected port is chosen for packet transmission. For priority, the range is 0 to 255. The default is 128. The higher the priority, the more likely that the port will be used for PAgP transmission. |
| **Step 5**
  ```end```  
  **Example:**  
  `Device(config-if)# end` | Returns to privileged EXEC mode. |

Configuring LACP Hot-Standby Ports

When LACP is enabled, the software, by default, tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time; the remaining eight links are placed in hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.

You can override the default behavior by specifying the maximum number of active ports in a channel, in which case, the remaining ports become hot-standby ports. For example, if you specify a maximum of five ports in a channel, up to 11 ports become hot-standby ports.

If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the device MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

Configuring the LACP Max Bundle Feature (CLI)

When you specify the maximum number of bundled LACP ports allowed in a port channel, the remaining ports in the port channel are designated as hot-standby ports.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of LACP ports in a port channel. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface port-channel channel-number
3. lACP max-bundle max-bundle-number
4. end

### Configuring LACP Port-Channel Standalone Disable

To disable the standalone EtherChannel member port state on a port channel, perform this task on the port channel interface:

### SUMMARY STEPS

1. `configure terminal`
2. `interface port-channel channel-group`
3. `port-channel standalone-disable`
4. `end`
5. `show etherchannel`
Configuring the LACP Port Channel Min-Links Feature (CLI)

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

To configure the minimum number of links that are required for a port channel. Perform the following tasks.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface port-channel channel-number
4. port-channel min-links min-links-number
5. end
### Detailed Steps

<table>

### Configuring the LACP System Priority (CLI)

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the **lacp system-priority** global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Follow these steps to configure the LACP system priority. This procedure is optional.
**SUMMARY STEPS**

1. enable
2. configure terminal
3. lacp system-priority *priority*
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

- Default EtherChannel Configuration, on page 747
- Layer 2 EtherChannel Configuration Guidelines, on page 749
- Monitoring EtherChannel, PAgP, and LACP Status, on page 769

**Configuring the LACP Port Priority (CLI)**

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the `show etherchannel summary` privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).
If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Follow these steps to configure the LACP port priority. This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. lACP port-priority priority
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

Monitoring EtherChannel, PAgP, and LACP Status

You can display EtherChannel, PAgP, and LACP status using the commands listed in this table.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`clear lacp {channel-group-number counters</td>
<td>clears LACP channel-group information and traffic counters.}</td>
</tr>
</tbody>
</table>
Command | Description
---|---
```
clear pagp { channel-group-number counters | counters }
```
Clears PAgP channel-group information and traffic counters.

```
show etherchannel [ channel-group-number { detail | load-balance | port | port-channel | protocol | summary }] | {detail | load-balance | port | port-channel | protocol | auto | summary }
```
Displays EtherChannel information in a brief, detailed, and one-line summary form. Also displays the load-balance or frame-distribution scheme, port, port-channel, protocol, and Auto-LAG information.

```
show pagp [ channel-group-number ] { counters | internal | neighbor }
```
Displays PAgP information such as traffic information, the internal PAgP configuration, and neighbor information.

```
show pagp [ channel-group-number ] dual-active
```
Displays the dual-active detection status.

```
show lacp [ channel-group-number ] { counters | internal | neighbor | sys-id }
```
Displays LACP information such as traffic information, the internal LACP configuration, and neighbor information.

```
show running-config
```
Verifies your configuration entries.

```
show etherchannel load-balance
```
Displays the load balance or frame distribution scheme among ports in the port channel.

## Configuration Examples for Configuring EtherChannels
### Configuring Layer 2 EtherChannels: Examples

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAgP mode **desirable**:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1-2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode desirable non-silent
Device(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode **active**:
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode passive
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# switchport mode access
Device(config-if)# switchport access vlan 10
Device(config-if)# channel-group 5 mode passive
Device(config-if)# exit

PoE or LACP negotiation errors may occur if you configure two ports from switch to the access point (AP). This scenario can be avoided if the port channel configuration is on the switch side. For more details, see the following example:

interface Port-channel1
  switchport access vlan 20
  switchport mode access
  switchport nonegotiate
  no port-channel standalone-disable  <--this one
  spanning-tree portfast

If the port reports LACP errors on port flap, you should include the following command as well: **no errdisable detect cause pagp-flap**

---

**Configuring Layer 3 EtherChannels: Examples**

This example shows how to configure a Layer 3 EtherChannel. It assigns two ports to channel 5 with the LACP mode **active**:

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
This example shows how to configure a cross-stack Layer 3 EtherChannel. It assigns two ports on stack member 2 and one port on stack member 3 to channel 7 using LACP active mode:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 7 mode active
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# no ip address
Device(config-if)# no switchport
Device(config-if)# channel-group 7 mode active
Device(config-if)# exit
```

### Configuring LACP Hot-Standby Ports: Example

This example shows how to configure an Etherchannel (port channel 2) that will be active when there are at least three active ports, will comprise up to seven active ports and the remaining ports (up to nine) as hot-standby ports:

```
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# port-channel min-links 3
Device(config-if)# lACP max-bundle 7
```

### Configuring Auto LAG: Examples

This example shows how to configure Auto-LAG on a switch

```
device> enable
device# configure terminal
device (config)# port-channel auto
device (config-if)# end
device# show etherchannel auto
```

The following example shows the summary of EtherChannel that was created automatically.

```
device# show etherchannel auto
Flags:  D - down  P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby (LACP only)
        R - Layer3  S - Layer2
        U - in use  f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
```
w - waiting to be aggregated
d - default port
A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators: 1

Group Port-channel Protocol Ports
-----------------------------------------------
1 Po1(SU) LACP Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)

The following example shows the summary of auto EtherChannel after executing the `port-channel 1 persistent` command.

device# **port-channel 1 persistent**

device# **show etherchannel summary**

Switch# **show etherchannel summary**

Flags: D - down P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3 S - Layer2
U - in use f - failed to allocate aggregator
M - not in use, minimum links not met
u - unsuitable for bundling
w - waiting to be aggregated
d - default port
A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators: 1

Group Port-channel Protocol Ports
-----------------------------------------------
1 Po1(SU) LACP Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another device.

- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

Caution

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.
Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

Modes of Operation

UDLD supports two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

Related Topics

- Enabling UDLD Globally (CLI), on page 779
- Enabling UDLD on an Interface (CLI), on page 780

Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
- One of the fiber strands in the cable is disconnected.
In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heartbeat whose presence guarantees the health of the link. Conversely, the loss of the heartbeat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

---

Note

Udld is enabled with udld aggressive mode globally. When Rx cable or Tx is cable from switch1, then the switch1 and switch2 ports will go into Not connected state. They do not go to error disabled state. Also the port does not show any light if you check the physical connection.

Switch1 (Tx) ________________________ (Rx) Switch2
Switch1 (Rx) ________________________ (Tx) Switch2

Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

---

Related Topics

- Enabling UDLD Globally (CLI), on page 779
- Enabling UDLD on an Interface (CLI), on page 780

---

Neighbor Database Maintenance

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the device receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the device receives a new hello message before an older cache entry ages, the device replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the device is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.
Event-Driven Detection and Echoing

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

- Enabling UDLD Globally (CLI), on page 779
- Enabling UDLD on an Interface (CLI), on page 780

UDLD Reset Options

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The `udld reset` interface configuration command.
- The `shutdown` interface configuration command followed by the `no shutdown` interface configuration command restarts the disabled port.
- The `no udld {aggressive | enable}` global configuration command followed by the `udld {aggressive | enable}` global configuration command reenables the disabled ports.
- The `no udld port` interface configuration command followed by the `udld port [aggressive]` interface configuration command reenables the disabled fiber-optic port.
- The `errdisable recovery cause udld` global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the `errdisable recovery interval interval` global configuration command specifies the time to recover from the UDLD error-disabled state.

</tbody>
</table>
How to Configure UDLD

### Enabling UDLD Globally (CLI)

Follow these steps to enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic ports on the device.

#### SUMMARY STEPS

1. `configure terminal`
2. `udld {aggressive | enable | message time message-timer-interval}`
3. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> udld {aggressive</td>
<td>enable</td>
</tr>
<tr>
<td>Example: Device(config)# udld enable message time 10</td>
<td></td>
</tr>
</tbody>
</table>

- **aggressive**—Enables UDLD in aggressive mode on all fiber-optic ports.
- **enable**—Enables UDLD in normal mode on all fiber-optic ports on the device. UDLD is disabled by default.
- An individual interface configuration overrides the setting of the `udld enable` global configuration command.
- **message time message-timer-interval**—Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are detected to be bidirectional. The range is from 1 to 90 seconds; the default value is 15.

**Note** This command affects fiber-optic ports only. Use the `udld` interface configuration command to enable UDLD on other port types.
### Enabling UDLD on an Interface (CLI)

Follow these steps either to enable UDLD in the aggressive or normal mode or to disable UDLD on a port.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `udld port [aggressive]`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

### Purpose

Command or Action

Device(config-if)# **udld port aggressive**

- **udld port**—Enables UDLD in normal mode on the specified port.
- **udld port aggressive**—(Optional) Enables UDLD in aggressive mode on the specified port.

**Note** Use the no **udld port** interface configuration command to disable UDLD on a specified fiber-optic port.

### Step 4

**end**

Example:

Device(config-if)# **end**

Returns to privileged EXEC mode.

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Device for Access Point Discovery

- Ensure that the Control and Provisioning of Wireless Access Points (CAPWAP) UDP ports 5246 and 5247 (similar to the Lightweight Access Point Protocol (LWAPP) UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the device.

- If access control lists (ACLs) are in the control path between the device and its access points, you must open new protocol ports to prevent access points from being stranded.

- If an access point is in the UP state and its IP address changes, the access point tears down the existing CAPWAP tunnel and rejoins the device.
• Access points must be discovered by a device before they can become an active part of the network. The lightweight access points support the following device discovery processes:
  • Layer 3 CAPWAP discovery—You can enable this feature on different subnets from the access point. This feature uses IP addresses and UDP packets rather than the MAC addresses used by Layer 2 discovery.
  • Locally stored device IP address discovery—If the access point was previously associated to a device, the IP addresses of the primary, secondary, and tertiary devices are stored in the access point’s nonvolatile memory. This process of storing device IP addresses on an access point for later deployment is called priming the access point.
  • DHCP server discovery—This feature uses DHCP option 43 to provide device IP addresses to the access points. Cisco switches support a DHCP server option that is typically used for this capability.
  • DNS discovery—The access point can discover devices through your domain name server (DNS). You must configure your DNS to return device IP addresses in response to CISCO-CAPWAP-CONTROLLER.localdomain, where localdomain is the access point domain name. When an access point receives an IP address and DNS information from a DHCP server, it contacts the DNS to resolve CISCO-CAPWAP-CONTROLLER.localdomain. When the DNS sends a list of device IP addresses, the access point sends discovery requests to the devices.

Restrictions for Configuring the Device for Access Point Discovery

• Ensure that the devices are configured with the correct date and time. If the date and time configured on the device precedes the creation and installation date of certificates on the access points, the access point fails to join the device.

• During the discovery process, access points that are supported by the Cisco device, such as the 1140, 1260, 3500, 1040, 1600, 2600, or 3600 query only for Cisco devices.

Information About Configuring the Device for Access Point Discovery

In a CAPWAP environment, a lightweight access point discovers a device by using CAPWAP discovery mechanisms and then sends a CAPWAP join request to the device. The device sends a CAPWAP join response to the access point that allows the access point to join the device. When the access point joins the device, the device manages its configuration, firmware, control transactions, and data transactions.

Access Point Communication Protocols

Cisco lightweight access points use the IETF standard CAPWAP to communicate with the device and other lightweight access points on the network.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a device to manage a collection of wireless access points. CAPWAP is implemented in device for these reasons:
• To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP
• To manage RFID readers and similar devices
• To enable devices to interoperate with third-party access points in the future

Viewing Access Point Join Information

Join statistics for an access point that sends a CAPWAP discovery request to the device at least once are maintained on the device even if the access point is rebooted or disconnected. These statistics are removed only when the device is rebooted or when you choose to clear the statistics.

Troubleshooting the Access Point Join Process

Access points can fail to join a device for many reasons such as a RADIUS authorization is pending, self-signed certificates are not enabled on the device, the access point and device’s regulatory domains do not match, and so on.

You can configure the access points to send all CAPWAP-related errors to a syslog server. You do not need to enable any debug commands on the device because all of the CAPWAP error messages can be viewed from the syslog server itself.

The state of the access point is not maintained on the device until it receives a CAPWAP join request from the access point, so it can be difficult to determine why the CAPWAP discovery request from a certain access point was rejected. In order to troubleshoot such joining issues without enabling CAPWAP debug commands on the device, the device collects information for all access points that send a discovery message to this device and maintains information for any access points that have successfully joined this device.

The device collects all join-related information for each access point that sends a CAPWAP discovery request to the device. Collection begins when the first discovery message is received from the access point and ends when the last configuration payload is sent from the device to the access point.

When the device is maintaining join-related information for the maximum number of access points, it does not collect information for any more access points.

You can also configure a DHCP server to return a syslog server IP address to the access point using option 7 on the server. The access point then starts sending all syslog messages to this IP address.

You can configure the syslog server IP address through the access point CLI, if the access point is not connected to the device by entering the `capwap ap log-server syslog_server_IP_address` command.

When the access point joins a device for the first time, the device pushes the global syslog server IP address (the default is 255.255.255.255) to the access point. After that, the access point sends all syslog messages to this IP address, until it is overridden by one of the following scenarios:

• The access point is still connected to the same device, and you changed the global syslog server IP address configuration on the device by using the `ap syslog host Syslog_Server_IP_Address` command. In this case, the device pushes the new global syslog server IP address to the access point.

• The access point is still connected to the same device, and you configured a specific syslog server IP address for the access point on the device by using the `ap name Cisco_AP syslog host Syslog_Host_IP_Address` command. In this case, the device pushes the new specific syslog server IP address to the access point.
How to Configure Access Point Discovery

Configuring the Syslog Server for Access Points (CLI)

SUMMARY STEPS

1. `show ap config global`
2. `show ap name Cisco_AP config general`

DETAILED STEPS

<table>

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example

For more information about the AP join process, see *DHCP OPTION 43 for Lightweight Cisco Aironet Access Points Configuration Example*.

Configuring AP Pass Through

Information About AP Pass Through

AP pass through allows all the access points connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join another controller on the network.

Prior to this release, all access points connected Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches would be terminated on the device when the wireless management vlan is turned on.

Unsupported access points connected to the device were unable join a controller on a different vlan. AP pass through allows the connected AP to join another wireless controller on the network by assigning different vlan.

The advantages of AP pass through are:

- Allows partial deployment of Cisco New Generation Wireless Controllers where some APs are connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches but other APs continue to join other controllers on the network.

- The APs that are not supported on the Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches are allowed to join other controllers on the network.

- The wireless LAN controller is used to provide access to both wired and wireless guests. AP Pass through allows the AP to pass through Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join any other controller when wired guest accessing is turned on.

Configuring AP Pass Through

All access points on VLANs other than the one with supported access points will be put into the AP pass-through mode and will not terminate on the Device.

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>

<tr>
<td><code>Device(config)# wireless management interface vlan10</code></td>
<td>Sets the 10-Gigabit Ethernet interface. The command prompt changes from (config)# to (config-if)#.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 3**

interface GigabitEthernet1/0/1  
Example:  
`Device(config)# interface TenGigabitEthernet1/0/1`  
Sets the 10-Gigabit Ethernet interface. The command prompt changes from (config)# to (config-if)#.  

**Step 4**

description Supported AP switchport access `vlan_id`  
Example:  
`Device(config-if)# switchport access vlan10`  
Specifies the VLAN for which this access port will carry traffic. |

**Step 5**

description Unsupported AP switchport access `vlan_id`  
Example:  
`Device(config-if)# switchport access vlan20`  
Configures the ports that are connected to the unsupported access points with a vlan other than the wireless management VLAN. |
Configuring Data Encryption

• Finding Feature Information, on page 793
• Prerequisites for Configuring Data Encryption, on page 793
• Restrictions for Configuring Data Encryption, on page 793
• Information About Data Encryption, on page 794
• How to Configure Data Encryption, on page 794
• Configuration Examples for Configuring Data Encryption, on page 795

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Data Encryption

• Cisco 1260, 3500, 3600, 801, 1140, 1310, and 1520 series access points support Datagram Transport Layer Security (DTLS) data encryption.
• You can use the device to enable or disable DTLS data encryption for a specific access point or for all access points.
• Non-Russian customers who use the Cisco device do not need a data DTLS license.

Restrictions for Configuring Data Encryption

• Encryption limits throughput at both the device and the access point, and maximum throughput is desired for most enterprise networks.
• If your device does not have a data DTLS license and if the access point associated with the device has DTLS enabled, the data path will be unencrypted.
In images that do not have a DTLS license, the DTLS commands are not available.

Information About Data Encryption

The device enables you to encrypt Control and Provisioning of Wireless Access Points (CAPWAP) control packets (and optionally, CAPWAP data packets) that are sent between the access point and the device using DTLS. DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS. CAPWAP control packets are management packets exchanged between a device and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data). If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

How to Configure Data Encryption

Configuring Data Encryption (CLI)

SUMMARY STEPS

1. configure terminal
2. ap link-encryption
3. end
4. show ap link-encryption
5. show wireless dtls connections

DETAILED STEPS

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count

- You can configure the retransmission intervals and retry count both at a global and a specific access point level. A global configuration applies these configuration parameters to all the access points. Alternatively, when you configure the retransmission level and retry count at a specific access point level, the values are applied to that particular access point. The access point specific configuration has a higher precedence than the global configuration.
Information About Retransmission Interval and Retry Count

The device and the access points exchange packets using the Control and Provisioning of Wireless Access Points (CAPWAP) reliable transport protocol. For each request, a response is defined. This response is used to acknowledge the receipt of the request message. Response messages are not explicitly acknowledged; therefore, if a response message is not received, the original request message is retransmitted after the retransmit interval. If the request is not acknowledged after a maximum number of retransmissions, the session is closed and the access points reassociate with another device.

How to Configure Access Point Retransmission Interval and Retry Count

Configuring the Access Point Retransmission Interval and Retry Count (CLI)

SUMMARY STEPS

1. enable
2. configure terminal
3. ap capwap retransmit interval interval_time
4. ap capwap retransmit count count_value
5. end
6. ap name Cisco_AP capwap retransmit interval interval_time

Configuring Authentication for Access Points

• Finding Feature Information, on page 807
• Prerequisites for Configuring Authentication for Access Points, on page 807
• Restrictions for Configuring Authentication for Access Points, on page 808
• Information about Configuring Authentication for Access Points, on page 808
• How to Configure Authentication for Access Points, on page 808
• Configuration Examples for Configuring Authentication for Access Points, on page 814

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Authentication for Access Points

• You can set a global username, password, and enable password for all access points that are currently joined to the device and any that join in the future inherit as they join the device. If desired, you can override the global credentials and assign a unique username, password, and enable password for a specific access point.

• After an access point joins the device, the access point enables console port security, and you are prompted for your username and password whenever you log into the access point’s console port. When you log in, you are in nonprivileged mode, and you must enter the enable password in order to use the privileged mode.

• The global credentials that you configure on the device are retained across device and access point reboots. They are overwritten only if the access point joins a new device that is configured with a global username and password. If the new device is not configured with global credentials, the access point retains the global username and password configured for the first device.

• You must track the credentials used by the access points. Otherwise, you might not be able to log into an access point’s console port. If you need to return the access points to the default Cisco/Cisco username
and password, you must clear the device’s configuration and the access point’s configuration to return them to factory-default settings. To reset the default access point configuration, enter the `ap name Cisco_AP mgmtuser username Cisco password Cisco` command. Entering the command does not clear the static IP address of the access point. Once the access point rejoins a device, it adopts the default Cisco/Cisco username and password.

