- If the user deletes the file used by an active capture session, the capture session cannot create a new file, and all further packets captured are lost. The user will then need to restart the capture point.
Introduction to Packet Capture

Overview of Packet Capture Tool

The Packet Capture feature is an onboard packet capture facility that allows network administrators to capture packets flowing to, through, and from the device and to analyze them locally or save and export them for offline analysis by using tools such as Wireshark and Embedded Packet Capture (EPC). This feature simplifies network operations by allowing devices to become active participants in the management and operation of the network. This feature facilitates troubleshooting by gathering information about the packet format. This feature also facilitates application analysis and security.

The Embedded Packet Capture is supported on Lan Base. Embedded Packet Capture with Wireshark is supported on IP Base and IP Services.

Information about Wireshark

Wireshark Overview

Wireshark is a packet analyzer program, formerly known as Ethereal, that supports multiple protocols and presents information in a text-based user interface.

The ability to capture and analyze traffic provides data on network activity. Prior to Cisco IOS Release XE 3.3.0(SE), only two features addressed this need: SPAN and debug platform packet. Both have limitations. SPAN is ideal for capturing packets, but can only deliver them by forwarding them to some specified local or remote destination; it provides no local display or analysis support.

So the need exists for a traffic capture and analysis mechanism that is applicable to both hardware and software forwarded traffic and that provides strong packet capture, display, and analysis support, preferably using a well known interface.

Wireshark dumps packets to a file using a well known format called .pcap, and is applied or enabled on individual interfaces. You specify an interface in EXEC mode along with the filter and other parameters. The Wireshark application is applied only when you enter a start command, and is removed only when Wireshark stops capturing packets either automatically or manually.

Note

The current version of Wireshark installed on the switch is 1.10.8.

Capture Points

A capture point is the central policy definition of the Wireshark feature. The capture point describes all of the characteristics associated with a given instance of Wireshark: which packets to capture, where to capture them from, what to do with the captured packets, and when to stop. Capture points can be modified after creation, and do not become active until explicitly activated with a start command. This process is termed activating the capture point or starting the capture point. Capture points are identified by name and can also be manually or automatically deactivated or stopped.

Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.
In case of stacked systems, the capture point is activated on the active member. A switchover will terminate any active packet capture session and it will have to be restarted.

Attachment Points

An attachment point is a point in the logical packet process path associated with a capture point. An attachment point is an attribute of the capture point. Packets that impact an attachment point are tested against capture point filters; packets that match are copied and sent to the associated Wireshark instance of the capture point. A specific capture point can be associated with multiple attachment points, with limits on mixing attachment points of different types. Some restrictions apply when you specify attachment points of different types. Attachment points are directional (input or output or both) with the exception of the Layer 2 VLAN attachment point, which is always bidirectional.

In case of stacked systems, the attachment points on all stack members are valid. EPC captures the packets from all the defined attachment points. However these packets are processed only on the active member.

Filters

Filters are attributes of a capture point that identify and limit the subset of traffic traveling through the attachment point of a capture point, which is copied and passed to Wireshark. To be displayed by Wireshark, a packet must pass through an attachment point, as well as all of the filters associated with the capture point.

A capture point has the following types of filters:
- Core system filter—The core system filter is applied by hardware, and its match criteria is limited by hardware. This filter determines whether hardware-forwarded traffic is copied to software for Wireshark purposes.
• Display filter—The display filter is applied by Wireshark. Packets that fail the display filter are not displayed.

Core System Filter
You can specify core system filter match criteria by using the class map or ACL, or explicitly by using the CLI.

Note
When specifying CAPWAP as an attachment point, the core system filter is not used.

In some installations, you need to obtain authorization to modify the configuration, which can lead to extended delays if the approval process is lengthy. This can limit the ability of network administrators to monitor and analyze traffic. To address this situation, Wireshark supports explicit specification of core system filter match criteria from the EXEC mode CLI. The disadvantage is that the match criteria that you can specify is a limited subset of what class map supports, such as MAC, IP source and destination addresses, ether-type, IP protocol, and TCP/UDP source and destination ports.

If you prefer to use configuration mode, you can define ACLs or have class maps refer capture points to them. Explicit and ACL-based match criteria are used internally to construct class maps and policy maps.

Note The ACL and class map configuration are part of the system and not aspects of the Wireshark feature.

Display Filter
With the display filter, you can direct Wireshark to further narrow the set of packets to display when decoding and displaying from a .pcap file.

Related Topics

Actions
Wireshark can be invoked on live traffic or on a previously existing .pcap file. When invoked on live traffic, it can perform four types of actions on packets that pass its display filters:

• Captures to buffer in memory to decode and analyze and store
• Stores to a .pcap file
• Decodes and displays
• Stores and displays

When invoked on a .pcap file only, only the decode and display action is applicable.

Storage of Captured Packets to Buffer in Memory
Packets can be stored in the capture buffer in memory for subsequent decode, analysis, or storage to a .pcap file.

The capture buffer can be in linear or circular mode. In linear mode, new packets are discarded when the buffer is full. In circular mode, if the buffer is full, the oldest packets are discarded to accommodate the new packets. Although the buffer can also be cleared when needed, this mode is mainly used for debugging network
traffic. However, it is not possible to only clear the contents of the buffer alone without deleting it. Stop the current captures and restart the capture again for this to take effect.

---

**Note**

If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

---

**Storage of Captured Packets to a .pcap File**

- **Note**
  
  When WireShark is used on switches in a stack, packet captures can be stored only on flash or USB flash devices connected to the active switch.

  For example, if flash1 is connected to the active switch, and flash2 is connected to the secondary switch, only flash1 can be used to store packet captures.

  Attempts to store packet captures on devices other than flash or USB flash devices connected to the active switch will probably result in errors.

Wireshark can store captured packets to a .pcap file. The capture file can be located on the following storage devices:

- on-board flash storage (flash:)
- USB drive (usbflash0:)

- **Note**
  
  Attempts to store packet captures on unsupported devices or devices not connected to the active switch will probably result in errors.

When configuring a Wireshark capture point, you can associate a filename. When the capture point is activated, Wireshark creates a file with the specified name and writes packets to it. If the file already exists at the time of creation of the capture point, Wireshark queries you as to whether the file can be overwritten. If the file already exists at the time of activating the capture point, Wireshark will overwrite the existing file. Only one capture point may be associated with a given filename.

If the destination of the Wireshark writing process is full, Wireshark fails with partial data in the file. You must ensure that there is sufficient space in the file system before you start the capture session. With Cisco IOS Release IOS XE 3.3.0(SE), the file system full status is not detected for some storage devices.

You can reduce the required storage space by retaining only a segment, instead of the entire packet. Typically, you do not require details beyond the first 64 or 128 bytes. The default behavior is to store the entire packet.

To avoid possible packet drops when processing and writing to the file system, Wireshark can optionally use a memory buffer to temporarily hold packets as they arrive. Memory buffer size can be specified when the capture point is associated with a .pcap file.

---

**Packet Decoding and Display**

Wireshark can decode and display packets to the console. This functionality is possible for capture points applied to live traffic and for capture points applied to a previously existing .pcap file.
Decoding and displaying packets may be CPU intensive.

Wireshark can decode and display packet details for a wide variety of packet formats. The details are displayed by entering the `monitor capture name start` command with one of the following keyword options, which place you into a display and decode mode:

- **brief**—Displays one line per packet (the default).
- **detailed**—Decodes and displays all the fields of all the packets whose protocols are supported. Detailed modes require more CPU than the other two modes.
- **(hexadecimal) dump**—Displays one line per packet as a hexadecimal dump of the packet data and the printable characters of each packet.

When you enter the `capture` command with the decode and display option, the Wireshark output is returned to Cisco IOS and displayed on the console unchanged.

**Live Traffic Display**

Wireshark receives copies of packets from the core system. Wireshark applies its display filters to discard uninteresting packets, and then decodes and displays the remaining packets.

**.pcap File Display**

Wireshark can decode and display packets from a previously stored .pcap file and direct the display filter to selectively displayed packets.

**Packet Storage and Display**

Functionally, this mode is a combination of the previous two modes. Wireshark stores packets in the specified .pcap file and decodes and displays them to the console. Only the core filters are applicable here.

**Wireshark Capture Point Activation and Deactivation**

After a Wireshark capture point has been defined with its attachment points, filters, actions, and other options, it must be activated. Until the capture point is activated, it does not actually capture packets.

Before a capture point is activated, some functional checks are performed. A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.*

*When performing a wireless capture with a CAPWAP tunneling interface, the core system filter is not required and cannot be used.

The display filters are specified as needed.

After Wireshark capture points are activated, they can be deactivated in multiple ways. A capture point that is storing only packets to a .pcap file can be halted manually or configured with time or packet limits, after which the capture point halts automatically.
When a Wireshark capture point is activated, a fixed rate policer is applied automatically in the hardware so that the CPU is not flooded with Wireshark-directed packets. The disadvantage of the rate policer is that you cannot capture contiguous packets beyond the established rate even if more resources are available.

The set packet capture rate is 1000 packets per sec (pps). The 1000 pps limit is applied to the sum of all attachment points. For example, if we have a capture session with 3 attachment points, the rates of all 3 attachment points added together is policed to 1000 pps.

__Note__

Policer is not supported for control-plane packet capture. When activating control-plane capture points, you need to be extra cautious, so that it does not flood the CPU.

---

### Wireshark Features

This section describes how Wireshark features function in the environment:

- If port security and Wireshark are applied on an ingress capture, a packet that is dropped by port security will still be captured by Wireshark. If port security is applied on an ingress capture, and Wireshark is applied on an egress capture, a packet that is dropped by port security will not be captured by Wireshark.

- Packets dropped by Dynamic ARP Inspection (DAI) are not captured by Wireshark.

- If a port that is in STP blocked state is used as an attachment point and the core filter is matched, Wireshark will capture the packets that come into the port, even though the packets will be dropped by the switch.

- Classification-based security features—Packets that are dropped by input classification-based security features (such as ACLs and IPSG) are not caught by Wireshark capture points that are connected to attachment points at the same layer. In contrast, packets that are dropped by output classification-based security features are caught by Wireshark capture points that are connected to attachment points at the same layer. The logical model is that the Wireshark attachment point occurs after the security feature lookup on the input side, and symmetrically before the security feature lookup on the output side.

On ingress, a packet goes through a Layer 2 port, a VLAN, and a Layer 3 port/SVI. On egress, the packet goes through a Layer 3 port/SVI, a VLAN, and a Layer 2 port. If the attachment point is before the point where the packet is dropped, Wireshark will capture the packet. Otherwise, Wireshark will not capture the packet. For example, Wireshark capture policies connected to Layer 2 attachment points in the input direction capture packets dropped by Layer 3 classification-based security features. Symmetrically, Wireshark capture policies attached to Layer 3 attachment points in the output direction capture packets dropped by Layer 2 classification-based security features.

- Routed ports and switch virtual interfaces (SVIs)—Wireshark cannot capture the output of an SVI because the packets that go out of an SVI's output are generated by CPU. To capture these packets, include the control plane as an attachment point.

- VLANs—Starting with Cisco IOS Release 16.1, when a VLAN is used as a Wireshark attachment point, packet capture is supported on L2 and L3 in both input and output directions.

- Redirection features—In the input direction, features traffic redirected by Layer 3 (such as PBR and WCCP) are logically later than Layer 3 Wireshark attachment points. Wireshark captures these packets even though they might later be redirected out another Layer 3 interface. Symmetrically, output features redirected by Layer 3 (such as egress WCCP) are logically prior to Layer 3 Wireshark attachment points, and Wireshark will not capture them.

- SPAN—Wireshark cannot capture packets on interface configured as a SPAN destination.
• SPAN—Wireshark is able to capture packets on interfaces configured as a SPAN source in the ingress direction, and may be available for egress direction too.

• You can capture packets from a maximum of 1000 VLANs at a time, if no ACLs are applied. If ACLs are applied, the hardware will have less space for Wireshark to use. As a result, the maximum number of VLANs than can be used for packet capture at a time will be lower. Using more than 1000 VLANs tunnels at a time or extensive ACLs might have unpredictable results. For example, mobility may go down.

  Note  Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

Wireless Packet Capture in Wireshark

• Wireless traffic is encapsulated inside CAPWAP packets. However, capturing only a particular wireless client's traffic inside a CAPWAP tunnel is not supported when using the CAPWAP tunnel as an attachment point. To capture only a particular wireless client's traffic, use the client VLAN as an attachment point and formulate the core filter accordingly.

• Limited decoding of inner wireless traffic is supported. Decoding of inner wireless packets inside encrypted CAPWAP tunnels is not supported.

• No other interface type can be used with the CAPWAP tunneling interface on the same capture point. A CAPWAP tunneling interface and a Level 2 port cannot be attachment points on the same capture point.

• You cannot specify a core filter when capturing packets for Wireshark via the CAPWAP tunnel. However, you can use the Wireshark display filters for filtering wireless client traffic against a specific wireless client.

• You can capture packets from a maximum of 135 CAPWAP tunnels at a time if no ACLs are applied. If ACLs are applied, the hardware memory will have less space for Wireshark to use. As a result, the maximum number of CAPWAP tunnels than can be used for packet capture at a time will be lower. Using more than 135 CAPWAP tunnels at a time or using extensive ACLs might have unpredictable results. For example, mobility may go down.

  Note  Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

Guidelines for Wireshark

• During Wireshark packet capture, hardware forwarding happens concurrently.

• Before starting a Wireshark capture process, ensure that CPU usage is moderate and that sufficient memory (at least 200 MB) is available.

• If you plan to store packets to a storage file, ensure that sufficient space is available before beginning a Wireshark capture process.
• The CPU usage during Wireshark capture depends on how many packets match the specified conditions and on the intended actions for the matched packets (store, decode and display, or both).

• Where possible, keep the capture to the minimum (limit by packets, duration) to avoid high CPU usage and other undesirable conditions.

• Because packet forwarding typically occurs in hardware, packets are not copied to the CPU for software processing. For Wireshark packet capture, packets are copied and delivered to the CPU, which causes an increase in CPU usage.

To avoid high CPU usage, do the following:
  • Attach only relevant ports.
  • Use a class map, and secondarily, an access list to express match conditions. If neither is viable, use an explicit, in-line filter.
  • Adhere closely to the filter rules. Restrict the traffic type (such as, IPv4 only) with a restrictive, rather than relaxed ACL, which elicits unwanted traffic.

• Always limit packet capture to either a shorter duration or a smaller packet number. The parameters of the capture command enable you to specify the following:
  • Capture duration
  • Number of packets captured
  • File size
  • Packet segment size

• Run a capture session without limits if you know that very little traffic matches the core filter.

• You might experience high CPU (or memory) usage if:
  • You leave a capture session enabled and unattended for a long period of time, resulting in unanticipated bursts of traffic.
  • You launch a capture session with ring files or capture buffer and leave it unattended for a long time, resulting in performance or system health issues.

• During a capture session, watch for high CPU usage and memory consumption due to Wireshark that may impact performance or health. If these situations arise, stop the Wireshark session immediately.

• Avoid decoding and displaying packets from a .pcap file for a large file. Instead, transfer the .pcap file to a PC and run Wireshark on the PC.

• You can define up to eight Wireshark instances. An active show command that decodes and displays packets from a .pcap file or capture buffer counts as one instance. However, only one of the instances can be active.

• Whenever an ACL that is associated with a running capture is modified, you must restart the capture for the ACL modifications to take effect. If you do not restart the capture, it will continue to use the original ACL as if it had not been modified.

• To avoid packet loss, consider the following:
• Use store-only (when you do not specify the display option) while capturing live packets rather than decode and display, which is a CPU-intensive operation (especially in detailed mode).

• If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

• If you use the default buffer size and see that you are losing packets, you can increase the buffer size to avoid losing packets.

• Writing to flash disk is a CPU-intensive operation, so if the capture rate is insufficient, you may want to use a buffer capture.

• The Wireshark capture session always operates in streaming mode at the rate of 1000 pps.

• The streaming capture mode rate is 1000 pps.

• If you want to decode and display live packets in the console window, ensure that the Wireshark session is bounded by a short capture duration.

---

**Warning**

A Wireshark session with either a longer duration limit or no capture duration (using a terminal with no auto-more support using the `term len 0` command) may make the console or terminal unusable.

• When using Wireshark to capture live traffic that leads to high CPU usage, consider applying a QoS policy temporarily to limit the actual traffic until the capture process concludes.

• All Wireshark-related commands are in EXEC mode; no configuration commands exist for Wireshark.

  If you need to use access list or class-map in the Wireshark CLI, you must define an access list and class map with configuration commands.

• No specific order applies when defining a capture point; you can define capture point parameters in any order, provided that CLI allows this. The Wireshark CLI allows as many parameters as possible on a single line. This limits the number of commands required to define a capture point.

• All parameters except attachment points take a single value. Generally, you can replace the value with a new one by reentering the command. After user confirmation, the system accepts the new value and overrides the older one. A `no` form of the command is unnecessary to provide a new value, but it is necessary to remove a parameter.

• Wireshark allows you to specify one or more attachment points. To add more than one attachment point, reenter the command with the new attachment point. To remove an attachment point, use the `no` form of the command. You can specify an interface range as an attachment point. For example, enter `monitor capture mycap interface GigabitEthernet1/0/1 in` where interface GigabitEthernet1/0/1 is an attachment point.

  If you also need to attach interface GigabitEthernet1/0/2, specify it in another line as follows:

  `monitor capture mycap interface GigabitEthernet1/0/2 in`

• You cannot make changes to a capture point when the capture is active.

• The action you want to perform determines which parameters are mandatory. The Wireshark CLI allows you to specify or modify any parameter prior to entering the `start` command. When you enter the `start` command, Wireshark will start only after determining that all mandatory parameters have been provided.
• If the file already exists at the time of creation of the capture point, Wireshark queries you as to whether the file can be overwritten. If the file already exists at the time of activating the capture point, Wireshark will overwrite the existing file.

• The core filter can be an explicit filter, access list, or class map. Specifying a newer filter of these types replaces the existing one.

Note
A core filter is required except when using a CAPWAP tunnel interface as a capture point attachment point.

• You can terminate a Wireshark session with an explicit stop command or by entering q in automore mode. The session could terminate itself automatically when a stop condition such as duration or packet capture limit is met, or if an internal error occurs, or resource is full (specifically if disk is full in file mode).

• Dropped packets will not be shown at the end of the capture. However, only the count of dropped, oversized packets will be displayed.

Information About Embedded Packet Capture
Embedded Packet Capture Overview
Embedded Packet Capture (EPC) provides an embedded systems management facility that helps in tracing and troubleshooting packets. This feature allows network administrators to capture data packets flowing through, to, and from a Cisco device. The network administrator may define the capture buffer size and type (circular, or linear) and the maximum number of bytes of each packet to capture. The packet capture rate can be throttled using further administrative controls. For example, options allow for filtering the packets to be captured using an Access Control List and, optionally, further defined by specifying a maximum packet capture rate or by specifying a sampling interval.

Benefits of Embedded Packet Capture
• Ability to capture IPv4 and IPv6 packets in the device, and also capture non-IP packets with MAC filter or match any MAC address.
• Extensible infrastructure for enabling packet capture points. A capture point is a traffic transit point where a packet is captured and associated with a buffer.

• Facility to export the packet capture in packet capture file (PCAP) format suitable for analysis using any external tool.

• Methods to decode data packets captured with varying degrees of detail.

Packet Data Capture

Packet data capture is the capture of data packets that are then stored in a buffer. You can define packet data captures by providing unique names and parameters.

You can perform the following actions on the capture:

• Activate captures at any interface.

• Apply access control lists (ACLs) or class maps to capture points.

Note

Network Based Application Recognition (NBAR) and MAC-style class map is not supported.

• Destroy captures.

• Specify buffer storage parameters such as size and type. The size ranges from 1 MB to 100 MB. The default buffer is linear; the other option for the buffer is circular.

• Specify match criteria that includes information about the protocol, IP address or port address.

Configuring Packet Capture

How to Configure Wireshark

To configure Wireshark, perform these basic steps.

1. Define a capture point.

2. (Optional) Add or modify the capture point's parameters.

3. Activate or deactivate a capture point.

4. Delete the capture point when you are no longer using it.
Defining a Capture Point

The example in this procedure defines a very simple capture point. If you choose, you can define a capture point and all of its parameters with one instance of the `monitor capture` command.

You must define an attachment point, direction of capture, and core filter to have a functional capture point. An exception to needing to define a core filter is when you are defining a wireless capture point using a CAPWAP tunneling interface. In this case, you do not define your core filter. It cannot be used.

Follow these steps to define a capture point.

**SUMMARY STEPS**

1. `enable`
2. `show capwap summary`
3. `monitor capture {capture-name} {interface interface-type interface-id | control-plane} {in | out | both}
   match {any | ipv4 any any | ipv6 any any}
4. `monitor capture {capture-name} [match {any | ipv4 any any | ipv6 any any}]
5. `show monitorcapture {capture-name} [parameter]
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>

### Defining a Capture Point

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# show capwap summary</td>
<td>Use this command only if you are using a CAPWAP tunnel as an attachment point to perform a wireless capture. See the CAPWAP example in the examples section.</td>
</tr>
</tbody>
</table>

**Note**

Defines the capture point, specifies the attachment point with which the capture point is associated, and specifies the direction of the capture.

The keywords have these meanings:

- **capture-name**—Specifies the name of the capture point to be defined (mycap is used in the example). Capture Name should be less than or equal to 8 characters. Only alphanumerics and underscore (_) is permitted.

- **interface interface-type interface-id | control-plane | in | out | both**

  - (Optional) **interface interface-type interface-id**—Specifies the attachment point with which the capture point is associated (GigabitEthernet1/0/1 is used in the example).

  **Note** Optionally, you can define multiple attachment points and all of the parameters for this capture point with this one command instance. These parameters are discussed in the instructions for modifying capture point parameters. Range support is also available both for adding and removing attachment points.

  Use one of the following for **interface-type**:

  - **GigabitEthernet**—Specifies the attachment point as GigabitEthernet.

  - **vlan**—Specifies the attachment point as a VLAN.

    **Note** Only ingress capture (in) is allowed when using this interface as an attachment point.

  - **capwap**—Specifies the attachment point as a CAPWAP tunnel.

    **Note** When using this interface as an attachment point, a core filter cannot be used.

  - (Optional) **control-plane**—Specifies the control plane as an attachment point.

  - **in | out | both**—Specifies the direction of capture.

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
What to do next

You can add additional attachment points, modify the parameters of your capture point, then activate it, or if you want to use your capture point just as it is, you can now activate it.

---

Note

You cannot change a capture point's parameters using the methods presented in this topic.

If the user enters an incorrect capture name, or an invalid/non existing attachment point, the switch will show errors like "Capture Name should be less than or equal to 8 characters. Only alphanumeric characters and underscore (_) is permitted" and "% Invalid input detected at "marker" respectively.

Adding or Modifying Capture Point Parameters

Although listed in sequence, the steps to specify values for the parameters can be executed in any order. You can also specify them in one, two, or several lines. Except for attachment points, which can be multiple, you can replace any value with a more recent value by redefining the same option. You will need to confirm interactively when certain parameters already specified are being modified.

Follow these steps to modify a capture point's parameters.

**Before you begin**

A capture point must be defined before you can use these instructions.

**SUMMARY STEPS**

1. enable
2. monitor capture {capture-name} match {any | mac mac-match-string | ipv4 {any | host | protocol} {any | host} | ipv6 {any | host | protocol} {any | host}}
3. monitor capture {capture-name} limit { [duration seconds] [packet-length size] [packets num]}
4. monitor capture {capture-name} file {location filename}
5. monitor capture {capture-name} file {buffer-size size}
6. show monitor capture {capture-name} [parameter]
7. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| enable
| Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**
| monitor capture {capture-name} match {any | mac mac-match-string | ipv4 {any | host | protocol} {any | host} | ipv6 {any | host | protocol} {any | host}}
| Example: Device# monitor capture mycap match ipv4 any any | Defines the core system filter (ipv4 any any), defined either explicitly, through ACL or through a class map. |
| **Step 3**
| monitor capture {capture-name} limit { [duration seconds] [packet-length size] [packets num]}
| Example: Device# monitor capture mycap limit duration 60 packet-len 400 | Specifies the session limit in seconds (60), packets captured, or the packet segment length to be retained by Wireshark (400). |
| **Step 4**
| monitor capture {capture-name} file {location filename} | Specifies the file association, if the capture point intends to capture packets rather than only display them. |
### Command or Action

<table>
<thead>
<tr>
<th>Example:</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# monitor capture mycap file location flash:mycap.pcap</td>
<td>Note If the file already exists, you have to confirm if it can be overwritten.</td>
</tr>
<tr>
<td>Device# monitor capture mycap file location bootdisk:mycap.pcap</td>
<td>Note File option does not exist on LAN base license.</td>
</tr>
</tbody>
</table>

### Step 5

**monitor capture** `{capture-name}` **file** `{buffer-size size}`

**Example:**

Device# monitor capture mycap file buffer-size 100

### Step 6

**show monitor capture** `{capture-name} [ parameter`  
**Example:**

Device# show monitor capture mycap parameter  
  monitor capture mycap interface  
  GigabitEthernet1/0/1 in  
  monitor capture mycap match ipv4 any any  
  monitor capture mycap limit duration 60  
  packet-len 400  
  monitor capture point mycap file location  
  bootdisk:mycap.pcap  
  monitor capture mycap file buffer-size 100

### Step 7

**end**

**Example:**

Device(config)# end

### Examples

#### Modifying Parameters

**Associating or Disassociating a Capture File**

Device# monitor capture point mycap file location flash:mycap.pcap
Device# no monitor capture mycap file

**Specifying a Memory Buffer Size for Packet Burst Handling**

Device# monitor capture mycap buffer size 100

**Defining an Explicit Core System Filter to Match Both IPv4 and IPv6**

Device# monitor capture mycap match any

### What to do next

if your capture point contains all of the parameters you want, activate it.

Deleting Capture Point Parameters

Although listed in sequence, the steps to delete parameters can be executed in any order. You can also delete them in one, two, or several lines. Except for attachment points, which can be multiple, you can delete any parameter.

Follow these steps to delete a capture point's parameters.

**Before you begin**

A capture point parameter must be defined before you can use these instructions to delete it.

**SUMMARY STEPS**

1. `enable`
2. `no monitor capture {capture-name} match`
3. `no monitor capture {capture-name} limit [duration] [packet-length] [packets]`
4. `no monitor capture {capture-name} file [location] [buffer-size]`
5. `show monitor capture {capture-name} [parameter]`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

### Deleting a Capture Point

#### Before you begin

A capture point must be defined before you can use these instructions to delete it. You have to stop the capture point before you can delete it.

#### SUMMARY STEPS

1. `enable`

---

**What to do next**

If your capture point contains all of the parameters you want, activate it.

**Note**

If the parameters are deleted when the capture point is active, the switch will show an error "Capture is active".

**What to do next**

You can define a new capture point with the same name as the one you deleted. These instructions are usually performed when one wants to start over with defining a capture point.

**Related Topics**

How to Configure Wireshark, on page 1039
Activating and Deactivating a Capture Point

Follow these steps to activate or deactivate a capture point.

**Before you begin**

A capture point can be activated even if an attachment point and a core system filter have been defined and the associated filename already exists. In such an instance, the existing file will be overwritten.