- You can configure global authentication settings for all access points that are currently joined to the device and any that join in the future. If desired, you can override the global authentication settings and assign unique authentication settings for a specific access point.

- This feature is supported on the following hardware:
  - All Cisco switches that support authentication.
  - Cisco Aironet 1140, 1260, 1310, 1520, 1600, 2600, 3500, and 3600 access points

### Restrictions for Configuring Authentication for Access Points

- The device name in the AP configuration is case sensitive. Therefore, make sure to configure the exact system name on the AP configuration. Failure to do this results in the AP fallback not working.

### Information about Configuring Authentication for Access Points

Cisco IOS access points are shipped from the factory with `Cisco` as the default enable password. This password allows users to log into the nonprivileged mode and enter the `show` and `debug` commands that pose a security threat to your network. You must change the default enable password to prevent unauthorized access and to enable users to enter configuration commands from the access point’s console port.

You can configure 802.1X authentication between a lightweight access point and a Cisco switch. The access point acts as an 802.1X supplicant and is authenticated by the switch where it uses EAP-FAST with anonymous PAC provisioning.

### How to Configure Authentication for Access Points

#### Configuring Global Credentials for Access Points (CLI)

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ap mgmtuser username user_name password 0 password secret 0 secret_value`
4. `end`
5. `ap name Cisco_AP mgmtuser username user_name password password secret secret`
6. `show ap summary`
7. `show ap name Cisco_AP config general`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ap mgmtuser username user_name password 0 password secret 0 secret_value</td>
<td>Configures the global username and password and enables the password for all access points that are currently joined to the device and any access points that join the device in the future. In the command, the parameter 0 specifies that an unencrypted password will follow and 8 specifies that an AES encrypted password will follow.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ap mgmtuser apusr1 password appass 0 secret 0 appass1</td>
<td></td>
</tr>

### Configuration Examples for Configuring Authentication for Access Points

#### Displaying the Authentication Settings for Access Points: Examples

This example shows how to display the authentication settings for all access points that join the device:

```
Device# show ap summary
Number of APs................................. 1
Global AP User Name......................... globalap
Global AP Dot1x User Name............... globalDot1x
```

This example shows how to display the authentication settings for a specific access point:

```
Device# show ap name AP02 config dot11 24ghz general
Cisco AP Identifier......................... 0
Cisco AP Name............................... TSIM_AP2
... 
AP Dot1x User Mode.......................... AUTOMATIC
AP Dot1x User Name......................... globalDot1x
```
Converting Autonomous Access Points to Lightweight Mode

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Converting Autonomous Access Points to Lightweight Mode

- Access points that are converted to lightweight mode do not support Wireless Domain Services (WDS). Converted access points communicate only with Cisco wireless LAN devices and cannot communicate with WDS devices. However, the device provides functionality that is equivalent to WDS when the access point associates to it.

- All Cisco lightweight access points support 16 Basic Service Set Identifiers (BSSIDs) per radio and a total of 16 wireless LANs per access point. When a converted access point associates to a device, only
wireless LANs with IDs 1 through 16 are pushed to the access point unless the access point is a member of an access point group.

• Access points that are converted to lightweight mode must get an IP address and discover the device using DHCP, DNS, or IP subnet broadcast.

Information About Autonomous Access Points Converted to Lightweight Mode

You can convert autonomous Cisco Aironet access points to lightweight mode. When you upgrade the access points to lightweight mode, the access point communicates with the device and receives a configuration and software image from the device.

Reverting from Lightweight Mode to Autonomous Mode

After you convert an autonomous access point to lightweight mode, you can convert the access point from a lightweight unit back to an autonomous unit by loading a Cisco IOS release that supports autonomous mode (Cisco IOS Release 12.3(7)JA or earlier releases). If the access point is associated with a device, you can use the device to load the Cisco IOS release. If the access point is not associated to a device, you can load the Cisco IOS release using TFTP. In either method, the access point must be able to access a TFTP server that contains the Cisco IOS release to be loaded.

Using DHCP Option 43 and DHCP Option 60

Cisco Aironet access points use the type-length-value (TLV) format for DHCP option 43. You must program the DHCP servers to return the option based on the access point’s DHCP Vendor Class Identifier (VCI) string (DHCP option 60).

See the product documentation for your DHCP server for instructions on configuring DHCP option 43. The Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode document contains example steps for configuring option 43 on a DHCP server.

If the access point is ordered with the Service Provider Option - AIR-OPT60-DHCP selected, the VCI string for that access point will be different than those strings listed in the previous table. The VCI string has the following suffix: ServiceProvider. For example, a 1260 with this option returns this VCI string: Cisco AP c1260-ServiceProvider.

Note

The device IP address that you obtain from the DHCP server should be a unicast IP address. Do not configure the device IP address as a multicast address when configuring DHCP option 43.

How Converted Access Points Send Crash Information to the Device

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the device. If the unit rebooted because of a crash, the device pulls up the crash file using existing CAPWAP messages and
stores it in the device flash memory. The crash information copy is removed from the access point flash memory when the device pulls it from the access point.

### Uploading Memory Core Dumps from Converted Access Points

By default, access points converted to lightweight mode do not send memory core dumps to the device. This section provides instructions to upload access point core dumps using the device GUI or CLI.

### Displaying MAC Addresses for Converted Access Points

There are some differences in the way that controllers display the MAC addresses of converted access points on information pages in the controller GUI:

- On the AP Summary page, the controller lists the Ethernet MAC addresses of converted access points.
- On the AP Detail page, the controller lists the BSS MAC addresses and Ethernet MAC addresses of converted access points.
- On the Radio Summary page, the device lists converted access points by the radio MAC address.

### Configuring a Static IP Address for a Lightweight Access Point

If you want to specify an IP address for an access point rather than having one assigned automatically by a DHCP server, you can use the controller GUI or CLI to configure a static IP address for the access point. Static IP addresses are generally used only for deployments with a limited number of APs.

An access point cannot discover the device using domain name system (DNS) resolution if a static IP address is configured for the access point, unless you specify a DNS server and the domain to which the access point belongs. You can configure these parameters using either the device CLI or the GUI.

---

**Note**

If you configure an access point to use a static IP address that is not on the same subnet on which the access point’s previous DHCP address was, the access point falls back to a DHCP address after the access point reboots. If the access point falls back to a DHCP address, enter the `show ap config general Cisco_AP CLI` command to show that the access point is using a fallback IP address. However, the GUI shows both the static IP address and the DHCP address, but it does not identify the DHCP address as a fallback address.
How to Convert a Lightweight Access Point Back to an Autonomous Access Point

Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)

**SUMMARY STEPS**

1. `enable`
2. `ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> <code>Device# enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename</code></td>
<td>Converts the lightweight access point back to autonomous mode.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> <code>Device# ap name AP02 tftp-downgrade 10.0.0.1 tsrvname</code></td>
<td>Note After entering this command, you must wait until the access point reboots and then reconfigure the access point using the CLI or GUI.</td>
</tr>
</tbody>
</table>

Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)

**Step 1** Configure the PC on which your TFTP server software runs with a static IP address in the range of 10.0.0.2 to 10.0.0.30.

**Step 2** Make sure that the PC contains the access point image file (such as `c1140-k9w7-tar.123-7.JA.tar` for a 1140 series access point) in the TFTP server folder and that the TFTP server is activated.

**Step 3** Rename the access point image file in the TFTP server folder to `c1140-k9w7-tar.default` for a 1140 series access point.

**Step 4** Connect the PC to the access point using a Category 5 (CAT5) Ethernet cable.

**Step 5** Disconnect power from the access point.

**Step 6** Press and hold the **MODE** button while you reconnect power to the access point.

**Note** The **MODE** button on the access point must be enabled.

**Step 7** Hold the **MODE** button until the status LED turns red (approximately 20 to 30 seconds), and release the **MODE** button.

**Step 8** Wait until the access point reboots as indicated by all LEDs turning green followed by the Status LED blinking green.
Step 9  After the access point reboots, reconfigure the access point using the GUI or the CLI.

Authorizing Access Points (CLI)

SUMMARY STEPS

1. enable

### Recovering the Access Point Using the TFTP Recovery Procedure

**Step 1**  
Download the required recovery image from Cisco.com (ap3g2-k9w8-tar.152-2.JA.tar) and install it in the root directory of your TFTP server.
Step 2  Connect the TFTP server to the same subnet as the target access point and power-cycle the access point. The access point boots from the TFTP image and then joins the device to download the oversized access point image and complete the upgrade procedure.

Step 3  After the access point has been recovered, you can remove the TFTP server.

Configuration Examples for Converting Autonomous Access Points to Lightweight Mode

Displaying the IP Address Configuration for Access Points: Example

This example shows how to display the IP address configuration for the access point:

```
Device# show ap name AP03 dot11 24ghz config general
Cisco AP Identifier.............. 4
Cisco AP Name............................. AP6
IP Address Configuration.................. Static IP assigned
IP Address................................ 10.10.10.118
IP NetMask................................ 255.255.255.0
Gateway IP Addr........................... 10.10.10.1
Domain.................................... Domain1
Name Server................................ 10.10.10.205
... 
```

Displaying Access Point Crash File Information: Example

This example shows how to display access point crash file information. Using this command, you can verify whether the file is downloaded to the device:

```
Device# show ap crash-file
Local Core Files:
lrad_AP1130.rdump0 (156)
```

The number in parentheses indicates the size of the file. The size should be greater than zero if a core dump file is available.
Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges

A WGB is a mode that can be configured on an autonomous Cisco IOS access point to provide wireless connectivity to a lightweight access point on behalf of clients that are connected by Ethernet to the WGB access point. A WGB connects a wired network over a single wireless segment by learning the MAC addresses of its wired clients on the Ethernet interface and reporting them to the lightweight access point using Internet Access Point Protocol (IAPP) messaging. The WGB provides wireless access connectivity to wired clients by establishing a single wireless connection to the lightweight access point.

When a Cisco WGB is used, the WGB informs the access points of all the clients that it is associated with. The device is aware of the clients that are associated with the access point. When non-Cisco WGBs are used, the device has no information about the IP address of the clients on the wired segment behind the WGB. Without this information, the device drops the following types of messages:

- ARP REQ from the distribution system for the WGB client.
- ARP RPLY from the WGB client.
- DHCP REQ from the WGB client.
Monitoring the Status of Workgroup Bridges

• DHCP RPLY for the WGB client.

Monitoring the Status of Workgroup Bridges

The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. enable
2. show wireless wgb summary
3. show wireless wgb mac-address wgb_mac_address detail

DETAILED STEPS

<table>

<td>Device# show wireless wgb mac-address 00:0d:ed:dd:25:82 detail</td>
</tr>
</tbody>
</table>

Debugging WGB Issues (CLI)

The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. enable
2. debug iapp all
3. debug iapp error
4. debug iapp packet
## Lightweight Access Point

### Debugging WGB Issues (CLI)

5. `debug mobility handoff [switch switch_number]`
6. `debug dhcp`
7. `debug dot11 mobile`
8. `debug dot11 state`

### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  enable
  
  **Example:**
  
  `Device# enable`
  
  Enters privileged EXEC mode. |
| **Step 2**
  `debug iapp all`
  
  **Example:**
  
  `Device# debug iapp all`
  
  Enables debugging for IAPP messages. |
| **Step 3**
  `debug iapp error`
  
  **Example:**
  
  `Device# debug iapp error`
  
  Enables debugging for IAPP error events. |
| **Step 4**
  `debug iapp packet`
  
  **Example:**
  
  `Device# debug iapp packet`
  
  Enables debugging for IAPP packets. |
| **Step 5**
  `debug mobility handoff [switch switch_number]`
  
  **Example:**
  
  `Device# debug mobility handoff`
  
  Enables debugging for any roaming issues. |
| **Step 6**
  `debug dhcp`
  
  **Example:**
  
  `Device# debug dhcp`
  
  Debug an IP assignment issue when DHCP is used. |
| **Step 7**
  `debug dot11 mobile`
  
  **Example:**
  
  `Device# debug dot11 mobile`
  
  Enables dot11/mobile debugging. Debug an IP assignment issue when static IP is used. |
| **Step 8**
  `debug dot11 state`
  
  **Example:**
  
  `Device# debug dot11 state`
  
  Enables dot11/state debugging. Debug an IP assignment issue when static IP is used. |
Configuration Examples for Configuring Workgroup Bridges

WGB Configuration: Example

This example shows how to configure a WGB access point using static WEP with a 40-bit WEP key:

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# dot11 ssid WGB_with_static_WEP
Device(config-ssid)# authentication open
Device(config-ssid)# guest-mode
Device(config-ssid)# exit
Device(config)# interface dot11Radio 0
Device(config)# station-role workgroup-bridge
Device(config-if)# encry mode wep 40
Device(config-if)# encry key 1 size 40 0 1234567890
Device(config-if)# ssid WGB_with_static_WEP
Device(config-if)# end

Verify that the WGB is associated to an access point by entering this command on the WGB:

show dot11 association

Information similar to the following appears:

Device# show dot11 associations
802.11 Client Stations on Dot11Radio0:
SSID [FCVTESTING] :
MAC Address IP address Device Name Parent State
000b.8581.6aee 10.11.12.1 WGB-client map1 - Assoc
Configuring Probe Request Forwarding

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Probe Request Forwarding

Probe requests are 802.11 management frames that are sent by clients to request information about the capabilities of Service Set Identifiers (SSIDs). By default, access points forward acknowledged probe requests to the device for processing. Acknowledged probe requests are probe requests for SSIDs that are supported by the access point. If desired, you can configure access points to forward both acknowledged and unacknowledged probe requests to the device. The device can use the information from unacknowledged probe requests to improve the location accuracy.

How to Configure Probe Request Forwarding (CLI)

The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. configure terminal
2. wireless probe filter
3. wireless probe filter num_probes interval
4. `end`
5. `show wireless probe`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> wireless probe filter</td>
<td>Enables or disables the filtering of probe requests forwarded from an access point to the device.</td>
</tr>
<tr>
<td>Example: <code>Device(config)# wireless probe filter</code></td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong> If you enable probe filtering, the default filter setting, the access point forwards only acknowledged probe requests to the device. If you disable probe filtering, the access point forwards both acknowledged and unacknowledged probe requests to the device.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> wireless probe filter <code>num_probes interval</code></td>
<td>Limits the number of probe requests sent to the device per client per access point radio in a given interval. You must specify the following arguments with this command:</td>
</tr>
<tr>
<td>Example: <code>Device(config)# wireless probe filter 5 5</code></td>
<td></td>

Optimizing RFID Tracking

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Optimizing RFID Tracking on Access Points

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

How to Optimize RFID Tracking on Access Points

Optimizing RFID Tracking on Access Points (CLI)

SUMMARY STEPS

1. `ap name Cisco_AP mode monitor submode none`
2. `ap name Cisco_AP dot11 24ghz shutdown`
3. `ap name Cisco_AP monitor-mode tracking-opt`
4. `ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]}`
5. `ap name Cisco_AP no dot11 24ghz shutdown`
6. `show ap monitor-mode summary`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**<br>`ap name Cisco_AP mode monitor submode none`<br>*Example:*<br>Device# ap name 3602a mode monitor submode none | Specifies the monitor submode for the access point as none.  
*Note* A warning message indicates that changing the access point’s mode will cause the access point to reboot and prompts you to specify whether you want to continue by entering `Y`.  
After you enter `Y`, the access point reboots. |
| **Step 2**<br>`ap name Cisco_AP dot11 24ghz shutdown`<br>*Example:*<br>Device# ap name AP01 dot11 24ghz shutdown | Disables the access point radio. |
| **Step 3**<br>`ap name Cisco_AP monitor-mode tracking-opt`<br>*Example:*<br>Device# ap name TSIM_AP1 monitor-mode tracking-opt | Configures the access point to scan only the Dynamic Channel Assignment (DCA) channels supported by its country of operation.  
*Note* To disable tracking optimization for an access point, enter the `ap name Cisco_AP monitor-mode tracking-opt no-optimization` command. |
| **Step 4**<br>`ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]}`<br>*Example:*<br>Device# ap name AP01 monitor-mode dot11b fast-channel 1 2 3 4 | Chooses up to four specific 802.11b channels to be scanned by the access point.  
*Note* In the United States, you can assign any value from 1 to 11 (inclusive) to the channel variable. Other countries support additional channels. You must assign at least one channel. |
| **Step 5**<br>`ap name Cisco_AP no dot11 24ghz shutdown`<br>*Example:*<br>Device# ap name AP01 no dot11 24ghz shutdown | Enables the access point radio. |

CHAPTER 53

Configuring Country Codes

• Finding Feature Information, on page 835
• Prerequisites for Configuring Country Codes, on page 835
• Information About Configuring Country Codes, on page 836
• How to Configure Country Codes (CLI), on page 836
• Configuration Examples for Configuring Country Codes, on page 839

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Country Codes

• Generally, you configure one country code per device; you configure one code that matches the physical location of the device and its access points. You can configure up to 20 country codes per device. This multiple-country support enables you to manage access points in various countries from a single device.

• When the multiple-country feature is used, all devices that are going to join the same RF group must be configured with the same set of countries, configured in the same order.

• Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.

• The country list configured on the RF group leader determines which channels the members would operate on. This list is independent of which countries have been configured on the RF group members.

• For devices in the Japan regulatory domain, you must have had one or more Japan country codes (JP, J2, or J3) configured on your device at the time you last booted your device.

• For devices in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your device.
Information About Configuring Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio’s broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- JP—Allows only -J radios to join the controller
- J2—Allows only -P radios to join the controller
- J3—Uses the -U frequencies but allows -U, -P and -Q (other than 1550/1600/2600/3600) radios to join the WLC
- J4—Allows 2.4G JPU and 5G PQU to join the controller.

Note

The 1550, 1600, 2600, and 3600 APs require J4.

See the Channels and Maximum Power Settings for Cisco Aironet Lightweight Access Points document for the list of channels and power levels supported by access points in the Japanese regulatory domains.

How to Configure Country Codes (CLI)

Note

The procedure to perform this task using the device GUI is not currently available.

SUMMARY STEPS

1. enable
2. show wireless country supported
3. configure terminal
4. ap dot11 24ghz shutdown
5. ap dot11 5ghz shutdown
6. ap country country_code
7. end
8. show wireless country channels
9. configure terminal
10. no ap dot11 5ghz shutdown
11. no ap dot11 24ghz shutdown
12. end
13. ap name Cisco_AP shutdown
14. configure terminal
15. ap country country_code
16. end
17. ap name Cisco_AP no shutdown

CHAPTER 54

Configuring Link Latency

- Finding Feature Information, on page 841
- Prerequisites for Configuring Link Latency, on page 841
- Restrictions for Configuring Link Latency, on page 841
- Information About Configuring Link Latency, on page 842
- How to Configure Link Latency, on page 843
- How to Configure TCP MSS, on page 845
- Performing a Link Test (CLI), on page 846
- Configuration Examples for Configuring Link Latency, on page 847

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Link Latency

- The device displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the device is up or can be cleared and allowed to restart.

- You can configure link latency for a specific access point using the device GUI or CLI or for all access points joined to the device using the CLI.

Restrictions for Configuring Link Latency

- Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the device. It does not measure network latency or ping responses.
Information About Configuring Link Latency

You can configure link latency on the device to measure the link between an access point and the device. You can use this feature with all access points that are joined to the device where the link can be a slow or unreliable WAN connection.

TCP MSS

If the client’s maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the device or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the ping link test, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the CCX link test, the device can also test the link quality in the access point-to-client direction. The device issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and device. Not only can the access point or device initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or device.

The device shows the link-quality metrics for CCX link tests in both directions (out—the access point to the client; in—the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)
- Total number of packets that are retried
- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet
The controller shows this metric regardless of direction:

- Link test request-reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCXv4 or v5, the controller performs a ping link test on the client. If a client supports CCXv4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

# How to Configure Link Latency

## Configuring Link Latency (CLI)

### SUMMARY STEPS

1. enable
2. configure terminal
3. ap link-latency
4. ap tcp-adjust-mss size size
5. show ap name Cisco_AP config general
6. ap name Cisco_AP link-latency [reset]
7. show ap name Cisco_AP config general

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enters privileged EXEC mode.</td>
</tr>
</tbody>
</table>
|        | Example:
|        | Device# enable                        |                                                                         |
| Step 2 | configure terminal                    | Enters global configuration mode.                                       |
|        | Example:
<p>|        | Device# configure terminal            |                                                                         |
| Step 3 | ap link-latency                       | Enables link latency for all access points that are currently associated with the device. |
|        | Example:                              |                                                                         |
|        | Device(config)# ap link-latency       |                                                                         |
|        | <strong>Note</strong>                              | To disable link latency for all the access points that are associated with the device, use the <strong>no ap link-latency</strong> command. |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong></td>
<td>These commands enable or disable link latency only for access points that are currently joined to the device. You have to enable or disable link latency for the access points that join in the future.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To enable or disable link latency for specific access points that are associated with the device, enter the following commands in Privileged EXEC mode:</td>
</tr>
<tr>
<td>• <strong>ap name Cisco_AP</strong></td>
<td>link-latency—Enables link latency.</td>
</tr>
<tr>
<td>• <strong>ap name Cisco_AP no</strong></td>
<td>link-latency—Disables link latency.</td>
</tr>
</tbody>
</table>

**Step 4**  
**ap tcp-adjust-mss size** *size*  
**Example:**  
Device(config)# ap tcp-adjust-mss size 537

Configure TCP MSS adjust size for all access points. The range is from 536 to 1363.

**Step 5**  
**show ap name Cisco_AP config general**  
**Example:**  
Device(config)# show ap name AP02 config general

Displays the general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

The output of this command contains the following link latency results:

• **Current Delay**—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.

• **Maximum Delay**—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.

• **Minimum Delay**—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.

**Step 6**  
**ap name Cisco_AP link-latency [reset]**  
**Example:**  
Device(config)# ap name AP02 link-latency reset

Clears the current, minimum, and maximum link latency statistics on the device for a specific access point.
### How to Configure TCP MSS

**Configuring TCP MSS (CLI)**

#### SUMMARY STEPS

1. configure terminal
2. `ap tcp-adjust-mss size size_value`
3. reload
4. `show ap tcp-adjust-mss`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>ap tcp-adjust-mss size size_value</code></td>
<td>Enables the TCP MSS on the particular access point that you specify.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# <code>ap tcp-adjust-mss size 537</code></td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To enable TCP MSS on all the access points that are associated with the device, enter the <code>ap tcp-adjust-mss size size_value</code> command, where the size parameter is from 536 to 1363 bytes. The default value varies for different clients.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>reload</td>
<td>Reboots the device in order for your change to take effect.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# <code>reload</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>show ap tcp-adjust-mss</code></td>
<td>Displays the current TCP MSS setting for all the access points that are associated with the device.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# <code>show ap tcp-adjust-mss</code></td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To display the TCP MSS settings that correspond to a specific access point, enter the <code>show ap name Cisco_AP tcp-adjust-mss</code> command.</td>
<td></td>
</tr>
</tbody>
</table>
Performing a Link Test (CLI)

The procedure to perform this task using the device GUI is not currently available.

### SUMMARY STEPS

1. `test wireless linktest mac_address`
2. `configure terminal`
3. `wireless linktest frame-size frame_size`
4. `wireless linktest number-of-frames number_of_frames`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>test wireless linktest mac_address</code></td>
<td>Runs a link test.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# test wireless linktest</td>
<td></td>
</tr>
<tr>
<td>00:0d:88:c5:8a:d1</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**                           |                                                   |
| `configure terminal`                 | Enters global configuration mode.                |
| Example:                             |                                                   |
| Device# configure terminal           |                                                   |

| **Step 3**                           |                                                   |
| `wireless linktest frame-size frame_size` | Configures the link test frame size for each packet. |
| Example:                             |                                                   |
| Device(config)# wireless linktest    |                                                   |
| frame-size 41                        |                                                   |

| **Step 4**                           |                                                   |
| `wireless linktest number-of-frames number_of_frames` | Configures the number of frames to send for the link test. |
| Example:                             |                                                   |
| Device(config)# wireless linktest    |                                                   |
| number-of-frames 50                  |                                                   |

| **Step 5**                           |                                                   |
| `end`                                | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |
| Example:                             |                                                   |
| Device(config)# end                   |                                                   |
Configuration Examples for Configuring Link Latency

Running a Link Test: Example

This example shows how to run a link test:

```
Device# test wireless linktest 6470.0227.ca55
Device# show wireless linktest statistic

Link Test to 64700227CA55 with 500 frame-size.
Client MAC Address : 6470.0227.ca55
AP Mac Address     : 44e4.d901.19c0
Link Test Packets Sent : 20
Link Test Packets Received : 20
Link Test Pkts Lost(Total/AP->Clnt/Clnt->AP) : 0/0/0
Link Test Pkts round trip time (min/max/avg) : 9ms/31ms/14ms
RSSI at AP (min/max/average) : -53dBm/-51dBm/-52dBm
RSSI at Client (min/max/average) : -48dBm/-40dBm/-44dBm
```

Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

```
Device# show ap name AP01 config general

Configuring Power over Ethernet

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Power over Ethernet

When an access point that has been converted to lightweight mode (such as an AP1262) access point is powered by a power injector that is connected to a Cisco pre-Intelligent Power Management (pre-IPM) switch, you must configure Power over Ethernet (PoE), which is also known as inline power.

How to Configure Power over Ethernet

Configuring Power over Ethernet (CLI)

SUMMARY STEPS

1. ap name Cisco_AP power injector installed
2. ap name Cisco_AP power injector override
3. ap name Cisco_AP power injector switch-mac-address switch_mac_address
4. show ap name Cisco_AP config general
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> ap name <em>Cisco_AP</em> power injector installed</td>
<td>Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# ap name AP02 power injector installed</td>
<td></td>
</tr>
</tbody>
</table>

**Note** Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail.

| **Step 2** ap name *Cisco_AP* power injector override | Removes the safety checks and allows the access point to be connected to any switch port. You can use this command if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The access point assumes that a power injector is always connected. If you relocate the access point, it continues to assume that a power injector is present. |
| **Example:** Device# ap name AP02 power injector override |

**Note** Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail.

| **Step 3** ap name *Cisco_AP* power injector switch-mac-address *switch_mac_address* | Sets the MAC address of the switch port that has a power injector. |
| **Example:** Device# ap name AP02 power injector switch-mac-address 10a.2d.5c.3d |

**Note** Enter this command if you know the MAC address of the connected switch port and do not want to automatically detect it using the installed option.

| **Step 4** show ap name *Cisco_AP* config general | Displays common information that includes the PoE settings for a specific access point. |
| **Example:** Device# show ap name AP02 config general |

**Note** The Power Type/Mode text box shows “degraded mode” if the access point is not operating at full power.

## Configuration Examples for Configuring Power over Ethernet

### Displaying Power over Ethernet Information: Example

This example shows how to display common information that includes the PoE settings for a specific access point:

Device# show ap name AP01 config general

Cisco AP Identifier.............. 1
Cisco AP Name..................... AP1
...
PoE Pre-Standard Switch......... Enabled
PoE Power Injector MAC Addr..... Disabled
Power Type/Mode.................. PoE/Low Power (degraded mode)
...
Displaying Power over Ethernet Information: Example

Mobility

• Information About Mobility, on page 855
• Mobility Network Elements, on page 861
• Mobility Control Protocols, on page 865
• Configuring Mobility, on page 873
Information About Mobility

- Overview, on page 855
- Wired and Wireless Mobility, on page 856
- Features of Mobility, on page 856
- Sticky Anchoring for Low Latency Roaming, on page 858
- Bridge Domain ID and L2/L3 Roaming, on page 858
- Link Down Behavior, on page 858
- Platform Specific Scale Requirement for the Mobility Controller, on page 858

Overview

The delivers more services at access layer other than merely providing increased speeds and feeds. Wireless services is now integrated with the switch, which ensures that the access layer switch terminates the wireless users data plane, thereby delivering on the promise of Cisco's unified architecture. Unification implies that mobility services are provided to both wireless and wired stations.

The provides seamless roaming, which requires transparency of the network configuration and deployment options to the client.

From the end user's perspective, any mobility event must not change its IP address, its default router or DHCP server. This means that as stations roam, they must be able to

- Send an ARP to their default router, or
- Transmit a DHCP request to the server that had previously assigned their address.

From the infrastructure's perspective, as mobility events occur, the station's traffic must follow its current point of attachment, which can either be a mobility agent (MA) or mobility controller (MC). This must be true regardless of whether the station has moved to a network that is configured for a different subnet. The period from which the station is not receiving traffic following its mobility event must be as short as possible, even below 40 ms whenever possible, which includes any authentication procedures that are required.

From the infrastructure's perspective, the mobility management solution must have four main components, and all of these functions must be performed within the constraints of roaming:

- Initial Association—This function is used to identify the user's new point of attachment in the network.
- Context Transfer—This function is used to transfer state information associated with the station. This ensures that the station's static and real-time policies, including security and application ACLs, and services, remain the same across handoffs.
• Handoff—This function is used to signal that the station's point of attachment has changed, and control of the station should be relinquished by the previous access.

• Data Plane—This function is typically tied to the handoff process, and ensures that the station's traffic continues to be delivered and received from the station without any noticeable performance degradation.

Caution

If you have configured virtual routing and forwarding (VRF) on wireless management interface VLAN, the mobility feature may not work as expected.

Wired and Wireless Mobility

One of the key features of the Converged access solution (applicable to both the Cisco Catalyst 3850 Switch and Cisco WLC 5700 Series Controller) is its ability to provide a device with an IP address and maintain its session persistence, across mobility events from ethernet connections to wireless and vice-versa. This feature allows users to remain on an ethernet network when possible, and make use of the freedom of mobility associated with wireless when necessary.

This feature leverages support from both the client and the infrastructure and uses the two factor authentication-device and user. The device authentication credentials is cached in the mobility controller (MC). When a device transitions across link layers, the device credentials is validated, and if a match is found, the MC ensures that the same IP address is assigned to the new interface.

Features of Mobility

• Mobility Controller (MC)—The controller provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and policy based control protocols, such as RADIUS. This eliminates the need for the infrastructure servers to maintain a user's location as it transitions throughout the network. The MC sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members. A sub-domain is synonymous to the MC that forms it. Each sub-domain consists of an MC and zero or more access switches that have AP's associated to them.

• Mobility Agents (MA)—A mobility agent is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. A mobility agent is the wireless component that maintains client mobility state machine for a mobile client that is connected via an AP to the device that the MA is running on.

• Mobility Sub Domain—It is an autonomous portion of the mobility domain network. A mobility sub-domain comprises of a single mobility controller and its associated mobility agents (MAs).

Note

Even when more than one mobility controller is present, only one MC can be active at any given time.

A mobility sub-domain is the set of devices managed by the active mobility controller. A mobility sub-domain comprises of a set of mobility agents and associated access points.
• Mobility Group— A collection of mobility controllers (MCs) across which fast roaming is supported. The concept of mobility group is the same as a collection of buildings in a campus across which frequent roaming is expected.

• Mobility Domain— A collection of mobility sub-domains across which mobility is supported. The term mobility domain may be the same as a campus network.

• Mobility Oracle (MO)—The mobility oracle acts as the point of contact for mobility events that occur across mobility sub-domains. It also maintains a local database of each station in the entire mobility domain, their home and current sub-domain. A mobility domain includes one or more mobility oracle, though only one would be active at any given time.

• Mobility Tunnel Endpoint (MTE)— The mobility tunnel endpoint (MTE) provides data plane services for mobile devices through the use of tunneling. This minimizes the impact of roaming events on the network by keeping the user's point of presence on the network a constant.

• Point of Attachment— A station's point of attachment is where its data path is initially processed upon entry in the network. This could either be the access switch that is currently providing it service, or the wireless LAN controller.

• Point of Presence— A station's point of presence is the place in the network where the station is being advertised. For instance, if an access switch is advertising reachability to the station via a routing protocol, the interface on which the route is being advertised is considered the station's point of presence.

• Switch Peer Group (SPG)— A peer group is a statically created list of neighboring access switches between which fast mobility services is provided. A peer group limits the scope of interactions between switches during handoffs to only those that are geographically proximate.

• Station—A user's device that connects to and requests service from the network. The device may have a wired, wireless or both interfaces.

• Switch in the same SPG—A peer switch that is part of the peer group of the local switch.

• Switch outside the SPG—A peer access switch that is not part of the local switch's peer group.

• Foreign Mobility Controller— The mobility controller providing mobility management service for the station in a foreign mobility sub-domain. The foreign mobility controller acts as a liaison between access switches in the foreign sub-domain and the mobility controller in the home domain.

• Foreign Mobility Sub-Domain— The mobility sub-domain, controlled by a mobility controller, supporting a station which is anchored in another mobility sub-domain.

• Foreign Switch— The access switch in the foreign mobility sub-domain currently providing service to the station.

• Anchor Mobility Controller— The mobility controller providing a single point of control and mobility management service for stations in their home mobility sub-domain.

• Anchor Mobility Sub-Domain— The mobility sub-domain, controlled by a mobility controller, for a station where its IP address was assigned.

• Anchor Switch— The switch in the home mobility sub-domain that last provided service to a station.
Sticky Anchoring for Low Latency Roaming

Sticky Anchoring ensures low roaming latency from the client's point of presence is maintained at the switch where the client initially joins the network. It is expensive to apply client policies at a switch for a roaming client. There can be considerable delay as it involves contacting the AAA server for downloadable ACLs which is not acceptable for restoring time sensitive client traffic.

To manage this delay, when the client roams between APs connected to different switches, irrespective of whether it is an intra sub-domain roam or inter sub-domain roam, the client traffic is always tunneled to the switch where the client first associates. The client is anchored at its first point of attachment for its lifetime in the network.

This behavior is enabled by default. You can also disable this behavior to allow the client anchoring only for inter-subnet roams. This configuration is per WLAN config and is available under the WLAN config mode. The customer can configure different SSIDs for time sensitive and non time sensitive applications.

Bridge Domain ID and L2/L3 Roaming

Bridge domain ID provides the mobility nodes with information to decide on specific roam type, either as L2 or L3 roam. It also allows the network administrators to reuse the VLAN IDs across network distribution. When the VLAN IDs do not have the associated subnet configurations, they may require additional parameter to use in conjunction with VLAN ID. The network administrator ensures that the given VLAN under the same bridge domain ID are associated with the unique subnet. The mobility nodes will first check for the bridge domain ID for the given node and the VLAN ID associated with the client to identify the roam type. The bridge domain ID and the VLAN ID must be same to treat a roam as L2 roam.

The bridge domain ID is configured for each SPG when creating a SPG and later on the MC. The bridge domain ID could be same for more than one SPG and all the MAs under the SPG will share the same bridge domain ID. This information is pushed to the MAs as part of the configuration download when MA comes up initially. If the bridge domain ID is modified when the system is up, it will be pushed to all the MAs in the modified SPG and will take immediate effect for the future roams.

Link Down Behavior

This section provides information about data synchronization between MA-MC and MC-MO when MC or MO faces downtime in absence of redundancy manager. When Keepalive is configured between MA-MC or MC-MO the clients database is synchronized between the MO and the MCs and the MC and its MAs respectively.

Platform Specific Scale Requirement for the Mobility Controller

The Mobility Controller (MC) role is supported on a number of different platforms like, the Cisco WLC 5700 Series, CUWN and Catalyst 3850 Switches. The scale requirements on these three platforms are summarized in the table below:
<table>
<thead>
<tr>
<th>Scalability</th>
<th>Catalyst 3850 as MC</th>
<th>Catalyst 3650 as MC</th>
<th>Cisco WLC 5700 as MC</th>
<th>CUWN 5508 as MC</th>
<th>WiSM2 as MC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max number of MC in Mobility Domain</td>
<td>8</td>

- Guest Controller, on page 863

Mobility Agent

A Mobility Controller resides on the switch. It is both, control path and data path entity and is responsible for:

- Handling the mobility events on the switch
- Configuring the datapath elements on the switch for mobility, and
- Communicating with the mobility controller

As MA, the device performs the datapath functions by terminating the CAPWAP tunnels that encapsulate 802.11 traffic sourced by wireless stations.

This allows the device to apply features to wired and wireless traffic in a uniform fashion. As far as device is concerned, 802.11 is just another access medium.

The MA performs the following functions:

- Support the mobility protocol – The MA is responsible for responding in a timely manner, ensuring the device is capable of achieving its roaming budget.
- Point of presence – If the wireless subnets are not available at the MC, the MA assumes the point of presence if the wireless client VLAN is not available at the new point of attachment and tunnel the client traffic accordingly.
- ARP Server – When the network is configured in a layer 2 mode, the MA is responsible for advertising reachability for the stations connected to it. If tunneling is employed, the ARP request is transmitted on behalf of the station through the tunnel, which the point of presence (anchor switch) would bridge onto its uplink interface.
- Proxy IGMP – The MA on the device is responsible for subscribing to multicast groups on behalf of a station after a roaming event has occurred. This information is passed as part of the context to the new device. This ensures the multicast flows follow the user as it roams.
- Routing – When the device is connected to a layer 3 access network, the MA is responsible for injecting routes for the stations that are associated with it for which tunneling is not provided.
• 802.1X Authenticator – The authenticator function is included in the MA, and handles both wired and wireless stations.
• Secure PMK Sharing – When a station successfully authenticates to the network, the MA forwards the PMK to the MC. The MC is responsible for flooding the PMK to all the MAs under its sub-domain and to the peer MCs in the mobility group.

The MA also performs the following datapath functions:

• Mobility tunnel – If tunneling is used, the MA encapsulates and decapsulates packets from the mobility tunnel to the MC, and to other MA in the peer group, if the access switches are serving as points of presence. The MA supports the tunneling of client data traffic between the point of attachment and the point of attachment. The packet format used for other switches is CAPWAP with an 802.3 payload. The MA also supports reassembly and fragmentation for mobility tunnels.
• Encryption – The mobility control traffic between the mobility nodes is DTLS encrypted. The MA also encrypts the CAPWAP control and data (optional) at the point of attachment.
• CAPWAP – The device supports the CAPWAP control and data planes. The device forwarding logic is responsible for terminating the CAPWAP tunnels with 802.11 as well as 802.3 payloads. Since support for large frames (greater than 1500 bytes) is not universally available, the device supports CAPWAP fragmentation and reassembly.

## Mobility Controller

The main function of mobility controller is to coordinate the client roaming beyond a switch peer group. The other features of the mobility controller are:

• Station Database—The Mobility Controller maintains a database of all the clients that are connected within the local mobility sub-domain.
• Mobility Protocol—The MC supports the mobility protocol which ensures the target roaming point responds in a timely manner and achieves the 150ms roaming budget
• Interface to Mobility Oracle—The Mobility Controller acts as a gateway between the and the Mobility Oracle. When the Mobility Controller does not find a match in its local database, it suggests a match for a wireless client entry (in its database) and forwards the request to the Mobility Oracle, which manages the Mobility Domain.

### Note

Mobility Oracle function can be enabled on an MC only if it is supported by the platform.

• ARP Server—When tunneling is employed for a station, its point of presence on the network is the Mobility Tunnel Endpoint (MTE). The Mobility Controller responds to any ARP requests received for the stations it is responsible for.
• Routing—When the Mobility Controller is connected to a layer three network, the Mobility Controller is responsible for injecting routes for the stations it supports into the network.
• Configures MTE—The Mobility Controller is the control point for the for all mobility management related requests. When a change in a station’s point of attachment occurs, the Mobility Controller is responsible for configuring the forwarding policy on the MTE.
• NTP Server—The Mobility Controller acts as an NTP server to the and supports all the nodes to have their clocks synchronized with it.
The Cisco 5700 series WLC and other controller platforms that have the Mobility Controller function enabled by default should not be added to a switch peer group (SPG).

**Mobility Oracle**

The Mobility Oracle coordinates the client roams beyond the subdomain on a need basis and consists of the following features:

- **Station Database**—The Mobility Oracle maintains a database of all stations that are serviced within the mobility domain. This database is populated during the Mobility Oracle's interactions with all the Mobility Controllers, in all of the mobility sub-domains it supports.

- **Interface to Mobility Controller**—When the Mobility Oracle receives a request from a Mobility Controller, it performs a station lookup, and forwards, whenever needed, the request to the proper Mobility Controller.

- **NTP Server**—The Mobility Oracle acts as an NTP server to the Mobility Controllers and synchronizes all the clocks within the mobility domain.

**Guest Controller**

The guest access feature provides guest access to wireless clients. The guest tunnels use the same format as the mobility tunnels. Using the guest access feature, there is no need to configure guest VLANs on the access switch. Traffic from the wired and wireless clients terminates on Guest Controller. Since the guest VLAN is not present on the access switch, the traffic is tunneled to the MTE over the existing mobility tunnel, and then via a guest tunnel to the Guest Controller.

The advantage of this approach is that all guest traffic passes through the MTE before it is tunneled to the Guest Controller. The Guest Controller only needs to support tunnels between itself and all the MTEs.

The disadvantage is that the traffic from the guest client is tunneled twice - once to the MTE and then again to the Guest Controller.

Clients cannot roam to Guest Controllers because roaming is not supported on Guest Controllers. This restriction is applicable only for the IOS-XE guest anchor, and not for AireOS.
Mobility Control Protocols

- About Mobility Control Protocols, on page 865
- Initial Association and Roaming, on page 865
- Initial Association, on page 866
- Intra Switch Handoff, on page 867
- Intra Switch Peer Group Handoff, on page 867
- Inter Switch Peer Group Handoff, on page 868
- Inter Sub Domain Handoff, on page 869
- Inter Mobility Group Handoff, on page 871

About Mobility Control Protocols

The mobility control protocol is used regardless of whether tunneled or routed. The mobility control protocol is used for mobility events between the MO, MC and MA.

The mobility architecture uses both,

- Distributed approach, using the direct communication with the switches in their respective SPG, as well as
- Centralized approach, using the MC and MO.

The goal is to reduce the overhead on the centralized MC, while limiting the interactions between switches to help scale the overall system.

Initial Association and Roaming

The following scenarios are applicable to the mobility management protocol:

- Initial Association
- Intra Switch Roam
- Intra Switch Peer Group Roam
- Inter Switch Peer Group Roam
- Inter Sub-Domain Roam
- Inter Group Roam
The illustration below explains the initial association process followed by the device:

1. When a station initially associates with a mobility agent, the MA performs a lookup to determine whether keying information for key caching is locally available in the MA. If no keying information is available, which is the case when the station first appears in the network, the device prompts the device to authenticate itself to generate the Pairwise Master Key (PMK). The PMK is generated on the client and the RADIUS server side, and the RADIUS sever forwards the PMK to the authenticator, the MA.
2. The MA sends the PMK to the MC.
3. After receiving the PMK from the MA, the MC transmits the PMK to all the MAs in its sub-domain, and to all the other MCs in its mobility group.
4. The mobility group is a single key domain. This ensures that 802.11r compliant stations recognize the key domain, and attempts to utilize the fast transition procedures defined in 802.11r.
The 802.11r protocol defines a key domain, which is a collection of access points that share keying information.

5. (Refer to step 2B in the illustration). Since the station is new to the mobility sub-domain, as indicated by the fact that the PMK is not in the MA local key cache, the MA transmits a mobile announce message to the MC.

6. The MC checks if the client exists in its database. As the client cannot be found, the MC in turn forwards it to the MO, if available.

7. (Refer to step 5 in the illustration). As the station is new to the network, the MO returns a negative response (NACK), which is forwarded by the MC to the device. If the Mobility Oracle is not available then the MC is responsible for not responding to the Mobile Announce.

8. The MA on the device informs the MC about the station's new point of attachment via the Handoff Complete message.

9. The MA then informs the other MAs in its switch peer group (SPG) about the station's new point of attachment via the Handoff Notification message. It is necessary to transmit this notification to the MAs in its SPG to allow local handoff without interacting with the MC. The Handoff Notification message sent to MAs in SPG need not carry all the information in Handoff Complete message sent to the MC.

10. (Refer to step 7B in the illustration). The MC updates its database and forwards the Handoff Complete message to the Mobility Oracle. This ensures that the Mobility Oracle's database is updated to record the station's current home mobility sub-domain.

To eliminate race conditions that could occur with devices moving quickly across device, regardless of whether they are within a mobility sub-domain or not, the messages between MA and MC/MO are time synchronized. This would allow the MC and MO to properly process requests, if they are received out of order.

The Handoff Notification sent to MAs in the SPG are not acknowledged.

Intra Switch Handoff

Mobility events within an MA are completely transparent to the SPG and the MC. When a station moves across APs on the same MA and attempts to perform a fast handoff, the PMK is present on the MA. The MA will complete the fast handoff without invoking any additional signal.

Intra Switch Peer Group Handoff

The switch peer group (SPG) is a group of MAs between which users may roam, and expect fast roaming services. Allowing the MA to handoff directly within a SPG reduces the overhead on the MC as it requires fewer messages to be exchanged.

After the initial association is complete the station moves to another MA belonging to its SPG. In an intra switch peer group roam, the initial association, the stations PMK was forwarded to all MAs in the mobility sub-domain.
The following process explains the intra switch peer group handoff:

1. In the initial association example, the Handoff Notification message is sent to all MAs in its SPG to know the station's current point of attachment.
2. The new MA sends a unicast Mobile Announce message to the previous MA to which the client is associated.
3. After the handoff completion, the new MA transmits a Handoff Complete message to the MC.
4. The new device sends a Handoff Notification to all MA in its own SPG to inform them about the clients new point of presence.

**Inter Switch Peer Group Handoff**

The Intra SPG roams do not cover all possible scenarios and there can be cases where it is possible for mobility events to occur between two MAs that are not in the same SPG.

When a MA does not have any information about a station's current point of attachment, because of the Handoff Notification message getting lost in the network, or because of the the station roaming to an MA that is not in the new SPG, the MA consults the MC. The MC provides information about the clients point of presence within the mobility sub-domain. This eliminates the need to consult all other MCs within the mobility sub-domain.
The image above illustrates an example of a mobility event that occurs across MAs that are not in the same SPG, but within the same mobility sub-domain.

The MA color matches the circle representing its SPG.

1. The new MA will have the PMK for the station, which was forwarded to each MA in the mobility sub-domain upon client initial authentication.
2. Since the MA had not been previously notified of the station's presence on a neighboring MA inside a different SPG transmits the mobile announce to the sub-domain's MC.
3. (Refer to step 2 in the illustration) On receiving the mobile announce message, the MC performs a lookup in its database, and forwards the request to the MA that was previously providing service to the station. This information is known to the MC through a previously received Handoff Complete message sent in a reliable fashion from the old MA.
4. (Refer to step 3 in the illustration) The old MA, shown in green above, transmits a Handoff message directly to the new MA.
5. The old MA needs to notify other MAs within its SPG of the fact that the station has left the group using a Station Left message. This ensures that if the station were to come back to one of the MA, they would be aware of the fact that the station is no longer being serviced by the old MA.
6. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the MC.
7. The new MA then transmits the Handoff Notification to the other MAs within its SPG.

**Inter Sub Domain Handoff**

A sub-domain is an ensemble formed by a mobility controller and the mobility agents it directly manages. An inter sub-domain mobility event implies communication between two mobility controllers. These 2 mobility controllers can be configured with the same mobility group value and recognize each other. They will appear in each other's mobility list, or they can be configured with different mobility group values, and still recognize each other.
When the roaming event occurs across sub-domains between MCs in the same mobility group, the 802.11r key domain advertised by the new APs are the same. Additionally, the client PMK is also transmitted to all MCs upon the client's initial authentication. The new MC does not need to force the client to reauthenticate, and the new MC also knows which previous MC was managing the wireless client mobility.

*Figure 63: Inter Sub Domain Handoff*

The following steps are involved in the inter sub domain handoff, when mobility controllers belong to the same mobility group:

1. When a client's PMK was sent by the initial MA to all the MCs in the mobility group, the new MA already had already received the client PMK from its MC, and re-authentication is not required.
2. The new MA was not notified previously of the station's presence on a neighboring MA inside a different SPG it transmits the mobile announce to the sub-domain's MC.
3. On receiving the mobile announce message, the MC forwards the mobile announce to the MO, which performs a lookup in its database, and forwards the request to the MC that was previously providing service to the station.
4. The previous MC, in turn, forwards the request to the MA that was previously providing service to the station.
5. The old MA, shown in yellow color above, transmits a Handoff message directly to the new MA.
6. The old MA must notify the other MAs within its SPG of the fact that the station has left the SPG using a Station Left message. This ensures that if the station comes back to one of the MA, the MA is aware of the fact that the station is no longer serviced by the old MA.
7. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the new Mobility Controller.
8. The new MA then transmits the Handoff Notification to all other MAs.
9. The new MC then transmits the Handoff Complete to the old MC.
Inter Mobility Group Handoff

A mobility group is formed by MCs sharing the same mobility group name, and knowing each other. Since the roaming event occurs across mobility groups, the 802.11r key domain advertised by the new APs differ. This forces the client to re-authenticate. They are propagated only within a mobility group, and roaming across mobility groups requires the stations to re-authenticate when they cross mobility group boundaries. When the authentication is complete, the PMK that is generated is pushed to the MAs and MCs within the same mobility group. The stations cache the PMK from the previous sub-domain because each PMK is associated to a given sub-domain (802.11y key domain). This ensures that you do not have to re-authenticate when the PMK roams back to the previous sub-domain within the pmk cache timeout interval. The remaining procedure follows the inter-sub-domain handoff steps, except that these steps relate to inter mobility group roaming.
Configuring Mobility

• Configuring Mobility Controller, on page 873
• Configuring Mobility Agent, on page 879

Configuring Mobility Controller

Configuring Converged Access Controllers

Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)

Before you begin

• On the mobility agent, you can only configure the IP address of the mobility controller.
• On the mobility controller, you can define the peer group and the IP address of each peer group member.

SUMMARY STEPS

1. wireless mobility controller
2. wireless mobility controller peer-group SPG1
3. wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr
4. wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr
5. wireless mobility controller peer-group SPG2
6. wireless mobility controller peer-group SPG2 member ip member-ip-addr public-ip public-ip-addr
7. wireless mobility controller peer-group SPG1 bridge-domain-id id

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 wireless mobility controller</td>
<td>Enables the mobility controller functionality on the device. This command is applicable only to the switch. The controller is by default a mobility controller.</td>
</tr>
</tbody>
</table>

Example:

Device(config)# wireless mobility controller
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td><code>wireless mobility controller peer-group SPG1</code>&lt;br&gt;<code>Example:</code>&lt;br&gt;<code>Device(config)# wireless mobility controller peer-group SPG1</code></td>
<td>Creates a peer group named SPG1.</td>
</tr>
</tbody>
</table>
| 3    | `wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr`<br>`Example:`<br>`Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip 10.10.20.2` | Adds a mobility agent to the peer group.  
**Note**  
The 10.10.20.2 is the mobility agent's direct IP address. When NAT is used, use the optional public IP address to enter the mobility agent's NATed address. When NAT is not used, the public IP address is not used and the device displays the mobility agent's direct IP address. |
| 4    | `wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr`<br>`Example:`<br>`Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip 10.10.20.2` | Adds another member to the peer group SPG1. |
| 5    | `wireless mobility controller peer-group SPG2`<br>`Example:`<br>`Device(config)# wireless mobility controller peer-group SPG2` | Creates another peer group SPG2. |
| 6    | `wireless mobility controller peer-group SPG2 member ip member-ip-addr public-ip public-ip-addr`<br>`Example:`<br>`Device(config)# wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip 10.10.10.20` | Adds a member to peer group SPG2. |
| 7    | `wireless mobility controller peer-group SPG1 bridge-domain-id id`<br>`Example:`<br>`Device(config)# wireless mobility controller peer-group SPG1 bridge-domain-id 54` | (Optional) Adds a bridge domain to SPG1 used for defining the subnet-VLAN mapping with other SPGs. |

**Example**

This example shows how to create peer group and add members to it:

```
Device(config)# wireless mobility controller
Device(config)# wireless mobility controller peer-group SPG1
Device(config)# wireless mobility controller peer-group SPG1
Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip
```
### Configuring Local Mobility Group (CLI)

Configuration for wireless mobility groups and mobility group members where the mobility group is a group of MCs.

**Before you begin**

MCs can belong only to one mobility group, and can know MCs in several mobility groups.

#### SUMMARY STEPS

1. wireless mobility group name *group-name*
2. wireless mobility group member ip *member-ip-addr* public-ip *public-ip-addr*
3. wireless mobility group keepalive interval *time-in-seconds*
4. wireless mobility group keepalive count *count*

Device(config)# wireless mobility group keepalive interval 5
Device(config)# wireless mobility group keepalive count 3

Adding a Peer Mobility Group (CLI)

Before you begin
MCs belong to only one group, and can know MCs in several groups.

SUMMARY STEPS

1. wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>wireless mobility group member ip</td>
<td>Adds the member as a peer MC in a different group than the Mygroup.</td>
</tr>
<tr>
<td>member-ip-addr public-ip public-ip-addr</td>
<td></td>
</tr>
<tr>
<td>group group-name</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# wireless mobility</td>
<td></td>
</tr>
<tr>
<td>group member ip member-ip-addr public-</td>
<td></td>
</tr>
<tr>
<td>ip public-ip-addr group group-name</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Optional Parameters for Roaming Behavior

Use this configuration to disable the sticky anchor. This command can also be used, if required, between all MA's and MC's where roaming is expected for the target SSID.

SUMMARY STEPS

1. wlan open21
2. no mobility anchor sticky

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>wlan open21</td>
<td>Configures a WLAN.</td>
</tr>
<tr>
<td></td>

</table>
Pointing the Mobility Controller to a Mobility Oracle (CLI)

Before you begin
You can configure a mobility oracle on a known mobility controller.

SUMMARY STEPS
1. `wireless mobility group member ip member-ip-addr group group-name`
2. `wireless mobility oracle ip oracle-ip-addr`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

  - `wireless mobility group member ip member-ip-addr group group-name`
  
  **Example:**
  
  Device(config)# wireless mobility group member ip 10.10.10.10 group Group3

| **Step 2**

  - `wireless mobility oracle ip oracle-ip-addr`
  
  **Example:**
  
  Device(config)# wireless mobility oracle ip 10.10.10.10

Configuring Guest Controller

A guest controller is used when the client traffic is tunneled to a guest anchor controller in the demilitarized zone (DMZ). The guest client goes through a web authentication process. The web authentication process is optional, and the guest is allowed to pass traffic without authentication too.
Enable the WLAN on the mobility agent on which the guest client connects with the mobility anchor address of the guest controller.

On the guest controller WLAN, which can be Cisco 5500 Series WLC, Cisco WiSM2, or Cisco 5700 Series WLC, configure the IP address of the mobility anchor as its own IP address. This allows the traffic to be tunneled to the guest controller from the mobility agent.

**Note**

With Cisco 5700 Series WLC as the guest anchor controller and Cisco 5500 Series WLC or Cisco WiSM2 as export foreign controller, the guest user role per user is not supported on the Cisco 5700 Series WLC.

### SUMMARY STEPS

1. `wlan wlan-id`
2. `mobility anchor guest-anchor-ip-addr`
3. `client vlan vlan-name`
4. `security open`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong><code>wlan wlan-id</code></td>
<td>Creates a WLAN for the client.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# wlan Mywlan1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>mobility anchor guest-anchor-ip-addr</code></td>
<td>Enables the guest anchors (GA) IP address on the MA.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-wlan)# Mobility anchor 10.10.10.2</td>
<td>Note To enable guest anchor on the mobility controller, you need not enter the IP address. Enter the <code>mobility anchor</code> command in the WLAN configuration mode to enable GA on the mobility controller.</td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>client vlan vlan-name</code></td>
<td>Assigns a VLAN to the client's WLAN.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-wlan)# client vlan gc_ga_vlan1</td>

Example

Device(config)# wlan Mywlan1
Device(config-wlan)# mobility anchor 10.10.10.2
Device(config-wlan)# client vlan gc_ga_vlan1
Device(config-wlan)# security open

Configuring Mobility Agent

Configuring Mobility Agent by Pointing to Mobility Controller (CLI)

Before you begin

- By default, the switches are configured as mobility agents.
Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.

You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.

On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

**SUMMARY STEPS**

1. `configure terminal`
2. `wireless management interface vlan 21`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> wireless management interface vlan 21</td>
<td>Enables the wireless functionality on the device and activates the mobility agent function. This ensures the APs have a place to terminate the CAPWAP tunnel.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device (config)# wireless management interface vlan 21</code></td>
<td></td>
</tr>
</tbody>
</table>

**Example**

This example shows how to add a mobility agent into the mobility group by pointing it to a mobility controller:

```
Device(config)# wireless management interface vlan 21
```

### Configuring the Mobility Controller for the Mobility Agent (CLI)

**SUMMARY STEPS**

1. `wireless mobility controller`
2. `wireless mobility controller ip ip-addr`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> wireless mobility controller</td>
<td>Enables the mobility function on the device.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>wireless mobility controller</code></td>
<td></td>
</tr>
<tr>
<td><code>Example:</code></td>
<td></td>
</tr>
</tbody>
</table>
### Adding a Mobility Controller Role to the Mobility Agent

**SUMMARY STEPS**

1. `wireless mobility controller ip 10.10.21.3`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>wireless mobility controller ip 10.10.21.3</code></td>
<td>Converts the mobility agent to a mobility controller.</td>
</tr>
</tbody>
</table>

**Example**

This example shows how to add the mobility controller role to a mobility agent:

```
Device(config)# wireless mobility controller ip 10.10.21.3
Mobility role changed to Mobility Controller.
Please save config and reboot the whole stack.
```

### Configuring Optional Parameters on a Mobility Agent (CLI)

This section shows how to configure load-balancing on a device.

- By default, the load-balancing is enabled and it cannot be disabled.
• The device supports a maximum of 2000 clients and the default threshold value is fifty percent of client max load.

• When the device reaches its threshold, it redistributes the new clients load to other mobility agents in the same SPG, if their client load is lower.

**SUMMARY STEPS**

1. **wireless mobility load-balance threshold threshold-value**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>wireless mobility load-balance threshold threshold-value</td>
<td>Configures the threshold that triggers load-balancing.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# wireless mobility load-balance threshold 150</td>
<td></td>
</tr>
</tbody>
</table>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.
- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured device.
- All devices configured with the `cns config partial` global configuration command must access the event bus. The DeviceID, as originated on the device, must match the DeviceID of the corresponding device definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

Related Topics

- DeviceID, on page 888
Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured devices can share the same value for ConfigID.
- Within the scope of a single instance of the event bus, no two configured devices can share the same value for DeviceID.

Information About Configuring the Configuration Engine

Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (devices and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
  - Web server
  - File manager
  - Namespace mapping server

- Event service (event gateway)
- Data service directory (data models and schema)

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.
Figure 64: Cisco Configuration Engine Architectural Overview

Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the device. The Configuration Service delivers device and service configurations to the device for initial configuration and mass reconfiguration by logical groups. Devices receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the device and facilitates the communication between the device and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.
NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, cisco.cns.config.load. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured device. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term ConfigID is the unique identifier for a device. Within the scope of the event bus namespace, the term DeviceID is the CNS unique identifier for a device.

ConfigID

Each configured device has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of device CLI attributes. The ConfigID defined on the device must match the ConfigID for the corresponding device definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the device hostname is reconfigured.

DeviceID

Each configured device participating on the event bus has a unique DeviceID, which is analogous to the device source address so that the device can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the device. However, the DeviceID variable and its usage reside within the event gateway adjacent to the device.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the device. The event gateway represents the device and its corresponding DeviceID to the event bus.
The device declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the device.

**Related Topics**

- Prerequisites for Configuring the Configuration Engine, on page 885

### Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the device hostname is reconfigured.

When changing the device hostname on the device, the only way to refresh the DeviceID is to break the connection between the device and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the device sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

**Caution**

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the device acquires *after*, not *before*, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

**Related Topics**

- Refreshing DeviceIDs, on page 900

### Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a device, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the cn=<value> of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the device.

These and other associated attributes (tag value pairs) are set when you run **Setup** on the Cisco Configuration Engine.

### Cisco IOS CNS Agents

The CNS event agent feature allows the device to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the device Cisco IOS software, allow the device to be connected and automatically configured.

**Related Topics**

- Enabling the Cisco IOS CNS Agent, on page 893

### Initial Configuration

When the device first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution
device acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new device and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the device.

The device automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the device loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the device.

The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

**Figure 65: Initial Configuration**

Related Topics
- Enabling an Initial Configuration for Cisco IOS CNS Agent, on page 895
- Monitoring CNS Configurations, on page 903

**Incremental (Partial) Configuration**

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the device. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the device to initiate a pull operation.

The device can check the syntax of the configuration before applying it. If the syntax is correct, the device applies the incremental configuration and publishes an event that signals success to the configuration server. If the device does not apply the incremental configuration, it publishes an event showing an error status. When the device has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

Related Topics
- Enabling a Partial Configuration for Cisco IOS CNS Agent, on page 902
- Monitoring CNS Configurations, on page 903
Synchronized Configuration

When the device receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the device not to save the updated configuration into its NVRAM. The device uses the updated configuration as its running configuration. This ensures that the device configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

Automated CNS Configuration

To enable automated CNS configuration of the device, you must first complete the prerequisites listed in this topic. When you complete them, power on the device. At the setup prompt, do nothing; the device begins the initial configuration. When the full configuration file is loaded on your device, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

Table 67: Prerequisites for Enabling Automatic Configuration

<table>
<thead>
<tr>
<th>Device</th>
<th>Required Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access device</td>
<td>Factory default (no configuration file)</td>
</tr>
<tr>
<td>Distribution device</td>
<td>• IP helper address&lt;br&gt; • Enable DHCP relay agent&lt;br&gt; • IP routing (if used as default gateway)</td>
</tr>

2 A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.
# How to Configure the Configuration Engine

## Enabling the CNS Event Agent

You must enable the CNS event agent on the device before you enable the CNS configuration agent.

Follow these steps to enable the CNS event agent on the device.

### SUMMARY STEPS

1. enable
2. configure terminal
3. `cns event {hostname | ip-address} [port-number] [[keepalive seconds retry-count] [failover-time seconds] [reconnect-time time] | backup]`
4. end
5. show running-config
6. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;Example:&lt;br&gt;Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;Example:&lt;br&gt;Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>**cns event {hostname</td>
</tr>
</tbody>
</table>

### Example:

- For `hostname | ip-address`, enter either the hostname or the IP address of the event gateway.
- (Optional) For `port-number`, enter the port number for the event gateway. The default port number is 11011.
- (Optional) For `keepalive seconds`, enter how often the device sends keepalive messages. For `retry-count`, enter the number of unanswered keepalive messages that the device sends before the connection is terminated. The default for each is 0.
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| end               | • (Optional) For **failover-time seconds**, enter how long the device waits for the primary gateway route after the route to the backup gateway is established.  
|                   | • (Optional) For **reconnect-time time**, enter the maximum time interval that the device waits before trying to reconnect to the event gateway.  
|                   | • (Optional) Enter **backup** to show that this is the backup gateway. (If omitted, this is the primary gateway.) |

**Note** Though visible in the command-line help string, the **encrypt** and the **clock-timeout** **time** keywords are not supported.

### Step 4
**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

### Step 5
**Example:**

```
Device# show running-config
```

Verifies your entries.

### Step 6
**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

**What to do next**

To verify information about the event agent, use the `show cnsevent connections` command in privileged EXEC mode.

To disable the CNS event agent, use the `no cnsevent { ip-address | hostname }` global configuration command.

**Related Topics**

[Event Service](#), on page 887

---

### Enabling the Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent on the device.
Before you begin

You must enable the CNS event agent on the device before you enable this agent.

SUMMARY STEPS

1. enable
2. configure terminal
3. cns config initial \{hostname | ip-address\} \[port-number\]
4. cns config partial \{hostname | ip-address\} \[port-number\]
5. end
6. show running-config
7. copy running-config startup-config
8. Start the Cisco IOS CNS agent on the device.

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> cns config initial {hostname</td>
<td>ip-address} [port-number]</td>
</tr>
<tr>
<td>Example: Device(config)# cns config initial 10.180.1.27 10</td>
<td></td>
</tr>
<tr>
<td>• For {hostname</td>
<td>ip-address}, enter either the hostname or the IP address of the configuration server.</td>
</tr>
<tr>
<td>• (Optional) For port number, enter the port number for the configuration server.</td>
<td></td>
</tr>
<tr>
<td>This command enables the Cisco IOS CNS agent and initiates an initial configuration on the device.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> cns config partial {hostname</td>
<td>ip-address} [port-number]</td>
</tr>
<tr>
<td>Example: Device(config)# cns config partial 10.180.1.27 10</td>
<td></td>
</tr>
<tr>
<td>• For {hostname</td>
<td>ip-address}, enter either the hostname or the IP address of the configuration server.</td>
</tr>
<tr>
<td>• (Optional) For port number, enter the port number for the configuration server.</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Enables the Cisco IOS CNS agent and initiates a partial configuration on the device.</td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>show running-config</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Start the Cisco IOS CNS agent on the device.</td>
</tr>
</tbody>
</table>

**What to do next**

You can now use the Cisco Configuration Engine to remotely send incremental configurations to the device.

</tbody>
</table>
| `cns connect dhcp` | • Enter the `name` of the CNS connect profile.  
  • (Optional) For `retries number`, enter the number of connection retries. The range is 1 to 30. The default is 3.  
  • (Optional) For `retry-interval seconds`, enter the interval between successive connection attempts to the Configuration Engine. The range is 1 to 40 seconds. The default is 10 seconds.  
  • (Optional) For `sleep seconds`, enter the amount of time before which the first connection attempt occurs. The range is 0 to 250 seconds. The default is 0.  
  • (Optional) For `timeout seconds`, enter the amount of time after which the connection attempts end. The range is 10 to 2000 seconds. The default is 120. |
| **Step 8** | **discover** `{controller controller-type | dlci [subinterface subinterface-number] | interface [interface-type] | line line-type}`  
**Example:**  
Device(config-cns-conn)# discover interface gigabitethernet |
| **Step 9** | `template name [... name]`  
**Example:**  
Device(config-cns-conn)# template template-dhcp |
| **Step 10** | Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile. |
| **Step 11** | `exit`  
**Example:**  
Device(config-cns-conn)# exit |
| **Step 12** | `hostname name`  
**Example:** |
### Command or Action

</table>
### Command or Action

**Example:**

RemoteDevice(config)# cns config initial 10.1.1.1
  no-persist

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>RemoteDevice(config)# cns config initial 10.1.1.1 no-persist</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For `{hostname</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For <code>port-number</code>, enter the port number of the configuration server. The default port number is 80.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Enable <strong>event</strong> for configuration success, failure, or warning messages when the configuration is finished.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Enable <strong>no-persist</strong> to suppress the automatic writing to NVRAM of the configuration pulled as a result of entering the <strong>cns config initial</strong> global configuration command. If the <strong>no-persist</strong> keyword is not entered, using the <strong>cns config initial</strong> command causes the resultant configuration to be automatically written to NVRAM.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For <strong>page page</strong>, enter the web page of the initial configuration. The default is /Config/config/asp.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Enter <strong>source ip-address</strong> to use for source IP address.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Enable <strong>syntax-check</strong> to check the syntax when this parameter is entered.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Though visible in the command-line help string, the <strong>encrypt</strong>, <strong>status url</strong>, and <strong>inventory</strong> keywords are not supported.</td>
</tr>
</tbody>
</table>

**Step 17**

end

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 18**

show running-config

**Example:**

Device# show running-config

Verifies your entries.

**Step 19**

copy running-config startup-config

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
What to do next

To verify information about the configuration agent, use the `show cns config connections` command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the `no cns config initial { ip-address | hostname }` global configuration command.

Refreshing DeviceIDs

Follow these steps to refresh a DeviceID when changing the hostname on the device.

SUMMARY STEPS

1. `enable`
2. `show cns config connections`
3. Make sure that the CNS event agent is properly connected to the event gateway.
4. `show cns event connections`
5. Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.
6. `configure terminal`
7. `no cns event ip-address port-number`
8. `cns event ip-address port-number`
9. `end`
10. Make sure that you have reestablished the connection between the device and the event connection by examining the output from `show cns event connections`. 
11. `show running-config`
12. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>show cns config connections</code></td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show cns config connections</td>
</tr>
<tr>
<td></td>
<td>Displays whether the CNS event agent is connecting to the gateway, connected, or active, and the gateway used by the event agent, its IP address and port number.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Make sure that the CNS event agent is properly connected to the event gateway.</td>
</tr>
<tr>
<td></td>
<td>Examine the output of <code>show cns config connections</code> for the following:</td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Connection is active.</td>
</tr>
<tr>
<td>• Connection is using the currently configured device hostname. The DeviceID will be refreshed to correspond to the new hostname configuration using these instructions.</td>
</tr>
</tbody>
</table>

### Step 4
**show cns event connections**

**Example:**

Device# show cns event connections

Displays the event connection information for your device.

### Step 5
Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.

### Step 6
**configure terminal**

**Example:**

Device# configure terminal

Enters global configuration mode.

### Step 7
**no cns event ip-address port-number**

**Example:**

Device(config)# no cns event 172.28.129.22 2012

Specifies the IP address and port number that you recorded in Step 5 in this command.

This command breaks the connection between the device and the event gateway. It is necessary to first break, then reestablish, this connection to refresh the DeviceID.

### Step 8
**cns event ip-address port-number**

**Example:**

Device(config)# cns event 172.28.129.22 2012

Specifies the IP address and port number that you recorded in Step 5 in this command.

This command reestablishes the connection between the device and the event gateway.

### Step 9
**end**

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

### Step 10
Make sure that you have reestablished the connection between the device and the event connection by examining the output from **show cns event connections**.

### Step 11
**show running-config**

**Example:**

Device# show running-config

Verifies your entries.
Enabling a Partial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent and to initiate a partial configuration on the device.

SUMMARY STEPS

1. enable
2. configure terminal
3. cns config partial \{ip-address | hostname\} [port-number] [source ip-address]
4. end
5. show running-config
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> cns config partial {ip-address</td>
<td>hostname} [port-number] [source ip-address]</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# cns config partial 172.28.129.22 2013</td>
<td></td>
</tr>
<tr>
<td>* For {ip-address</td>
<td>hostname}, enter the IP address or the hostname of the configuration server.</td>
</tr>
<tr>
<td>* (Optional) For port-number, enter the port number of the configuration server. The default port number is 80.</td>
<td></td>
</tr>
</tbody>
</table>
What to do next

To verify information about the configuration agent, use either the `show cns config stats` or the `show cns config outstanding` command in privileged EXEC mode.

To disable the Cisco IOS agent, use the `no cns config partial { ip-address | hostname }` global configuration command. To cancel a partial configuration, use the `cns config cancel` global configuration command.

## Monitoring CNS Configurations

### Table 68: CNS show Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show cns config connections</td>
<td>Displays the status of the CNS Cisco IOS CNS agent connections.</td>
</tr>
</tbody>
</table>

Device# `show cns config connections`
### Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show cns config outstanding</code></td>
<td>Displays information about incremental (partial) CNS configurations that have started but are not yet completed.</td>
</tr>
<tr>
<td><code>show cns config stats</code></td>
<td>Displays statistics about the Cisco IOS CNS agent.</td>
</tr>
<tr>
<td><code>show cns event connections</code></td>
<td>Displays the status of the CNS event agent connections.</td>
</tr>
<tr>
<td><code>show cns event gateway</code></td>
<td>Displays the event gateway information for your device.</td>
</tr>
<tr>
<td><code>show cns event stats</code></td>
<td>Displays statistics about the CNS event agent.</td>
</tr>
<tr>
<td><code>show cns event subject</code></td>
<td>Displays a list of event agent subjects that are subscribed to by applications.</td>
</tr>
</tbody>
</table>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About CDP

CDP Overview

CDP is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With CDP, network management applications can learn the device type and the Simple Network Management Protocol (SNMP) agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

CDP runs on all media that support Subnetwork Access Protocol (SNAP). Because CDP runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each CDP-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information, which is the length of time a receiving device holds CDP information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.
On the device, CDP enables Network Assistant to display a graphical view of the network. The device uses CDP to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command device by default.

### How to Configure CDP

#### Configuring CDP Characteristics

You can configure these CDP characteristics:

- Frequency of CDP updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version-2 advertisements

---

**Note**

Steps 3 through 5 are all optional and can be performed in any order.

Follow these steps to configure the CDP characteristics.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. cdp timer seconds
4. cdp holdtime seconds
5. cdp advertise-v2
6. end
7. show running-config
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable  
Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal  
Example: Device# configure terminal | Enters the global configuration mode. |
| Step 3 | cdp timer seconds  
Example: Device(config)# cdp timer 20 | (Optional) Sets the transmission frequency of CDP updates in seconds.  
The range is 5 to 254; the default is 60 seconds. |
| Step 4 | cdp holdtime seconds  
Example: Device(config)# cdp holdtime 60 | (Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it.  
The range is 10 to 255 seconds; the default is 180 seconds. |
| Step 5 | cdp advertise-v2  
Example: Device(config)# cdp advertise-v2 | (Optional) Configures CDP to send Version-2 advertisements.  
This is the default state. |
| Step 6 | end  
Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config  
Example: Device# show running-config | Verifies your entries. |
Disabling CDP

CDP is enabled by default.

Note

Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to disable the CDP device discovery capability.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no cdp run`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

### Enabling CDP

CDP is enabled by default.

---

**Note**

Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to enable CDP when it has been disabled.

**Before you begin**

CDP must be disabled, or it cannot be enabled.
### SUMMARY STEPS

1. enable
2. configure terminal
3. cdprun
4. end
5. show running-config
6. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>

</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td>Example:</td>
</tr>
<tr>
<td><code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>
### What to do next

Use the `show run all` command to show that CDP has been enabled. If you enter only `show run`, the enabling of CDP may not be displayed.

**Related Topics**
- Default CDP Configuration, on page 908
- Disabling CDP, on page 910

### Disabling CDP on an Interface

CDP is enabled by default on all supported interfaces to send and to receive CDP information.

**Note**
Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to disable CDP on a port.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `no cdp enable`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SNMP

Supported SNMP Versions

This software release supports the following SNMP versions:

- SNMPv1—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- SNMPv2C replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:

- SNMPv2C—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.

- SNMPv3—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
  - Message integrity—Ensures that a packet was not tampered with in transit.
  - Authentication—Determines that the message is from a valid source.
  - Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

Note

To select encryption, enter the `priv` keyword.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent’s MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

<table>
<thead>
<tr>
<th>Model</th>
<th>Level</th>
<th>Authentication</th>
<th>Encryption</th>
<th>Result</th>

<td>noAuthNoPriv</td>
<td>Username</td>
<td>No</td>
<td>Uses a username match for authentication.</td>
</tr>
</tbody>
</table>
### Restrictions for SNMP

#### Version Restrictions

- SNMPv1 does not support informs.

---

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.
Information About SNMP

SNMP Overview

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime Infrastructure. The agent and MIB reside on the device. To configure SNMP on the device, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager’s requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get-request</td>
<td>Retrieves a value from a specific variable.</td>
</tr>
<tr>
<td>get-next-request</td>
<td>Retrieves a value from a variable within a table.</td>
</tr>
<tr>
<td>get-bulk-request</td>
<td>Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data.</td>
</tr>
<tr>
<td>get-response</td>
<td>Replies to a get-request, get-next-request, and set-request sent by an NMS.</td>
</tr>
<tr>
<td>set-request</td>
<td>Stores a value in a specific variable.</td>
</tr>
<tr>
<td>trap</td>
<td>An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.</td>
</tr>
</tbody>
</table>

Table 71: SNMP Operations

3 With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

4 The get-bulk command only works with SNMPv2 or later.

SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- Get a MIB variable—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.
• Set a MIB variable—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

Related Topics
Disabling the SNMP Agent, on page 925
Monitoring SNMP Status, on page 943

SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the device, the community string definitions on the NMS must match at least one of the three community string definitions on the device.

A community string can have one of the following attributes:

• Read-only (RO)—Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.
• Read-write (RW)—Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.
• When a cluster is created, the command device manages the exchange of messages among member devices and the SNMP application. The Network Assistant software appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device and propagates them to the member devices.

Related Topics
Configuring Community Strings, on page 927

SNMP MIB Variables Access

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure 2.0 software uses the device MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in get-request, get-next-request, and set-request format.

Figure 66: SNMP Network

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
SNMP Notifications

SNMP allows the device to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps or informs, or both. Use the `snmp-server host` command to specify whether to send SNMP notifications as traps or informs.

---

**Note**

SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the device and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network.

Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the device is a concern and notification is not required, use traps.

**Related Topics**

- Configuring SNMP Notifications, on page 932

SNMP ifIndex MIB Object Values

The SNMP agent's IF-MIB module comes up shortly after reboot. As various physical interface drivers are initialized they register with the IF-MIB module, essentially saying "Give me an ifIndex number". The IF-MIB module assigns the next available ifIndex number on a first-come-first-served basis. That is, minor differences in driver initialization order from one reboot to another can result in the same physical interface getting a different ifIndex number than it had before the reboot (unless ifIndex persistency is enabled of course).

Default SNMP Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>

<td>None enabled except the trap for TCP connections (tty).</td>
</tr>
<tr>
<td>SNMP version</td>
<td>If no version keyword is present, the default is Version 1.</td>
</tr>
<tr>
<td>SNMPv3 authentication</td>
<td>If no keyword is entered, the default is the noauth (noAuthNoPriv) security level.</td>
</tr>
<tr>
<td>SNMP notification type</td>
<td>If no type is specified, all notifications are sent.</td>
</tr>
</tbody>
</table>
This is the default when the device starts and the startup configuration does not have any `snmp-server` global configuration commands.

**SNMP Configuration Guidelines**

If the device starts and the device startup configuration has at least one `snmp-server` global configuration command, the SNMP agent is enabled.

An SNMP group is a table that maps SNMP users to SNMP views. An SNMP user is a member of an SNMP group. An SNMP host is the recipient of an SNMP trap operation. An SNMP engine ID is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The `snmp-server host` global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.

- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.

- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the `snmp-server engineID` global configuration command with the `remote` option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.

- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.

- If a local user is not associated with a remote host, the device does not send informs for the auth (authNoPriv) and the priv (authPriv) authentication levels.

- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the `snmp-server user` `username` global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

**How to Configure SNMP**

**Disabling the SNMP Agent**

The `no snmp-server` global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenable all versions of the SNMP agent by the first
Disabling the SNMP Agent

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first `snmp-server` global configuration command entered on the device.

### SUMMARY STEPS
1. `enable`
2. `configure terminal`
3. `no snmp-server`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>

</tr>
</tbody>
</table>
Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the device. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

Follow these steps to configure a community string on the device.

SUMMARY STEPS

1. enable
2. configure terminal
3. snmp-server community string [view view-name] [ro | rw] [access-list-number]
4. access-list access-list-number {deny | permit} source [source-wildcard]
5. end
6. show running-config
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

Device# configure terminal

**Step 3**

`snmp-server community string [view view-name] [ro | rw] [access-list-number]`

**Example:**

Device(config)# snmp-server community comaccess ro 4

**Purpose**

Configures the community string.

**Note**

The `@` symbol is used for delimiting the context information. Avoid using the `@` symbol as part of the SNMP community string when configuring this command.

- For `string`, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings of any length.
- (Optional) For `view`, specify the view record accessible to the community.
- (Optional) Specify either read-only (`ro`) if you want authorized management stations to retrieve MIB objects, or specify read-write (`rw`) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects.
- (Optional) For `access-list-number`, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.

---

**Step 4**

`access-list access-list-number {deny | permit} source [source-wildcard]`

**Example:**

Device(config)# access-list 4 deny any

(Optional) If you specified an IP standard access list number in Step 3, then create the list, repeating the command as many times as necessary.

- For `access-list-number`, enter the access list number specified in Step 3.
- The `deny` keyword denies access if the conditions are matched. The `permit` keyword permits access if the conditions are matched.
- For `source`, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent.
- (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.

Recall that the access list is always terminated by an implicit deny statement for everything.

---

**Step 5**

`end`

**Example:**

Returns to privileged EXEC mode.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config)#  end</td>
<td></td>
</tr>
<tr>
<td>Step 6 show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
<tr>
<td>Step 7 copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the `no snmp-server` community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

**Related Topics**

- [SNMP Community Strings](#), on page 923

---

**Configuring SNMP Groups and Users**

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Follow these steps to configure SNMP groups and users on the device.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `snmp-server engineID { local engineid-string | remote ip-address [udp-port port-number] engineid-string}
4. `snmp-server group group-name {v1 | v2c | v3 {auth | noauth | priv}} {read readview} {write writeview} {notify notifyview} {access access-list}
5. `snmp-server user username group-name {remote host [udp-port port]} {v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth | md5 | sha] auth-password} {priv [des | 3des | aes {128 | 192 | 256}] priv-password"
6. end
7. show running-config
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>DETAILED STEPS</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>snmp-server engineID {local engineid-string</td>
<td>remote ip-address [udp-port port-number] engineid-string}</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# snmp-server engineID local 1234</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>snmp-server group group-name {v1</td>
<td>v2c</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# snmp-server group public v2c access lmnop</td>
<td></td>
</tr>
</tbody>
</table>

- The `engineid-string` is a 24-character ID string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. The Step Example configures an engine ID of 123400000000000000000000.
- If you select `remote`, specify the `ip-address` of the device that contains the remote copy of SNMP and the optional User Datagram Protocol (UDP) port on the remote device. The default is 162.

For `group-name`, specify the name of the group.
Specify one of the following security models:
- `v1` is the least secure of the possible security models.
- `v2c` is the second least secure model. It allows transmission of informs and integers twice the normal width.
- `v3`, the most secure, requires you to select one of the following authentication levels:
  - `auth`—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>noauth — Enables the noAuthNoPriv security level. This is the default if no keyword is specified.</td>
<td></td>
</tr>
<tr>
<td>priv — Enables Data Encryption Standard (DES) packet encryption (also called privacy).</td>
<td></td>
</tr>
</tbody>
</table>

(Optional) Enter `read readview` with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.

(Optional) Enter `write writeview` with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.

(Optional) Enter `notify notifyview` with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.

(Optional) Enter `access access-list` with a string (not to exceed 64 characters) that is the name of the access list.

---

**Step 5**