A capture point with no associated filename can only be activated to display. When the filename is not specified, the packets are captured into the buffer. Live display (display during capture) is available in both file and buffer modes.

If no display filters are specified, packets are not displayed live, and all the packets captured by the core system filter are displayed. The default display mode is brief.

---

**Note**

When using a CAPWAP tunneling interface as an attachment point, core filters are not used, so there is no requirement to define them in this case.

---

**SUMMARY STEPS**

1. enable
2. monitor capture {capture-name} start [display [display-filter filter-string]] [brief | detailed | dump]
3. monitor capture {capture-name} stop
4. end
5. show running-config
6. copy running-config startup-config

---

**DETAILED STEPS**

### Clearing the Capture Point Buffer

Follow these steps to clear the buffer contents or save them to an external file for storage.

---

**Note**  
If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss. Do not try to clear buffer on an active capture point.

---

**Note**  
Clearing buffer on an active capture point is supported only on Lan Base as this only clears the content. On all other licenses, it deletes the buffer itself, hence cannot be run during active capture.

---

### SUMMARY STEPS

1. **enable**  
2. **monitor capture** \{capture-name\} [clear | export filename]  
3. **end**  
4. **show running-config**  
5. **copy running-config startup-config**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
</tbody>
</table>
| enable            | Enables privileged EXEC mode. Enter your password if prompted.  
| Example:          |         |
| Device> enable    |         |
### Clearing the Capture Point Buffer

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>monitor capture <code>{capture-name}</code> [clear</td>
<td>export</td>
</tr>
<tr>
<td></td>
<td>filename]</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# monitor capture mycap clear</td>
<td></td>
</tr>
</tbody>
</table>

#### Note
When the clear command is run,

- On Lan base - the command clears the buffer contents without deleting the buffer
- On all other licenses - the command deletes the buffer itself.

Export - Saves the captured packets in the buffer as well as deletes the buffer.

#### Examples: Capture Point Buffer Handling

**Exporting Capture to a File**

Device# monitor capture mycap export flash:mycap.pcap

Storage configured as File for this capture

**Clearing Capture Point Buffer**

Device# monitor capture mycap clear

Capture configured with file options

#### What to do next

**Note**
If you try to clear the capture point buffer on licenses other than LAN Base, the switch will show an error "Failed to clear capture buffer: Capture Buffer BUSY".
How to Implement Embedded Packet Capture

Managing Packet Data Capture

**Note**

Export of an active capture point is only supported on LAN Base licence. On all other license we need to stop the capture first and only then export.

**SUMMARY STEPS**

1. `enable`
2. `monitor capture capture-name access-list access-list-name`
3. `monitor capture capture-name limit duration seconds`
4. `monitor capture capture-name interface interface-name both`
5. `monitor capture capture-name buffer circular size bytes`
6. `monitor capture capture-name start`
7. `monitor capture capture-name stop`
8. `monitor capture capture-name export file-location/file-name`
9. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;Example:&lt;br&gt;Device&gt; enable</td>
</tr>
<tr>
<td>*</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>monitor capture capture-name access-list access-list-name</code>&lt;br&gt;Example:&lt;br&gt;Device# monitor capture mycap access-list v4acl</td>
</tr>
<tr>
<td>*</td>
<td>Configures a monitor capture specifying an access list as the core filter for the packet capture.</td>
</tr>
</tbody>
</table>
### Purpose

#### Command or Action

| Step 3 | `monitor capture capture-name limit duration seconds` | Configures monitor capture limits.

**Example:**
```
Device# monitor capture mycap limit duration 1000
```

| Step 4 | `monitor capture capture-name interface interface-name both` | Configures monitor capture specifying an attachment point and the packet flow direction.

**Example:**
```
Device# monitor capture mycap interface GigabitEthernet 0/0/1 both
```

| Step 5 | `monitor capture capture-name buffer circular size bytes` | Configures a buffer to capture packet data.

**Example:**
```
Device# monitor capture mycap buffer circular size 10
```

| Step 6 | `monitor capture capture-name start` | Starts the capture of packet data at a traffic trace point into a buffer.

**Example:**
```
Device# monitor capture mycap start
```

| Step 7 | `monitor capture capture-name stop` | Stops the capture of packet data at a traffic trace point.

**Example:**
```
Device# monitor capture mycap stop
```

| Step 8 | `monitor capture capture-name export file-location/file-name` | Exports captured data for analysis.

**Example:**
```
Device# monitor capture mycap export tftp://10.1.88.9/mycap.pcap
```

| Step 9 | `end` | Returns to privileged EXEC mode.

**Example:**
```
Device# end
```

---

**What to do next**

**Note**

If you try to export an active capture point on licenses other than LAN Base, the switch will show an error "Failed to Export: Capture Buffer BUSY".

---
Monitoring and Maintaining Captured Data

Perform this task to monitor and maintain the packet data captured. Capture buffer details and capture point details are displayed.

**SUMMARY STEPS**

1. enable
2. show monitor capture capture-buffer-name buffer dump
3. show monitor capture capture-buffer-name parameter
4. debug epc capture-point
5. debug epc provision
6. end

**DETAILED STEPS**

### Monitoring Packet Capture

#### Configuration Examples for Wireshark

**Example: Displaying a Brief Output from a .pcap File**

You can display the output from a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap brief
```

- Starting the packet display ........ Press Ctrl + Shift + 6 to exit
- Host 10.10.10.1 (10.10.10.2) sent 15 packets

```
1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=0/0, ttl=254
2 0.000051000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=0/0, ttl=255 (request in 1)
3 0.000908000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=1/256, ttl=254
4 0.001782000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=1/256, ttl=255 (request in 3)
5 0.002961000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=2/512, ttl=254
6 0.003676000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=2/512, ttl=255 (request in 5)
7 0.004835000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=3/768, ttl=254
8 0.005579000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=3/768, ttl=255 (request in 7)
9 0.006850000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=4/1024, ttl=254
10 0.007586000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=4/1024, ttl=255 (request in 9)
11 0.008768000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=5/1280, ttl=254
12 0.009497000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=5/1280, ttl=255 (request in 11)
13 0.010695000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=6/1536, ttl=254
14 0.011427000 10.10.10.1 -> 10.10.10.2 ICMP 114 Echo (ping) reply id=0x002e, seq=6/1536, ttl=255 (request in 13)
15 0.012728000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=7/1922, ttl=254
```
Example: Displaying Detailed Output from a .pcap File

You can display the detailed .pcap file output by entering:

```
Device# show monitor capture file flash:mycap.pcap detailed
```

Starting the packet display ........ Press Ctrl + Shift + 6 to exit

Example: Displaying Packets from a .pcap File using a Display Filter

You can display the .pcap file packets output by entering:

```
Device# show monitor capture file flash:mycap.pcap display-filter "ip.src == 10.10.10.2" brief
```

Starting the packet display ....... Press Ctrl + Shift + 6 to exit

```
1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=0/0, ttl=254
2 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=1/256, ttl=254
3 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=2/512, ttl=254
4 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=3/768, ttl=254
5 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=4/1024, ttl=254
6 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=5/1280, ttl=254
7 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=6/1536, ttl=254
8 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=7/1792, ttl=254
9 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=8/2048, ttl=254
10 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=9/2304, ttl=254
11 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=10/2560, ttl=254
12 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e, seq=11/2816, ttl=254
```

Example: Displaying the Number of Packets Captured in a .pcap File

You can display the number of packets captured in a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap packet-count
```

```
File name: /flash/mycap.pcap
Number of packets: 50
```

Example: Displaying a Single Packet Dump from a .pcap File

You can display a single packet dump from a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap packet-number 10 dump
```

Starting the packet display ....... Press Ctrl + Shift + 6 to exit

```
0000 00 e1 6d 31 f1 80 00 e1 6d 31 f1 80 00 45 00 .ml....ml....E.

Example: Displaying Statistics of Packets Captured in a .pcap File

You can display the statistics of the packets captured in a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap statistics "h225,counter"
```

---

Example: Simple Capture and Display

This example shows how to monitor traffic in the Layer 3 interface Gigabit Ethernet 1/0/1:

**Step 1:** Define a capture point to match on the relevant traffic by entering:

```
Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 50
Device# monitor capture mycap buffer size 100
```

To avoid high CPU utilization, a low packet count and duration as limits has been set.

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```
Device# show monitor capture mycap parameter
```

```
Device# show monitor capture mycap
```

```
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
Status : Inactive
Filter Details:
  IPv4
    Source IP: any
    Destination IP: any
    Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
  Buffer Size (in MB): 100
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 50
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packet sampling rate: 0 (no sampling)
```

**Step 3:** Start the capture process and display the results.

```
Device# monitor capture mycap start display
Starting the packet display .......... Press Ctrl + Shift + 6 to exit
```

```
1 0.000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030, seq=0/0, ttl=254
2 0.003682 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030, seq=1/256, ttl=254
3 0.006586 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
```
seq=2/512, ttl=254
4 0.008941 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
seq=3/768, ttl=254
5 0.011138 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
seq=4/1024, ttl=254
6 0.014099 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
seq=5/1280, ttl=254
7 0.016868 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
seq=6/1536, ttl=254
8 0.019210 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
seq=7/1792, ttl=254
9 0.024785 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0030,
seq=8/2048, ttl=254
--More--

Step 4: Delete the capture point by entering:

Device# no monitor capture mycap

A stop command is not required in this particular case since we have set a limit and the capture will automatically stop once that limit is reached.

For more information on syntax to be used for pcap statistics, refer the "Additional References" section.

Example: Simple Capture and Store

This example shows how to capture packets to a filter:

Step 1: Define a capture point to match on the relevant traffic and associate it to a file by entering:

Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 50
Device# monitor capture mycap file location flash:mycap.pcap

Step 2: Confirm that the capture point has been correctly defined by entering:

Device# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/3 in
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location flash:mycap.pcap
Example: Simple Capture and Store

```plaintext
monitor capture mycap limit packets 50 duration 60

Device# show monitor capture mycap

Status Information for Capture mycap
  Target Type:
    Interface: GigabitEthernet1/0/3, Direction: in
  Status : Inactive
Filter Details:
  IPv4
    Source IP: any
    Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
File Details:
  Associated file name: flash:mycap.pcap
Limit Details:
  Number of Packets to capture: 50
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packet sampling rate: 0 (no sampling)

Step 3: Launch packet capture by entering:
Device# monitor capture mycap start

Step 4: Display extended capture statistics during runtime by entering:
Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 15 seconds
  Packets received - 40
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 40
  Bytes received - 7280
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 4560

Step 5: After sufficient time has passed, stop the capture by entering:
Device# monitor capture mycap stop
Capture statistics collected at software (Buffer & Wireshark):
  Capture duration - 20 seconds
  Packets received - 50
  Packets dropped - 0
  Packets oversized - 0

Note
Alternatively, you could allow the capture operation stop automatically after the time has elapsed or the packet count has been met.
The mycap.pcap file now contains the captured packets.

Step 6: Display extended capture statistics after stop by entering:
```
Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 20 seconds
  Packets received - 50
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 50
  Bytes received - 8190
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent ~ 5130

Step 7: Display the packets by entering:
Device# show monitor capture file flash:mycap.pcap
Starting the packet display ........ Press Ctrl + Shift + 6 to exit

1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=0/0, ttl=254
2 0.002555000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=1/256, ttl=254
3 0.006199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=2/512, ttl=254
4 0.009199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=3/768, ttl=254
5 0.011647000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=4/1024, ttl=254
6 0.014168000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=5/1280, ttl=254
7 0.016737000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=6/1536, ttl=254
8 0.019403000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=7/1792, ttl=254
9 0.022151000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=8/2048, ttl=254
10 0.024722000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=9/2304, ttl=254
11 0.026890000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=10/2560, ttl=254
12 0.028862000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031, seq=11/2816, ttl=254
   --More--

For more information on syntax to be used for pcap statistics, refer the "Additional References" section.

Step 8: Delete the capture point by entering:
Device# no monitor capture mycap

Example: Using Buffer Capture

This example shows how to use buffer capture:

**Step 1:** Launch a capture session with the buffer capture option by entering:

```
Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap buffer circular size 1
Device# monitor capture mycap start
```

**Step 2:** Determine whether the capture is active by entering:

```
Device# show monitor capture mycap
```

```
Status Information for Capture mycap
Target Type: Interface: GigabitEthernet1/0/3, Direction: in
Status : Active
Filter Details: IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details: Buffer Type: CIRCULAR
Buffer Size (in MB): 1
File Details: File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Maximum number of packets to capture per second: 1000
  Packet sampling rate: 0 (no sampling)
```

**Step 3:** Display extended capture statistics during runtime by entering:

```
Device# show monitor capture mycap capture-statistics
```

```
Capture statistics collected at software:
  Capture duration - 88 seconds
  Packets received - 1000
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 1000
  Bytes received - 182000
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 114000
```

**Step 4:** Stop the capture by entering:

```
Device# monitor capture mycap stop
```

```
Capture statistics collected at software (Buffer):
  Capture duration - 2185 seconds
  Packets received - 51500
```

Clearing the Capture Point Buffer, on page 1053
How to Configure Wireshark, on page 1039
Capture Points, on page 1029
Attachment Points, on page 1030
Step 5: Display extended capture statistics after stop by entering:

```
Device# show monitor capture mycap capture-statistics
```

Capture statistics collected at software:
- Capture duration: 156 seconds
- Packets received: 2000
- Packets dropped: 0
- Packets oversized: 0
- Packets errored: 0
- Packets sent: 2000
- Bytes received: 364000
- Bytes dropped: 0
- Bytes oversized: 0
- Bytes errored: 0
- Bytes sent: 228000

Step 6: Determine whether the capture is active by entering:

```
Device# show monitor capture mycap
```

Status Information for Capture mycap
- Target Type: Interface: GigabitEthernet1/0/3, Direction: in
- Status: Inactive
- Filter Details:
  - IPv4
    - Source IP: any
    - Destination IP: any
    - Protocol: any
- Buffer Details:
  - Buffer Type: CIRCULAR
  - Buffer Size (in MB): 1
- File Details:
  - File not associated
- Limit Details:
  - Number of Packets to capture: 0 (no limit)
  - Packet Capture duration: 0 (no limit)
  - Packet Size to capture: 0 (no limit)
  - Maximum number of packets to capture per second: 1000
  - Packet sampling rate: 0 (no sampling)

Step 7: Display the packets in the buffer by entering:

```
Device# show monitor capture mycap buffer brief
```

Starting the packet display ........ Press Ctrl + Shift + 6 to exit

```
1 0.000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40057/31132, ttl=254
2 0.000030 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40058/31388, ttl=254
3 0.000052 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40059/31644, ttl=254
4 0.000073 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40060/31900, ttl=254
5 0.000094 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40061/32156, ttl=254
6 0.000115 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40062/32412, ttl=254
7 0.000137 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038, seq=40063/32668, ttl=254
8 0.000158 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0038,
```
Notice that the packets have been buffered.

Step 8: Display the packets in other display modes.

Device# show monitor capture mycap buffer detailed
Starting the packet display ......... Press Ctrl + Shift + 6 to exit

Frame 1: 114 bytes on wire (912 bits), 114 bytes captured (912 bits) on interface 0
  Interface id: 0
  Encapsulation type: Ethernet (1)
  Arrival Time: Nov 6, 2015 18:10:06.297972000 UTC
  [Time shift for this packet: 0.000000000 seconds]
  Epoch Time: 1446833406.297972000 seconds
  [Time delta from previous captured frame: 0.000000000 seconds]
  [Time delta from previous displayed frame: 0.000000000 seconds]
  [Time since reference or first frame: 0.000000000 seconds]
  Frame Number: 1
  Frame Length: 114 bytes (912 bits)
  Capture Length: 114 bytes (912 bits)
  [Frame is marked: False]
  [Frame is ignored: False]
    Destination: Cisco_31:f1:c6 (00:e1:6d:31:f1:c6)
    Address: Cisco_31:f1:c6 (00:e1:6d:31:f1:c6)

    Address: Cisco_f3:63:46 (00:e1:6d:31:f1:c6)
    ........ ..0. .... .... .... .... .... = LG bit: Globally unique address (factory default)
    ........ ...0 .... .... .... .... .... = IG bit: Individual address (unicast)
  Type: IP (0x0800)
  Internet Protocol Version 4, Src: 10.10.10.2 (10.10.10.2), Dst: 10.10.10.1 (10.10.10.1)
    Version: 4
    Header length: 20 bytes
    Differentiated Services Field: 0x00 (DSCP 0x00: Default; ECN: 0x00: Not-ECT (Not
    ECN-Capable Transport))
    0000 00.. = Differentiated Services Codepoint: Default (0x00)
    .... .... = Explicit Congestion Notification: Not-ECT (Not ECN-Capable Transport)
    (0x00)
  Total Length: 100
  Identification: 0xabdd (43997)
  Flags: 0x00
    0... ..... = Reserved bit: Not set
    .0. ..... = Don't fragment: Not set
    ..0. ..... = More fragments: Not set
  Fragment offset: 0
  Time to live: 254
  Protocol: ICMP (1)
  Header checksum: 0xe8a4 [validation disabled]
  [Good: False]
  [Bad: False]
Example: Using Buffer Capture

Source: 10.10.10.2 (10.10.10.2)
Destination: 10.10.10.1 (10.10.10.1)

Internet Control Message Protocol
Type: 8 (Echo (ping) request)
Code: 0
Checksum: 0xa620 [correct]
Identifier (BE): 56 (0x0038)
Identifier (LE): 14336 (0x3800)
Sequence number (BE): 40057 (0x9c79)
Sequence number (LE): 31132 (0x799c)
Data (72 bytes)

DATA: 000000ab63153063abcdabcdabcdabcdabcdabcdabcdabcd...

Frame 2: 114 bytes on wire (912 bits), 114 bytes captured (912 bits) on interface 0

Device# show monitor capture mycap buffer dump
Starting the packet display ........ Press Ctrl + Shift + 6 to exit

Step 9: Clear the buffer by entering:
Device# monitor capture mycap clear

Note - Clearing the buffer deletes the buffer along with the contents.

If you require the buffer contents to be displayed, run the clear commands after show commands.

Step 10: Restart the traffic, wait for 10 seconds, then display the buffer contents by entering:
We cannot run show from buffer during an active capture. Capture should be stopped before running show from buffer. We can however run a show on a pcap file during an active capture in both file and buffer mode. In file mode, we can display the packets in the current capture session’s pcap file as well when the capture is active.

**Note**

We cannot run show from buffer during an active capture. Capture should be stopped before running show from buffer. We can however run a show on a pcap file during an active capture in both file and buffer mode. In file mode, we can display the packets in the current capture session’s pcap file as well when the capture is active.

```
Device# monitor capture mycap start
Switch# show monitor capture mycap

Status Information for Capture mycap
Target Type:
    Interface: GigabitEthernet1/0/3, Direction: in
    Status : Active
Filter Details:
    IPv4
    Source IP: any
    Destination IP: any
    Protocol: any
Buffer Details:
    Buffer Type: CIRCULAR
    Buffer Size (in MB): 1
File Details:
    File not associated
Limit Details:
    Number of Packets to capture: 0 (no limit)
    Packet Capture duration: 0 (no limit)
    Packet Size to capture: 0 (no limit)
    Maximum number of packets to capture per second: 1000
    Packet sampling rate: 0 (no sampling)

Step 11: Stop the packet capture and display the buffer contents by entering:

Device# monitor capture mycap stop
Capture statistics collected at software (Buffer):
    Capture duration - 111 seconds
    Packets received - 5000
    Packets dropped - 0
    Packets oversized - 0

Step 12: Determine whether the capture is active by entering:

Device# show monitor capture mycap
Status Information for Capture mycap
Target Type:
    Interface: GigabitEthernet1/0/3, Direction: in
    Status : Inactive
Filter Details:
    IPv4
    Source IP: any
    Destination IP: any
    Protocol: any
Buffer Details:
    Buffer Type: CIRCULAR
    Buffer Size (in MB): 1
File Details:
    File not associated
Limit Details:
    Number of Packets to capture: 0 (no limit)
    Packet Capture duration: 0 (no limit)
    Packet Size to capture: 0 (no limit)
Maximum number of packets to capture per second: 1000
Packet sampling rate: 0 (no sampling)

Step 13: Display the packets in the buffer by entering:

```
Device# show monitor capture mycap buffer brief
Starting the packet display .......... Press Ctrl + Shift + 6 to exit
```

```
1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=0/0, ttl=254
2 0.000030000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=1/256, ttl=254
3 0.000051000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=2/512, ttl=254
4 0.000072000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=3/768, ttl=254
5 0.000093000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=4/1024, ttl=254
6 0.000114000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=5/1280, ttl=254
7 0.000135000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=6/1536, ttl=254
8 0.000157000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=7/192, ttl=254
9 0.000178000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=8/2048, ttl=254
10 0.000199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=9/2560, ttl=254
11 0.000220000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=10/2048, ttl=254
12 0.000241000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=11/2048, ttl=254
```

```
Step 14: Store the buffer contents to the mycap.pcap file in the internal flash: storage device by entering:

Device# monitor capture mycap export flash:mycap.pcap
Exported Successfully
```

```
Note
The current implementation of export is such that when the command is run, export is "started" but not complete when it returns the prompt to the user. So we have to wait for a message display on the console from Wireshark before it can run a display of packets in the file.
```

Step 15: Display capture packets from the file by entering:

```
Device# show monitor capture file flash:mycap.pcap
Starting the packet display .......... Press Ctrl + Shift + 6 to exit
```

```
1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=0/0, ttl=254
2 0.000030000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=1/256, ttl=254
3 0.000051000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=2/512, ttl=254
4 0.000072000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=3/768, ttl=254
5 0.000093000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=4/1024, ttl=254
```

Example: Simple Capture and Store of Packets in Egress Direction

This example shows how to capture packets to a filter:

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Device# monitor capture mycap interface Gigabit 1/0/1 out match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 100
Device# monitor capture mycap file location flash:mycap.pcap buffer-size 90
```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```
Device# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 out
  monitor capture mycap file location flash:mycap.pcap buffer-size 90
  monitor capture mycap limit packets 100 duration 60
```

```
Device# show monitor capture mycap
```

**Status Information for Capture mycap**

**Target Type:**
- **Interface:** GigabitEthernet1/0/1, **Direction:** out
- **Status:** Inactive

**Filter Details:**
- **IPv4**
Step 3: Launch packet capture by entering:

```
Device# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode
```

```
Device# *Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.
```

**Note**

Allow the capture operation stop automatically after the time has elapsed or the packet count has been met. When you see the following message in the output, will know that the capture operation has stopped:

```
*Oct 14 09:36:34.632: %BUFCAP-6-DISABLE_ASYNC: Capture Point mycap disabled. Reason : Wireshark Session Ended
```

The mycap.pcap file now contains the captured packets.

Step 4: Display the packets by entering:

```
Device# show monitor capture file flash:mycap.pcap
Starting the packet display ........ Press Ctrl + Shift + 6 to exit
```

```
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

Step 5: Delete the capture point by entering:

```
Device# no monitor capture mycap
```

Configuring Flexible NetFlow

Prerequisites for Flexible NetFlow

The following are prerequisites for your Flexible NetFlow configuration:

• You must configure a source interface. If you do not configure a source interface, the exporter will remain in a disabled state.

• You must configure a valid record name for every flow monitor.

• You must enable IPv6 routing to export the flow records to an IPv6 destination server.

• You must configure IPFIX export protocol for the flow exporter to export netflow records in IPFIX format.

• You are familiar with the Flexible NetFlow key fields as they are defined in the following commands in the Cisco IOS Flexible NetFlow Command Reference:
  • match datalink—Datalink (layer2) fields
  • match flow—Flow identifying fields
  • match interface—Interface fields
  • match ipv4—IPv4 fields
  • match ipv6—IPv6 fields
  • match transport—Transport layer fields
  • match wireless—Wireless fields
match flow cts—CTS fields

You are familiar with the Flexible NetFlow non key fields as they are defined in the following commands in the Cisco IOS Flexible NetFlow Command Reference:

- collect counter—Counter fields
- collect flow—Flow identifying fields
- collect interface—Interface fields
- collect timestamp—Timestamp fields
- collect transport—Transport layer fields
- collect wireless—Wireless fields

IPv4 Traffic

- The networking device must be configured for IPv4 routing.
- One of the following must be enabled on your router and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding or distributed Cisco Express Forwarding.

IPv6 Traffic

- The networking device must be configured for IPv6 routing.
- One of the following must be enabled on your router and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding IPv6 or distributed Cisco Express Forwarding.

Restrictions for Flexible NetFlow

The following are restrictions for Flexible NetFlow:

- Flexible NetFlow is not supported on the L2 port-channel interface, but is supported on the L2 port-channel member ports.
- Flexible NetFlow is not supported on the L3 port-channel interface, but is supported on the L3 port-channel member ports.
- Traditional NetFlow (TNF) accounting is not supported.
- Flexible NetFlow version 9 and version 10 export formats are supported. However, if you have not configured the export protocol, version 9 export format is applied by default.
- Microflow policing feature shares the NetFlow hardware resource with FNF.
- Only one flow monitor per interface and per direction is supported.
- Layer 2, IPv4, and IPv6 traffic types are supported. Multiple flow monitors of different traffic types can be applied for a given interface and direction. Multiple flow monitors of same traffic type cannot be applied for a given interface and direction.
• Layer 2, VLAN, WLAN and Layer 3 interfaces are supported, but the device does not support SVI and tunnels.

• The following NetFlow table sizes are supported:

<table>
<thead>
<tr>
<th>Trim Level</th>
<th>Ingress NetFlow Table</th>
<th>Egress NetFlow Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAN Base</td>
<td>Not supported</td>
<td>Not supported</td>
</tr>
<tr>
<td>IP Base</td>
<td>8 K</td>
<td>16 K</td>
</tr>
<tr>
<td>IP Services</td>
<td>8 K</td>
<td>16 K</td>
</tr>
</tbody>
</table>

• Depending on the switch type, a switch will have one or two forwarding ASICs. The capacities listed in the above table are on a per-ASIC basis.

• The switch can support either one or two ASICs. Each ASIC has 8K ingress and 16 K egress entries, whereas each TCAM can handle up to 6K ingress and 12K egress entries.

• The NetFlow tables are on separate compartments and cannot be combined. Depending on which ASIC processed the packet, the flows will be created in the table in the corresponding ASIC.

• NetFlow hardware implementation supports four hardware samplers. You can select a sampler rate from 1 out of 2 to 1 out of 1024. Only random sampling mode is supported.

• NetFlow hardware uses hash tables internally. Hash collisions can occur in the hardware. Therefore, in spite of the internal overflow Content Addressable Memory (CAM), the actual NetFlow table utilization could be about 80 percent.

• Depending on the fields that are used for the flow, a single flow could take two consecutive entries. IPv6 flows also take two entries. In these situations, the effective usage of NetFlow entries is half the table size, which is separate from the above hash collision limitation.

• The device supports up to 15 flow monitors.

• SSID-based NetFlow accounting is supported. SSID is treated in a manner similar to an interface. However, certain fields are not supported such as userID.

• The NetFlow software implementation supports distributed NetFlow export, so the flows are exported from the same device in which the flow was created.

• Ingress flows are present in the ASIC that first received the packets for the flow. Egress flows are present in the ASIC from which the packets actually left the device set up.