```
snmp-server user username group-name {remote host [udp-port port]} {v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password]} [priv {des | 3des | aes {128 | 192 | 256}} priv-password]
```

 adds a new user for an SNMP group.

The `username` is the name of the user on the host that connects to the agent.

The `group-name` is the name of the group to which the user is associated.

Enter `remote` to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.

Enter the SNMP version number (`v1`, `v2c`, or `v3`). If you enter `v3`, you have these additional options:

- `encrypted` specifies that the password appears in encrypted format. This keyword is available only when the `v3` keyword is specified.

- `auth` is an authentication level setting session that can be either the HMAC-MD5-96 (`md5`) or the HMAC-SHA-96 (`sha`) authentication level and requires a password string `auth-password` (not to exceed 64 characters).

If you enter `v3` you can also configure a private (priv) encryption algorithm and password string `priv-password` using the following keywords (not to exceed 64 characters):

- `priv` specifies the User-based Security Model (USM).
- `des` specifies the use of the 56-bit DES algorithm.
- `3des` specifies the use of the 168-bit DES algorithm.
### Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the device generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Devices running this Cisco IOS release can have an unlimited number of trap managers.

#### Related Topics

- [SNMP Configuration Guidelines](#), on page 925
- [Monitoring SNMP Status](#), on page 943

#### Command or Action | Purpose
---|---
| **aes** specifies the use of the DES algorithm. You must select either 128-bit, 192-bit, or 256-bit encryption. (Optional) Enter `access access-list` with a string (not to exceed 64 characters) that is the name of the access list. | **Step 6**
| **end**
| Example: `Device(config)# end` | Returns to privileged EXEC mode.
| **show running-config**
| Example: `Device# show running-config` | Turns on the SNMP service, which is disabled by default.
| **copy running-config startup-config**
| Example: `Device# copy running-config startup-config` | (Optional) Saves your entries in the configuration file.

### Note

Many commands use the word **traps** in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword **traps** refers to traps, informs, or both. Use the `snmp-server host` global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the `snmp-server enable traps` global configuration command combined with the `snmp-server host` global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

### Note

The `snmp-server enable traps` command does not support traps for local-authentication on your device.

<tr>
<td>flash</td>
<td>Generates SNMP FLASH notifications. In a device stack, you can optionally enable notification for flash insertion or removal, which would cause a trap to be issued whenever a device in the stack is removed or inserted (physical removal, power cycle, or reload).</td>
</tr>
<tr>
<td>fru-ctrl</td>
<td>Generates entity field-replaceable unit (FRU) control traps. In the device stack, this trap refers to the insertion or removal of a device in the stack.</td>
</tr>
<tr>
<td>hsrp</td>
<td>Generates a trap for Hot Standby Router Protocol (HSRP) changes.</td>
</tr>
<tr>
<td>ipmulticast</td>
<td>Generates a trap for IP multicast routing changes.</td>
</tr>
<tr>
<td>mac-notification</td>
<td>Generates a trap for MAC address notifications.</td>
</tr>
<tr>
<td>ospf</td>
<td>Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes.</td>
</tr>
<tr>
<td>pim</td>
<td>Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes.</td>
</tr>
</tbody>
</table>
| port-security             | Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.  
**Note** When you configure a trap by using the notification type **port-security**, configure the port security trap first, and then configure the port security trap rate:  
1. `snmp-server enable traps port-security`  
2. `snmp-server enable traps port-security trap-rate rate`  
| snmp                      | Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down. |
Configuring SNMP Notifications

<table>

<td>vlancreate</td>
<td>Generates SNMP VLAN created traps.</td>
</tr>
<tr>
<td>vlandelete</td>
<td>Generates SNMP VLAN deleted traps.</td>
</tr>
<tr>
<td>vtp</td>
<td>Generates a trap for VLAN Trunking Protocol (VTP) changes.</td>
</tr>
</tbody>
</table>

Follow these steps to configure the device to send traps or informs to a host.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `snmp-server engineID remote ip-address engineid-string`
4. `snmp-server user username group-name { remote host [ udp-port port] } { v1 [ access access-list] | v2c [ access access-list] | v3 [ encrypted] [ access access-list] [ auth { md5 | sha} auth-password] }`
5. `snmp-server group group-name { v1 | v2c | v3 { auth | noauth | priv }} [ read readview] [ write writeview] [ notify notifyview] [ access access-list]`
6. `snmp-server host host-addr [ informs | traps] [ version { 1 | 2c | 3 { auth | noauth | priv } }] community-string [ notification-type]`
7. `snmp-server enable traps notification-types`
8. `snmp-server trap-source interface-id`
9. `snmp-server queue-length length`
10. `snmp-server trap-timeout seconds`
11. end
12. show running-config
13. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>

<tr>
<td><strong>Example:</strong> Device(config)# snmp-server host 203.0.113.1 comaccess snmp</td>
<td></td>
</tr>
<tr>
<td><strong>For host-addr</strong>, specify the name or Internet address of the host (the targeted recipient).</td>
<td>(Optional) Specify <strong>traps</strong> (the default) to send SNMP traps to the host.</td>
</tr>
<tr>
<td>(Optional) Specify <strong>informs</strong> to send SNMP informs to the host.</td>
<td>(Optional) Specify the SNMP version (1, 2c, or 3). SNMPv1 does not support informs.</td>
</tr>
<tr>
<td>(Optional) For Version 3, select authentication level <strong>auth</strong>, <strong>noauth</strong>, or <strong>priv</strong>.</td>
<td>(Optional) For Version 3, select authentication level <strong>auth</strong>, <strong>noauth</strong>, or <strong>priv</strong>.</td>
</tr>
<tr>
<td><strong>Note</strong> The <strong>priv</strong> keyword is available only when the cryptographic software image is installed.</td>
<td><strong>Note</strong> The <strong>priv</strong> keyword is available only when the cryptographic software image is installed.</td>
</tr>
<tr>
<td>For <strong>community-string</strong>, when <strong>version 1</strong> or <strong>version 2c</strong> is specified, enter the password-like community string sent with the notification operation. When <strong>version 3</strong> is specified, enter the SNMPv3 username.</td>
<td>For <strong>community-string</strong>, when <strong>version 1</strong> or <strong>version 2c</strong> is specified, enter the password-like community string sent with the notification operation. When <strong>version 3</strong> is specified, enter the SNMPv3 username.</td>
</tr>
</tbody>
</table>
### Configuring SNMP Notifications

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</strong></td>
<td></td>
</tr>
</tbody>
</table>
| **Step 7** - `snmp-server enable traps notification-types` **Example:** Device(config)# snmp-server enable traps snmp | Enables the device to send traps or informs and specifies the type of notifications to be sent. For a list of notification types, see the table above, or enter `snmp-server enable traps`.
(Optional) For `notification-type`, use the keywords listed in the table above. If no type is specified, all notifications are sent. |
| **Step 8** - `snmp-server trap-source interface-id` **Example:** Device(config)# snmp-server trap-source GigabitEthernet1/0/1 | (Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs. |
| **Step 9** - `snmp-server queue-length length` **Example:** Device(config)# snmp-server queue-length 20 | (Optional) Establishes the message queue length for each trap host. The range is 1 to 1000; the default is 10. |
| **Step 10** - `snmp-server trap-timeout seconds` **Example:** Device(config)# snmp-server trap-timeout 60 | (Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds. |
| **Step 11** - `end` **Example:** Device(config)# end | Returns to privileged EXEC mode. |
| **Step 12** - `show running-config` **Example:** Device# show running-config | Verifies your entries. |
What to do next

The `snmp-server host` command specifies which hosts receive the notifications. The `snmp-server enable traps` command globally enables the method for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an `snmp-server host informs` command for the host and globally enable informs by using the `snmp-server enable traps` command.

To remove the specified host from receiving traps, use the `no snmp-server host host` global configuration command. The `no snmp-server host` command with no keywords disables traps, but not informs, to the host. To disable informs, use the `no snmp-server host informs` global configuration command. To disable a specific trap type, use the `no snmp-server enable traps notification-types` global configuration command.

SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string `public`. This configuration does not cause the device to send any traps.

```
Device(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string `public`. The device also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33...
using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string public is sent with the traps.

```
Device(config)# snmp-server community public
Device(config)# snmp-server enable traps vtp
Device(config)# snmp-server host 192.180.1.27 version 2c public
Device(config)# snmp-server host 192.180.1.111 version 1 public
Device(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the comaccess community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host cisco.com using the community string public.

```
Device(config)# snmp-server community comaccess ro 4
Device(config)# snmp-server enable traps snmp authentication
Device(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host cisco.com. The community string is restricted. The first line enables the device to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous snmp-server host commands for the host cisco.com.

```
Device(config)# snmp-server enable traps entity
Device(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the device to send all traps to the host myhost.cisco.com using the community string public:

```
Device(config)# snmp-server enable traps
Device(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send auth (authNoPriv) authentication-level informs when the user enters global configuration mode:

```
Device(config)# snmp-server engineID remote 192.180.1.27 0000006300100a1c0b4011b
Device(config)# snmp-server group authgroup v3 auth
Device(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Device(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Device(config)# snmp-server enable traps
Device(config)# snmp-server inform retries 0
```

CHAPTER 63

Configuring Service Level Agreements

This chapter describes how to use Cisco IOS IP Service Level Agreements (SLAs) on the switch. Unless otherwise noted, the term *switch* refers to a standalone switch or a switch stack.

- Finding Feature Information, on page 947
- Restrictions on SLAs, on page 947
- Information About SLAs, on page 948
- How to Configure IP SLAs Operations, on page 953
- Monitoring IP SLA Operations, on page 966
- Monitoring IP SLA Operation Examples, on page 967
- Additional References, on page 968

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [http://www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Restrictions on SLAs

This section lists the restrictions on SLAs.

The following are restrictions on IP SLAs network performance measurement:

- The device does not support VoIP service levels using the gatekeeper registration delay operations measurements.

- Only a Cisco IOS device can be a source for a destination IP SLAs responder.

- You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.
Information About SLAs

Cisco IOS IP Service Level Agreements (SLAs)

Cisco IOS IP SLAs send data across the network to measure performance between multiple network locations or across multiple network paths. They simulate network data and IP services and collect network performance information in real time. Cisco IOS IP SLAs generate and analyze traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLA operations can be used for troubleshooting, problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLA operations, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLA packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs are Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collect and analyze the following performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like Cisco Prime Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products.

Using IP SLAs can provide the following benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring
  - Measurement of jitter, latency, or packet loss in the network.
  - Continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Network operation troubleshooting by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.
- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the device supports MPLS).

**Network Performance Measurement with Cisco IOS IP SLAs**

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices.

*Figure 67: Cisco IOS IP SLAs Operation*

The following figure shows how IP SLAs begin when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

**Related Topics**

- Restrictions on SLAs, on page 947

**IP SLA Responder and IP SLA Control Protocol**

The IP SLA responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLA request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLA Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond.
The IP SLA responder can be a Cisco IOS Layer 2, responder-configurable device. The responder does not need to support full IP SLA functionality.

The following figure shows where the Cisco IOS IP SLA responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLA operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLA packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

Figure 68: Cisco IOS IP SLAs Operation

You do not need to enable the responder on the destination device for all IP SLA operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP).

Response Time Computation for IP SLAs

Switches, controllers, and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimize these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLA test packets use time stamping to minimize the processing delays.

When the IP SLA responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

Figure 69: Cisco IOS IP SLA Responder Time Stamping

The following figure demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is
applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt level to allow for greater accuracy.

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

**IP SLAs Operation Scheduling**

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the `pending` option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the Cisco RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLA operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLA multi-operations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the *Cisco IOS IP SLAs Configuration Guide*.

**IP SLA Operation Threshold Monitoring**

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as the following:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold
- One-way packet loss
- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency
An IP SLA threshold violation can also trigger another IP SLA operation for further analysis. For example, the frequency could be increased or an Internet Control Message Protocol (ICMP) path echo or ICMP path jitter operation could be initiated for troubleshooting.

ICMP Echo

The ICMP echo operation measures the end-to-end response time between a Cisco device and any other device that uses IP. The response time is computed by measuring the time it takes to send an ICMP echo request message to a destination and receive an ICMP echo reply. Many customers use IP SLA ICMP-based operations, in-house ping testing, or ping-based dedicated probes to measure this response time. The IP SLA ICMP echo operation conforms to the same specifications as ICMP ping testing, and both methods result in the same response times.

Related Topics

Analyzing IP Service Levels by Using the ICMP Echo Operation, on page 963

UDP Jitter

Jitter is a simple term that describes interpacket delay variance. When multiple packets are sent consecutively at an interval of 10 ms from source to destination, the destination should receive them 10 ms apart (if the network is behaving correctly). However, if there are delays in the network (such as queuing, arriving through alternate routes, and so on), the time interval between packet arrivals might be more or less than 10 ms. A positive jitter value indicates that the packets arrived more than 10 ms apart. A negative jitter value indicates that the packets arrived less than 10 ms apart. If the packets arrive 12 ms apart, the positive jitter is 2 ms; if the packets arrive 8 ms apart, the negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLA UDP jitter operation can be used as a multipurpose data gathering operation. The packets generated by IP SLAs carry sequence information and time stamps from the source and operational target that include packet sending and receiving data. Based on this data, UDP jitter operations measure the following:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), you can use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

To provide accurate one-way delay (latency) measurements, time synchronization (as provided by NTP) is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

How to Configure IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the Cisco IOS IP SLAs Configuration Guide. It does include several operations as examples, including configuring the responder, configuring a UDP jitter operation, which requires a responder, and configuring an ICMP echo operation, which does not require a responder. For details about configuring other operations, see the Cisco IOS IP SLAs Configuration Guide.

Default Configuration

No IP SLAs operations are configured.

Configuration Guidelines

For information on the IP SLA commands, see the Cisco IOS IP SLAs Command Reference, Release 12.4T command reference.

For detailed descriptions and configuration procedures, see the Cisco IOS IP SLAs Configuration Guide, Release 12.4TL.

Not all of the IP SLA commands or operations described in the referenced guide are supported on the device. The device supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the show ip sla application privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

Device# show ip sla application

   IP Service Level Agreements
   Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

   Supported Operation Types:
      icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
dns, udpJitter, dhcp, ftp, udpApp, wspApp

   Supported Features:
      IPSLAs Event Publisher

   IP SLAs low memory water mark: 33299323
   Estimated system max number of entries: 24389

   Estimated number of configurable operations: 24389
   Number of Entries configured : 0
   Number of active Entries      : 0
   Number of pending Entries    : 0
   Number of inactive Entries   : 0
Configuring the IP SLA Responder

The IP SLA responder is available only on Cisco IOS software-based devices, including some Layer 2 devices that do not support full IP SLA functionality.

Follow these steps to configure the IP SLA responder on the target device (the operational target):

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip sla responder {tcp-connect | udp-echo} ip-address ip-address port port-number`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 | `configure terminal` | Enters the global configuration mode. |
| Example: | `Device# configure terminal` | |

| Step 3 | `ip sla responder {tcp-connect | udp-echo} ip-address ip-address port port-number` | Configures the device as an IP SLA responder. |
| Example: | `Device(config)# ip sla responder udp-echo 172.29.139.134 5000` | |

The keywords have these meanings:

- **tcp-connect**—Enables the responder for TCP connect operations.
- **udp-echo**—Enables the responder for User Datagram Protocol (UDP) echo or jitter operations.
- **ip-address**—Enter the destination IP address.
- **port port-number**—Enter the destination port number.