• The reported value for the bytes count field (called “bytes long”) is Layer-2-packet-size—18 bytes. For classic Ethernet traffic (802.3), this will be accurate. For all other Ethernet types, this field will not be accurate. Use the "bytes layer2" field, which always reports the accurate Layer 2 packet size. For information about supported Flexible NetFlow fields, see Supported Flexible NetFlow Fields, on page 1094.

• Configuration of IPFIX exporter on an AVC flow monitor is not supported.

• Flexible NetFlow export is not supported on the Ethernet management port, Gi0/0.

• When a flow record has only Source Group Tag (SGT) and Destination Group Tag (DGT) fields (or only either of the two) and if both the values are not applicable, then a flow will still be created with zero
values for SGT and DGT. The flow records are expected to include source and destination IP addresses, along with SGT and DGT fields.

- The flow monitor with flow record, that contains the CTS field, cannot be attached on the WLAN (SSID).
- When QoS marked packet is received on an interface which has NetFlow configured on the egress direction, the QoS value of the packet will be captured by the collector. However, when the packet is received on an interface which has NetFlow configured on the ingress direction, the QoS value of the packet will not be captured by the collector.

## Information About Flexible Netflow

### Flexible NetFlow Overview

Flexible NetFlow uses flows to provide statistics for accounting, network monitoring, and network planning. A flow is a unidirectional stream of packets that arrives on a source interface and has the same values for the keys. A key is an identified value for a field within the packet. You create a flow using a flow record to define the unique keys for your flow.

The device supports the Flexible NetFlow feature that enables enhanced network anomalies and security detection. Flexible NetFlow allows you to define an optimal flow record for a particular application by selecting the keys from a large collection of predefined fields.

All key values must match for the packet to count in a given flow. A flow might gather other fields of interest, depending on the export record version that you configure. Flows are stored in the Flexible NetFlow cache.

You can export the data that Flexible NetFlow gathers for your flow by using an exporter and export this data to a remote system such as a Flexible NetFlow collector. The Flexible NetFlow collector can use an IPv4 or IPv6 address.

You define the size of the data that you want to collect for a flow using a monitor. The monitor combines the flow record and exporter with the Flexible NetFlow cache information.

### Wireless Flexible NetFlow Overview

The wireless Flexible NetFlow infrastructure supports the following:

- Flexible NetFlow Version 9.0
- User-based rate limiting
- Microflow policing
- Voice and video flow monitoring
- Reflexive access control list (ACL)

#### Microflow Policing and User-Based Rate Limiting

Microflow policing associates a 2-color 1-rate policer and related drop statistics to each flow present in the NetFlow table. When the flow mask comprises all packet fields, this functionality is known as microflow policing. When the flow mask comprises either source or destination only, this functionality is known as user-based rate limiting.

#### Voice and Video Flow Monitoring
Voice and video flows are full flow mask-based entries. The ASIC provides the flexibility to program the policer parameters, share policers across multiple flows and rewrite the IP address and Layer 4 port numbers of these flows.

For dynamic entries, the NetFlow engine will use the policer parameters that are derived for the flow based on the policy (ACL/QoS-based policies). Dynamic entries cannot share policer across multiple flows.

**Note**

Reflexive ACL

Reflexive ACLs allow IP packets to be filtered based on upper-layer session information. The ACLs allow outbound traffic and limit inbound traffic in response to the sessions that originate inside the trusted network. The reflexive ACLs are transparent to the filtering mechanism until a data packet that matches the reflexive entry activates it. At this time, a temporary ACL entry is created and added to the IP-named access lists. The information obtained from the data packet to generate the reflexive ACL entry is permit/deny bit, the source IP address and port, the destination IP address, port, and the protocol type. During reflexive ACL entry evaluation, if the protocol type is either TCP or UDP, then the port information must match exactly. For other protocols, there is no port information to match. After this ACL is installed, the firewall is then opened for the reply packets to pass through. At this time, a potential hacker could have access to the network behind the firewall. To narrow this window, an idle timeout period can be defined. However, in the case of TCP, if two FIN bits or an RST is detected, the ACL entry can be removed.

**Original NetFlow and Benefits of Flexible NetFlow**

Original NetFlow uses a fixed seven tuples of IP information to identify a flow.

Flexible NetFlow allows the flow to be user defined. The benefits of Flexible NetFlow include:

- High-capacity flow recognition, including scalability and aggregation of flow information.
- Enhanced flow infrastructure for security monitoring and dDoS detection and identification.
- New information from packets to adapt flow information to a particular service or operation in the network. The flow information available will be customizable by Flexible NetFlow users.
- Extensive use of Cisco’s flexible and extensible NetFlow Version 9 and version 10 export formats. With version 10 export format, support for variable length field for the wireless client's SSID is available.
- A comprehensive IP accounting feature that can be used to replace many accounting features, such as IP accounting, Border Gateway Protocol (BGP) Policy Accounting, and persistent caches.
- Support for ingress and egress NetFlow accounting.
Original NetFlow allows you to understand the activities in the network and thus to optimize network design and reduce operational costs.

Flexible NetFlow allows you to understand network behavior with more efficiency, with specific flow information tailored for various services used in the network. The following are some example applications for a Flexible NetFlow feature:

- Flexible NetFlow enhances Cisco NetFlow as a security monitoring tool. For instance, new flow keys can be defined for packet length or MAC address, allowing users to search for a specific type of attack in the network.

- Flexible NetFlow allows you to quickly identify how much application traffic is being sent between hosts by specifically tracking TCP or UDP applications by the class of service (CoS) in the packets.

- The accounting of traffic entering a Multiprotocol Label Switching (MPLS) or IP core network and its destination for each next hop per class of service. This capability allows the building of an edge-to-edge traffic matrix.

The figure below is an example of how Flexible NetFlow might be deployed in a network.

Figure 73: Typical Deployment for Flexible NetFlow

Flexible NetFlow Components

Flexible NetFlow consists of components that can be used together in several variations to perform traffic analysis and data export. The user-defined flow records and the component structure of Flexible NetFlow facilitates the creation of various configurations for traffic analysis and data export on a networking device with a minimum number of configuration commands. Each flow monitor can have a unique combination of flow record, flow exporter, and cache type. If you change a parameter such as the destination IP address for a flow exporter, it is automatically changed for all the flow monitors that use the flow exporter. The same flow monitor can be used in conjunction with different flow samplers to sample the same type of network traffic at different rates on different interfaces. The following sections provide more information on Flexible NetFlow components:
**Flow Records**

In Flexible NetFlow a combination of key and nonkey fields is called a record. Flexible NetFlow records are assigned to Flexible NetFlow flow monitors to define the cache that is used for storing flow data. Flexible NetFlow includes several predefined records that can help you get started using Flexible NetFlow.

A flow record defines the keys that Flexible NetFlow uses to identify packets in the flow, as well as other fields of interest that Flexible NetFlow gathers for the flow. You can define a flow record with any combination of keys and fields of interest. The device supports a rich set of keys. A flow record also defines the types of counters gathered per flow. You can configure 64-bit packet or byte counters. The device enables the following match fields as the defaults when you create a flow record:

- match datalink — Layer 2 attributes
- match flow direction — Specifies a match to the fields identifying the direction of flow.
- match interface — Interface attributes
- match ipv4 — IPv4 attributes
- match ipv6 — IPv6 attributes
- match transport — Transport layer fields
- match wireless — Wireless fields
- match flow cts — CTS fields

**Related Topics**

Creating a Flow Record

**NetFlow Predefined Records**

Flexible NetFlow includes several predefined records that you can use to start monitoring traffic in your network. The predefined records are available to help you quickly deploy Flexible NetFlow and are easier to use than user-defined flow records. You can choose from a list of already defined records that may meet the needs for network monitoring. As Flexible NetFlow evolves, popular user-defined flow records will be made available as predefined records to make them easier to implement.

The predefined records ensure backward compatibility with your existing NetFlow collector configurations for the data that is exported. Each of the predefined records has a unique combination of key and nonkey fields that offer you the built-in ability to monitor various types of traffic in your network without customizing Flexible NetFlow on your router.

Two of the predefined records (NetFlow original and NetFlow IPv4/IPv6 original output), which are functionally equivalent, emulate original (ingress) NetFlow and the Egress NetFlow Accounting feature in original NetFlow, respectively. Some of the other Flexible NetFlow predefined records are based on the aggregation cache schemes available in original NetFlow. The Flexible NetFlow predefined records that are based on the aggregation cache schemes available in original NetFlow do not perform aggregation. Instead each flow is tracked separately by the predefined records.

**User-Defined Records**

Flexible NetFlow enables you to define your own records for a Flexible NetFlow flow monitor cache by specifying the key and nonkey fields to customize the data collection to your specific requirements. When you define your own records for a Flexible NetFlow flow monitor cache, they are referred to as *user-defined records*. The values in nonkey fields are added to flows to provide additional information about the traffic in
the flows. A change in the value of a nonkey field does not create a new flow. In most cases the values for nonkey fields are taken from only the first packet in the flow. Flexible NetFlow enables you to capture counter values such as the number of bytes and packets in a flow as nonkey fields.

You can create user-defined records for applications such as QoS and bandwidth monitoring, application and end user traffic profiling, and security monitoring for DDoS attacks. Flexible NetFlow also includes several predefined records that emulate original NetFlow. Flexible NetFlow user-defined records provide the capability to monitor a contiguous section of a packet of a user-configurable size, and use it in a flow record as a key or a nonkey field along with other fields and attributes of the packet. The section may include any Layer 3 data from the packet. The packet section fields allow the user to monitor any packet fields that are not covered by the Flexible NetFlow predefined keys. The ability to analyze packet fields that are not collected with the predefined keys enables more detailed traffic monitoring, facilitates the investigation of DDoS attacks, and enables implementation of other security applications such as URL monitoring.

Flexible NetFlow provides predefined types of packet sections of a user-configurable size. The following Flexible NetFlow commands (used in Flexible NetFlow flow record configuration mode) can be used to configure the predefined types of packet sections:

- **collect ipv4 section header size bytes** --Starts capturing the number of bytes specified by the `bytes` argument from the beginning of the IPv4 header of each packet.
- **collect ipv4 section payload size bytes** --Starts capturing bytes immediately after the IPv4 header from each packet. The number of bytes captured is specified by the `bytes` argument.
- **collect ipv6 section header size bytes** --Starts capturing the number of bytes specified by the `bytes` argument from the beginning of the IPv6 header of each packet.
- **collect ipv6 section payload size bytes** --Starts capturing bytes immediately after the IPv6 header from each packet. The number of bytes captured is specified by the `bytes` argument.

The `bytes` values are the sizes in bytes of these fields in the flow record. If the corresponding fragment of the packet is smaller than the requested section size, Flexible NetFlow will fill the rest of the section field in the flow record with zeros. If the packet type does not match the requested section type, Flexible NetFlow will fill the entire section field in the flow record with zeros.

Flexible NetFlow adds a new Version 9 export format field type for the header and packet section types. Flexible NetFlow will communicate to the NetFlow collector the configured section sizes in the corresponding Version 9 export template fields. The payload sections will have a corresponding length field that can be used to collect the actual size of the collected section.

**Flexible NetFlow Match Parameters**

The following table describes Flexible NetFlow match parameters. You must configure at least one of the following match parameters for the flow records.
### Table 79: Match Parameters

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **match datalink {dot1q | ethertype | mac | vlan}** | Specifies a match to datalink or Layer 2 fields. The following command options are available:  
  - **dot1q**—Matches to the dot1q field.  
  - **ethertype**—Matches to the ethertype of the packet.  
  - **mac**—Matches the source or destination MAC fields.  
  - **vlan**—Matches to the VLAN that the packet is located on (input or output). |
| **match flow direction** | Specifies a match to the flow identifying fields. |
| **match interface {input | output}** | Specifies a match to the interface fields. The following command options are available:  
  - **input**—Matches to the input interface.  
  - **output**—Matches to the output interface. |
| **match ipv4 {destination | protocol | source | tos | ttl | version}** | Specifies a match to the IPv4 fields. The following command options are available:  
  - **destination**—Matches to the IPv4 destination address-based fields.  
  - **protocol**—Matches to the IPv4 protocols.  
  - **source**—Matches to the IPv4 source address based fields.  
  - **tos**—Matches to the IPv4 Type of Service fields.  
  - **ttl**—Matches to the IPv4 Time To Live fields.  
  - **version**—Matches to the IP version from the IPv4 header. |
Flexible NetFlow Collect Parameters

The following table describes the Flexible NetFlow collect parameters.

**Table 80: Collect Parameters**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>collect counter { bytes { layer2 { long }</td>
<td>long }</td>
</tr>
<tr>
<td>collect interface {input</td>
<td>output}</td>
</tr>
</tbody>
</table>
### Command

**collect timestamp absolute {first | last}**

Collects the fields for the absolute time the first packet was seen or the absolute time the most recent packet was last seen (in milliseconds).

---

**collect transport tcp flags**

Collects the following transport TCP flags:
- **ack** — TCP acknowledgement flag
- **cwr** — TCP congestion window reduced flag
- **ece** — TCP ECN echo flag
- **fin** — TCP finish flag
- **psh** — TCP push flag
- **rst** — TCP reset flag
- **syn** — TCP synchronize flag
- **urg** — TCP urgent flag

**Note** On the device, you cannot specify which TCP flag to collect. You can only specify to collect transport TCP flags. All TCP flags will be collected with this command.

### Flow Exporters

Flow exporters export the data in the flow monitor cache to a remote system, such as a server running NetFlow collector, for analysis and storage. Flow exporters are created as separate entities in the configuration. Flow exporters are assigned to flow monitors to provide data export capability for the flow monitors. You can create several flow exporters and assign them to one or more flow monitors to provide several export destinations. You can create one flow exporter and apply it to several flow monitors.

### NetFlow Data Export Format Version 10 (IPFIX)

Internet Protocol Flow Information Export (IPFIX) or version 10 is an Export Protocol that collects and exports predefined or user defined flow records. IPFIX is an IETF standard based on NetFlow version 9. The IPFIX format maintains the same principles of separate templates and records as NetFlow version 9. It supports variable length field for SSID of the wireless clients. For IPFIX exporting protocol, the default destination port is 4739, DSCP value is 0, and TTL is 255.

### NetFlow Data Export Format Version 9

The basic output of NetFlow is a flow record. Several different formats for flow records have evolved as NetFlow has matured. The most recent evolution of the NetFlow export format is known as Version 9. The distinguishing feature of the NetFlow Version 9 export format is that it is template-based. Templates provide an extensible design to the record format, a feature that should allow future enhancements to NetFlow services without requiring concurrent changes to the basic flow-record format. Using templates provides several key benefits:
• Third-party business partners who produce applications that provide collector or display services for NetFlow do not have to recompile their applications each time a new NetFlow feature is added. Instead, they should be able to use an external data file that documents the known template formats.

• New features can be added to NetFlow quickly without breaking current implementations.

• NetFlow is “future-proofed” against new or developing protocols because the Version 9 format can be adapted to provide support for them.

NetFlow Version 9 export format provides the following features and functionality:

• Variable field specification format

• Support for IPv4 or IPv6 destination address export

• More efficient network utilization

The Version 9 export format consists of a packet header followed by one or more template flow or data flow sets. A template flow set provides a description of the fields that will be present in future data flow sets. These data flow sets may occur later within the same export packet or in subsequent export packets. Template flow and data flow sets can be intermingled within a single export packet, as illustrated in the figure below.

*Figure 74: Version 9 Export Packet*

NetFlow Version 9 will periodically export the template data so the NetFlow collector will understand what data is to be sent and also export the data flow set for the template. The key advantage to Flexible NetFlow is that the user configures a flow record, which is effectively converted to a Version 9 template and then forwarded to the collector. The figure below is a detailed example of the NetFlow Version 9 export format, including the header, template flow, and data flow sets.
Flow Monitors

Flow monitors are the Flexible NetFlow component that is applied to interfaces to perform network traffic monitoring.

Flow monitors consist of a user-defined record, an optional flow exporter, and a cache that is automatically created at the time the flow monitor is applied to the first interface.

Flow data is collected from the network traffic and added to the flow monitor cache during the monitoring process based on the key and nonkey fields in the flow record.

Flexible NetFlow can be used to perform different types of analysis on the same traffic. In the figure below, packet 1 is analyzed using a record designed for standard traffic analysis on the input interface and a record designed for security analysis on the output interface.

Flow Monitors

The figure below shows a more complex example of how you can apply different types of flow monitors with custom records.

*Figure 77: Complex Example of Using Multiple Types of Flow Monitors with Custom Records*

There are three types of flow monitor caches. You change the type of cache used by the flow monitor after you create the flow monitor. The three types of flow monitor caches are described in the following sections:

**Normal**

The default cache type is “normal”. In this mode, the entries in the cache are aged out according to the timeout active and timeout inactive settings. When a cache entry is aged out, it is removed from the cache and exported via any exporters configured.
Immediate

A cache of type "immediate" ages out every record as soon as it is created. As a result, every flow contains just one packet. The commands that display the cache contents will provide a history of the packets seen.

This mode is desirable when you expect only very small flows and you want a minimum amount of latency between seeing a packet and exporting a report.

⚠️ Caution

This mode may result in a large amount of export data that can overload low-speed links and overwhelm any systems that you are exporting to. We recommended that you configure sampling to reduce the number of packets that are processed.

Note

The cache timeout settings have no effect in this mode.

Permanent

A cache of type "permanent" never ages out any flows. A permanent cache is useful when the number of flows you expect to see is low and there is a need to keep long-term statistics on the router. For example, if the only key field in the flow record is the 8-bit IP ToS field, only 256 flows can be monitored. To monitor the long-term usage of the IP ToS field in the network traffic, you can use a permanent cache. Permanent caches are useful for billing applications and for an edge-to-edge traffic matrix for a fixed set of flows that are being tracked. Update messages will be sent periodically to any flow exporters configured according to the "timeout update" setting.

Note

When a cache becomes full in permanent mode, new flows will not be monitored. If this occurs, a "Flows not added" message will appear in the cache statistics.

Note

A permanent cache uses update counters rather than delta counters. This means that when a flow is exported, the counters represent the totals seen for the full lifetime of the flow and not the additional packets and bytes seen since the last export was sent.

Flow Samplers

Flow samplers are created as separate components in a router’s configuration. Flow samplers are used to reduce the load on the device that is running Flexible NetFlow by limiting the number of packets that are selected for analysis.

Samplers use random sampling techniques (modes); that is, a randomly selected sampling position is used each time a sample is taken.

Flow sampling exchanges monitoring accuracy for router performance. When you apply a sampler to a flow monitor, the overhead load on the router of running the flow monitor is reduced because the number of packets that the flow monitor must analyze is reduced. The reduction in the number of packets that are analyzed by the flow monitor causes a corresponding reduction in the accuracy of the information stored in the flow monitor’s cache.
Samplers are combined with flow monitors when they are applied to an interface with the `ip flow monitor` command.

**Supported Flexible NetFlow Fields**

The following tables provide a consolidated list of supported fields in Flexible NetFlow (FNF) for various traffic types and traffic direction.

<table>
<thead>
<tr>
<th>Field</th>
<th>Layer 2 In</th>
<th>Layer 2 Out</th>
<th>IPv4 In</th>
<th>IP v4 Out</th>
<th>IPv6 In</th>
<th>IPv6 Out</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key or Collect Fields</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Interface input           | Yes        | —           | Yes     | —         | Yes     | —        | If you apply a flow monitor in the input direction:  
  • Use the `match` keyword and use the input interface as a key field.  
  • Use the `collect` keyword and use the output interface as a collect field. This field will be present in the exported records but with a value of 0. |
| Interface output          | —          | Yes         | —       | Yes       | —       | Yes      | If you apply a flow monitor in the output direction:  
  • Use the `match` keyword and use the output interface as a key field.  
  • Use the `collect` keyword and use the input interface as a collect field. This field will be present in the exported records but with a value of 0. |

---

**Note**

If the packet has a VLAN field, then that length is not accounted for.

## How to Configure Flexible NetFlow

To configure Flexible NetFlow, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.
2. Create an optional flow exporter by specifying the protocol and transport destination port, destination, and other parameters.
3. Create a flow monitor based on the flow record and flow exporter.
4. Create an optional sampler.
5. Apply the flow monitor to a Layer 2 port, Layer 3 port, or VLAN.
6. If applicable to your configuration, configure a WLAN to apply a flow monitor to.

## Configuring a Customized Flow Record

Perform this task to configure a customized flow record.

Customized flow records are used to analyze traffic data for a specific purpose. A customized flow record must have at least one `match` criterion for use as the key field and typically has at least one `collect` criterion for use as a nonkey field.

There are hundreds of possible permutations of customized flow records. This task shows the steps that are used to create one of the possible permutations. Modify the steps in this task as appropriate to create a customized flow record for your requirements.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `flow record record-name`
4. description description
5. match {ipv4 | ipv6} {destination | source} address
6. Repeat Step 5 as required to configure additional key fields for the record.
7. match flow cts {source | destination} group-tag
8. collect interface {input | output}
9. Repeat the above step as required to configure additional nonkey fields for the record.
10. end
11. show flow record record-name
12. show running-config flow record record-name

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> flow record record-name</td>
<td>Creates a flow record and enters Flexible NetFlow flow record configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# flow record FLOW-RECORD-1</td>
<td>• This command also allows you to modify an existing flow record.</td>
</tr>
<tr>
<td><strong>Step 4</strong> description description</td>
<td>(Optional) Creates a description for the flow record.</td>
</tr>
<tr>
<td>Example: Device(config-flow-record)# description Used for basic traffic analysis</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> match {ipv4</td>
<td>ipv6} {destination</td>
</tr>
<tr>
<td>Example: Device(config-flow-record)# match ipv4 destination address</td>
<td>Note This example configures the IPv4 destination address as a key field for the record. For information about the other key fields available for the match ipv4 command, and the other match commands that are available to configure key fields, refer to the Cisco IOS Flexible NetFlow Command Reference.</td>
</tr>
<tr>
<td><strong>Step 6</strong> Repeat Step 5 as required to configure additional key fields for the record.</td>
<td>——</td>
</tr>
</tbody>
</table>
### Command or Action

| Step 7 | `match flow cts {source | destination} group-tag`<br>`Example:`<br>Device(config-flow-record)# match flow cts source group-tag<br>Device(config-flow-record)# match flow cts destination group-tag | Purpose | **Note**<br>This example configures the CTS source group tag and destination group tag as a key field for the record. For information about the other key fields available for the `match` command, and the other `match` commands that are available to configure key fields, refer to the *Cisco IOS Flexible NetFlow Command Reference*.<br><br>**Note**<br>- **Ingress:**<br>  - In an incoming packet, if a header is present, SGT will reflect the same value as the header. If no value is present, it will show zero.<br>  - The DGT value will not depend on the ingress port SGACL configuration.<br>- **Egress:**<br>  - If either propagate SGT or CTS is disabled on the egress interface, then SGT will be zero.<br>  - In an outgoing packet, if SGACL configuration that corresponds to the (SGT, DGT) exists, DGT will be non-zero.<br>  - If SGACL is disabled on the egress port/VLAN or if global SGACL enforcement is disabled, then DGT will be zero. |

| Step 8 | `collect interface {input | output}`<br>`Example:`<br>Device(config-flow-record)# collect interface input | Configures the input interface as a nonkey field for the record. | **Note**<br>This example configures the input interface as a nonkey field for the record. For information on the other `collect` commands that are available to configure nonkey fields, refer to the *Cisco IOS Flexible NetFlow Command Reference*. |

| Step 9 | Repeat the above step as required to configure additional nonkey fields for the record. |  |

| Step 10 | `end`<br>`Example:`<br> | Exits Flexible NetFlow flow record configuration mode and returns to privileged EXEC mode. |
Creating a Flow Exporter

You can create a flow exporter to define the export parameters for a flow.

Note Each flow exporter supports only one destination. If you want to export the data to multiple destinations, you must configure multiple flow exporters and assign them to the flow monitor.

You can export to a destination using IPv4 or IPv6 address.

<table>

### Creating a Flow Exporter

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

**flow exporter name**

**Example:**

```
Device(config)# flow exporter ExportTest
```

(Optional) Creates a flow exporter and enters flow exporter configuration mode. You can also use this command to modify an existing flow exporter.

**Step 3**

**description string**

**Example:**

```
Device(config-flow-exporter)# description ExportV9
```

(Optional) Describes this flow record as a maximum 63-character string.

**Step 4**

**destination {ipv4-address|ipv6-address}**

**Example:**

```
Device(config-flow-exporter)# destination 192.0.2.1 (IPv4 destination)
Device(config-flow-exporter)# destination 2001:0:0:24::10 (IPv6 destination)
```

Sets the IPv4/IPv6 destination address or hostname for this exporter.

**Step 5**

**dscp value**

**Example:**

```
Device(config-flow-exporter)# dscp 0
```

(Optional) Specifies the differentiated services codepoint value. The range is from 0 to 63. The default is 0.

**Step 6**

**source { source type }**

**Example:**

```
Device(config-flow-exporter)# source gigabitEthernet1/0/1
```

(Optional) Specifies the interface to use to reach the NetFlow collector at the configured destination. The following interfaces can be configured as source:

- **Auto Template**—Auto-Template interface
- **Capwap**—CAPWAP tunnel interface
- **GigabitEthernet**—Gigabit Ethernet IEEE 802
- **GroupVI**—Group virtual interface
- **Internal Interface**—Internal interface
- **Loopback**—Loopback interface
- **Null**—Null interface
- **Port-channel**—Ethernet Channel of interface
- **TenGigabitEthernet**—10-Gigabit Ethernet
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 7</strong> transport udp <em>number</em></td>
<td><em>(Optional)</em> Specifies the UDP port to use to reach the NetFlow collector. The range is from 0 to 65535. For IPFIX exporting protocol, the default destination port is 4739.</td>
</tr>
<tr>
<td><strong>Step 8</strong> ttl <em>seconds</em></td>
<td><em>(Optional)</em> Configures the time-to-live (TTL) value for datagrams sent by the exporter. The range is from 1 to 255 seconds. The default is 255.</td>
</tr>
<tr>
<td><strong>Step 9</strong> export-protocol {netflow-v9</td>
<td>ipfix}</td>
</tr>
<tr>
<td><strong>Step 10</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 11</strong> show flow exporter [name <em>record-name</em>]</td>
<td><em>(Optional)</em> Displays information about NetFlow flow exporters.</td>
</tr>
<tr>
<td><strong>Step 12</strong> copy running-config startup-config</td>
<td><em>(Optional)</em> Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

### What to do next
Define a flow monitor based on the flow record and flow exporter.

### Related Topics

  - Example: Monitoring IPv4 ingress traffic, on page 1115
  - Example: Monitoring IPv4 egress traffic, on page 1116
Creating a Customized Flow Monitor

Perform this required task to create a customized flow monitor.

Each flow monitor has a separate cache assigned to it. Each flow monitor requires a record to define the contents and layout of its cache entries. These record formats can be one of the predefined formats or a user-defined format. An advanced user can create a customized format using the `flow record` command.

**Before you begin**

If you want to use a customized record instead of using one of the Flexible NetFlow predefined records, you must create the customized record before you can perform this task. If you want to add a flow exporter to the flow monitor for data export, you must create the exporter before you can complete this task.

---

**Note**

You must use the `no ip flow monitor` command to remove a flow monitor from all of the interfaces to which you have applied it before you can modify the parameters for the `record` command on the flow monitor. For information about the `ip flow monitor` command, refer to the *Cisco IOS Flexible NetFlow Command Reference*.