**Note** The IP address and port number must match those configured on the source device for the IP SLA operation.

**Implementing IP SLA Network Performance Measurement**

Follow these steps to implement IP SLA network performance measurement on your device:

**Before you begin**

Use the `show ip sla application` privileged EXEC command to verify that the desired operation type is supported on your software image.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip sla operation-number
4. udp-jitter `{destination-ip-address | destination-hostname} destination-port [source-ip {ip-address | hostname}] [source-port port-number] [control {enable | disable}] [num-packets number-of-packets] [interval interpacket-interval]`
5. frequency seconds
6. threshold milliseconds
7. exit
8. ip sla schedule operation-number [life {forever | seconds}] [start-time {hh:mm [ss] [month day | day month] | pending | now | after hh:mm:ss} [ageout seconds] [recurring]`
9. end
10. show running-config
11. copy running-config startup-config
## DETAILED STEPS

<td><strong>Device(config-ip-sla)# udp-jitter 172.29.139.134 5000</strong></td>
</tr>
</tbody>
</table>

- **destination-ip-address | destination-hostname**—Specifies the destination IP address or hostname.
- **destination-port**—Specifies the destination port number in the range from 1 to 65535.
- **source-ip {ip-address | hostname}**—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination.
- **source-port port-number**—Specifies the source port number in the range from 1 to 65535. When a port number is not specified, IP SLA chooses an available port.
- **control**—Enables or disables sending of IP SLA control messages to the IP SLA responder. By default, IP SLA control messages are sent to the destination device to establish a connection with the IP SLA responder.
- **num-packets number-of-packets**—Enters the number of packets to be generated. The range is 1 to 6000; the default is 10.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) <strong>interval</strong> <em>inter-packet-interval</em>—Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>frequency</strong> <em>seconds</em></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-ip-sla-jitter)# frequency 45</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>threshold</strong> <em>milliseconds</em></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-ip-sla-jitter)# threshold 200</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>exit</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-ip-sla-jitter)# exit</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><strong>ip sla schedule</strong> <em>operation-number</em> [<strong>life</strong> {<strong>forever</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ip sla schedule 10 start-time now life forever</td>
</tr>
</tbody>
</table>

(Optional) Configures options for the SLA operation. This example sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.

(Optional) Configures threshold conditions. This example sets the threshold of the specified IP SLA operation to 200. The range is from 0 to 60000 milliseconds.

Exits the SLA operation configuration mode (UDP jitter configuration mode in this example), and returns to global configuration mode.

Configures the scheduling parameters for an individual IP SLA operation.

- **operation-number**—Enter the RTR entry number.
- (Optional) **life**—Sets the operation to run indefinitely (**forever**) or for a specific number of **seconds**. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour).
- (Optional) **start-time**—Enters the time for the operation to begin collecting information:
  
  To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.

  Enter **pending** to select no information collection until a start time is selected.

  Enter **now** to start the operation immediately.

  Enter **after hh:mm:ss** to show that the operation should start after the entered time has elapsed.

- (Optional) **ageout seconds**—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out).
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>(Optional) recurring</td>
<td>Set the operation to automatically run every day.</td>
</tr>
</tbody>

Analyzing IP Service Levels by Using the ICMP Echo Operation

Follow these steps to configure an ICMP echo operation on the source device:

Before you begin
This operation does not require the IP SLA responder to be enabled.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip sla operation-number
4. icmp-echo \{destination-ip-address | destination-hostname\} [source-ip \{ip-address | hostname\} | source-interface interface-id]
5. frequency seconds
6. exit
7. ip sla schedule operation-number [life \{forever | seconds\}] [start-time \{hh:mm [:ss] [month day] | pending | now | after hh:mm:ss \[ageout seconds\] | recurring]
8. end
9. show running-config
10. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip sla operation-number</td>
<td>Creates an IP SLA operation and enters IP SLA configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# ip sla 10</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 4**

```plaintext
icmp-echo {destination-ip-address | destination-hostname} [source-ip {ip-address | hostname} | source-interface interface-id]  
```

**Example:**

```
Device(config-ip-sla)# icmp-echo 172.29.139.134
```

**Purpose:** Configures the IP SLA operation as an ICMP Echo operation and enters ICMP echo configuration mode.

- `destination-ip-address` | `destination-hostname`—Specifies the destination IP address or hostname.
- `(Optional) source-ip {ip-address | hostname}`—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination.
- `(Optional) source-interface interface-id`—Specifies the source interface for the operation.

**Step 5**

```plaintext
frequency seconds  
```

**Example:**

```
Device(config-ip-sla-echo)# frequency 30
```

**Purpose:** (Optional) Sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.

**Step 6**

```plaintext
exit  
```

**Example:**

```
Device(config-ip-sla-echo)# exit
```

**Purpose:** Exits UDP echo configuration mode, and returns to global configuration mode.

**Step 7**

```plaintext
ip sla schedule operation-number [life {forever | seconds}] [start-time {hh:mm:ss} [month day | day month] | pending | now | after hh:mm:ss] [ageout seconds] [recurring]  
```

**Example:**

```
Device(config)# ip sla schedule 5 start-time now life forever
```

**Purpose:** Configures the scheduling parameters for an individual IP SLA operation.

- `operation-number`—Enter the RTR entry number.
- `(Optional) life`—Sets the operation to run indefinitely (forever) or for a specific number of seconds. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour)
- `(Optional) start-time`—Enter the time for the operation to begin collecting information:
  - To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.
  - Enter **pending** to select no information collection until a start time is selected.
  - Enter **now** to start the operation immediately.
  - Enter **after hh:mm:ss** to indicate that the operation should start after the entered time has elapsed.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) <strong>ageout</strong> seconds—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds; the default is 0 seconds (never ages out).</td>
<td></td>
</tr>
<tr>
<td>• (Optional) <strong>recurring</strong>—Sets the operation to automatically run every day.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# <strong>end</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# <strong>show running-config</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# <strong>copy running-config startup-config</strong></td>
<td></td>

</tbody>
</table>

### Configuring an ICMP Echo IP SLA Operation

This example shows how to configure an ICMP echo IP SLA operation:

```
Device(config)# **ip sla** 12
Device(config-ip-sla)# **icmp-echo** 172.29.139.134
Device(config-ip-sla-echo)# **frequency** 30
Device(config-ip-sla-echo)# **exit**
Device(config)# **ip sla schedule** 5 **start-time** now **life** forever
Device(config)# **end**
Device# **show ip sla configuration** 22

IP SLAs, Infrastructure Engine-II.
```

</table>

### Monitoring IP SLA Operation Examples

The following example shows all IP SLAs by application:

```
Device# show ip sla application

IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

Supported Operation Types:
  icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
dns, udpJitter, dhcp, ftp, udpApp, wapApp

Supported Features:
  IPSLAs Event Publisher

IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389

Estimated number of configurable operations: 24389
Number of Entries configured : 0
Number of active Entries : 0
Number of pending Entries : 0
Number of inactive Entries : 0
Time of last change in whole IP SLAs: *13:04:37.668 UTC Wed Dec 19 2012
```

The following example shows all IP SLA distribution statistics:

```
Device# show ip sla enhanced-history distribution-statistics

Point by point Enhanced History
Entry = Entry Number
Int = Aggregation Interval
BucI = Bucket Index
StartT = Aggregation Start Time
Pth = Path index
Hop = Hop in path index
Comps = Operations completed
OvrTh = Operations completed over thresholds
SumCmp = Sum of RTT (milliseconds)
SumCmp2L = Sum of RTT squared low 32 bits (milliseconds)
SumCmp2H = Sum of RTT squared high 32 bits (milliseconds)
TMax = RTT maximum (milliseconds)
TMin = RTT minimum (milliseconds)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring Local Policies

The policy map attributes supported on the device are QoS, VLAN, session timeout, and ACL.

Information About Configuring Local Policies

Local policies can profile devices based on HTTP and DHCP to identify the end devices on the network. Users can configure device-based policies and enforce the policies per user or per device policy on the network.

Local policies allow profiling of mobile devices and basic onboarding of the profiled devices to a specific VLAN. They also assign ACL and QoS or configure session timeouts.

You can configure local policies as two separate components:

- Defining policy attributes as service templates specific to clients joining the network and applying policy match criteria.
- Applying match criteria to the policy.

The following policy match attributes are used for configuring local policies:

- Device—Defines the type of device. Windows-based computer, Smartphone, Apple devices such as iPad and iPhone.
- Username—Defines the username of the user.
- User role—Defines the user type or the user group the user belongs to, such as a student or employee.
- MAC—Defines the mac-address of the endpoint.
- MAC OUI—Defines the mac-address OUI.

Once the device has a match corresponding to these parameters per end point, the policy can be added. Policy enforcement allows basic device on-boarding of mobile devices based on the following session attributes:

- VLAN
- QoS
- ACL
- Session timeout

You can configure these policies and enforce endpoints with specified policies. The wireless clients are profiled based on MAC OUI and DHCP. The device uses these attributes and predefined classification profiles to identify devices.

Replacing Default Profile Text File

If a new device is not classified, contact the Cisco support team with the device MAC address. The Cisco support team will provide a new `dc_default_profile.txt` file with the MAC address included in the file. You need to replace the `dc_default_profile.txt` file with the earlier file. Follow these steps to change the `dc_default_profile.txt` file:

1. Stop device classifier by entering this command:
   ```
   device(config)# no device classifier
   ```
2. Copy the file by entering this command:
   ```
   device# device classifier profile location filepath
   ```
3. Start the device classifier by entering this command:
device(config)# device classifier

Disabling session monitor on trunk ports

On uplink trunk ports, you should not create any session monitoring. By default, session monitoring is enabled. You should disable session monitoring.

1. Enter into global configuration mode by entering this command:
   
   device# configure terminal

2. Enter into interface configuration mode by entering this command:

   device(config)# interface interface-id

3. Disable session monitoring by entering this command:

   device(config-if)# no access-session monitor

### How to Configure Local Policies

#### Configuring Local Policies (CLI)

To configure local policies, complete these procedures:

1. Create a service template.
2. Create an interface template.
3. Create a parameter map.
4. Create a policy map.
5. Apply a local policy on a WLAN.

#### Creating an Interface Template (CLI)

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
### Command or Action

#### Step 2

**template interface-template-name**

Example:

```
Device(config)# template cisco-phone-template
Device(config-template)#
```

**Purpose**

Enters interface template configuration mode.

#### Step 3

**switchport mode access**

Example:

```
Device(config-template)# switchport mode access
```

Sets the interface as a nontrunking nontagged single-VLAN Ethernet interface. An access port can carry traffic in one VLAN only. By default, an access port carries traffic for VLAN1.

#### Step 4

**switchport voice vlan vlan_id**

Example:

```
Device(config-template)# switchport voice vlan 20
```

Specifies to forward all voice traffic through the specified VLAN. You can specify a value from 1 to 4094.

#### Step 5

**end**

Example:

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

### Creating a Parameter Map (CLI)

Parameter map is preferred to use than class map.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>parameter-map type subscriber attribute-to-service</code></td>
<td>Specifies the parameter map type and name.</td>
</tr>
<tr>
<td><code>parameter-map-name</code></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# parameter-map type subscriber attribute-to-service Aironet-Policy-para</td>
<td></td>
</tr>
</tbody>
</table>
### Creating a Class Map (CLI)

#### Purpose

**Command or Action**

**Purpose**

| Step 3 | map-index map { device-type | mac-address | oui | user-role | username } { eq | not-eq | regex filter-name } |
|------|--------------------------|
| Example: | Device(config-parameter-map-filter)# 10 map device-type eq "WindowsXP-Workstation" |

Specifies parameter map attribute filter criteria.

<table>
<thead>
<tr>
<th>Step 4</th>
<th>interface-template interface-template-name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-parameter-map-filter-submode)# interface-template cisco-phone-template Device(config-parameter-map-filter-submode)#</td>
</tr>
</tbody>
</table>

Enters service template configuration mode.

<table>
<thead>
<tr>
<th>Step 5</th>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
</tr>
</tbody>
</table>

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

#### Creating a Class Map (CLI)

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>

| Step 1 | configure terminal |
| Example: | Device# configure terminal |

Enters global configuration mode.

| Step 2 | class-map type control subscriber class-map-name { match-all | match-any | match-first } |
| Example: | Device(config)# class-map type control subscriber CLASS_AC_1 match-all |

Specifies the class map type and name.

| Step 3 | match { device-type | mac-address | oui | username | userrole } filter-type-name |
| Example: | |

Specifies class map attribute filter criteria.
Creating a Policy Map (CLI)

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Specifies the policy map type.</td>
</tr>
<tr>
<td><code>policy-map type control subscriber policy-map-name</code></td>
<td>Select the policy map type and configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# policy-map type control subscriber Aironet-Policy</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specifies match criteria to the policy map.</td>

### Applying a Local Policy for a Device on a WLAN (CLI)

#### Before you begin

If the service policy contains any device type-based rules in the parameter map, ensure that the device classifier is already enabled.

#### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

Device# configure terminal

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>wlan wlan-name</td>
<td>Enters WLAN configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

Device(config)# wlan wlan1

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>service-policy type control subscriber policymapname</td>
<td>Applies local policy to WLAN.</td>
</tr>
</tbody>
</table>

**Example:**

Device(config-wlan)# service-policy type control subscriber Aironet-Policy
### Monitoring Local Policies

The following commands can be used to monitor local policies configured on the device.

**Table 75: Monitoring Local Policies Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show access-session</code></td>
<td>Displays the summary of access session with authorization status, method and domain for each client or MAC address displayed.</td>
</tr>
<tr>
<td><code>show access-session cache</code></td>
<td>Displays the latest classification for the client.</td>
</tr>
<tr>
<td><code>show device classifier attached</code></td>
<td>Displays the latest classification for the client based on parameters such as Mac, DHCP, or HTTP.</td>
</tr>
<tr>
<td><code>show access-session mac details</code></td>
<td>Displays the policy mapped, service template used, and attributes for the client.</td>
</tr>
</tbody>
</table>
show access-session mac mac-address policy

Displays the policy mapped, service template used, and attributes for the client.

In addition, you can view the Resultant Policy that displays the following information:

• The final attributes applied to the session when the session has locally configured attributes.
• Attributes applied from the server.

Examples: Local Policies Configuration

Note

At the end of each configuration command line, enter CTRL Z to execute the command and proceed to the next line.

This example shows how to create interface template:

Device# configure terminal
Device(config)# template cisco-phone-template
Device(config-template)# switchport mode access
Device(config-template)# switchport voice vlan 20
Device(config-template)# end

This example shows how to create parameter map:

Device# configure terminal
Device(config)# parameter-map type subscriber attribute-to-service param-wired
Device(config-parameter-map-filter)#10 map device-type regex Cisco-IP-Phone
Device(config-parameter-map-filter-submode)#10 interface-template cisco-phone-template
Device(config-parameter-map)# end

This example shows how to create policy map:

Device(config)# policy-map type control subscriber apple-tsim
Device(config-policy-map)# event identity-update match-all
Device(config-policy-map)# 1 class always do-until-failure
Device(config-policy-map)# 1 map attribute-to-service table apple-tsim-param
Device(config-policy-map)# end

This example shows how to apply policy to a device on a WLAN:

Prerequisites for SPAN and RSPAN

SPAN

- You can limit SPAN traffic to specific VLANs by using the `filter vlan` keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

RSPAN

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.
Restrictions for SPAN and RSPAN

SPAN

The restrictions for SPAN are as follows:

• On each device, you can configure 66 sessions. A maximum of 8 source sessions can be configured and the remaining sessions can be configured as RSPAN destinations sessions. A source session is either a local SPAN session or an RSPAN source session.

• For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.

• The destination port cannot be a source port; a source port cannot be a destination port.

• You cannot have two SPAN sessions using the same destination port.

• When you configure a device port as a SPAN destination port, it is no longer a normal device port; only monitored traffic passes through the SPAN destination port.

• Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the `no monitor session {session_number | all | local | remote}` global configuration command to delete configured SPAN parameters.

• For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the `encapsulation replicate` keywords are specified. If the keywords are not specified, the packets are sent in native form.

• You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.

• You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

• Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.

• Wireshark does not capture egress packets when egress span is active.

• You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.

• You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.

• You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.

• SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.

• When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

The device does not support a combination of local SPAN and RSPAN in a single session.
- An RSPAN source session cannot have a local destination port.
- An RSPAN destination session cannot have a local source port.
- An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

RSPAN

The restrictions for RSPAN are as follows:
- RSPAN does not support BPDU packet monitoring or other Layer 2 device protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating devices.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the device does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the device.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- To use RSPAN, the switch must be running the LAN Base image.

Information About SPAN and RSPAN

SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the device or on another device that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.
Local SPAN

Local SPAN supports a SPAN session entirely within one device; all source ports or source VLANs and destination ports are in the same device or device stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

Figure 70: Example of Local SPAN Configuration on a Single Device

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port 5.

Figure 71: Example of Local SPAN Configuration on a Device Stack

This is an example of a local SPAN in a device stack, where the source and destination ports reside on different stack members.

Related Topics

Creating a Local SPAN Session, on page 996
Remote SPAN

RSPAN supports source ports, source VLANs, and destination ports on different devices (or different device stacks), enabling remote monitoring of multiple devices across your network.

Figure 72: Example of RSPAN Configuration

The figure below shows source ports on Device A and Device B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating devices. The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source device must have either ports or VLANs as RSPAN sources. The destination is always a physical port, as shown on Device C in the figure.

SPAN and RSPAN Concepts and Terminology

SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination device.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

A single RSPAN session with multiple source and destination ports can be in the same session but more than one source session with the source being the same remote vlan is not allowed.

Traffic monitoring in a SPAN session has these restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
Monitored Traffic

SPAN sessions can monitor these traffic types:

- **Receive (Rx) SPAN**—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the device. A copy of each packet received by the source is sent to the destination port for that SPAN session. Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification. Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

- **Transmit (Tx) SPAN**—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the device. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified. Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port. Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- **Both**—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

The default configuration for local SPAN session ports is to send all packets untagged. However, when you enter the `encapsulation replicate` keywords while configuring a destination port, these changes occur:

- Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.

- Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Device congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:
• A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
• An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.
• An egress packet dropped because of device congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the device through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

**Source Ports**

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis.

In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions.

The device supports any number of source ports (up to the maximum number of available ports on the device) and any number of source VLANs (up to the maximum number of VLANs supported).

You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

• It can be monitored in multiple SPAN sessions.
• Each source port can be configured with a direction (ingress, egress, or both) to monitor.
• It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
• For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
• It can be an access port, trunk port, routed port, or voice VLAN port.
• It cannot be a destination port.
• Source ports can be in the same or different VLANs.
• You can monitor multiple source ports in a single session.

**Source VLANs**

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

• All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
• On a given port, only traffic on the monitored VLAN is sent to the destination port.
• If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
• If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.

• You cannot use filter VLANs in the same session with VLAN sources.

• You can monitor only Ethernet VLANs.

### VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

### Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same device or device stack as the source port. For an RSPAN session, it is located on the device containing the RSPAN destination session. There is no destination port on a device or device stack running only an RSPAN source session.
- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.

**Note**

When QoS is configured on the SPAN destination port, QoS takes effect immediately.

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.
- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can be an EtherChannel group (ON mode only).
• It cannot be a VLAN.

• It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).

• When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.

• If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.

• It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).

• A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.

• The maximum number of destination ports in a device or device stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

• For local SPAN, if the encapsulation replicate keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with encapsulation replicate enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.

• For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

• All traffic in the RSPAN VLAN is always flooded.

• No MAC address learning occurs on the RSPAN VLAN.

• RSPAN VLAN traffic only flows on trunk ports.

• RSPAN VLANs must be configured in VLAN configuration mode by using the remote-span VLAN configuration mode command.

• STP can run on RSPAN VLAN trunks but not on SPAN destination ports.

• An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate devices.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

Related Topics

Creating an RSPAN Source Session, on page 1005
SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

• Routing—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the device, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the device routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.

• STP—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.

• CDP—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.

• VTP—You can use VTP to prune an RSPAN VLAN between devices.

• VLAN and trunking—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.

• EtherChannel—You can configure an EtherChannel group as a source port or a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored.

If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.

A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

• Multicast traffic can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.

• A private-VLAN port cannot be a SPAN destination port.

• A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.
• An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

**SPAN and RSPAN and Device Stacks**

Because the stack of devices represents one logical device, local SPAN source ports and destination ports can be in different devices in the stack. Therefore, the addition or deletion of devices in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a device is removed from the stack or an inactive session can become active when a device is added to the stack.

**Flow-Based SPAN**

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session. The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.

You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL—Filters only IPv4 packets.
- IPv6 FSPAN ACL—Filters only IPv6 packets.
- MAC FSPAN ACL—Filters only non-IP packets.

If a VLAN-based FSPAN session configured on a stack cannot fit in the hardware memory on one or more devices, it is treated as unloaded on those devices, and traffic meant for the FSPAN ACL and sourcing on that device is not copied to the SPAN destination ports. The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the devices where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

IPv4 and MAC FSPAN ACLs are supported on all feature sets. IPv6 FSPAN ACLs are supported only in the advanced IP Services feature set.

Configuration Guidelines

SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the `no monitor session session_number source {interface interface-id | vlan vlan-id}` global configuration command or the `no monitor session session_number destination interface interface-id` global configuration command. For destination interfaces, the `encapsulation` options are ignored with the `no` form of the command.

- To monitor all VLANs on the trunk port, use the `no monitor session session_number filter` global configuration command.

Related Topics

Creating a Local SPAN Session and Configuring Incoming Traffic, on page 999
Example: Configuring Local SPAN, on page 1019

RSPAN Configuration Guidelines

- All the SPAN configuration guidelines apply to RSPAN.

- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.

- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source devices.
• For RSPAN configuration, you can distribute the source ports and the destination ports across multiple devices in your network.

• Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.

• You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
  • The same RSPAN VLAN is used for an RSPAN session in all the devices.
  • All participating devices support RSPAN.

Creating an RSPAN Destination Session and Configuring Incoming Traffic, on page 1011
Examples: Creating an RSPAN VLAN, on page 1021

FSPAN and FRSPAN Configuration Guidelines

• When at least one FSPAN ACL is attached, FSPAN is enabled.

• When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

How to Configure SPAN and RSPAN

Creating a Local SPAN Session

Follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

SUMMARY STEPS

1. enable
2. configure terminal
3. no monitor session {session_number | all | local | remote}
4. monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]
5. monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate]}
6. end
7. show running-config
8. copy running-config startup-config

|--------|--------------------------------------------------------------------------------------------------|
| **Example:** |
| Device(config)# monitor session 1 destination interface gigabitethernet1/0/2 encapsulation replicate |

**Note** For local SPAN, you must use the same session number for the source and destination interfaces.

• For `session_number`, specify the session number entered in step 4.

• For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.

• (Optional) [, | -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.

(Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).

**Note** You can use `monitor session session_number destination` command multiple times to configure multiple destination ports.

## Creating a Local SPAN Session and Configuring Incoming Traffic

Follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** `{session_number | all | local | remote}`
4. **monitor session** `session_number source` `{interface interface-id | vlan vlan-id} [, -, both | rx | tx}
5. **monitor session** `session_number destination` `{interface interface-id [, -] [encapsulation replicate] [ingress {dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id}]}
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Removes any existing SPAN configuration for the session.</td>
</tr>
</tbody>
</table>

## Creating a Local SPAN Session and Configuring Incoming Traffic

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| *local*—Removes all local sessions.  
*remote*—Removes all remote SPAN sessions. |

### Step 4

**monitor session session_number source {interface interface-id | vlan vlan-id} [ , | - ] [ both | rx | tx ]**

**Example:**

```
Device(config)# monitor session 2 source gigabitethernet1/0/1 rx
```

Specifies the SPAN session and the source port (monitored port).

### Step 5

**monitor session session_number destination {interface interface-id [ , | - ] [ encapsulation replicate ] [ ingress { dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id } ] }**

**Example:**

```
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6
```

Specifies the SPAN session, the destination port, the packet encapsulation, and the ingress VLAN and encapsulation.

- For *session_number*, specify the session number entered in Step 4.
- For *interface-id*, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.
- (Optional) [ , | - ]—Specifies a series or range of interfaces. Enter a space before and after the comma or hyphen.
- (Optional) *encapsulation replicate* specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).
- *ingress* enables forwarding of incoming traffic on the destination port and to specify the encapsulation type:
  - *dot1q vlan vlan-id*—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN.
  - *untagged vlan vlan-id* or *vlan vlan-id*—Accepts incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.

### Step 6

**end**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

### Step 7

**show running-config**

**Example:**

Verifies your entries.
### Specifying VLANs to Filter

Follow these steps to limit SPAN source traffic to specific VLANs.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source interface interface-id`
5. `monitor session session_number filter vlan vlan-id [, | -]`
6. `monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate]}`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

**DETAILED STEPS**

</tbody>
</table>

| **Step 4** | Specifies the characteristics of the source port (monitored port) and SPAN session. |
| monitor session session_number source interface interface-id | - For `session_number`, the range is 1 to 66. |
| **Example:** | - For `interface-id`, specify the source port to monitor. The interface specified must already be configured as a trunk port. |
| Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx |

| **Step 5** | Limits the SPAN source traffic to specific VLANs. |
| monitor session session_number filter vlan vlan-id [, -] | - For `session_number`, enter the session number specified in Step 4. |
| **Example:** | - For `vlan-id`, the range is 1 to 4094. |
| Device(config)# monitor session 2 filter vlan 1 - 5 , 9 | - (Optional) Use a comma (,) to specify a series of VLANs, or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen. |

| **Step 6** | Specifies the SPAN session and the destination port (monitoring port). |
| monitor session session_number destination {interface interface-id [, -] [encapsulation replicate]} | - For `session_number`, specify the session number entered in Step 4. |
| **Example:** | - For `interface-id`, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. |
| Device(config)# monitor session 2 destination interface gigabitethernet1/0/1 | - (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. |
| | - (Optional) `encapsulation replicate` specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). |

| **Step 7** | Returns to privileged EXEC mode. |
| end | **Example:** |
Configuring a VLAN as an RSPAN VLAN

Follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `vlan vlan-id`
4. `remote-span`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
`enable`  
**Example:**
Device> `enable`  | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
`configure terminal`  
**Example:**
Device# `configure terminal`  | Enters the global configuration mode. |
### Configuring a VLAN as an RSPAN VLAN

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 3 | `vlan vlan-id` | Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094. The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs). **Example:**  
Device(config)# vlan 100 |
| Step 4 | `remote-span` | Configures the VLAN as an RSPAN VLAN. **Example:**  
Device(config-vlan)# remote-span |
| Step 5 | `end` | Returns to privileged EXEC mode. **Example:**  
Device(config-vlan)# end |
| Step 6 | `show running-config` | Verifies your entries. **Example:**  
Device# show running-config |
| Step 7 | `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. **Example:**  
Device# copy running-config startup-config |

**What to do next**

You must create the RSPAN VLAN in all devices that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one device, and VTP propagates it to the other devices in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination devices and any intermediate devices.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the `no remote-span` VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the `no monitor session session_number source {interface interface-id | vlan vlan-id}` global configuration command. To remove the RSPAN VLAN from the session, use the `no monitor session session_number destination remote vlan vlan-id`.  

---

**Network Management**

---

**Command or Action**

**Purpose**

Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094. The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs).

Configures the VLAN as an RSPAN VLAN.

Returns to privileged EXEC mode.

Verifies your entries.

(Optional) Saves your entries in the configuration file.
Creating an RSPAN Source Session

Follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]`
5. `monitor session session_number destination remote vlan vlan-id`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

</table>
| **Step 4**  
monitor session session_number source interface interface-id  
Example:  
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx | Specifies the characteristics of the source port (monitored port) and SPAN session.  
- For *session_number*, the range is 1 to 66.  
- For *interface-id*, specify the source port to monitor. The interface specified must already be configured as a trunk port. |
| **Step 5**  
monitor session session_number filter vlan vlan-id [, -]  
Example:  
Device(config)# monitor session 2 filter vlan 1 - 5 , 9 | Limits the SPAN source traffic to specific VLANs.  
- For *session_number*, enter the session number specified in step 4.  
- For *vlan-id*, the range is 1 to 4094.  
- (Optional) [, -] Use a comma (,) to specify a series of VLANs or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen. |
| **Step 6**  
monitor session session_number destination remote vlan vlan-id  
Example:  
Device(config)# monitor session 2 destination remote vlan 902 | Specifies the RSPAN session and the destination remote VLAN (RSPAN VLAN).  
- For *session_number*, enter the session number specified in Step 4.  
- For *vlan-id*, specify the RSPAN VLAN to carry the monitored traffic to the destination port. |
| **Step 7**  
end  
Example:  
Device(config)# end | Returns to privileged EXEC mode. |
| **Step 8**  
show running-config  
Example:  
Device# show running-config | Verifies your entries. |
| **Step 9**  
copy running-config startup-config  
Example:  
Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different device or device stack; that is, not the device or device stack on which the source session was configured.

Follow these steps to define the RSPAN VLAN on that device, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

SUMMARY STEPS

1. enable
2. configure terminal
3. vlan vlan-id
4. remote-span
5. exit
6. no monitor session {session_number | all | local | remote}
7. monitor session session_number source remote vlan vlan-id
8. monitor session session_number destination interface interface-id
9. end
10. show running-config
11. copy running-config startup-config

### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 2</th>
<th>configure terminal</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
</tbody>
</table>

**Purpose**

Enters global configuration mode.

| Step 3 | no monitor session {session_number | all | local | remote} |
|--------|---------------- |
| **Example:** | Device(config)# no monitor session 2 |

Removes any existing SPAN configuration for the session.
- For *session_number*, the range is 1 to 66.
- **all**—Removes all SPAN sessions.
- **local**—Removes all local sessions.
- **remote**—Removes all remote SPAN sessions.

| Step 4 | monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx] |
|--------|-----------------------------------------------|
| **Example:** | Device(config)# monitor session 2 source interface gigabitethernet1/0/1 |

Specifies the SPAN session and the source port (monitored port).
- For *session_number*, the range is 1 to 66.
- For *interface-id*, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (*port-channel port-channel-number*). Valid port-channel numbers are 1 to 48.
- For *vlan-id*, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).

**Note**

A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.

- (Optional) [, | -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.
- (Optional) [both | rx | tx]—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic.
  - **both**—Monitors both sent and received traffic. This is the default.
  - **rx**—Monitors received traffic.
  - **tx**—Monitors sent traffic.
<table>
<thead>
<tr>

<tr>
<td><strong>Step 6</strong> monitor session session_number filter {ip</td>
<td>ipv6</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# monitor session 2 filter ipv6 access-group 4</td>
<td>• For session_number, specify the session number entered in Step 4.</td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Note** You can use the monitor session session_number source command multiple times to configure multiple source ports.

**Note** SpecifiestheSPANsession,thetypesofpacketstofilter,andtheACLstouseinanFSPANsession.

**Note** For local SPAN, you must use the same session number for the source and destination interfaces.

You can use monitor session session_number destination command multiple times to configure multiple destination ports.
Configuring an FRSPAN Session

Follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [, -] [both | rx | tx]`
5. `monitor session session_number destination remote vlan vlan-id`
6. `vlan vlan-id`
7. `remote-span`
8. `exit`
9. `monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}`
10. `end`
11. `show running-config`
12. `copy running-config startup-config`

### Command or Action

<table>
<thead>
<tr>
<th>Step 2</th>
<th>configure terminal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
</tbody>
</table>

| Step 3 | no monitor session \{session_number | all | local | remote\} |
|--------|------------------|
| Example: | Device(config)# no monitor session 2 |

| Step 4 | monitor session session_number source \{interface interface-id | vlan vlan-id\} [, -] \{both | rx | tx\} |
|--------|----------------------------------|
| Example: | Device(config)# monitor session 2 source interface gigabitethernet1/0/1 |

### Purpose

- **Step 2**: Enters global configuration mode.
- **Step 3**: Removes any existing SPAN configuration for the session.
  - For `session_number`, the range is 1 to 66.
  - `all`—Removes all SPAN sessions.
  - `local`—Removes all local sessions.
  - `remote`—Removes all remote SPAN sessions.
- **Step 4**: Specifies the SPAN session and the source port (monitored port).
  - For `session_number`, the range is 1 to 66.
  - For `interface-id`, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (`port-channel port-channel-number`). Valid port-channel numbers are 1 to 48.
  - For `vlan-id`, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).

**Note**: A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.

- (Optional) [, -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.
- (Optional) `both` | `rx` | `tx`—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic.
  - `both`—Monitors both sent and received traffic. This is the default.
  - `rx`—Monitors received traffic.
  - `tx`—Monitors sent traffic.

</tr>
</thead>
<tbody>
<tr>
<td>show monitor</td>
<td>Displays the current SPAN, RSPAN, FSPAN, or FRSPAN configuration.</td>
</tr>
</tbody>
</table>

### SPAN and RSPAN Configuration Examples

#### Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```plaintext
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1
Device(config)# monitor session 1 destination interface gigabitethernet1/0/2
Device(config)# encapsulation replicate
Device(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```plaintext
Device> enable
Device# configure terminal
```
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1
Device(config)# end

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source vlan 1 - 3 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2
Device(config)# monitor session 2 source vlan 10
Device(config)# end

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with IEEE 802.1Q encapsulation and VLAN 6 as the default ingress VLAN:

Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source gigabitethernet1/0/1 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6
Device(config)# end

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination interface gigabitethernet1/0/1
Device(config)# end

Local SPAN, on page 986
SPAN Sessions, on page 988
SPAN Configuration Guidelines, on page 995
Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# vlan 901
Device(config-vlan)# remote span
Device(config-vlan)# end
```

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Device(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 1 source interface port-channel 2
Device(config)# monitor session 1 destination remote vlan 901
Device(config)# end
```

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination remote vlan 902
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 1 source remote vlan 901
Device(config)# monitor session 1 destination interface gigabitethernet2/0/1
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 2 source remote vlan 901
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6
Device(config)# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Packet Capture

• Packet capture is supported on Catalyst 3850 and Catalyst 3650.
• Wireshark is supported only on switches running IP Base image or IP Services image.
• Embedded Packet Capture is supported only on switches running Lan Base image.

The Embedded Packet Capture (EPC) software subsystem consumes CPU and memory resources during its operation. You must have adequate system resources for different types of operations. Some guidelines for using the system resources are provided in the table below.
Table 78: System Requirements for the EPC Subsystem

<table>
<thead>
<tr>
<th>System Resources</th>
<th>Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardware</td>
<td>CPU utilization requirements are platform dependent.</td>
</tr>
<tr>
<td>Memory</td>
<td>The packet buffer is stored in DRAM. The size of the packet buffer is user specified.</td>
</tr>
<tr>
<td>Diskspace</td>
<td>Packets can be exported to external devices. No intermediate storage on flash disk is required.</td>
</tr>
</tbody>
</table>

Restrictions for Packet Capture

Restrictions for Packet Capture

- Starting in Cisco IOS Release XE 3.3.0(SE), global packet capture on Wireshark is not supported.
- Display filters are supported on Wireshark.
- The CLI for configuring Wireshark requires that the feature be executed only from EXEC mode. Actions that usually occur in configuration submode (such as defining capture points), are handled at the EXEC mode instead. All key commands are not NVGEN’d and are not synchronized to the standby supervisor in NSF and SSO scenarios.
- Packets captured in the output direction of an interface might not reflect the changes made by rewrite (includes TTL, VLAN tag, CoS, checksum, MAC addresses, DSCP, precedent, UP, etc.).
- The Rewrite information of both ingress and egress packets are not captured.
- Limiting circular file storage by file size is not supported.
- File limit is limited to the size of the flash in IP Base and IP Services.
- Decoding of protocols such as Control and Provisioning of Wireless Access Points (CAPWAP) Is supported in IP Base and IP Services.
- In IP Base and IP Services, in file mode, the packets will be written to the files without export.
- The LAN Base image supports Embedded Wireshark with the following limitations:
  - Capture filters and display filters are not supported.
  - Active capture decoding is not available.
  - The output format is different from previous releases.
- Embedded Packet Capture (EPC) captures multicast packets only on ingress and does not capture the replicated packets on egress.

Wireless Packet Capture

- The only form of wireless capture is a CAPWAP tunnel capture.
• When capturing CAPWAP tunnels, no other interface types can be used as attachment points on the same capture point.

• Capturing multiple CAPWAP tunnels is supported.

• Core filters are not applied and should be omitted when capturing a CAPWAP tunnel.

• To capture a CAPWAP data tunnel, each CAPWAP tunnel is mapped to a physical port and an appropriate ACL will be applied to filter the traffic.

• To capture a CAPWAP non-data tunnel, the switch is set to capture traffic on all ports and apply an appropriate ACL to filter the traffic.

Configuration Limitations

• Up to 8 capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.

• Neither VRFs, management ports, nor private VLANs can be used as attachment points.

• Only one ACL (IPv4, IPv6 or MAC) is allowed in a Wireshark class map.

• Wireshark cannot capture packets on a destination SPAN port.

• Wireshark stops capturing when one of the attachment points (interfaces) attached to a capture point stops working. For example, if the device that is associated with an attachment point is unplugged from the . To resume capturing, the capture must be restarted manually.

• CPU-injected packets are considered control plane packets. Therefore, these types of packets will not be captured on an interface egress capture.

• MAC ACL is only used for non-IP packets such as ARP. It will not be supported on a Layer 3 port or SVI.

• MAC filter will not capture IP packets even if it matches the MAC address. This applies to all interfaces (L2 Switchport, L3 Routed Port)

• MAC filter cannot capture L2 packets (ARP) on L3 interfaces.

• IPv6-based ACLs are not supported in VACL.

• Layer 2 EtherChannels are not supported.

• Starting from Cisco IOS release 16.1, Layer 3 PortChannel Support is available.

• It is not possible to modify a capture point parameter when a capture is already active or has started.

• ACL logging and Wireshark are incompatible. Once Wireshark is activated, it takes priority. All traffic, including that being captured by ACL logging on any ports, will be redirected to Wireshark. We recommended that you deactivate ACL logging before starting Wireshark. Otherwise, Wireshark traffic will be contaminated by ACL logging traffic.

• Wireshark does not capture packets dropped by floodblock.

• If you capture both PACL and RACL on the same port, only one copy is sent to the CPU. If you capture a DTLS-encrypted CAPWAP interface, two copies are sent to Wireshark, one encrypted and the other
decrypted. The same behavior will occur if we capture a Layer 2 interface carrying DTLS-encrypted CAPWAP traffic. The core filter is based on the outer CAPWAP header.

- Starting from Cisco IOS release 16.1:
  - L3 port channel support is added.
  - Minor changes have been made in the display format.
  - Ability to display the number of packets in a cap file
  - Clearing the captured buffer deletes the buffer along with its contents. It cannot be run when the packet capture is active.
  - Additional warning message is displayed for control plane capturing.
  - In buffer mode, the packet display is allowed only after stop.
  - Packet statistics displayed at stop, in IP Services and IP Base.
  - Ability to query the number of packets captured in a pcap file.
  - When the display is from a cap file, display details of the selected packet can be viewed using packet-number.
  - Display filter can be used in file mode.
  - Statistics of packet capture (packets and bytes received, dropped) can be displayed either during the capture or after capture stop.
  - The system can query statistics on a pcap cap file's contents, as supported by Wireshark.
  - The packet capture session is always in streaming mode irrespective of the size of the buffer. There is no lock-step mode anymore.
  - Clearing buffer on an active capture point is supported only on Lan Base as this only clears the content. On all other licenses, it deletes the buffer itself, hence cannot be run during active capture.

⚠️ **Warning**  
Control plane packets are not rate limited and performance impacting. Please use filters to limit control plane packet capture.

- If the user changes interface from Switch port to routed port (L2 -> L3) or vice versa, they must delete the capture point and create a new one, once the interface comes back up. Stop/start the capture point will not work.