---

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `flow monitor monitor-name`
4. `description description`
5. `record {record-name | netflow-original | netflow {ipv4 | ipv6} record [peer]}
6. `cache {entries number | timeout {active | inactive | update} seconds | type {immediate | normal | permanent}}`
7. Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.
8. `statistics packet protocol`
9. `statistics packet size`
10. `exporter exporter-name`
11. `end`
12. `show flow monitor [[name] monitor-name [cache [format {csv | record | table}]]] [statistics]]`
13. `show running-config flow monitor monitor-name`
14. `copy running-config startup-config`

**DETAILED STEPS**

</tr>
</tbody>
</table>
| **Step 3**        | **flow monitor** `monitor-name`  
Example:  
Device(config)# flow monitor FLOW-MONITOR-1  
| Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode.  
• This command also allows you to modify an existing flow monitor.  |
| **Step 4**        | `description description`  
Example:  
Device(config-flow-monitor)# description Used for basic ipv4 traffic analysis  
| (Optional) Creates a description for the flow monitor.  |
| **Step 5**        | `record {record-name | netflow-original | netflow {ipv4 | ipv6} record [peer]}`  
Example:  
Device(config-flow-monitor)# record FLOW-RECORD-1  
| Specifies the record for the flow monitor.  |
| **Step 6**        | `cache {entries number | timeout {active | inactive | update} seconds | type {immediate | normal | permanent}}`  
Example:  
Device(config-flow-monitor)# cache type normal  
| The values for the keywords associated with the `timeout` keyword have no effect when the cache type is set to `immediate`.  
Associates a flow cache with the specified flow monitor.  |
| **Step 7**        | Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.  
—  |
| **Step 8**        | `statistics packet protocol`  
Example:  
Device(config-flow-monitor)# statistics packet protocol  
| (Optional) Enables the collection of protocol distribution statistics for Flexible NetFlow monitors.  |
| **Step 9**        | `statistics packet size`  
Example:  
Device(config-flow-monitor)# statistics packet size  
| (Optional) Enables the collection of size distribution statistics for Flexible NetFlow monitors.  |
| **Step 10**       | `exporter exporter-name`  
Example:  
Device(config-flow-monitor)# exporter EXPORTER-1  
| (Optional) Specifies the name of an exporter that was created previously.  |
Configuring and Enabling Flow Sampling
Creating a Flow Sampler

Perform this required task to configure and enable a flow sampler.

**Note**
When you specify the "NetFlow original," or the "NetFlow IPv4 original input," or the "NetFlow IPv6 original input" predefined record for the flow monitor to emulate original NetFlow, the flow monitor can be used only for analyzing input (ingress) traffic.

When you specify the "NetFlow IPv4 original output" or the "NetFlow IPv6 original output" predefined record for the flow monitor to emulate the Egress NetFlow Accounting feature, the flow monitor can be used only for analyzing output (egress) traffic.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `sampler sampler-name`
4. `description description`
5. `mode {random} 1 out-of window-size`
6. `exit`
7. `interface type number`
8. `{ip | ipv6} flow monitor monitor-name [sampler sampler-name] {input | output}`
9. `end`
10. `show sampler sampler-name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

`enable`

*Example:* `Device> enable`

Enables privileged EXEC mode.

- Enter your password if prompted.

| **Step 2**

`configure terminal`

*Example:* `Device# configure terminal`

Enters global configuration mode.

| **Step 3**

`sampler sampler-name`

*Example:* `Device(config)# sampler SAMPLER-1`

Creates a sampler and enters sampler configuration mode.

- This command also allows you to modify an existing sampler.

| **Step 4**

`description description`

*Example:* `Device(config-sampler)# description Sample at 50%`

(Optional) Creates a description for the flow sampler.

| **Step 5**

`mode {random} 1 out-of window-size`

*Example:* `Device(config-sampler)# mode random 1 out-of 2`

Specifies the sampler mode and the flow sampler window size.

- The range for the `window-size` argument is from 0 to 1024 to 32768.

| **Step 6**

`exit`

*Example:* `Device(config-sampler)# exit`

Exits sampler configuration mode and returns to global configuration mode.

| **Step 7**

`interface type number`

*Example:* `Device(config)# interface GigabitEthernet 0/0/0`

Specifies an interface and enters interface configuration mode.

| **Step 8**

`{ip | ipv6} flow monitor monitor-name [sampler sampler-name] {input | output}`

*Example:* Assigns the flow monitor and the flow sampler that you created to the interface to enable sampling.
### Applying a Flow to an Interface

You can apply a flow monitor and an optional sampler to an interface.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface type`
3. `{ip flow monitor | ipv6 flow monitor} name [sampler name] { input}
4. `end`
5. `show flow interface [interface-type number]`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>

<td></td>
</tr>
<tr>
<td>Device(config)# interface GigabitEthernet1/0/1</td>
<td></td>
</tr>
</tbody>
</table>

Flexible NetFlow is not supported on the L2 port-channel interface, but is supported on the L2 port-channel member ports.

Flexible NetFlow is not supported on the L3 port-channel member ports, but is supported on the L3 port-channel interface.

Command parameters for the interface configuration include:
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• GigabitEthernet—GigabitEthernet IEEE 802</td>
<td></td>
</tr>
<tr>
<td>• Loopback—Loopback interface</td>
<td></td>
</tr>
<tr>
<td>• TenGigabitEthernet—10-Gigabit Ethernet</td>
<td></td>
</tr>
<tr>
<td>• Vlan—Catalyst VLANs</td>
<td></td>
</tr>
<tr>
<td>• Range—Interface range</td>
<td></td>
</tr>
<tr>
<td>• WLAN—WLAN interface</td>
<td></td>
</tr>
</tbody>
</table>

Step 3  
[ip flow monitor | ipv6 flow monitor\]name \[|sampler name\] \{ input\}  

Example:  
Device(config-if)# ip flow monitor MonitorTest input

Step 4  
end  

Example:  
Device(config-flow-monitor)# end

Step 5  
show flow interface [interface-type number]  

Example:  
Device# show flow interface

Step 6  
copy running-config startup-config  

Example:  
Device# copy running-config startup-config

### Configuring a Bridged NetFlow on a VLAN

You can apply a flow monitor and an optional sampler to a VLAN.

**SUMMARY STEPS**

1. configure terminal  
2. vlan [configuration] vlan-id  
3. ip flow monitor monitor name \[sampler sampler name\] \{ input | output\}  
4. copy running-config startup-config
### Detailed Steps

### Configuring Layer 2 NetFlow

You can define Layer 2 keys in Flexible NetFlow records that you can use to capture flows in Layer 2 interfaces.

### Summary Steps

1. configure terminal
2. flow record name
3. match datalink \{dot1q | ethertype | mac | vlan\}
4. end
5. show flow record [name ]
6. copy running-config startup-config
### DETAILED STEPS

Configuration Examples for Flexible NetFlow

**Example: Configuring a Flow**

This example shows how to create a flow and apply it to an interface:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Device(config)# flow export export1
Device(config-flow-exporter)# destination 10.0.101.254
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# exit
Device(config)# flow record record1
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match ipv4 protocol
```
Example: Monitoring IPv4 ingress traffic

This example shows how to monitor IPv4 ingress traffic (int g1/0/11 sends traffic to int g1/0/36 and int g3/0/11).

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# flow record fr-1
Device(config-flow-record)# match transport source-port
Device(config-flow-record)# match transport destination-port
Device(config-flow-record)# match flow cts source group-tag
Device(config-flow-record)# match flow cts destination group-tag
Device(config-flow-record)# collect counter byte long
Device(config-flow-record)# collect counter packet long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit
Device(config)# flow monitor monitor1
Device(config-flow-monitor)# record record1
Device(config-flow-monitor)# exporter export1
Device(config-flow-monitor)# exit
Device(config)# interface tenGigabitEthernet 1/0/1
Device(config-if)# ip flow monitor monitor1 input
Device(config-if)# end

Monitors

Example: Monitoring IPv4 ingress traffic

This example shows how to monitor IPv4 ingress traffic (int g1/0/11 sends traffic to int g1/0/36 and int g3/0/11).
Example: Monitoring IPv4 egress traffic

Device(config-flow-record)# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# flow record fr-1 out
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match interface output
Device(config-flow-record)# collect counter bytes long
Device(config-flow-record)# collect counter packets long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit

Device(config)# flow exporter fe-1
Device(config-flow-exporter)# destination 10.5.120.16
Device(config-flow-exporter)# source Vlan105
Device(config-flow-exporter)# dscp 32
Device(config-flow-exporter)# ttl 200
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Monitors

Example: Monitoring IPv4 egress traffic

Device(config)# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# flow exporter fe-1
Device(config-flow-exporter)# destination 10.5.120.16
Device(config-flow-exporter)# source Vlan105
Device(config-flow-exporter)# dscp 32
Device(config-flow-exporter)# ttl 200
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow exporter fe-ipfix6
Example: Configuring IPv4 Flexible NetFlow in WLAN (Ingress Direction)

The following example shows how to configure IPv4 Flexible NetFlow on WLAN ingress direction:

```
Device(config)# configure terminal
Device(config)# flow record fr_v4
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 protocol
Device(config-flow-record)# match ipv4 tos
Device(config-flow-record)# match ipv4 ttl
Device(config-flow-record)# match ipv4 version
Device(config-flow-record)# match wireless ssid
Device(config-flow-record)# collect wireless ap mac address
Device(config-flow-record)# collect counter packets long
Device(config-flow-record)# collect counter bytes long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit

Device(config)# flow monitor fm_v4
Device(config-flow-monitor)# record fr_v4
Device(config-flow-monitor)# exit

Device(config)# show flow monitor fm_v4-output cache format table
```
Example: Configuring IPv6 and Transport Flag Flexible NetFlow in WLAN (Egress Direction)

The following example shows how to configure IPv6 and transport flag Flexible NetFlow on WLAN egress direction:

```
Device# configure terminal
Device(config)# flow record fr_v6
Device(config-flow-record)# match ipv6 destination address
Device(config-flow-record)# match ipv6 source address
Device(config-flow-record)# match ipv6 hop-limit
Device(config-flow-record)# match ipv6 protocol
Device(config-flow-record)# match ipv6 traffic
Device(config-flow-record)# match ipv6 version
Device(config-flow-record)# match wireless ssid
Device(config-flow-record)# collect wireless ap mac address
Device(config-flow-record)# collect counter bytes long
Device(config-flow-record)# collect transport tcp flags
Device(config-flow-record)# exit

Device(config)# flow monitor fm_v6
Device(config-flow-monitor)# record fr_v6
Device(config-flow-monitor)# exit

Device(config)# wlan wlan_1
Device(config-wlan)# ipv6 flow monitor fm_v6 out
Device(config-wlan)# end

Device# show flow monitor fm_v6 cache
```

On the device, you cannot specify which TCP flag to collect. You can only specify to collect transport TCP flags.

PART X

QoS

• Configuring QoS, on page 1125
Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.
Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Auto-QoS

The prerequisites for auto-QoS are the same as the prerequisites for standard QoS.

Restrictions for Auto-QoS

The following are restrictions for auto-QoS:

- Auto-qos is not supported on SVI interfaces.
- Auto-QoS is not supported on an Etherchannel interface. When applied on member ports, all port-channel interfaces should share the same Auto-QoS policy.
- The `trust device device_type` command available in interface configuration mode is a stand-alone command on the switch. When using this command, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.
- When upgrading your software release from a pre- 3.2.2 software version to a 3.2.2 or later software version, you must follow the auto-QoS upgrade procedure described in this chapter.
- Do not configure the `auto qos voip cisco-phone` option for IP phones that support video. This option causes DSCP markings of video packets to get overwritten, because these packets do not have Expedited Forwarding priority, which results in these packets getting classified in the class-default class.
- Auto-QoS does not generate configuration when it is pushed from the startup-configuration using the `auto qos voip cisco-phone` command to the running-configuration. This is expected behavior and this is to prevent overwriting of user-created customized QoS policies by the default configuration, if any, every time the command `auto qos voip cisco-phone` is pushed from the startup-config.

You can use any of the following workarounds for this limitation:

- Configure the `auto qos voip cisco-phone` command manually on the switch interfaces.
- For new switches, if you push auto-QoS commands through startup-config, the command should include each of the following as part of the standard template

  1. Interface-level:

     - `trust device cisco-phone`
     - `auto qos voip cisco-phone`
     - `service-policy input` AutoQos-4.0-CiscoPhone-Input-Policy
     - `service-policy output` AutoQos-4.0-Output-Policy

  2. Global-level:

     - Class-map

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
• Policy-map
• ACL(ACE)

• If the `auto qos voip cisco-phone` command is already configured on an interface but policies are not being generated, disable the command from all the interfaces and reconfigure the command on each interface manually.

## Information About Configuring Auto-QoS

### Auto-QoS Overview
You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows.

The switch employs the MQC model. This means that instead of using certain global configurations, auto-QoS applied to any interface on a switch configures several global class maps and policy maps.

Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

QoS is needed in both directions, both on inbound and outbound. When inbound, the switch port needs to trust the DSCP in the packet (done by default). When outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

### Auto-QoS Compact Overview
When you enter an auto-QoS command, the switch displays all the generated commands as if the commands were entered from the CLI. You can use the auto-QoS compact feature to hide the auto-QoS generated commands from the running configuration. This would make it easier to comprehend the running-configuration and also help to increase efficient usage of memory.

### Auto-QoS Global Configuration Templates
In general, an auto-QoS command generates a series of class maps that either match on ACLs or on DSCP and/or CoS values to differentiate traffic into application classes. An input policy is also generated, which matches the generated classes and in some cases, polices the classes to a set bandwidth. Eight egress-queue class maps are generated. The actual egress output policy assigns a queue to each one of these eight egress-queue class maps.

The auto-QoS commands only generate templates as needed. For example, the first time any new auto-QoS command is used, global configurations that define the eight queue egress service-policy are generated. From this point on, auto-QoS commands applied to other interfaces do not generate templates for egress queuing because all auto-QoS commands rely on the same eight queue models, which have already been generated from the first time a new auto-QoS command was used.
Auto-QoS Policy and Class Maps

After entering the appropriate auto-QoS command, the following actions occur:

• Specific class maps are created.
• Specific policy maps (input and output) are created.
• Policy maps are attached to the specified interface.
• Trust level for the interface is configured.

Effects of Auto-QoS on Running Configuration

When auto-QoS is enabled, the auto qos interface configuration commands and the generated global configuration are added to the running configuration.

The switch applies the auto-QoS-generated commands as if the commands were entered from the CLI. An existing user configuration can cause the application of the generated commands to fail or to be overridden by the generated commands. These actions may occur without warning. If all the generated commands are successfully applied, any user-entered configuration that was not overridden remains in the running configuration. Any user-entered configuration that was overridden can be retrieved by reloading the switch without saving the current configuration to memory. If the generated commands are not applied, the previous running configuration is restored.

Effects of Auto-Qos Compact on Running Configuration

If auto-QoS compact is enabled:

• Only the auto-QoS commands entered from the CLI are displayed in running-config.
• The generated global and interface configurations are hidden.
• When you save the configuration, only the auto-qos commands you have entered are saved (and not the hidden configuration).
• When you reload the switch, the system detects and re-executes the saved auto-QoS commands and the AutoQoS SRND4.0 compliant config-set is generated.
Do not make changes to the auto-QoS-generated commands when auto-QoS compact is enabled, because user-modifications are overridden when the switch reloads.

When auto-qos global compact is enabled:

- `show derived-config` command can be used to view hidden AQC derived commands.
- AQC commands will not be stored to memory. They will be regenerated every time the switch is reloaded.
- When compaction is enabled, auto-qos generated commands should not be modified.
- If the interface is configured with auto-QoS and if AQC needs to be disabled, auto-qos should be disabled at interface level first.

How to Configure Auto-QoS

Configuring Auto-QoS (CLI)

For optimum QoS performance, configure auto-QoS on all the devices in your network.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. Depending on your auto-QoS configuration, use one of the following commands:
   - `auto qos voip {cisco-phone | cisco-softphone | trust}`
   - `auto qos video {cts | ip-camera | media-player}`
   - `auto qos classify [police]
     auto qos trust {cos | dscp}`
4. `end`
5. `show auto qos interface interface-id`

**DETAILED STEPS**

<td>the uplink port that is connected to another trusted switch or router in</td>
</tr>
<tr>
<td>Device(config)# interface</td>
<td>network interior, and enters the interface configuration mode.</td>
</tr>
</tbody>
</table>
The following commands enable auto-QoS for VoIP:

- `auto qos voip cisco-phone` — If the port is connected to a Cisco IP Phone, the QoS labels of incoming packets are only trusted (conditional trust through CDP) when the telephone is detected.

**Note** Do not configure the `auto qos voip cisco-phone` option for IP phones that support video. This option causes DSCP markings of video packets to get overwritten, because these packets do not have Expedited Forwarding priority, which results in these packets getting classified in the class-default class.

- `auto qos voip cisco-softphone` — The port is connected to device running the Cisco SoftPhone feature. This command generates a QoS configuration for interfaces connected to PCs running the Cisco IP SoftPhone application and mark, as well as police traffic coming from such interfaces. Ports configured with this command are considered untrusted.

- `auto qos voip trust` — The uplink port is connected to a trusted switch or router, and the VoIP traffic classification in the ingress packet is trusted.

The following commands enable auto-QoS for the specified video device (system, camera, or media player):

- `auto qos video cts` — A port connected to a Cisco Telepresence system. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco TelePresence is detected.

- `auto qos video ip-camera` — A port connected to a Cisco video surveillance camera. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco camera is detected.

- `auto qos video media-player` — A port connected to a CDP-capable Cisco digital media player. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a digital media player is detected.

The following command enables auto-QoS for classification:

- `auto qos classify police` — This command generates a QoS configuration for untrusted interfaces. The

**Upgrading Auto-QoS (CLI)**

This procedure should only be followed when upgrading your software release from a pre- 3.2.2 software version to a 3.2.2 or later software version.

**Before you begin**

Prior to upgrading, you need to remove all auto-QoS configurations currently on the switch. This sample procedure describes that process.
After following this sample procedure, you must then reboot the switch with the new or upgraded software image and reconfigure auto-QoS.

**SUMMARY STEPS**

1. `show auto qos`
2. `no auto qos`
3. `show running-config | i autoQos`
4. `no policy-map policy-map_name`
5. `show running-config | i AutoQoS`
6. `show auto qos`
7. `write memory`

**DETAILED STEPS**

---

**Step 1**

`show auto qos`

**Example:**

```
Device# show auto qos
GigabitEthernet2/0/3
auto qos voip cisco-phone
GigabitEthernet2/0/27
auto qos voip cisco-softphone
```

In privileged EXEC mode, record all current auto QoS configurations by entering this command.

**Step 2**

`no auto qos`

**Example:**

```
Device(config-if)# no auto qos
```

In interface configuration mode, run the appropriate `no auto qos` command on each interface that has an auto QoS configuration.

**Step 3**

`show running-config | i autoQos`

**Example:**

```
Device# show running-config | i autoQos
```

Return to privileged EXEC mode, and record any remaining auto QoS maps class maps, policy maps, access lists, table maps, or other configurations by entering this command.

**Step 4**

`no policy-map policy-map_name`

**Example:**

```
Device(config)# no policy-map pmap_101
Device(config)# no class-map cmap_101
```
Device(config)# no ip access-list extended AutoQoS-101
Device(config)# no table-map 101
Device(config)# no table-map policed-dscp

In global configuration mode, remove the QoS class maps, policy maps, access-lists, table maps, and any other auto QoS configurations by entering these commands:

- no policy-map policy-map-name
- no class-map class-map-name
- no ip access-list extended Auto-QoS-x
- no table-map table-map-name
- no table-map policed-dscp

**Step 5** show running-config | i AutoQoS

**Example:**

Device# show running-config | i AutoQoS

Return to privileged EXEC mode, run this command again to ensure that no auto-QoS configuration or remaining parts of the auto-QoS configuration exists

**Step 6** show auto qos

**Example:**

Device# show auto qos

Run this command to ensure that no auto-QoS configuration or remaining parts of the configuration exists.

**Step 7** write memory

**Example:**

Device# write memory

Write the changes to the auto QoS configuration to NV memory by entering the `write memory` command.

---

**What to do next**

Reboot the switch with the new or upgraded software image.

After rebooting with the new or upgraded software image, re-configure auto-QoS for the appropriate switch interfaces as determined by running the `show auto qos` command described in step 1.

**Note**

There is only one table-map for exceed and another table-map for violate markdown per switch or stack. If the switch already has a table-map under the exceed action, then the auto-qos policy cannot be applied.
Enabling Auto-Qos Compact

To enable auto-Qos compact, enter this command:

**SUMMARY STEPS**

1. `configure terminal`
2. `auto qos global compact`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>auto qos global compact</code></td>
<td>Enables auto-Qos compact and generates (hidden) the global configurations for auto-QoS.</td>
</tr>
<tr>
<td>Example:</td>
<td>You can then enter the auto-QoS command you want to configure in the interface configuration mode and the interface commands that the system generates are also hidden.</td>
</tr>
<tr>
<td><code>Device(config)# auto qos global compact</code></td>
<td>To display the auto-QoS configuration that has been applied, use these the privileged EXEC commands:</td>
</tr>
<tr>
<td></td>
<td>• <code>show derived-config</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show policy-map</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show access-list</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show class-map</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show table-map</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show auto-qos</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show policy-map interface</code></td>
</tr>
<tr>
<td></td>
<td>• <code>show ip access-lists</code></td>
</tr>
</tbody>
</table>
|                            | These commands will have keyword *AutoQos-*.

**What to do next**

To disable auto-QoS compact, remove auto-Qos instances from all interfaces by entering the `no` form of the corresponding auto-QoS commands and then enter the `no auto qos global compact` global configuration command.
Monitoring Auto-QoS

Table 83: Commands for Monitoring Auto-QoS

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show auto qos [interface [interface-id]]</code></td>
<td>Displays the initial auto-QoS configuration. You can compare the <code>show auto qos</code> and the <code>show running-config</code> command output to identify the user-defined QoS settings.</td>
</tr>
<tr>
<td><code>show running-config</code></td>
<td>Displays information about the QoS configuration that might be affected by auto-QoS. You can compare the <code>show auto qos</code> and the <code>show running-config</code> command output to identify the user-defined QoS settings.</td>
</tr>
<tr>
<td><code>show derived-config</code></td>
<td>Displays the hidden <code>mls qos</code> command which get configured along with the running configs because of auto-qos template.</td>
</tr>
</tbody>
</table>

Troubleshooting Auto-QoS

To troubleshoot auto-QoS, use the `debug auto qos` privileged EXEC command. For more information, see the `debug auto qos` command in the command reference for this release.

To disable auto-QoS on a port, use the `no` form of the `auto qos` command interface configuration command, such as `no auto qos voip`. Only the auto-QoS-generated interface configuration commands for this port are removed. If this is the last port on which auto-QoS is enabled and you enter the `no auto qos voip` command, auto-QoS is considered disabled even though the auto-QoS-generated global configuration commands remain (to avoid disrupting traffic on other ports affected by the global configuration).

Configuration Examples for Auto-QoS

Example: `auto qos trust cos`

The following is an example of the `auto qos trust cos` command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-Trust-Cos-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- class-default (match-any)
Example: auto qos trust cos

- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
- AutoQos-4.0-Output-Trans-Data-Queue (match-any)
- AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
- AutoQos-4.0-Output-Scavenger-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

**auto qos global compact**

The following is an example of the `auto qos global compact` command.

```
Device# configure terminal
Device(config)# auto qos global compact
Device(config)# interface GigabitEthernet1/2
Device(config-if)# auto qos voip cisco-phone

Device# show auto-qos

GigabitEthernet1/2
auto qos voip cisco-phone

Device# show running-config interface GigabitEthernet 1/0/2

interface GigabitEthernet1/0/2
auto qos voip cisco-phone
end
```
Where to Go Next for Auto-QoS

Review the QoS documentation if you require any specific QoS changes to your auto-QoS configuration.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for QoS

Before configuring standard QoS, you must have a thorough understanding of these items:

- Standard QoS concepts.
- Wireless concepts and network topologies.
- Classic Cisco IOS QoS.
- Modular QoS CLI (MQC).
- Understanding of QoS implementation.
- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?
• Bandwidth requirements and speed of the network.
• Location of congestion points in the network.

QoS Components

QoS consists of the following key components:

• Classification—Classification is the process of distinguishing one type of traffic from another based upon ACLs, Differentiated Services Code Point (DSCP), Class of Service (CoS), and other factors.

• Marking and mutation—Marking is used on traffic to convey specific information to a downstream device in the network, or to carry information from one interface in a to another. When traffic is marked, QoS operations on that traffic can be applied. This can be accomplished directly using the set command or through a table map, which takes input values and translates them directly to values on output.

• Shaping and policing—Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that downstream devices are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface. Policing is used to impose a maximum rate on a traffic class. If the rate is exceeded, then a specific action is taken as soon as the event occurs.

• Queuing—Queueing is used to prevent traffic congestion. Traffic is sent to specific queues for servicing and scheduling based upon bandwidth allocation. Traffic is then scheduled or sent out through the port.

• Bandwidth—Bandwidth allocation determines the available capacity for traffic that is subject to QoS policies.

• Trust—Trust enables traffic to pass through the , and the DSCP, precedence, or CoS values coming in from the end points are retained in the absence of any explicit policy configuration.

QoS Terminology

The following terms are used interchangeably in this QoS configuration guide:

• Upstream (direction towards the ) is the same as ingress.

• Downstream (direction from the ) is the same as egress.

Note
Upstream is wireless to wired. Downstream is wired to wireless. Wireless to wireless has no specific term.
Information About QoS

QoS Overview

By configuring the quality of service (QoS), you can provide preferential treatment to specific types of traffic at the expense of other traffic types. Without QoS, the device offers best-effort service to each packet, regardless of the packet contents or size. The device sends the packets without any assurance of reliability, delay bounds, or throughput.

The following are specific features provided by QoS:

- Low latency
- Bandwidth guarantee
- Buffering capabilities and dropping disciplines
- Traffic policing
- Enables the changing of the attribute of the frame or packet header
- Relative services

Related Topics

Restrictions for QoS on Wireless Targets, on page 1206

Modular QoS Command-Line Interface

With the device, QoS features are enabled through the Modular QoS command-line interface (MQC). The MQC is a command-line interface (CLI) structure that allows you to create traffic policies and attach these policies to interfaces. A traffic policy contains a traffic class and one or more QoS features. A traffic class is used to classify traffic, while the QoS features in the traffic policy determine how to treat the classified traffic. One of the main goals of MQC is to provide a platform-independent interface for configuring QoS across Cisco platforms.

Wireless QoS Overview

Wireless QoS can be configured on the following wireless targets:

- Wireless ports, including all physical ports to which an access point can be associated.
- Radio
- SSID (applicable on a per-radio, per-AP, and per-SSID)
- Client

From Cisco IOS XE Release 3E, marking and policing actions for ingress SSID and client policies are applied at the access point. The SSID and client ingress policies that you configure in the are moved to the access point. The access point performs policing and marking actions for each packet. However, the selects the QoS policies. Marking and policing of egress SSID and client policies are applied at the .

The following table displays how policies are supported for the wireless targets.
<table>
<thead>
<tr>
<th>Wireless Target</th>
<th>Policies on Wireless Targets Supported</th>
<th>Policies Supported Egress Direction</th>
<th>Policies Supported Ingress Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wireless port</td>
<td>Yes</td>

<td>Yes</td>
<td>Yes - user configurable</td>
<td>Yes - user configurable</td>
</tr>
<tr>
<td>Client</td>
<td>Yes</td>
<td>Yes - user configurable</td>
<td>Yes - user configurable</td>
</tr>
</tbody>
</table>

Additional policies that are user configured include multidestination policers and VLANs.

Wireless QoS supports the following features:

- Queuing in the egress direction.
- Policing of wireless traffic
- Marking of wireless traffic.
- Shaping of wireless traffic in the egress direction.
- Approximate Fair Drop (AFD) in the egress direction.
- Mobility support for QoS.
- Compatibility with precious metal QoS policies available on Cisco Unified Wireless Controllers.
- Combination of CLI/Traffic Class (TCLAS) and CLI/snooping.
- Application control (can drop or mark the data traffic) by configuring an AVC QoS client policy.
- Drop action for ingress policies.
- QoS statistics for client and SSID targets in the ingress direction.
- QoS attribute for local profiling policy.
- Hierarchical policies.

**QoS and IPv6 for Wireless**

The supports QoS for both IPv4 and IPv6 traffic, and client policies can now have IPv4 and IPv6 filters.
# Wired and Wireless Access Supported Features

The following table describes the supported features for both wired and wireless access.

**Table 85: Supported QoS Features for Wired and Wireless Access**

<table>
<thead>
<tr>

<tr>
<td></td>
<td></td>
<td>• CAPWAP multicast tunnel</td>
</tr>
</tbody>
</table>

| Configuration Sequence         | QoS policy installed using the service-policy command. | • When an access point joins the switch, the switch installs a policy on the port. The port policy has a child policy called port_child_policy. |
|                                |                                                           | • A policy is installed on the radio which has a shaper configured to the radio rate. The default radio policy (which cannot be modified) is attached to the radio. |
|                                |                                                           | • The default client policies take effect when a WMM client associates, and if admission control is enabled on the radio. |
|                                |                                                           | • User can modify the port_child_policy to add more classes. |
|                                |                                                           | • User can attach a user-defined policy at the SSID level. |
|                                |                                                           | • User can attach a user-defined policy at the client level. |

| Number of queues permitted at port level | Up to 8 queues supported on a port. | Only four queues supported. |
### Supported QoS Features on Wireless Targets

Port Policies
The device supports port-based policies. The port policies includes port shaper and a child policy (port_child_policy).
Port child policies only apply to wireless ports and not to wired ports on the switch. A wireless port is defined as a port to which APs join. A default port child policy is applied on the switch to the wireless ports at startup. The port shaper rate is limited to 1G.

Port shaper specifies the traffic policy applicable between the device and the AP. This is the sum of the radio rates supported on the access point.

The child policy determines the mapping between packets and queues defined by the port-child policy. The child policy can be configured to include voice, video, class-default, and non-client-nrt classes where voice and video are based on DSCP value (which is the outer CAPWAP header DSCP value). The definition of class-default is known to the system as any value other than voice and video DSCP.

The DSCP value is assigned when the packet reaches the port. Before the packet arrives at the port, the SSID policies are applied on the packet. Port child policy also includes multicast percentage for a given port traffic. By default, the port child policy allocates up to 10 percent of the available rate.

### Port Policy Format

This section describes the behavior of the port policies on a switch. The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suit the QoS configuration. The switch is preconfigured with a default class map and a policy map.

Default class map:

```
Class Map match-any non-client-nrt-class
  Match non-client-nrt
```

The above port policy processes all network traffic to the Q3 queue. You can view the class map by executing the `show class-map` command.

Default policy map:

```
Policy Map port_child_policy
  Class non-client-nrt-class
    bandwidth remaining ratio 10
```

The class map and policy map listed are system-defined policies and cannot be changed.

The following is the system-defined policy map available on the ports on which wireless devices are associated. The format consists of a parent policy and a service child policy (port_child_policy). To customize the policies to suite your network needs, you must configure the port child policy.
The parent policy is system generated and cannot be changed. You must configure the `port_child_policy` policy to suit the QoS requirements on your network.

Depending on the type of traffic in your network, you can configure the port child policy. For example, in a typical wireless network deployment, you can assign specific priorities to voice and video traffic. Here is an example:

```
Policy-map port_child_policy
  Class voice-policy-name (match dscp ef)
    Priority level 1
    Police (multicast-policer-name-voice) Multicast Policer
  Class video-policy-name (match dscp af41)
    Priority level 2
    Police (multicast-policer-name-video) Multicast Policer
  Class non-client-nrt-class traffic (match non-client-nrt)
    Bandwidth remaining ratio (brr-value-nrt-q2)
  Class class-default (NRT Data)
    Bandwidth remaining ratio (brr-value-q3)
```

In the above port child policy:

- **voice-policy-name** — Refers to the name of the class that specifies rules for the traffic for voice packets. Here the DSCP value is mapped to a value of 46 (represented by the keyword `ef`). The voice traffic is assigned the highest priority of 1.

- **video-policy-name** — Refers to the name of the class that specifies rules for the traffic for video packets. The DSCP value is mapped to a value of 34 (represented by the keyword `af41`).

- **multicast-policer-name-voice** — If you need to configure multicast voice traffic, you can configure policing for the voice class map.

- **multicast-policer-name-video** — If you need to configure multicast video traffic, you can configure policing for the video class map.

In the above sample configuration, all voice and video traffic is directed to the Q0 and Q1 queues, respectively. These queues maintain a strict priority. The packets in Q0 and Q1 are processed in that order. The bandwidth remaining ratios `brr-value-nrt-q2` and `brr-value-q3` are directed to the Q2 and Q3 respectively specified by the class maps and `class-default` and `non-client-nrt`. The processing of packets on Q2 and Q3 are based on a weighted round-robin approach. For example, if the `brr-value-nrtq2` has a value of 90 and `brr-value-nrtq3` is 10, the packets in queue 2 and queue 3 are processed in the ratio of 9:1.

Radio Policies

The radio policies are system defined and are not user configurable. Radio wireless targets are only applicable in the egress direction.

Radio policies are applicable on a per-radio, per-access point basis. The rate limit on the radios is the practical limit of the AP radio rate. This value is equivalent to the sum of the radios supported by the access point.

The following radios are supported:

• 802.11 a/n
• 802.11 b/n
• 802.11 ac

SSID Policies

You can create QoS policies on SSID BSSID (Basic Service Set Identification) in both the ingress and egress directions. By default, there is no SSID policy. All traffic is transmitted as best effort because the wireless traffic is untrusted. You can configure an SSID policy based on the SSID name. The policy is applicable on a per BSSID.

The types of policies you can create on SSID include marking by using table maps (table-maps), shape rate, and RT1 (Real Time 1) and RT2 (Real Time 2) policies. If traffic is ingress, you usually configure a marking and policing policy on the SSID. If traffic is downstream, you can configure marking and queuing.

There should be a one-to-one mapping between the policies configured on a port and an SSID. For example, if you configure class voice and class video on the port, you can have a similar policy on the SSID.

SSID priorities can be specified by configuring bandwidth remaining ratio. Queuing SSID policies are applied in the egress direction.

Related Topics

Applying an SSID or Client Policy on a WLAN (CLI), on page 1224
Supported QoS Features on Wireless Targets, on page 1171
Examples: SSID Policy
Examples: Configuring Downstream SSID Policy, on page 1264

Client Policies

Client policies are applicable in the ingress and egress direction. The wireless control module of the device applies the default client policies when admission control is enabled for WMM clients. When admission control is disabled, there is no default client policy. You can configure policing and marking policies on clients.

Note

A client policy can have both IPv4 and IPv6 filters.

You can configure client policies in the following ways:
• Using AAA
• Using the Cisco IOS MQC CLI
  • You can use **service policy client** command in the WLAN configuration.
• Using the default configuration
• Using local policies (native profiling)

Use the **show wireless client mac address** `mac_address service-policy` command to display the source of the client policy (for example, local profiling policy, AAA, or CLI). The precedence order of client policies is AAA > local policy > WLAN service client policy CLI > default configuration.

---

**Note**

If you configured AAA by configuring the unified wireless controller procedure, and using the MQC QoS commands, the policy configuration performed through the MQC QoS commands takes precedence.

---

**Note**

When applying client policies on a WLAN, you must disable the WLAN before modifying the client policy. SSID policies can be modified even if the WLAN is enabled.

The default client policy is enabled only on Wi-Fi Multimedia (WMM) clients that are admission control (ACM)-enabled.

**Policy Chaining**

Every packet has a maximum of two applicable policies, first at the client target and second at the SSID target. The client policing action is applied to the packet before the marking action that is specified in the client policy. After the client policing and marking actions are applied to the packet, the SSID policy action is applied to the updated packet. If no custom policies are specified, the system trust configuration is applied to the packet. Egress trust is based on DSCP, and ingress trust is based on WLAN user priority.

**Hierarchical QoS**

The supports hierarchical QoS (HQoS). HQoS allows you to perform:

• Hierarchical classification—Traffic classification is based upon other classes.
• Hierarchical policing—The process of having the policing configuration at multiple levels in a hierarchical policy.
• Hierarchical shaping—Shaping can also be configured at multiple levels in the hierarchy.
Hierarchical shaping is only supported for the port shaper, where for the parent you only have a configuration for the class default, and the only action for the class default is shaping.

Related Topics
Examples: Hierarchical Classification, on page 1261
Examples: Hierarchical Policy Configuration, on page 1261

Hierarchical Wireless QoS

The device supports hierarchical QoS for wireless targets. Hierarchical QoS policies are applicable on port, radio, SSID, and client. QoS policies configured on the device (including marking, shaping, policing) can be applied across the targets. If the network contains non-realtime traffic, the non-realtime traffic is subject to approximate fair drop. Hierarchy refers to the process of application of the various QoS policies on the packets arriving to the device. You can configure policing in both the parent and child policies.

For hierarchical client and SSID policies, you only configure marking either in the parent or child policy.

Wireless Packet Format

Figure 78: Wireless Packet Path in the Egress Direction during First Pass

This figure displays the wireless packet flow and encapsulation used in hierarchical wireless QoS. The incoming packet enters the device. The device encapsulates this incoming packet and adds the 802.11e and CAPWAP headers.
Hierarchical AFD

Approximate Fair Dropping (AFD) is a feature provided by the QoS infrastructure in Cisco IOS. For wireless targets, AFD can be configured on SSID (via shaping) and clients (via policing). AFD shaping rate is only applicable for downstream direction. Unicast real-time traffic is not subjected to AFD drops.

QoS Implementation

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (class) information. Classification can also be carried in the Layer 2 frame.
Figure 79: QoS Classification Layers in Frames and Packets

Layer 2 Frame Prioritization Bits

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.
Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.

End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

Packet Classification

Packet classification is the process of identifying a packet as belonging to one of several classes in a defined policy, based on certain criteria. The Modular QoS CLI (MQC) is a policy-class based language. The policy class language is used to define the following:

- Class-map template with one or several match criteria
- Policy-map template with one or several classes associated to the policy map

The policy map template is then associated to one or several interfaces on the .

Packet classification is the process of identifying a packet as belonging to one of the classes defined in the policy map. The process of classification will exit when the packet being processed matches a specific filter in a class. This is referred to as first-match exit. If a packet matches multiple classes in a policy, irrespective of the order of classes in the policy map, it would still exit the classification process after matching the first class.

If a packet does not match any of the classes in the policy, it would be classified into the default class in the policy. Every policy map has a default class, which is a system-defined class to match packets that do not match any of the user-defined classes.

Packet classification can be categorized into the following types:

- Classification based on information that is propagated with the packet
- Classification based on information that is specific
- Hierarchical classification
Classification Based on Information That is Propagated with the Packet

Classification that is based on information that is part of the packet and propagated either end-to-end or between hops, typically includes the following:

- Classification based on Layer 3 or 4 headers
- Classification based on Layer 2 information

Classification Based on Layer 3 or Layer 4 Header

This is the most common deployment scenario. Numerous fields in the Layer 3 and Layer 4 headers can be used for packet classification.

At the most granular level, this classification methodology can be used to match an entire flow. For this deployment type, an access control list (ACLs) can be used. ACLs can also be used to match based on various subsets of the flow (for example, source IP address only, or destination IP address only, or a combination of both).

Classification can also be done based on the precedence or DSCP values in the IP header. The IP precedence field is used to indicate the relative priority with which a particular packet needs to be handled. It is made up of three bits in the IP header's type of service (ToS) byte.

The following table shows the different IP precedence bit values and their names.

**Table 87: IP Precedence Values and Names**

<table>
<thead>
<tr>
<th>IP Precedence Value</th>
<th>IP Precedence Bits</th>
<th>IP Precedence Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>000</td>
<td>Routine</td>
</tr>
<tr>
<td>1</td>
<td>001</td>
<td>Priority</td>
</tr>
<tr>
<td>2</td>
<td>010</td>
<td>Immediate</td>
</tr>
<tr>
<td>3</td>
<td>011</td>
<td>Flash</td>
</tr>
<tr>
<td>4</td>
<td>100</td>
<td>Flash Override</td>
</tr>
<tr>
<td>5</td>
<td>101</td>
<td>Critical</td>
</tr>
<tr>
<td>6</td>
<td>110</td>
<td>Internetwork control</td>
</tr>
<tr>
<td>7</td>
<td>111</td>
<td>Network control</td>
</tr>
</tbody>
</table>

All routing control traffic in the network uses IP precedence value 6 by default. IP precedence value 7 also is reserved for network control traffic. Therefore, the use of IP precedence values 6 and 7 is not recommended for user traffic.

The DSCP field is made up of 6 bits in the IP header and is being standardized by the Internet Engineering Task Force (IETF) Differentiated Services Working Group. The original ToS byte contained the DSCP bits has been renamed the DSCP byte. The DSCP field is part of the IP header, similar to IP precedence.
DSCP field is a super set of the IP precedence field. Therefore, the DSCP field is used and is set in ways similar to what was described with respect to IP precedence.

**Note**
The DSCP field definition is backward-compatible with the IP precedence values.

**Classification Based on Layer 2 Header**

A variety of methods can be used to perform classification based on the Layer 2 header information. The most common methods include the following:

- **MAC address-based classification (only for access groups)**—Classification is based upon the source MAC address (for policies in the input direction) and destination MAC address (for policies in the output direction).
- **Class-of-Service**—Classification is based on the 3 bits in the Layer 2 header based on the IEEE 802.1p standard. This usually maps to the ToS byte in the IP header.
- **VLAN ID**—Classification is based on the VLAN ID of the packet.

**Note**
Some of these fields in the Layer 2 header can also be set using a policy.

**Classification Based on Information that is Device Specific (QoS Groups)**

The also provides classification mechanisms that are available where classification is not based on information in the packet header or payload.

At times you might be required to aggregate traffic coming from multiple input interfaces into a specific class in the output interface. For example, multiple customer edge routers might be going into the same access on different interfaces. The service provider might want to police all the aggregate voice traffic going into the core to a specific rate. However, the voice traffic coming in from the different customers could have a different ToS settings. QoS group-based classification is a feature that is useful in these scenarios.

Policies configured on the input interfaces set the QoS group to a specific value, which can then be used to classify packets in the policy enabled on output interface.

The QoS group is a field in the packet data structure internal to the . It is important to note that a QoS group is an internal label to the and is not part of the packet header.

**Hierarchical Classification**

The permits you to perform a classification based on other classes. Typically, this action may be required when there is a need to combine the classification mechanisms (that is, filters) from two or more classes into a single class map.

**QoS Wired Model**

To implement QoS, the must perform the following tasks:

- Traffic classification—Distinguishes packets or flows from one another.
• Traffic marking and policing—Assigns a label to indicate the given quality of service as the packets move through the , and then make the packets comply with the configured resource usage limits.

• Queueing and scheduling—Provides different treatment in all situations where resource contention exists.

• Shaping—Ensures that traffic sent from the meets a specific traffic profile.

**Ingress Port Activity**

The following activities occur at the ingress port of the:

- **Classification**—Classifying a distinct path for a packet by associating it with a QoS label. For example, the maps the CoS or DSCP in the packet to a QoS label to distinguish one type of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.

- **Policing**—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.

- **Marking**—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).

**Note**

Applying polices on the wireless ingress port is not supported on the.

**Egress Port Activity**

The following activities occur at the egress port of the:

- **Policing**—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.

- **Marking**—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).

- **Queueing**—Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, Weighted Tail Drop (WTD) differentiates traffic classes and subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.

**Classification**

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is enabled on the. By default, QoS is enabled on the.

During classification, the performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.
Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:

- If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.
- If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.
- If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the packet offers best-effort service to the packet.
- If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

Note: When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate-limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the `access-list` global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the `mac access-list extended` global configuration command.

Class Maps

A class map is a mechanism that you use to name a specific traffic flow (or class) and isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

You create a class map by using the `class-map` global configuration command or the `class` policy-map configuration command. You should use the `class-map` command when the map is shared among many ports. When you enter the `class-map` command, the system enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the `match` class-map configuration command.

You can create a default class by using the `class class-default` policy-map configuration command. The default class is system-defined and cannot be configured. Unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as default traffic.

Related Topics

Creating a Traffic Class (CLI), on page 1208
Policy Maps

A policy map specifies which traffic class to act on. Actions can include the following:

- Setting a specific DSCP or IP precedence value in the traffic class
- Setting a CoS value in the traffic class
- Setting a QoS group
- Setting a wireless LAN (WLAN) value in the traffic class
- Specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile

Before a policy map can be effective, you must attach it to a port.

You create and name a policy map using the `policy-map` global configuration command. When you enter this command, the enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the `class` or `set` policy-map configuration and policy-map class configuration commands.

The policy map can also be configured using the `police` and `bandwidth` policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded. In addition, the policy-map can further be configured using the `priority` policy-map class configuration command, to schedule priority for the class or the queuing policy-map class configuration commands, `queue-buffers` and `queue-limit`.

To enable the policy map, you attach it to a port by using the `service-policy` interface configuration command.

**Note**

You cannot configure both `priority` and `set` for a policy map. If both these commands are configured for a policy map, and when the policy map is applied to an interface, error messages are displayed. The following example shows this restriction:

```
Switch# configure terminal
Switch(config)# class-map cmap
Switch(config-cmap)# exit
Switch(config)# class-map classmap1
Switch(config-cmap)# exit
Switch(config)# policy-map pmap
Switch(config-pmap)# class cmap
Switch(config-pmap-c)# priority
Switch(config-pmap-c)# exit
Switch(config-pmap-c)# class classmap1
Switch(config-pmap-c)# set
Switch(config-pmap-c)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# interface gigabitethernet 0/1/1
Switch(config-if)# service-policy output pmap
```

Non-queuing action only is unsupported in a queuing policy!!!
%QOS-6-POLICY_INST_FAILED:
Service policy installation failed

Creating a Traffic Policy (CLI), on page 1211
Policy Map on Physical Port

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions can include setting a specific DSCP or IP precedence value in the traffic class, specifying the traffic bandwidth limitations for each matched traffic class (policer), and taking action when the traffic is out of profile (marking).

A policy map also has these characteristics:

• A policy map can contain multiple class statements, each with different match criteria and policers.

• A policy map can contain a predefined default traffic class explicitly placed at the end of the map.

When you configure a default traffic class by using the `class class-default` policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (`class-default`).

• A separate policy-map class can exist for each type of traffic received through a port.

Related Topics
- Attaching a Traffic Policy to an Interface (CLI), on page 1222

Policy Map on VLANs

The supports a VLAN QoS feature that allows the user to perform QoS treatment at the VLAN level (classification and QoS actions) using the incoming frame’s VLAN information. In VLAN-based QoS, a service policy is applied to an SVI interface. All physical interfaces belonging to a VLAN policy map then need to be programmed to refer to the VLAN-based policy maps instead of the port-based policy map.

Although the policy map is applied to the VLAN SVI, any policing (rate-limiting) action can only be performed on a per-port basis. You cannot configure the policer to take account of the sum of traffic from a number of physical ports. Each port needs to have a separate policer governing the traffic coming into that port.

Policing

After a packet is classified and has a DSCP-based, CoS-based, or QoS-group label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are out of profile or nonconforming. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP or CoS value of the packet and allowing the packet to pass through.
To avoid out-of-order packets, both conform and nonconforming traffic typically exit the same queue.

All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can only configure policing on a physical port.

After you configure the policy map and policing actions, attach the policy to an ingress port or SVI by using the service-policy interface configuration command.

**Token-Bucket Algorithm**

Policing uses a token-bucket algorithm. As each frame is received by the , a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).

How quickly the bucket fills is a function of the bucket depth (burst-byte), the rate at which the tokens are removed (rate-bps), and the duration of the burst above the average rate. The size of the bucket imposes an upper limit on the burst length and limits the number of frames that can be transmitted back-to-back. If the burst is short, the bucket does not overflow, and no action is taken against the traffic flow. However, if a burst is long and at a higher rate, the bucket overflows, and the policing actions are taken against the frames in that burst.

You configure the bucket depth (the maximum burst that is tolerated before the bucket overflows) by using the burst-byte option of the police policy-map class configuration command. You configure how fast (the average rate) that the tokens are removed from the bucket by using the rate option of the police policy-map class configuration command.

**Marking**

Marking is used to convey specific information to a downstream device in the network, or to carry information from one interface to another.

Marking can be used to set certain field/bits in the packet headers, or marking can also be used to set certain fields in the packet structure that is internal to the . Additionally, the marking feature can be used to define mapping between fields. The following marking methods are available for QoS:

- Packet header
- Device () specific information
- Table maps
Packet Header Marking

Marking on fields in the packet header can be classified into two general categories:

- IPv4/v6 header bit marking
- Layer 2 header bit marking

The marking feature at the IP level is used to set the precedence or the DSCP in the IP header to a specific value to get a specific per-hop behavior at the downstream device (switch or router), or it can also be used to aggregate traffic from different input interfaces into a single class in the output interface. The functionality is currently supported on both the IPv4 and IPv6 headers.

Marking in the Layer 2 headers is typically used to influence dropping behavior in the downstream devices (switch or router). It works in tandem with the match on the Layer 2 headers. The bits in the Layer 2 header that can be set using a policy map are class of service.

Switch Specific Information Marking

This form of marking includes marking of fields in the packet data structure that are not part of the packets header, so that the marking can be used later in the data path. This is not propagated between the switches. Marking of QoS-group falls into this category. This form of marking is only supported in policies that are enabled on the input interfaces. The corresponding matching mechanism can be enabled on the output interfaces on the same switch and an appropriate QoS action can be applied.

Table Map Marking

Table map marking enables the mapping and conversion from one field to another using a conversion table. This conversion table is called a table map.

Depending upon the table map attached to an interface, CoS, DSCP, and UP values (UP specific to wireless packets) of the packet are rewritten. The allows configuring both ingress table map policies and egress table map policies.

The stack supports a total of 14 table maps. Only one table map is supported per wired port, per direction.

As an example, a table map can be used to map the Layer 2 CoS setting to a precedence value in Layer 3. This feature enables combining multiple set commands into a single table, which indicates the method to perform the mapping. This table can be referenced in multiple policies, or multiple times in the same policy.

The following table shows the currently supported forms of mapping:

<table>
<thead>
<tr>
<th>The To Packet-Marking Type</th>
<th>The From Packet-Marking Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Precedence</td>
<td>CoS</td>
</tr>
<tr>
<td>Precedence</td>
<td>QoS Group</td>
</tr>
<tr>

<td>DSCP</td>
</tr>
<tr>
<td>QoS Group</td>
<td>Precedence</td>
</tr>
<tr>
<td>QoS Group</td>
<td>DSCP</td>
</tr>
</tbody>
</table>

A table map-based policy supports the following capabilities:

- **Mutation**—You can have a table map that maps from one DSCP value set to another DSCP value set, and this can be attached to an egress port.

- **Rewrite**—Packets coming in are rewritten depending upon the configured table map.

- **Mapping**—Table map based policies can be used instead of set policies.

The following steps are required for table map marking:

1. **Define the table map**—Use the `table-map` global configuration command to map the values. The table does not know of the policies or classes within which it will be used. The default command in the table map is used to indicate the value to be copied into the to field when there is no matching from field.

2. **Define the policy map**—You must define the policy map where the table map will be used.

3. **Associate the policy to an interface.**

---

**Note**

A table map policy on an input port changes the trust setting of that port to the from type of qos-marking.

---

**Traffic Conditioning**

To support QoS in a network, traffic entering the service provider network needs to be policed on the network boundary routers to ensure that the traffic rate stays within the service limit. Even if a few routers at the network boundary start sending more traffic than what the network core is provisioned to handle, the increased traffic load leads to network congestion. The degraded performance in the network makes it difficult to deliver QoS for all the network traffic.

Traffic policing functions (using the police feature) and shaping functions (using the traffic shaping feature) manage the traffic rate, but differ in how they treat traffic when tokens are exhausted. The concept of tokens comes from the token bucket scheme, a traffic metering function.

---

**Note**

When running QoS tests on network traffic, you may see different results for the shaper and policing data. Network traffic data from shaping provides more accurate results.
This table compares the policing and shaping functions.

**Table 89: Comparison Between Policing and Shaping Functions**

<table>
<thead>
<tr>
<th>Policing Function</th>
<th>Shaping Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sends conforming traffic up to the line rate and allows bursts.</td>
<td>Smooths traffic and sends it out at a constant rate.</td>
</tr>
<tr>
<td>When tokens are exhausted, action is taken immediately.</td>
<td>When tokens are exhausted, it buffers packets and sends them out later, when tokens are available. A class with shaping has a queue associated with it which will be used to buffer the packets.</td>
</tr>
<tr>
<td>Policing has multiple units of configuration – in bits per second, packets per second and cells per second.</td>
<td>Shaping has only one unit of configuration – in bits per second.</td>
</tr>
<tr>
<td>Policing has multiple possible actions associated with an event, marking and dropping being example of such actions.</td>
<td>Shaping does not have the provision to mark packets that do not meet the profile.</td>
</tr>
<tr>
<td>Works for both input and output traffic.</td>
<td>Implemented for output traffic only.</td>
</tr>
<tr>
<td>Transmission Control Protocol (TCP) detects the line at line speed but adapts to the configured rate when a packet drop occurs by lowering its window size.</td>
<td>TCP can detect that it has a lower speed line and adapt its retransmission timer accordingly. This results in less scope of retransmissions and is TCP-friendly.</td>
</tr>
</tbody>
</table>

**Policing**

The QoS policing feature is used to impose a maximum rate on a traffic class. The QoS policing feature can also be used with the priority feature to restrict priority traffic. If the rate is exceeded, then a specific action is taken as soon as the event occurs. The rate (committed information rate [CIR] and peak information rate [PIR]) and the burst parameters (conformed burst size \[B_c\] and extended burst size \[B_e\]) are all configured in bytes per second.

The following policing forms or policers are supported for QoS:

- Single-rate two-color policing
- Dual-rate three-color policing

**Note**

Single-rate three-color policing is not supported.

**Single-Rate Two-Color Policing**

Single-rate two-color policer is the mode in which you configure only a CIR and a \(B_c\).

The \(B_c\) is an optional parameter, and if it is not specified it is computed by default. In this mode, when an incoming packet has enough tokens available, the packet is considered to be conforming. If at the time of packet arrival, enough tokens are not available within the bounds of \(B_c\), the packet is considered to have exceeded the configured rate.
For information about the token-bucket algorithm, see Token-Bucket Algorithm, on page 1187.

**Dual-Rate Three-Color Policing**

With the dual rate policer, the support only color-blind mode. In this mode, you configure a committed information rate (CIR) and a peak information rate (PIR). As the name suggests, there are two token buckets in this case, one for the peak rate, and one for the conformed rate.

In the color-blind mode, the incoming packet is first checked against the peak rate bucket. If there are not enough tokens available, the packet is said to violate the rate. If there are enough tokens available, then the tokens in the conformed rate buckets are checked to determine if there are enough tokens available. The tokens in the peak rate bucket are decremented by the size of the packet. If it does not have enough tokens available, the packet is said to have exceeded the configured rate. If there are enough tokens available, then the packet is said to conform, and the tokens in both the buckets are decremented by the size of the packet.

The rate at which tokens are replenished depends on the packet arrival. Assume that a packet comes in at time $T_1$ and the next one comes in at time $T_2$. The time interval between $T_1$ and $T_2$ determines the number of tokens that need to be added to the token bucket. This is calculated as:

$$\text{Time interval between packets} \times \frac{\text{CIR}}{8 \text{ bytes}}$$

**Shaping**

Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that the downstream switches and routers are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface.

Shaping has a buffer associated with it that ensures that packets which do not have enough tokens are buffered as opposed to being immediately dropped. The number of buffers available to the subset of traffic being shaped is limited and is computed based on a variety of factors. The number of buffers available can also be tuned using specific QoS commands. Packets are buffered as buffers are available, beyond which they are dropped.

**Class-Based Traffic Shaping**

The uses class-based traffic shaping. This shaping feature is enabled on a class in a policy that is associated to an interface. A class that has shaping configured is allocated a number of buffers to hold the packets that do not have tokens. The buffered packets are sent out from the class using FIFO. In the most common form of usage, class-based shaping is used to impose a maximum rate for an physical interface or logical interface as a whole. The following shaping forms are supported in a class:
• Average rate shaping
• Hierarchical shaping

Shaping is implemented using a token bucket. The values of CIR, Bc and Be determine the rate at which the packets are sent out and the rate at which the tokens are replenished.

Note
For information about the token-bucket algorithm, see Token-Bucket Algorithm, on page 1187.

**Average Rate Shaping**

You use the `shape average` policy-map class command to configure average rate shaping.

This command configures a maximum bandwidth for a particular class. The queue bandwidth is restricted to this value even though the port has more bandwidth available. The supports configuring shape average by either a percentage or by a target bit rate value.

**Related Topics**

- Configuring Shaping (CLI), on page 1254
- Examples: Average Rate Shaping Configuration, on page 1268

**Hierarchical Shaping**

Shaping can also be configured at multiple levels in a hierarchy. This is accomplished by creating a parent policy with shaping configured, and then attaching child policies with additional shaping configurations to the parent policy.

There are two supported types of hierarchical shaping:

• Port shaper
• User-configured shaping

The port shaper uses the class default and the only action permitted in the parent is shaping. The queueing action is in the child with the port shaper. With the user configured shaping, you cannot have queueing action in the child.

**Related Topics**

- Configuring Shaping (CLI), on page 1254

**Queueing and Scheduling**

The uses both queueing and scheduling to help prevent traffic congestion. The supports the following queueing and scheduling features:

• Bandwidth
• Weighted Tail Drop
• Priority queues
• Queue buffers
When you define a queuing policy on a port, control packets are mapped to the best priority queue with the highest threshold. Control packets queue mapping works differently in the following scenarios:

- Without a quality of service (QoS) policy—If no QoS policy is configured, control packets with DSCP values 16, 24, 48, and 56 are mapped to queue 0 with the highest threshold of threshold2.

- With an user-defined policy—An user-defined queuing policy configured on egress ports can affect the default priority queue setting on control packets.

Control traffic is redirected to the best queue based on the following rules:

1. If defined in a user policy, the highest-level priority queue is always chosen as the best queue.
2. In the absence of a priority queue, Cisco IOS software selects queue 0 as the best queue. When the software selects queue 0 as the best queue, you must define the highest bandwidth to this queue to get the best QoS treatment to the control plane traffic.
3. If thresholds are not configured on the best queue, Cisco IOS software assigns control packets with Differentiated Services Code Point (DSCP) values 16, 24, 48, and 56 are mapped to threshold2 and reassigns the rest of the control traffic in the best queue to threshold1.

If a policy is not configured explicitly for control traffic, the Cisco IOS software maps all unmatched control traffic to the best queue with threshold2, and the matched control traffic is mapped to the queue as configured in the policy.

**Note**

To provide proper QoS for Layer 3 packets, you must ensure that packets are explicitly classified into appropriate queues. When the software detects DSCP values in the default queue, then it automatically reassigns this queue as the best queue.

**Bandwidth**

The supports the following bandwidth configurations:

- Bandwidth percent
- Bandwidth remaining ratio

**Related Topics**

[Configuring Bandwidth (CLI), on page 1242](#)

**Bandwidth Percent**

You can use the **bandwidth percent** policy-map class command to allocate a minimum bandwidth to a particular class. The total sum cannot exceed 100 percent and in case the total sum is less than 100 percent, then the rest of the bandwidth is divided equally among all bandwidth queues.

**Note**

A queue can oversubscribe bandwidth in case the other queues do not utilize the entire port bandwidth.

You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.
Bandwidth Remaining Ratio

You use the **bandwidth remaining ratio** policy-map class command to create a ratio for sharing unused bandwidth in specified queues. Any unused bandwidth will be used by these specific queues in the ratio that is specified by the configuration. Use this command when the **priority** command is also used for certain queues in the policy.

When you assign ratios, the queues will be assigned certain weights which are inline with these ratios.

You can specify ratios using a range from 0 to 100. For example, you can configure a bandwidth remaining ration of 2 on one class, and another queue with a bandwidth remaining ratio of 4 on another class. The bandwidth remaining ratio of 4 will be scheduled twice as often as the bandwidth remaining ratio of 2.

The total bandwidth ratio allocation for the policy can exceed 100. For example, you can configure a queue with a bandwidth remaining ratio of 50, and another queue with a bandwidth remaining ratio of 100.

**Related Topics**

- Configuring Queue Limits (CLI), on page 1251
- Examples: Queue-limit Configuration, on page 1269

Weighted Tail Drop

The egress queues use an enhanced version of the tail-drop congestion-avoidance mechanism called weighted tail drop (WTD). WTD is implemented on queues to manage the queue lengths and to provide drop precedences for different traffic classifications.

As a frame is enqueued to a particular queue, WTD uses the frame’s assigned QoS label to subject it to different thresholds. If the threshold is exceeded for that QoS label (the space available in the destination queue is less than the size of the frame), the drops the frame.

Each queue has three configurable threshold values. The QoS label determines which of the three threshold values is subjected to the frame.

**Figure 80: WTD and Queue Operation**

The following figure shows an example of WTD operating on a queue whose size is 1000 frames. Three drop percentages are configured: 40 percent (400 frames), 60 percent (600 frames), and 100 percent (1000 frames). These percentages indicate that up to 400 frames can be queued at the 40-percent threshold, up to 600 frames at the 60-percent threshold, and up to 1000 frames at the 100-percent threshold.

In the example, CoS value 6 has a greater importance than the other CoS values, and is assigned to the 100-percent drop threshold (queue-full state). CoS values 4 is assigned to the 60-percent threshold, and CoS values 3 is assigned to the 40-percent threshold. All of these threshold values are assigned using the **queue-limit cos** command.

Assuming the queue is already filled with 600 frames, and a new frame arrives. It contains CoS value 4 and is subjected to the 60-percent threshold. If this frame is added to the queue, the threshold will be exceeded, so the drops it.
Weighted Tail Drop Default Values

The following are the Weighted Tail Drop (WTD) default values and the rules for configuring WTD threshold values.

- If you configure less than three queue-limit percentages for WTD, then WTD default values are assigned to these thresholds.

The following are the WTD threshold default values:

<table>
<thead>
<tr>
<th>Threshold</th>
<th>Default Value Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>90</td>
</tr>
<tr>
<td>2</td>
<td>400</td>
</tr>
</tbody>
</table>

- If 3 different WTD thresholds are configured, then the queues are programmed as configured.
- If 2 WTD thresholds are configured, then the maximum value percentage will be 400.
- If a WTD single threshold is configured as x, then the maximum value percentage will be 400.
  - If the value of x is less than 90, then threshold 1=90 and threshold 0=x.
  - If the value of x equals 90, then threshold 1=90, threshold 0=80.
  - If the value x is greater than 90, then threshold 1=x, threshold 0=80.

Priority Queues

Each port supports eight egress queues, of which two can be given a priority.

You use the `priority level` policy class-map command to configure the priority for two classes. One of the classes has to be configured with a priority queue level 1, and the other class has to be configured with a priority queue level 2. Packets on these two queues are subjected to less latency with respect to other queues.

Note

You can configure a priority only with a level.

Only one strict priority or a priority with levels is allowed in one policy map. Multiple priorities with the same priority levels without kbps/percent are allowed in a policy map only if all of them are configured with police.

Related Topics

- Configuring Priority (CLI), on page 1246

Queue Buffer

Each 1-gigabit port on the is allocated 168 buffers for a wireless port and 300 buffers for a wired port. Each 10-gigabit port is allocated 1800 buffers. At boot time, when there is no policy map enabled on the wired port, there are two queues created by default. Wired ports can have a maximum of 8 queues configured using MQC-based policies. The following table shows which packets go into which one of the queues:
Table 91: DSCP, Precedence, and CoS - Queue Threshold Mapping Table

<table>
<thead>
<tr>
<th>DSCP, Precedence or CoS</th>
<th>Queue</th>
<th>Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control Packets</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>Rest of Packets</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

You can guarantee the availability of buffers, set drop thresholds, and configure the maximum memory allocation for a queue. You use the `queue-buffers` policy-map class command to configure the queue buffers. You use the `queue-limit` policy-map class command to configure the maximum thresholds.

There are two types of buffer allocations: hard buffers, which are explicitly reserved for the queue, and soft buffers, which are available for other ports when unused by a given port.

For the wireless port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 67 buffers are allocated for Queue 0 in the context of 1-gigabit ports. The soft maximum for this queue is set to 268 (calculated as 67 * 400/100) for 1-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

For the wired port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 120 buffers are allocated for Queue 0 in the context of 1-gigabit ports, and 720 buffers in the context of 10-gigabit ports. The soft maximum for this queue is set to 480 (calculated as 120 * 400/100) for 1-gigabit ports and 2880 for 10-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

Queue 1 does not have any hard buffers allocated. The default soft buffer limit is set to 400 (which is the maximum threshold). The threshold would determine the maximum number of soft buffers that can be borrowed from the common pool.

Queue Buffer Allocation

The buffer allocation to any queue can be tuned using the `queue-buffers ratio` policy-map class configuration command.

Related Topics

- Configuring Queue Buffers (CLI), on page 1249
- Examples: Queue Buffers Configuration, on page 1270

Dynamic Threshold and Scaling

Traditionally, reserved buffers are statically allocated for each queue. No matter whether the queue is active or not, its buffers are held up by the queue. In addition, as the number of queues increases, the portion of the reserved buffers allocated for each queue can become smaller and smaller. Eventually, a situation may occur where there are not enough reserved buffers to support a jumbo frame for all queues.

The supports Dynamic Thresholding and Scaling (DTS), which is a feature that provides a fair and efficient allocation of buffer resources. When congestion occurs, this DTS mechanism provides an elastic buffer allocation for the incoming data based on the occupancy of the global/port resources. Conceptually, DTS scales down the queue buffer allocation gradually as the resources are used up to leave room for other queues, and vice versa. This flexible method allows the buffers to be more efficiently and fairly utilized.
As mentioned in the previous sections, there are two limits configured on a queue—a hard limit and a soft limit.

Hard limits are not part of DTS. These buffers are available only for that queue. The sum of the hard limits should be less than the globally set up hard maximum limit. The global hard limit configured for egress queuing is currently set to 5705. In the default scenario when there are no MQC policies configured, the 24 1-gigabit ports would take up \[24 \times 67 = 1608\], and the 4 10-gigabit ports would take up \[4 \times 720 = 2880\], for a total of 4488 buffers, allowing room for more hard buffers to be allocated based upon the configuration.

Soft limit buffers participate in the DTS process. Additionally, some of the soft buffer allocations can exceed the global soft limit allocation. The global soft limit allocation for egress queuing is currently set to 7607. The sum of the hard and soft limits add up to 13312, which in turn translates to 3.4 MB. Because the sum of the soft buffer allocations can exceed the global limit, it allows a specific queue to use a large number of buffers when the system is lightly loaded. The DTS process dynamically adjusts the per-queue allocation as the system becomes more heavily loaded.

**Queuing in Wireless**

Queuing in the wireless component is performed based on the port policy and is applicable only in the downstream direction. The wireless module supports the following four queues:

- **Voice**—This is a strict priority queue. Represented by Q0, this queue processes control traffic and multicast or unicast voice traffic. All control traffic (such as CAPWAP packets) is processed through the voice queue. The QoS module uses a different threshold within the voice queue to process control and voice packets to ensure that control packets get higher priority over other non-control packets.

- **Video**—This is a strict priority queue. Represented by Q1, this queue processes multicast or unicast video traffic.

- **Data NRT**—Represented by Q2, this queue processes all non-real-time unicast traffic.

- **Multicast NRT**—Represented by Q3, this queue processes Multicast NRT traffic. Any traffic that does not match the traffic in Q0, Q1, or Q2 is processed through Q3.

---

**Note**

By default, the queues Q0 and Q1 are not enabled.

---

**Note**

A weighted round-robin policy is applied for traffic in the queues Q2 and Q3.

For upstream direction only one queue is available. Port and radio policies are applicable only in the downstream direction.

---

**Note**

The wired ports support eight queues.
Trust Behavior

Trust Behavior for Wired and Wireless Ports

For wired or wireless ports that are connected to the endpoints such as IP phones, laptops, cameras, telepresence units, or other devices, their DSCP, precedence, or CoS values coming in from these endpoints are trusted by the and therefore are retained in the absence of any explicit policy configuration.

This trust behavior is applicable to both upstream and downstream QoS.

The packets are enqueued to the appropriate queue per the default initial configuration. No priority queuing at the is done by default. This is true for unicast and multicast packets.

In scenarios where the incoming packet type differs from the outgoing packet type, the trust behavior and the queuing behavior are explained in the following table. Note that the default trust mode for a port is DSCP based. The trust mode ‘falls back’ to CoS if the incoming packet is a pure Layer 2 packet. You can also change the trust setting from DSCP to CoS. This setting change is accomplished by using an MQC policy that has a class default with a ‘set cos cos table default default-cos’ action, where default-cos is the name of the table map created (which only performs a default copy).

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired, all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

The default trust behavior in the case of wireless ports could be changed by using the qos wireless default untrust command.

Note

If you upgrade from Cisco IOS XE 3.2 SE Release to a later release, the default behavior of the wireless traffic is still untrusted. In this situation, you can use the no qos wireless-default untrust command to enable trust behavior for wireless traffic. However, if you install Cisco IOS XE 3.3 SE or a later release on the device, the default QoS behavior for wireless traffic is trust. Starting with Cisco IOS XE 3.3 SE Release and later, the packet markings are preserved in both egress and ingress directions for new installations (not upgrades) for wireless traffic.
Port Security on a Trusted Boundary for Cisco IP Phones

In a typical network, you connect a Cisco IP Phone to a port and cascade devices that generate data packets from the back of the telephone. The Cisco IP Phone guarantees the voice quality through a shared data link by marking the CoS level of the voice packets as high priority (CoS = 5) and by marking the data packets as low priority (CoS = 0). Traffic sent from the telephone to the is typically marked with a tag that uses the 802.1Q header. The header contains the VLAN information and the class of service (CoS) 3-bit field, which is the priority of the packet.

For most Cisco IP Phone configurations, the traffic sent from the telephone to the should be trusted to ensure that voice traffic is properly prioritized over other types of traffic in the network. By using the trust device interface configuration command, you configure the port to which the telephone is connected to trust the traffic received on that port.

The trust device device_type command available in interface configuration mode is a stand-alone command on the device. When using this command in an AutoQoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a corresponding device, input policy will take effect.

With the trusted setting, you also can use the trusted boundary feature to prevent misuse of a high-priority queue if a user bypasses the telephone and connects the PC directly to the. Without trusted boundary, the CoS labels generated by the PC are trusted by the (because of the trusted CoS setting). By contrast, trusted boundary uses CDP to detect the presence of a Cisco IP Phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the port and prevents misuse of a high-priority queue. Note that the trusted boundary feature is not effective if the PC and Cisco IP Phone are connected to a hub that is connected to the.

Configuring Trust Behavior for the Device Type

Wireless QoS Mobility

Wireless QoS mobility enables you to configure QoS policies so that the network provides the same service anywhere in the network. A wireless client can roam from one location to another and as a result the client can get associated to different access points associated with a different device. Wireless client roaming can be classified into two types:

- Intra-device roaming
- Inter-device roaming

The client policies must be available on all of the devices in the mobility group. The same SSID and port policy must be applied to all devices in the mobility group so that the clients get consistent treatment.
Inter-Device Roaming

When a client roams from one location to another, the client can get associated to access points either associated to the same device (anchor device) or a different device (foreign device). Inter-device roaming refers to the scenario where the client gets associated to an access point that is not associated to the same device before the client roamed. The host device is now foreign to the device to which the client was initially anchored.

In the case of inter-device roaming, the client QoS policy is always executed on the foreign controller. When a client roams from anchor device to foreign device, the QoS policy is uninstalled on the anchor device and installed on the foreign device. In the mobility handoff message, the anchor device passes the name of the policy to the foreign device. The foreign device should have a policy with the same name configured for the QoS policy to be applied correctly.

In the case of inter-device roaming, all of the QoS policies are moved from the anchor device to the foreign device. While the QoS policies are in transition from the anchor device to the foreign device, the traffic on the foreign device is provided the default treatment. This is comparable to a new policy installation on the client target.

Note

If the foreign device is not configured with the user-defined physical port policy, the default port policy is applicable to all traffic is routed through the NRT queue, except the control traffic which goes through RT1 queue. The network administrator must configure the same physical port policy on both the anchor and foreign devices symmetrically.

During inter-device roaming, client and SSID policy statistics are collected only for the duration that the client is associated with the foreign device. Cumulative statistics for the whole roaming (anchor device and foreign device) are not collected.

Intra-Device Roaming

With intra-device roaming, the client gets associated to an access point that is associated to the same device before the client roamed, but this association to the device occurs through a different access point.

Note

QoS policies remain intact in the case of intra-device roaming.

Precious Metal Policies for Wireless QoS

Wireless QoS is backward compatible with the precious metal policies offered by the unified wireless controller platforms. The precious metal policies are system-defined policies that are available on the controller.

The following policies are available:

- Platinum—Used for VoIP clients.
- Gold—Used for video clients.
- Silver—Used for traffic that can be considered best-effort.
- Bronze—Used for NRT traffic.
These policies (also known as profiles) can be applied to a WLAN based on the traffic. We recommend the configuration using the Cisco IOS MQC configuration. The policies are available in the system based on the precious metal policy required. You can configure precious metal policies only for SSID ingress and egress policies.

Based on the policies applied, the 802.1p, 802.11e (WMM), and DSCP fields in the packets are affected. These values are preconfigured and installed when the device is booted.

Note
Unlike the precious metal policies that were applicable in the Cisco Unified Wireless controllers, the attributes rt-average-rate, nrt-average-rate, and peak rates are not applicable for the precious metal policies configured on this device platform.

## Standard QoS Default Settings

### Default Wired QoS Configuration

There are two queues configured by default on each wired interface on the . All control traffic traverses and is processed through queue 0. All other traffic traverses and is processed through queue 1.

### DSCP Maps

#### Default CoS-to-DSCP Map

You use the CoS-to-DSCP map to map CoS values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default CoS-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

<table>
<thead>
<tr>
<th>CoS Value</th>
<th>DSCP Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>16</td>
</tr>
<tr>
<td>3</td>
<td>24</td>
</tr>
<tr>
<td>4</td>
<td>32</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>6</td>
<td>48</td>
</tr>
<tr>
<td>7</td>
<td>56</td>
</tr>
</tbody>
</table>
Default IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default IP-precedence-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

<table>
<thead>
<tr>
<th>IP Precedence Value</th>
<th>DSCP Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>2</td>
<td>16</td>
</tr>
<tr>
<td>3</td>
<td>24</td>
</tr>
<tr>
<td>4</td>
<td>32</td>
</tr>
<tr>
<td>5</td>
<td>40</td>
</tr>
<tr>
<td>6</td>
<td>48</td>
</tr>
<tr>
<td>7</td>
<td>56</td>
</tr>
</tbody>
</table>

Default DSCP-to-CoS Map

You use the DSCP-to-CoS map to generate a CoS value, which is used to select one of the four egress queues. The following table shows the default DSCP-to-CoS map. If these values are not appropriate for your network, you need to modify them.

<table>
<thead>
<tr>
<th>DSCP Value</th>
<th>CoS Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–7</td>
<td>0</td>
</tr>
<tr>
<td>8–15</td>
<td>1</td>
</tr>
<tr>
<td>16–23</td>
<td>2</td>
</tr>
<tr>
<td>24–31</td>
<td>3</td>
</tr>
<tr>
<td>32–39</td>
<td>4</td>
</tr>
<tr>
<td>40–47</td>
<td>5</td>
</tr>
<tr>
<td>48–55</td>
<td>6</td>
</tr>
<tr>
<td>56–63</td>
<td>7</td>
</tr>
</tbody>
</table>

Default Wireless QoS Configuration

The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected
to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suite the QoS configuration. The switch is preconfigured with a default class map and a policy map.

**Guidelines for QoS Policies**

Follow these guidelines to prevent clients from getting excluded due to malformed QoS policies:

- When a new QoS policy is added to the device, a QoS policy with the same name should be added to other device within the same roam or mobility domain.

- When a device is loaded with a software image of a later release, the new policy formats are supported. If you have upgraded the software image from an earlier release to a later release, you should save the configuration separately. When an earlier release image is loaded, some QoS policies might show as not supported, and you should restore those QoS policies to supported policy formats.

**Restrictions for QoS on Wired Targets**

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio polices are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the device to the wireless client. Upstream indicates that traffic is flowing from wireless client to the device.

The following are restrictions for applying QoS features on the device for the wired target:

- A maximum of 8 queuing classes are supported on the device port for the wired target.

- A maximum of 63 policers are supported per policy on the wired port for the wired target.

- In Cisco IOS XE Release 3.7.5E and later releases, by default all downlink ports are allocated 1 GB port buffer, even though the downlink port size is 10 GB. Prior to this change, all 1 GB downlink ports had 1 GB buffer and 10 GB downlink ports had 10 GB buffer.

- No more than two levels are supported in a QoS hierarchy.

- In a hierarchical policy, overlapping actions between parent and child are not allowed, except when a policy has the port shaper in the parent and queueing features in the child policy.

- A QoS policy cannot be attached to any EtherChannel interface.

- Policing in both the parent and child is not supported in a QoS hierarchy.

- Marking in both the parent and child is not supported in a QoS hierarchy.

- A mixture of queue limit and queue buffer in the same policy is not supported.
The queue-limit percent is not supported on the device because the `queue-buffer` command handles this functionality. Queue limit is only supported with the DSCP and CoS extensions.

- With shaping, there is an IPG overhead of 20 bytes for every packet that is accounted internally in the hardware. Shaping accuracy will be effected by this, specially for packets of small size.

- The classification sequence for all wired queuing-based policies should be the same across all wired upstream ports (10-Gigabit Ethernet), and the same for all downstream wired ports (1-Gigabit Ethernet).

- Empty classes are not supported.

- Class maps with empty actions are not supported. If there are two policies with the same order of class maps and if there are class maps with no action in one of the policies, there may be traffic drops. As a workaround, allocate minimal bandwidth for all the classes in `PRIORITY_QUEUE`.

- A maximum of 256 classes are supported per policy on the wired port for the wired target.

- The actions under a policer within a policy map have the following restrictions:
  - The conform action must be transmit.
  - The exceed/violate action for markdown type can only be `cos2cos`, `prec2prec`, `dscp2dscp`.
  - The markdown types must be the same within a policy.

- A port-level input marking policy takes precedence over an SVI policy; however, if no port policy is configured, the SVI policy takes precedence. For a port policy to take precedence, define a port-level policy; so that the SVI policy is overwritten.

- Classification counters have the following specific restrictions:
  - Classification counters count packets instead of bytes.
  - Filter-based classification counters are not supported
  - Only QoS configurations with marking or policing trigger the classification counter.
  - The classification counter is not port based. This means that the classification counter aggregates all packets belonging to the same class of the same policy which attach to different interfaces.
  - As long as there is policing or marking action in the policy, the class-default will have classification counters.
  - When there are multiple match statements in a class, then the classification counter only shows the traffic counter for one of the match statements.

- Table maps have the following specific restrictions:
  - Only one table map for policing exceeding the markdown and one table map for policing violating the markdown per direction per target is supported.
  - Table maps must be configured under the class-default; table maps are unsupported for a user-defined class.

- Hierarchical policies are required for the following:
Restrictions for QoS on Wired Targets

- Port-shapers
- Aggregate policers
- PV policy
- Parent shaping and child marking/policing

- For ports with wired targets, these are the only supported hierarchical policies:
  - Police chaining in the same policy is unsupported, except for wireless client.
  - Hierarchical queueing is unsupported in the same policy (port shaper is the exception).

  - In a parent class, all filters must have the same type. The child filter type must match the parent
    filter type with the following exceptions:
      - If the parent class is configured to match IP, then the child class can be configured to match the
        ACL.
      - If the parent class is configured to match CoS, then the child class can be configured to match the
        ACL.

- The `trust device device_type` command available in interface configuration mode is a stand-alone
  command on the device. When using this command in an AutoQoS configuration, if the connected peer
  device is not a corresponding device (defined as a device matching your trust policy), both CoS and
  DSCP values are set to "0" and any input policy will not take effect. If the connected peer device is a
  corresponding device, input policy will take effect.

The following are restrictions for applying QoS features on the VLAN to the wired target:

- For a flat or nonhierarchical policy, only marking or a table map is supported.

The following are restrictions and considerations for applying QoS features on EtherChannel and channel
member interfaces:

- QoS is not supported on an EtherChannel interface.

- QoS is supported on EtherChannel member interfaces in both ingress and egress direction. All
  EtherChannel members must have the same QoS policy applied. If the QoS policy is not the same, each
  individual policy on the different link acts independently.

- On attaching a service policy to channel members, the following warning message appears to remind
  the user to make sure the same policy is attached to all ports in the EtherChannel: 'Warning: add service
  policy will cause inconsistency with port xxx in ether channel xxx.'.

- Auto QoS is not supported on EtherChannel members.

---

**Note**

On attaching a service policy to an EtherChannel, the following message appears on the console: 'Warning:
add service policy will cause inconsistency with port xxx in ether channel xxx.' This warning message should
be expected. This warning message is a reminder to attach the same policy to other ports in the same
EtherChannel. The same message will be seen during boot up. This message does not mean there is a
discrepancy between the EtherChannel member ports.
Restrictions for QoS on Wireless Targets

General Restrictions

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio policies are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the device to the wireless client. Upstream indicates that traffic is flowing from wireless client to the device.

- Only port, SSID, and client (using AAA and Cisco IOS command-line interface) policies are user-configurable. Radio policies are set by the wireless control module and are not user-configurable.
- Port and radio policies are applicable only in the egress direction.
- SSID and client targets can be configured only with marking and policing policies.
- One policy per target per direction is supported.
- For the egress class-default SSID policy, you must configure the queue buffer ratio as 0 after you configure the average shape rate.
- Class maps in a policy map can have different types of filters. However, only one marking action (either table map, or set dscp, or set cos) is supported in a map in egress direction.
- For hierarchical client and SSID ingress policies, you cannot configure marking in both the parent and child policies. You can only configure marking either in the parent or child policy.
- You cannot configure multiple set actions in the same class.
- For both SSID and client ingress policies, supported set actions are only for DSCP, and CoS values.
- You cannot delete a group of WLANs or QoS policy.

Wireless QoS Restrictions on Ports

The following are restrictions for applying QoS features on a wireless port target:

- All wireless ports have similar parent policy with one class-default and one action shape under class-default. Shape rates are dependent on the 802.11a/b/g/ac bands.
- You can create a maximum of four classes in a child policy by modifying the `port_child_policy`.
- If there are four classes in the `port_child_policy` at the port level, one must be a non-client-nrt class and one must be class-default.
- No two classes can have the same priority level. Only priority level 1 (for voice traffic and control traffic) and 2 (for video) are supported.
- Priority is not supported in the multicast NRT class (non-client-nrt class) and class-default.
• If four classes are configured, two of them have to be priority classes. If only three classes are configured, at least one of them should be a priority class. If three classes are configured and there is no non-client-nrt class, both priority levels must be present.

• Only match DSCP is supported.

• The port policy applied by the wireless control module cannot be removed using the CLI.

• Both priority rate and police CIR (using MQC) in the same class is unsupported.

• Queue limit (which is used to configure Weighted Tail Drop) is unsupported.

**Wireless QoS Restrictions on SSID**

The following are restrictions for applying QoS features on SSID:

• One table map is supported at the ingress policy.

• Table maps are supported for the parent class-default only. Up to two table maps are supported in the egress direction and three table-maps can be configured when a QoS group is involved.

Table-maps are not supported at the client targets.

• If a wireless port has a default policy with only two queues (one for multicast-NRT, one for class-default), the policy at SSID level cannot have voice and video class in the egress direction.

• Policing without priority is not supported in the egress direction.

• Priority configuration at the SSID level is used only to configure the RT1 and RT2 policers (AFD for policer). Priority configuration does not include the shape rate. Therefore, priority is restricted for SSID policies without police.

• If set is not enabled in class-default, the classification at the SSID for voice or video must be a subset of the classification for the voice or video class at the port level.

• The mapping in the DSCP2DSCP and COS2COS table should be based on the classification function for the voice and video classes in the port level policy.

• No action is allowed under the class-default of a child policy.

• For SSID ingress policies, only UP and DSCP filters (match criteria) are supported. ACL and protocol match criteria are not supported.

• For a flat policy (non hierarchical), in the ingress direction, the policy configuration must be a set (table map) or policing or both.

**Wireless QoS Restrictions on Clients**

The following are restrictions for applying QoS policies on client targets:

• The default client policy is enabled only on WMM clients that are ACM-enabled.

• Queuing is not supported.

• Attaching, removing, or modifying client policies on a WLAN in the enabled state is not supported. You must shut down the WLAN to apply, remove, or modify a policy.
• Table-map configuration is not supported for client targets.

• Policing and set configured together in class-default is blocked in egress direction:

```
policy-map foo
class class-default
police X
set dscp Y
```

• Child policy is not supported under class-default if the parent policy contains other user-defined class maps in it.

• For flat egress client policy, policing in class-default and marking action in other classes are not supported.

• Only set marking actions are supported in the client policies.

• For client ingress policies, only ACL, UP, DSCP, and protocol filters (match criteria) are supported.

• All the filters in classes in a policy map for client policy must have the same attributes. Filters matching on protocol-specific attributes such as IPv4 or IPv6 addresses are considered as different attribute sets.

• For filters matching on ACLs, all ACEs (Access Control Entry) in the access list should have the same type and number of attributes.

• In client egress policies, all filters in the policy-map must match on the same marking attribute for filters matching on marking attributes. For example, If filter matches on DSCP, then all filters in the policy must match on DSCP.

• ACL matching on port ranges and subnet are only supported in ingress direction.

# How to Configure QoS

## Configuring Class, Policy, and Table Maps

### Creating a Traffic Class (CLI)

To create a traffic class containing match criteria, use the `class-map` command to specify the traffic class name, and then use the following `match` commands in class-map configuration mode, as needed.

**Before you begin**

All match commands specified in this configuration task are considered optional, but you must configure at least one match criterion for a class.
**SUMMARY STEPS**

1. configure terminal
2. class-map {class-map name | match-any}
3. match access-group {index number | name}
4. match class-map class-map name
5. match cos cos value
6. match dscp dscp value
7. match ip {dscp dscp value | precedence precedence value}
8. match non-client-nrt
9. match qos-group qos group value
10. match vlan vlan value
11. match wlan user-priority wlan value
12. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> class-map {class-map name</td>
<td>match-any}</td>
</tr>
</tbody>
</table>
| Example: Device(config)# class-map test_1000 Device(config-cmap)# | - Creates a class map to be used for matching packets to the class whose name you specify.  
  - If you specify match-any, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default. |
| **Step 3** match access-group {index number | name} | The following parameters are available for this command: |
| Example: Device(config-cmap)# match access-group 100 Device(config-cmap)# | - access-group  
  - class-map  
  - cos  
  - dscp  
  - ip  
  - non-client-nrt  
  - precedence  
  - qos-group  
  - vlan |
### Creating a Traffic Class (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>wlanuserpriority</td>
<td>• wlan user priority</td>
</tr>
<tr>
<td>(Optional) For this example, enter the access-group ID:</td>
<td></td>
</tr>
<tr>
<td>Accesslistindex(value from 1 to 2799)</td>
<td></td>
</tr>
<tr>
<td>Named access list</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**  
**match class-map class-map name**  
**Example:**  
```
Device(config-cmap)# match class-map test_2000
Device(config-cmap)#
```

(Optional) Matches to another class-map name.

**Step 5**  
**match cos cos value**  
**Example:**  
```
Device(config-cmap)# match cos 2 3 4 5
Device(config-cmap)#
```

(Optional) Matches IEEE 802.1Q or ISL class of service (user) priority values.  
- Enters up to 4 CoS values separated by spaces (0 to 7).

**Step 6**  
**match dscp dscp value**  
**Example:**  
```
Device(config-cmap)# match dscp af11 af12
Device(config-cmap)#
```

(Optional) Matches the DSCP values in IPv4 and IPv6 packets.

**Step 7**  
**match ip {dscp dscp value | precedence precedence value}**  
**Example:**  
```
Device(config-cmap)# match ip dscp af11 af12
Device(config-cmap)#
```

(Optional) Matches IP values including the following:  
- **dscp**—Matches IP DSCP (DiffServ codepoints).  
- **precedence**—Matches IP precedence (0 to 7).

**Step 8**  
**match non-client-nrt**  
**Example:**  
```
Device(config-cmap)# match non-client-nrt
Device(config-cmap)#
```

(Optional) Matches non-client NRT (Non-Real-Time).  
**Note** This match is applicable only for policies on a wireless port. It carries all the multi-destination and AP (non-client) bound traffic.

**Step 9**  
**match qos-group qos group value**  
**Example:**  
```
Device(config-cmap)# match qos-group 10
Device(config-cmap)#
```

(Optional) Matches QoS group value (from 0 to 31).
### Creating a Traffic Policy (CLI)

To create a traffic policy, use the `policy-map` global configuration command to specify the traffic policy name.

The traffic class is associated with the traffic policy when the `class` command is used. The `class` command must be entered after you enter the policy map configuration mode. After entering the `class` command, the is automatically in policy map class configuration mode, which is where the QoS policies for the traffic policy are defined.

The following policy map class-actions are supported:

- `admit`—Admits the request for Call Admission Control (CAC).
- `bandwidth`—Bandwidth configuration options.
- `exit`—Exits from the QoS class action configuration mode.
- `no`—Negates or sets default values for the command.
- `police`—Policer configuration options.
- `priority`—Strict scheduling priority configuration options for this class.

---

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 10</td>
<td><code>match vlan vlan value</code></td>
<td>(Optional) Matches a VLAN ID (from 1 to 4095).</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-cmap)# <code>match vlan 210</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-cmap)#</td>
<td></td>
</tr>
<tr>
<td>Step 11</td>
<td><code>match wlan user-priority wlan value</code></td>
<td>(Optional) Matches 802.11e specific values. Enter the user priority 802.11e user priority (0 to 7).</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-cmap)# <code>match wlan user priority 7</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-cmap)#</td>
<td></td>
</tr>
<tr>
<td>Step 12</td>
<td><code>end</code></td>
<td>Saves the configuration changes.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-cmap)# <code>end</code></td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

Configure the policy map.

<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-pmap-c)#</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Step 13**

set \{ cos | dscp | ip | precedence | qos-group | wlan \}

**Example:**

```
Device(config-pmap-c)# set cos 7
```

(Optional) Sets the QoS values. Possible QoS configuration values include:

- `cos`—Sets the IEEE 802.1Q/ISL class of service/user priority.
- `dscp`—Sets DSCP in IP(v4) and IPv6 packets.
- `ip`—Sets IP specific values.
- `precedence`—Sets precedence in IP(v4) and IPv6 packet.
- `qos-group`—Sets the QoS Group.
- `wlan`—Sets the WLAN user-priority.

**Step 14**

shape average \{ target_bit_rate | percent \}

**Example:**

```
Device(config-pmap-c) #shape average percent 50
```

(Optional) Sets the traffic shaping. Command parameters include:

- `target_bit_rate`—Target bit rate.
- `percent`—Percentage of interface bandwidth for Committed Information Rate.

For a more detailed example of this command and its usage, see Configuring Shaping (CLI), on page 1254.

**Step 15**

`end`

**Example:**

```
Device(config-pmap-c) #end
```

Saves the configuration changes.

---

**What to do next**

Configure the interface.

**Related Topics**

Policy Maps, on page 1185

**Configuring Client Policies**

You can configure client policies using one of the following methods:
Configuring Class-Based Packet Marking (CLI)

This procedure explains how to configure the following class-based packet marking features on your:

- CoS value
- DSCP value
- IP value
- Precedence value
- QoS group value
- WLAN value

**Before you begin**

You should have created a class map and a policy map before beginning this procedure.

**SUMMARY STEPS**

1. `configure terminal`
2. `policy-map policy name`
3. `class class name`
4. `set cos {cos value | cos table table-name | dscp table table-name | precedence table table-name | qos-group table table-name | wlan user-priority table table-name}`
### QoS

5. `set dscp {dscp value | default | dscp table table-map name | ef | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}`

6. `set ip {dscp | precedence}`

7. `set precedence {precedence value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name}`

8. `set qos-group {qos-group value | dscp table table-map name | precedence table table-map name}`

9. `set wlan-user-priority {wlan-user-priority value | cos table table-map name | dscp table table-map name | qos-group table table-map name | wlan table table-map name}`

10. `end`

11. `show policy-map`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal Example: Device# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> policy-map policy name Example: Device(config)# policy-map policy1 Device(config-pmap)#</td>
<td>Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</td>
</tr>
<tr>
<td><strong>Step 3</strong> class class name Example: Device(config-pmap)# class class1 Device(config-pmap-c)#</td>
<td>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</td>
</tr>
</tbody>
</table>

- **admit**—Admits the request for Call Admission Control (CAC).
- **bandwidth**—Bandwidth configuration options.
- **exit**—Exits from the QoS class action configuration mode.
- **no**—Negates or sets default values for the command.
- **police**—Policer configuration options.
- **priority**—Strict scheduling priority configuration options for this class.
- **queue-buffers**—Queue buffer configuration options.
- **queue-limit**—Queue maximum threshold for Weighted Tail Drop (WTD) configuration options.
Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• service-policy—Configures the QoS service policy.</td>
<td></td>
</tr>
<tr>
<td>• set—Sets QoS values using the following options:</td>
<td></td>
</tr>
<tr>
<td>• CoS values</td>
<td></td>
</tr>
<tr>
<td>• DSCP values</td>
<td></td>
</tr>
<tr>
<td>• Precedence values</td>
<td></td>
</tr>
<tr>
<td>• QoS group values</td>
<td></td>
</tr>
<tr>
<td>• WLAN values</td>
<td></td>
</tr>
<tr>
<td>• shape—Traffic-shaping configuration options.</td>
<td></td>
</tr>
</tbody>
</table>

Note

This procedure describes the available configurations using set command options. The other command options (admit, bandwidth, etc.) are described in other sections of this guide. Although this task lists all of the possible set commands, only one set command is supported per class.

Step 4

**set cos** {cos value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}

(Optional) Sets the specific IEEE 802.1Q Layer 2 CoS value of an outgoing packet. Values are from 0 to 7.

You can also set the following values using the **set cos** command:

- **cos table**—Sets the CoS value based on a table map.
- **dscp table**—Sets the code point value based on a table map.
- **precedence table**—Sets the code point value based on a table map.
- **qos-group table**—Sets the CoS value from QoS group based on a table map.
- **wlan user-priority table**—Sets the CoS value from the WLAN user priority based on a table map.

**Example:**

Device(config-pmap)# set cos 5
Device(config-pmap)#

Step 5

**set dscp** {dscp value | default | dscp table table-map name | ef | precedence table table-map name | qos-group table table-map name | wlan user-priority table table-map name}

(Optional) Sets the DSCP value.

In addition to setting specific DSCP values, you can also set the following using the **set dscp** command:

- **default**—Matches packets with default DSCP value (000000).
- **dscp table**—Sets the packet DSCP value from DSCP based on a table map.
- **ef**—Matches packets with EF DSCP value (101110).

**Example:**

Device(config-pmap)# set dscp af11
Device(config-pmap)#
**Table:**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• precedence table—Sets the packet DSCP value from precedence based on a table map.</td>
<td></td>
</tr>
<tr>
<td>• qos-group table—Sets the packet DSCP value from a QoS group based upon a table map.</td>
<td></td>
</tr>
<tr>
<td>• wlan user-priority table—Sets the packet DSCP value based upon a WLAN user-priority based upon a table map.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 6**

```
set ip {dscp | precedence}
```

**Example:**

```
Device(config-pmap)# set ip dscp c3
Device(config-pmap)#
```

(Optional) Sets IP specific values. These values are either IP DSCP or IP precedence values.

You can set the following values using the `set ip dscp` command:

- **dscp value**—Sets a specific DSCP value.
- **default**—Matches packets with default DSCP value (000000).
- **dscp table**—Sets the packet DSCP value from DSCP based on a table map.
- **ef**—Matches packets with EF DSCP value (101110).
- **precedence table**—Sets the packet DSCP value from precedence based on a table map.
- **qos-group table**—Sets the packet DSCP value from a QoS group based upon a table map.
- **wlan user-priority table**—Sets the packet DSCP value based upon a WLAN user-priority based upon a table map.

You can set the following values using the `set ip precedence` command:

- **precedence value**—Sets the precedence value (from 0 to 7).
- **cos table**—Sets the packet precedence value from Layer 2 CoS based on a table map.
- **dscp table**—Sets the packet precedence from DSCP value based on a table map.
- **precedence table**—Sets the precedence value from precedence based on a table map.
- **qos-group table**—Sets the precedence value from a QoS group based upon a table map.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 7** set precedence \{precedence value | cos table table-map name | dscp table table-map name | precedence table table-map name | qos-group table table-map name\} | (Optional) Sets precedence values in IPv4 and IPv6 packets. You can set the following values using the *set precedence* command:  
  - *precedence value*—Sets the precedence value (from 0 to 7).  
  - *cos table*—Sets the packet precedence value from Layer 2 CoS on a table map.  
  - *dscp table*—Sets the packet precedence from DSCP value on a table map.  
  - *precedence table*—Sets the precedence value from precedence based on a table map.  
  - *qos-group table*—Sets the precedence value from a QoS group based upon a table map. |
| **Example:** | |
| Device(config-pmap)# set precedence 5  
Device(config-pmap)# | |
| **Step 8** set qos-group \{qos-group value | dscp table table-map name | precedence table table-map name\} | (Optional) Sets QoS group values. You can set the following values using this command:  
  - *qos-group value*—A number from 1 to 31.  
  - *dscp table*—Sets the code point value from DSCP based on a table map.  
  - *precedence table*—Sets the code point value from precedence based on a table map. |
| **Example:** | |
| Device(config-pmap)# set qos-group 10  
Device(config-pmap)# | |
| **Step 9** set wlan-user-priority \{wlan user-priority value | cos table table-map name | dscp table table-map name | qos-group table table-map name | wlan table table-map name\} | (Optional) Sets the WLAN user priority value. You can set the following values using this command:  
  - *wlan user-priority value*—A value between 0 to 7.  
  - *cos table*—Sets the WLAN user priority value from CoS based on a table map.  
  - *dscp table*—Sets the WLAN user priority value from DSCP based on a table map.  
  - *qos-group table*—Sets the WLAN user priority value from QoS group based on a table map.  
  - *wlan table*—Sets the WLAN user priority value from the WLAN user priority based on a table map. |
| **Example:** | |
| Device(config-pmap)# set wlan user-priority 1  
Device(config-pmap)# | |
| **Step 10** end | Saves configuration changes. |
| **Example:** | |
| Device(config-pmap)# end | |
### Summary Steps

1. configure terminal
2. class-map *class-map-name*
3. match dscp *dscp-value-for-voice*
4. end
5. configure terminal
6. class-map *class-map-name*
7. match dscp *dscp-value-for-video*
8. end

### Detailed Steps

### Attaching a Traffic Policy to an Interface (CLI)

After the traffic class and traffic policy are created, you must use the `service-policy` interface configuration command to attach a traffic policy to an interface, and to specify the direction in which the policy should be applied (either on packets coming into the interface or packets leaving the interface).

**Before you begin**

A traffic class and traffic policy must be created before attaching a traffic policy to an interface.

#### SUMMARY STEPS

1. `configure terminal`
2. `interface type`
3. `service-policy {input policy-map | output policy-map }`
4. `end`
5. `show policy map`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal&lt;br&gt;<strong>Example:</strong> Device# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> interface type&lt;br&gt;<strong>Example:</strong></td>
<td>Enters interface configuration mode and configures an interface.</td>
</tr>
</tbody>
</table>
Command parameters for the interface configuration include:

- **Auto Template** — Auto-template interface
- **Capwap** — CAPWAP tunnel interface
- **GigabitEthernet** — Gigabit Ethernet IEEE 802
- **GroupVI** — Group virtual interface
- **Internal Interface** — Internal interface
- **Loopback** — Loopback interface
- **Null** — Null interface
- **Port-channel** — Ethernet Channel of interface
- **TenGigabitEthernet** — 10-Gigabit Ethernet
- **Tunnel** — Tunnel interface
- **Vlan** — Catalyst VLANs
- **Range** — Interface range

### Step 3

**service-policy {input policy-map | output policy-map}**

**Example:**

```
Device(config-if)# service-policy output policy_map_01
Device(config-if)#
```

Attaches a policy map to an input or output interface. This policy map is then used as the service policy for that interface.

In this example, the traffic policy evaluates all traffic leaving that interface.

### Step 4

**end**

**Example:**

```
Device(config-if)# end
Device#
```

Saves configuration changes.

### Step 5

**show policy map**

**Example:**

```
Device# show policy map
```

(Optional) Displays statistics for the policy on the specified interface.

**What to do next**

Proceed to attach any other traffic policy to an interface, and to specify the direction in which the policy should be applied.
### Applying an SSID or Client Policy on a WLAN (CLI)

#### Before you begin

You must have a service-policy map configured before applying it on an SSID.

#### SUMMARY STEPS

1. `configure terminal`
2. `wlan profile-name`
3. `service-policy [input | output] policy-name`
4. `service-policy client [input | output] policy-name`
5. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>wlan profile-name</code></td>
<td>Enters the WLAN configuration submode. The <code>profile-name</code> is the profile name of the configured WLAN.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>wlan test4</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> `service-policy [input</td>
<td>output] policy-name`</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-wlan)# <code>service-policy input policy-map-ssid</code></td>
<td>• <code>input</code>— Assigns the policy map to WLAN ingress traffic.</td>
</tr>
<tr>
<td></td>
<td>• <code>output</code>— Assigns the policy map to WLAN egress traffic.</td>
</tr>
<tr>
<td><strong>Step 4</strong> `service-policy client [input</td>
<td>output] policy-name`</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-wlan)# <code>service-policy client input policy-map-client</code></td>
<td>• <code>input</code>— Assigns the client policy for ingress direction on the WLAN.</td>
</tr>
<tr>
<td></td>
<td>• <code>output</code>— Assigns the client policy for egress direction on the WLAN.</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>end</code></td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press <code>Ctrl-Z</code> to exit global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>end</code></td>
<td></td>
</tr>
</tbody>
</table>
Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps (CLI)

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions supported are remarking and policing.

Before you begin

You should have already decided upon the classification, policing, and marking of your network traffic by policy maps prior to beginning this procedure.

SUMMARY STEPS

1. `configure terminal`
2. `class-map {class-map name | match-any}`
3. `match access-group { access list index | access list name }`
4. `policy-map policy-map-name`
5. `class {class-map-name | class-default}`
6. `set {cos | dscp | ip | precedence | qos-group | wlan user-priority}`
7. `police {target_bit_rate | cir | rate}`
8. `exit`
9. `exit`
10. `interface interface-id`
11. `service-policy input policy-map-name`
12. `end`
13. `show policy-map [policy-map-name [class class-map-name]]`
14. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>`class-map {class-map name</td>
<td>match-any}`</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# <code>class-map ipclass1</code></td>
<td>• Creates a class map to be used for matching packets to the class whose name you specify.</td>
</tr>
<tr>
<td>Device(config-cmap)# <code>exit</code></td>
<td>• If you specify <code>match-any</code>, one of the match criteria must be met for traffic entering the traffic class to be</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Step 3</strong> match access-group { access list index</td>
<td>access list name }</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Specifies the classification criteria to match to the class map. You can match on the following criteria:</td>
</tr>
<tr>
<td>Device(config-cmap)# match access-group 1000</td>
<td>• access-group—Matches to access group.</td>
</tr>
<tr>
<td>Device(config-cmap)# exit</td>
<td>• class-map—Matches to another class map.</td>
</tr>
<tr>
<td>Device(config)#</td>
<td>• cos—Matches to a CoS value.</td>
</tr>
<tr>
<td></td>
<td>• dscp—Matches to a DSCP value.</td>
</tr>
<tr>
<td></td>
<td>• ip—Matches to a specific IP value.</td>
</tr>
<tr>
<td></td>
<td>• non-client-nrt—Matches non-client NRT.</td>
</tr>
<tr>
<td></td>
<td>• precedence—Matches precedence in IPv4 and IPv6 packets.</td>
</tr>
<tr>
<td></td>
<td>• qos-group—Matches to a QoS group.</td>
</tr>
<tr>
<td></td>
<td>• vlan—Matches to a VLAN.</td>
</tr>
<tr>
<td></td>
<td>• wlan—Matches to a wireless LAN.</td>
</tr>
</tbody>
</table>

| **Step 4** policy-map policy-map-name | Creates a policy map by entering the policy map name, and enters policy-map configuration mode. |
| **Example:**                       | By default, no policy maps are defined. |
| Device(config)# policy-map flowit  |                                       |
| Device(config-pmap)#              |                                       |

| **Step 5** class {class-map-name | class-default} | Defines a traffic classification, and enter policy-map class configuration mode. |
| **Example:**                     | By default, no policy map class-maps are defined. |
| Device(config-pmap)# class ipclass1 | If a traffic class has already been defined by using the class-map global configuration command, specify its name for class-map-name in this command. |
| Device(config-pmap-c)#           | A class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any included in the class-default class, all packets that have not already matched the other traffic classes will match class-default. |

<p>| <strong>Step 6</strong> set {cos | dscp | ip | precedence | qos-group | wlan user-priority} | (Optional) Sets the QoS values. Possible QoS configuration values include: |
| <strong>Example:</strong>                     | • cos—Sets the IEEE 802.1Q/ISL class of service/user priority. |
| Device(config-pmap-c)# set dscp 45 | • dscp—Sets DSCP in IP(v4) and IPv6 packets. |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `Device(config-pmap-c)#` | - **ip**—Sets IP specific values.  
- **precedence**—Sets precedence in IP(v4) and IPv6 packet.  
- **qos-group**—Sets QoS group.  
- **wlan user-priority**—Sets WLAN user priority.  

In this example, the `set dscp` command classifies the IP traffic by setting a new DSCP value in the packet. |

**Step 7**

`police {target_bit_rate | cir | rate}`

**Example:**

```
Device(config-pmap-c)# police 100000  
conform-action transmit exceed-action drop  
Device(config-pmap-c)#
```

(Optional) Configures the policer:

- **target_bit_rate**—Specifies the bit rate per second, enter a value between 8000 and 10000000000.  
- **cir**—Committed Information Rate.  
- **rate**—Specifies the policer rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.  

In this example, the `police` command adds a policer to the class where any traffic beyond the 100000 set target bit rate is dropped. |

**Step 8**

`exit`

**Example:**

```
Device(config-pmap-c)# exit
```

Returns to policy map configuration mode. |

**Step 9**

`exit`

**Example:**

```
Device(config-pmap)# exit
```

Returns to global configuration mode. |

**Step 10**

`interface interface-id`

**Example:**

```
Device(config)# interface gigabitethernet 2/0/1
```

Specifies the port to attach to the policy map, and enters interface configuration mode.  

Valid interfaces include physical ports. |

**Step 11**

`service-policy input policy-map-name`

**Example:**

```
Device(config-if)# service-policy input flowit
```

Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported.
### Summary Steps

1. configure terminal
2. class-map { class-map name  |  match-any }
3. match vlan  vlan number
4. policy-map policy-map-name
5. description description
6. class {class-map-name  |  class-default}
7. set { cos  |  dscp  |  ip  |  precedence  |  qos-group  |  wlan user-priority }
8. police { target_bit_rate  |  cir  |  rate }
9. exit
10. exit
11. interface interface-id
12. service-policy input policy-map-name
13. end

---

**What to do next**

If applicable to your QoS configuration, configure classification, policing, and marking of traffic on SVIs by using policy maps.

---

**Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps (CLI)**

### Before you begin

You should have already decided upon the classification, policing, and marking of your network traffic by using policy maps prior to beginning this procedure.
**QoS**

14. `show policy-map [policy-map-name [class class-map-name]]`
15. `copy running-config startup-config`

### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>`class-map {class-map name</td>
<td>match-any }`</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config)# <code>class-map class_vlan100</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Creates a class map to be used for matching packets to the class whose name you specify.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If you specify <code>match-any</code>, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><code>match vlan vlan number</code></td>
<td>Specifies the VLAN to match to the class map.</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config-cmap)# <code>match vlan 100</code> Device(config-cmap)# <code>exit</code> Device(config)#</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td><code>policy-map policy-map-name</code></td>
<td>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config)# <code>policy-map policy_vlan100</code> Device(config-pmap)#</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td><code>description description</code></td>
<td>(Optional) Enters a description of the policy map.</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config-pmap)# <code>description vlan 100</code></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>`class {class-map-name</td>
<td>class-default}`</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config-pmap)# <code>class class_vlan100</code> Device(config-pmap-c)#</td>
<td></td>
</tr>
<tr>
<td></td>
<td>By default, no policy map class-maps are defined.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If a traffic class has already been defined by using the <code>class-map</code> global configuration command, specify its name for <code>class-map-name</code> in this command.</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>A</strong> class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any included in the class-default class, all packets that have not already matched the other traffic classes will match class-default.</td>
<td></td>
</tr>
</tbody>
</table>

#### Step 7

**set {cos | dscp | ip | precedence | qos-group | wlan user-priority}**

**Example:**

Device(config-pmap-c)# set dscp af23
Device(config-pmap-c)#

(Optional) Sets the QoS values. Possible QoS configuration values include:

- **cos**—Sets the IEEE 802.1Q/ISL class of service/user priority.
- **dscp**—Sets DSCP in IP(v4) and IPv6 packets.
- **ip**—Sets IP specific values.
- **precedence**—Sets precedence in IP(v4) and IPv6 packet.
- **qos-group**—Sets QoS group.
- **wlan user-priority**—Sets WLAN user-priority.

In this example, the set dscp command classifies the IP traffic by matching the packets with a DSCP value of AF23 (010010).

#### Step 8

**police {target_bit_rate | cir | rate}**

**Example:**

Device(config-pmap-c)# police 200000
conform-action transmit
exceed-action drop
Device(config-pmap-c)#

(Optional) Configures the policer:

- **target_bit_rate**—Specifies the bit rate per second. Enter a value between 8000 and 10000000000.
- **cir**—Committed Information Rate.
- **rate**—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.

In this example, the police command adds a policer to the class where any traffic beyond the 200000 set target bit rate is dropped.

#### Step 9

**exit**

**Example:**

Device(config-pmap-c)# exit

Returns to policy map configuration mode.

#### Step 10

**exit**

**Example:**

Device(config-pmap)# exit

Returns to global configuration mode.
<table>

<tr>
<td><code>Device# copy-running-config startup-config</code></td>
<td><strong>Configuring Table Maps (CLI)</strong></td>
</tr>
</tbody>
</table>

Table maps are a form of marking, and also enable the mapping and conversion of one field to another using a table. For example, a table map can be used to map and convert a Layer 2 CoS setting to a precedence value in Layer 3.

**Note**

A table map can be referenced in multiple policies or multiple times in the same policy.
SUMMARY STEPS

1. configure terminal
2. table-map name {default {default value | copy | ignore} | exit | map {from from value to to value } | no}
3. map from value to value
4. exit
5. exit
6. show table-map
7. configure terminal
8. policy-map
9. class class-default
10. set cos dscp table table map name
11. end

default 0 | Displays the table map configuration. |
| **Step 7** | **configure terminal**  
**Example:** |
|  
Device# **configure terminal**  
Device(config)# | Enters global configuration mode. |
| **Step 8** | **policy-map**  
**Example:** |
|  
Device(config)# **policy-map table-policy**  
Device(config-pmap)# | Configures the policy map for the table map. |
| **Step 9** | **class class-default**  
**Example:** |
|  
Device(config-pmap)# **class class-default**  
Device(config-pmap-c)# | Matches the class to the system default. |
| **Step 10** | **set cos dscp table table map name**  
**Example:** |
|  
Device(config-pmap-c)# **set cos dscp table table01**  
Device(config-pmap-c)# | If this policy is applied on input port, that port will have trust DSCP enabled on that port and marking will take place depending upon the specified table map. |
## Configuring Trust

### Configuring Trust Behavior for Wireless Traffic (CLI)

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the traffic came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired network, all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

### SUMMARY STEPS

1. configure terminal
2. qos wireless-default-untrust
3. end

### DETAILED STEPS

<tr>
<td></td>
<td>Device(config-pmap)# class voice</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>priority level level_value</td>
<td>The priority command assigns a strict scheduling priority for the class. <strong>Note</strong> Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-pmap-c)# priority level 1</td>
<td></td>
</tr>
</tbody>
</table>
| 17    | police [target_bit_rate | cir | rate ] | (Optional) Configures the policer:  
- **target_bit_rate**—Specifies the bit rate per second. Enter a value between 8000 and 1000000000.  
- **cir**—Committed Information Rate.  
- **rate**—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies. |
|       | Example:          |         |
|       | Device(config-pmap-c)# police cir 10m |         |
| 18    | admit cac wmm-tspec | Configures call admission control for the policy map. **Note** This command only configures CAC for wireless QoS. |
|       | Example:          |         |
|       | Device(config-pmap-c)# admit cac wmm-tspec Device(config-pmap-cac-wmm)# |         |
| 19    | rate value        | Configures the target bit rate (Kilo Bits per second). Enter a value from 8 to 10000000. |
|       | Example:          |         |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config-pmap-admit-cac-wmm)# rate 5000</code></td>
<td>Configures the WLAN UP value. Enter a value from 0 to 7.</td>
</tr>
</tbody>
</table>

#### Step 20

**wlan-up value**

**Example:**

```
Device(config-pmap-admit-cac-wmm)# wlan-up 6 7
```

#### Step 21

**exit**

**Example:**

```
Device(config-pmap-admit-cac-wmm)# exit
```

#### Step 22

**exit**

**Example:**

```
Device(config-pmap-c)# exit
```

#### Step 23

**class class name**

**Example:**

```
Device(config-pmap)# class video
```

#### Step 24

**priority level level_value**

**Example:**

```
Device(config-pmap-c)# priority level 2
```

#### Step 25

**police [target_bit_rate | cir | rate]**

**Example:**

```
Device(config-pmap-c)# police cir 20m
```

**Note**

Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.

### Configuring Bandwidth (CLI)

This procedure explains how to configure bandwidth on your network.

**Before you begin**

You should have created a class map for bandwidth before beginning this procedure.

#### SUMMARY STEPS

1. `configure terminal`
2. `policy-map policy name`
3. `class class name`
4. `bandwidth {Kb/s | percent percentage | remaining { ratio ratio }}`
5. `end`
6. `show policy-map`

#### DETAILED STEPS

</tr>
<tr>
<td><code>Device(config)# policy-map policy_bandwidth01</code></td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

**Step 3**

`class class name`

**Example:**

Device(config-pmap)# class class_bandwidth01
Device(config-pmap-c)#

Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:

- **word**—Class map name.
- **class-default**—System default class matching any otherwise unclassified packets.

**Step 4**

`bandwidth |Kb/s| percent| percentage| remaining | ratio | ratio`

**Example:**

Device(config-pmap-c)# bandwidth 200000
Device(config-pmap-c)#

Configures the bandwidth for the policy map. The parameters include:

- **Kb/s**—Configures a specific value in kilobits per second (from 20000 to 10000000).
- **percent**—Allocates minimum bandwidth to a particular class based on a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.

- **remaining**—Allocates minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the **priority** command is used for certain queues in the policy. You can also assign ratios rather than percentages to each queue; the queues will be assigned certain weights which are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.

**Note**

You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.

**Step 5**

`end`

**Example:**

Device(config-pmap-c)# end
Device#

Saves configuration changes.

**Step 6**

`show policy-map`

**Example:**

(Optional) Displays policy configuration information for all classes configured for all service policies.
What to do next

Configure any additional policy maps for QoS for your network. After creating the policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

<td></td>
<td>• <code>set-prec-transmit</code>—Rewrites the packet precedence and sends it.</td>
</tr>
<tr>
<td></td>
<td>• <code>transmit</code>—Transmits the packet.</td>
</tr>
</tbody>
</table>
### Configuring Priority (CLI)

This procedure explains how to configure priority on your device. The device supports giving priority to specified queues. There are two priority levels available (1 and 2).

#### Note

Queues supporting voice and video should be assigned a priority level of 1.

#### Before you begin

You should have created a class map for priority before beginning this procedure.

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Purpose: Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the device.</td>
</tr>
</tbody>
</table>

**Step 5**

**Example:**

```
Device(config-pmap-c)# end
Device#
```

**Step 6**

**Example:**

```
Device# show policy-map
```

(Optional) Displays policy configuration information for all classes configured for all service policies.

**Note**

The `show policy-map` command output does not display counters for conformed bytes and exceeded bytes.

---

**What to do next**

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

## SUMMARY STEPS

1. configure terminal  
2. policy-map policy name  
3. class class name  
4. priority \([\text{Kb/s} [\text{burst\_in\_bytes}] | \text{level} \text{ level\_value} [\text{Kb/s} [\text{burst\_in\_bytes}] | \text{percent} \text{ percentage} [\text{burst\_in\_bytes}]]\]| \text{percent} \text{ percentage} [\text{burst\_in\_bytes}]]\]
5. end  
6. show policy-map

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| 2    | policy-map policy name  
Example:  
Device(config)# policy-map policy_priority01  
Device(config-pmap)# | Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy. |
| 3    | class class name  
Example:  
Device(config-pmap)# class class_priority01  
Device(config-pmap-c)# | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:  
- \text{word}—Class map name.  
- \text{class-default}—System default class matching any otherwise unclassified packets. |
| 4    | priority \([\text{Kb/s} [\text{burst\_in\_bytes}] | \text{level} \text{ level\_value} [\text{Kb/s} [\text{burst\_in\_bytes}] | \text{percent} \text{ percentage} [\text{burst\_in\_bytes}]]\]| \text{percent} \text{ percentage} [\text{burst\_in\_bytes}]]\]  
Example:  
Device(config-pmap-c)# priority level 1  
Device(config-pmap-c)# | (Optional) The \text{priority} command assigns a strict scheduling priority for the class. The command options include:  
- \text{Kb/s}—Specifies the kilobits per second (from 1 to 2000000).  
- \text{burst\_in\_bytes}—Specifies the burst in bytes (from 32 to 2000000).  
- \text{level} \text{ level\_value}—Specifies the multilevel (1-2) priority queue.  
- \text{Kb/s}—Specifies the kilobits per second (from 1 to 2000000). |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>burst_in_bytes</td>
<td>Specifies the burst in bytes (from 32 to 2000000).</td>
</tr>

<td>percent</td>
<td>Percentage of the total bandwidth.</td>
</tr>
<tr>
<td>burst_in_bytes</td>
<td>Specifies the burst in bytes (from 32 to 2000000).</td>
</tr>
</tbody>
</table>

**Note**

Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.

### Step 5

**Example:**

Device(config-pmap-c)# end

Device#

### Step 6

**Example:**

Device# show policy-map

(Optional) Displays policy configuration information for all classes configured for all service policies.

### What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

### Related Topics

- Priority Queues, on page 1195

### Configuring Queues and Shaping

### Configuring Egress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you may need to perform all of the procedures in this section. You need to make decisions about these characteristics:

- Which packets are mapped by DSCP, CoS, or QoS group value to each queue and threshold ID?
• What drop percentage thresholds apply to the queues, and how much reserved and maximum memory is needed for the traffic type?
• How much of the fixed buffer space is allocated to the queues?
• Does the bandwidth of the port need to be rate limited?
• How often should the egress queues be serviced and which technique (shaped, shared, or both) should be used?

You can only configure the egress queues on the .

Configuring Queue Buffers (CLI)

The allows you to allocate buffers to queues. If there is no allocation made to buffers, then they are divided equally for all queues. You can use the queue-buffer ratio to divide it in a particular ratio. Since by default DTS (Dynamic Threshold and Scaling) is active on all queues, these are soft buffers.

Before you begin

The following are prerequisites for this procedure:

• You should have created a class map for the queue buffer before beginning this procedure.
• You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue buffers.

SUMMARY STEPS

1. configure terminal
2. policy-map policy name
3. class class name
4. bandwidth {Kb/s | percent percentage | remaining { ratio ratio value }}
5. queue-buffers {ratio ratio value}
6. end
7. show policy-map

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>policy-map policy name</td>
<td>Enters policy map configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Device(config)# policy-map policy_queuebuffer01&lt;br&gt;Device(config-pmap)#</td>
<td>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 3**

```
Device(config-pmap)# class class_queuebuffer01
Device(config-pmap-c)#
```

Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:

- **word**—Class map name.
- **class-default**—System default class matching any otherwise unclassified packets.

**Step 4**

```
Device(config-pmap-c)# bandwidth {Kb/s | percent percentage | remaining { ratio ratio_value }}
```

Example:

```
Device(config-pmap-c)# bandwidth percent 80
Device(config-pmap-c)#
```

Configures the bandwidth for the policy map. The command parameters include:

- **Kb/s**—Use this command to configure a specific value. The range is 20000 to 10000000.
- **percent**—Allocates a minimum bandwidth to a particular class using a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.
- **remaining**—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the **priority** command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.

**Note** You cannot mix bandwidth types on a policy map.

**Step 5**

```
Device(config-pmap-c)# queue-buffers ratio ratio_value
```

Example:

```
Device(config-pmap-c)# queue-buffers ratio 10
Device(config-pmap-c)#
```

Configures the relative buffer size for the queue.

**Note** The sum of all configured buffers in a policy must be less than or equal to 100 percent. Unallocated buffers are are evenly distributed to all the remaining queues. Ensure sufficient buffers are allocated to all queues including the priority queues.
### Purpose

Protocol Data Units (PDUs) for network control protocols such as spanning-tree and LACP utilize the priority queue or queue 0 (when a priority queue is not configured). Ensures sufficient buffers are allocated to these queues for the protocols to function.

### Step 6

**end**

**Example:**

```
Device(config-pmap-c)# end
Device#
```

Saves configuration changes.

### Step 7

**show policy-map**

**Example:**

```
Device# show policy-map
```

(Optional) Displays policy configuration information for all classes configured for all service policies.

### What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

### Related Topics

- Queue Buffer Allocation, on page 1196
- Examples: Queue Buffers Configuration, on page 1270

### Configuring Queue Limits (CLI)

You use queue limits to configure Weighted Tail Drop (WTD). WTD ensures the configuration of more than one threshold per queue. Each class of service is dropped at a different threshold value to provide for QoS differentiation. With the , each queue has 3 explicit programmable threshold classes—0, 1, 2. Therefore, the enqueue/drop decision of each packet per queue is determined by the packet’s threshold class assignment, which is determined by the DSCP, CoS, or QoS group field of the frame header.

WTD also uses a soft limit, and therefore you are allowed to configure the queue limit to up to 400 percent (maximum four times the reserved buffer from common pool). This soft limit prevents overrunning the common pool without impacting other features.

**Note**

You can only configure queue limits on the egress queues on wired ports.

### Before you begin

The following are prerequisites for this procedure:

- You should have created a class map for the queue limits before beginning this procedure.
You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue limits.

SUMMARY STEPS

1. configure terminal
2. policy-map policy name
3. class class name
4. bandwidth {Kb/s | percent percentage | remaining { ratio ratio value }}
5. queue-limit {packets packets | cos {cos value { maximum threshold value | percent percentage } | values {cos value | percent percentage } } | dscp {dscp value {maximum threshold value | percent percentage } | default {maximum threshold value | percent percentage } | ef {maximum threshold value | percent percentage } | dscp values dscp value}}
6. end
7. show policy-map

  * percent—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe |
### Purpose

Command or Action | Purpose
--- | ---
bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.
• remaining—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the priority command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.

| Step 5 | queue-limit \{packets packets | cos \{cos value \{maximum threshold value \| percent \| percentage \} \| values \{cos value \| percent \| percentage \} \} \| dscp \{dscp value \{maximum threshold value \| percent \| percentage \} \| match packet \{maximum threshold value \| percent \| percentage \} \| default \{maximum threshold value \| percent \| percentage \} \| ef \{maximum threshold value \| percent \| percentage \} \| dscp values dscp value \| percent \| percentage \} \}
--- | ---

**Example:**

Device(config-pmap-c)# queue-limit dscp 3 percent 20
Device(config-pmap-c)# queue-limit dscp 4 percent 30
Device(config-pmap-c)# queue-limit dscp 5 percent 40

Sets the queue limit threshold percentage values. With every queue, there are three thresholds (0,1,2), and there are default values for each of these thresholds. Use this command to change the default or any other queue limit threshold setting. For example, if DSCP 3, 4, and 5 packets are being sent into a specific queue in a configuration, then you can use this command to set the threshold percentages for these three DSCP values. For additional information about queue limit threshold values, see Weighted Tail Drop, on page 1194.

**Note** You cannot mix bandwidth types on a policy map.

**Step 6**

**Example:**

Device(config-pmap-c)# end
Device#

Saves configuration changes.

**Step 7**

**Example:**

Device# show policy-map

(Optional) Displays policy configuration information for all classes configured for all service policies.
What to do next

Proceed to configure any additional policy maps for QoS for your network. After creating your policy maps, proceed to attach the traffic policy or polices to an interface using the `service-policy` command.

Related Topics
- Weighted Tail Drop, on page 1194
- Examples: Queue-limit Configuration, on page 1269

Configuring Shaping (CLI)

You use the `shape` command to configure shaping (maximum bandwidth) for a particular class. The queue's bandwidth is restricted to this value even though the port has additional bandwidth left. You can configure shaping as an average percent, as well as a shape average value in bits per second.

Before you begin

You should have created a class map for shaping before beginning this procedure.

SUMMARY STEPS

1. `configure terminal`
2. `policy-map policy name`
3. `class class name`
4. `shape average {target bit rate | percent percentage}`
5. `end`
6. `show policy-map`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>

</tbody>
</table>

Enters the global configuration mode.

Enters policy map configuration mode. Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.

Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:

- `word`—Class map name.
### Command or Action | Purpose
--- | ---
| | • class-default—System default class matching any otherwise unclassified packets.

#### Step 4

**shape average** `target bit rate | percent percentage`

**Example:**

```
Device(config-pmap-c)# shape average percent 50
```

Configures the average shape rate. You can configure the average shape rate by target bit rates (bits per second) or by percentage of interface bandwidth for the Committed Information Rate (CIR).

**Note** For the egress class-default SSID policy, you must configure the queue buffer ratio as 0 after you configure the average shape rate.

#### Step 5

**end**

**Example:**

```
Device(config-pmap-c)# end
```

Saves configuration changes.

#### Step 6

**show policy-map**

**Example:**

```
Device# show policy-map
```

(Optional) Displays policy configuration information for all classes configured for all service policies.

---

### What to do next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the `service-policy` command.

</table>
| `show policy-map session [ input | output | uid UUID ]` | Displays the session QoS policy. Command parameters include:  
  - `input`—Input policy  
  - `output`—Output policy  
  - `uid`—Policy based on SSS unique identification. |
| `show policy-map type control subscriber { all | name }` | Displays the type QoS policy-map. |
| `show table-map` | Displays all the table maps and their configurations. |
| `show platform qos wireless [afd { client | ssid } | stats { bssid bssid-value | client name | ssid {ssid-value | all} client all}]` | Displays wireless targets. The following command parameters are supported:  
  - `afd`—AFD information  
  - `stats`—Statistics information |
| `show policy-map interface wireless ssid name ssid-name [radio type {24ghz | 5ghz} ap name ap-name | ap name ap-name']` | Displays SSID policy configuration on an access point. |
| `show wireless client mac-address mac_address service-policy {input | output}` | Displays details of the client policy. |
| `show wlan qos service-policies` | Displays the SSID policies configured on all WLANs. |
| `show ap name ap_name service-policy` | Displays all the policies configured on the AP. |

### Configuration Examples for QoS

#### Examples: Classification by Access Control Lists

This example shows how to classify packets for QoS by using access control lists (ACLs):

```
Device# configure terminal
Device(config)# access-list 101 permit ip host 12.4.1.1 host 15.2.1.1
Device(config)# class-map acl-101
Device(config-cmap)# description match on access-list 101
```
Device(config-cmap)# match access-group 101
Device(config-cmap)#

After creating a class map by using an ACL, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Related Topics
- Creating a Traffic Class (CLI), on page 1208
- Class Maps, on page 1184

Examples: Class of Service Layer 2 Classification

This example shows how to classify packets for QoS using a class of service Layer 2 classification:

Device# configure terminal
Device(config)# class-map cos
Device(config-cmap)# match cos ?
  <0-7>  Enter up to 4 class-of-service values separated by white-spaces
Device(config-cmap)# match cos 3 4 5
Device(config-cmap)#

After creating a class map by using a CoS Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Class of Service DSCP Classification

This example shows how to classify packets for QoS using a class of service DSCP classification:

Device# configure terminal
Device(config)# class-map dscp
Device(config-cmap)# match dscp af21 af22 af23
Device(config-cmap)#

After creating a class map by using a DSCP classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: VLAN ID Layer 2 Classification

This example shows how to classify for QoS using a VLAN ID Layer 2 classification:

Device# configure terminal
Device(config)# class-map vlan-120
Device(config-cmap)# match vlan ?
  <1-4095>  VLAN id
Device(config-cmap)# match vlan 120
Device(config-cmap)#

After creating a class map by using a VLAN Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.
Examples: Classification by DSCP or Precedence Values

This example shows how to classify packets by using DSCP or precedence values:

```
Device# configure terminal
Device(config)# class-map prec2
Device(config-cmap)# description matching precedence 2 packets
Device(config-cmap)# match ip precedence 2
Device(config-cmap)# exit
Device(config)# class-map ef
Device(config-cmap)# description EF traffic
Device(config-cmap)# match ip dscp ef
Device(config-cmap)#
```

After creating a class map by using a DSCP or precedence values, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Examples: Hierarchical Classification

The following is an example of a hierarchical classification, where a class named parent is created, which matches another class named child. The class named child matches based on the IP precedence being set to 2.

```
Device# configure terminal
Device(config)# class-map child
Device(config-cmap)# match ip precedence 2
Device(config-cmap)# exit
Device(config)# class-map parent
Device(config-cmap)# class-map child
Device(config-cmap)#
```

After creating the parent class map, you then create a policy map for the class, and apply the policy map to an interface for QoS.

Hierarchical QoS, on page 1176

Examples: Hierarchical Policy Configuration

The following is an example of a configuration using hierarchical polices:

```
Device# configure terminal
Device(config)# class-map c1
Device(config-cmap)# match dscp 30
Device(config-cmap)# exit

Device(config)# class-map c2
Device(config-cmap)# match precedence 4
Device(config-cmap)# exit

Device(config)# class-map c3
Device(config-cmap)# exit

Device(config)# policy-map child
```
Examples: Classification for Voice and Video

This example describes how to classify packet streams for voice and video using device specific information.

In this example, voice and video are coming in from end-point A into GigabitEthernet1/0/1 on the device and have precedence values of 5 and 6, respectively. Additionally, voice and video are also coming from end-point B into GigabitEthernet1/0/2 on the device with DSCP values of EF and AF11, respectively.

Assume that all the packets from the both the interfaces are sent on the uplink interface, and there is a requirement to police voice to 100 Mbps and video to 150 Mbps.

To classify per the above requirements, a class to match voice packets coming in on GigabitEthernet1/0/1 is created, named voice-interface-1, which matches precedence 5. Similarly another class for voice is created, named voice-interface-2, which will match voice packets in GigabitEthernet1/0/2. These classes are associated...
to two separate policies named input-interface-1, which is attached to GigabitEthernet1/0/1, and input-interface-2, which is attached to GigabitEthernet1/0/2. The action for this class is to mark the qos-group to 10. To match packets with QoS-group 10 on the output interface, a class named voice is created which matches on QoS-group 10. This is then associated to another policy named output-interface, which is associated to the uplink interface. Video is handled in the same way, but matches on QoS-group 20.

The following example shows how classify using the above device specific information:

```
Device(config)#
Device(config)# class-map voice-interface-1
Device(config-cmap)# match ip precedence 5
Device(config-cmap)# exit

Device(config)# class-map video-interface-1
Device(config-cmap)# match ip precedence 6
Device(config-cmap)# exit

Device(config)# class-map voice-interface-2
Device(config-cmap)# match ip dscp ef
Device(config-cmap)# exit

Device(config)# class-map video-interface-2
Device(config-cmap)# match ip dscp af11
Device(config-cmap)# exit

Device(config)# policy-map input-interface-1
Device(config-pmap)# class voice-interface-1
Device(config-pmap-c)# set qos-group 10
Device(config-pmap-c)# exit

Device(config-pmap)# class video-interface-1
Device(config-pmap-c)# set qos-group 20

Device(config-pmap-c)# policy-map input-interface-2
Device(config-pmap-c)# class voice-interface-2
Device(config-pmap-c)# set qos-group 10
Device(config-pmap-c)# class video-interface-2
Device(config-pmap-c)# set qos-group 20
Device(config-pmap-c)# exit
Device(config-pmap-c)# exit

Device(config)# class-map voice
Device(config-cmap)# match qos-group 10
Device(config-cmap)# exit

Device(config)# class-map video
Device(config-cmap)# match qos-group 20

Device(config)# policy-map output-interface
Device(config-pmap)# class voice
Device(config-pmap-c)# police 256000 conform-action transmit exceed-action drop
Device(config-pmap-c)# exit
Device(config-pmap-c)# exit

Device(config)# class video
Device(config-pmap-c)# police 1024000 conform-action transmit exceed-action drop
Device(config-pmap-c)# exit
Device(config-pmap-c)# exit
```
Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic

The following example provides a template for creating a port child policy for managing quality of service for voice and video traffic.

```plaintext
Policy-map port_child_policy
  Class voice (match dscp ef)
    Priority level 1
    Police Multicast Policer
  Class video (match dscp af41)
    Priority level 2
    Police Multicast Policer
  Class mcast-data (match non-client-nrt)
    Bandwidth remaining ratio <>
  Class class-default (NRT Data)
    Bandwidth remaining ratio <>
```

Note

Multicast Policer in the example above is not a keyword. It refers to the policing policy configured.

Two class maps with names voice and video are configured with DSCP assignments of 46 and 34. The voice traffic is assigned the priority of 1 and the video traffic is assigned the priority level 2 and is processed using Q0 and Q1. If your network receives multicast voice and video traffic, you can configure multicast policers. The non-client NRT data and NRT data are processed using the Q2 and Q3 queues.

**Examples: Average Rate Shaping Configuration**

The following example shows how to configure average rate shaping:

```
Device# configure terminal
Device(config)# class-map precl
```
Device(config-cmap)# description matching precedence 1 packets
Device(config-cmap)# match ip precedence 1
Device(config-cmap)# end

Device(config)# configure terminal
Device(config)# class-map prec2
Device(config-cmap)# description matching precedence 2 packets
Device(config-cmap)# match ip precedence 2
Device(config-cmap)# exit

Device(config)# policy-map shaper
Device(config-pmap)# class prec1
Device(config-pmap-c)# shape average 512000
Device(config-pmap-c)# exit

Device(config-pmap)# policy-map shaper
Device(config-pmap)# class prec2
Device(config-pmap-c)# shape average 512000
Device(config-pmap-c)# exit

Device(config-pmap)# class class-default
Device(config-pmap-c)# shape average 1024000

After configuring the class maps, policy map, and shape averages for your configuration, proceed to then apply the policy map to the interface for QoS.

Examples: Policing Action Configuration

The following example displays the various policing actions that can be associated to the policer. These actions are accomplished using the conforming, exceeding, or violating packet configurations. You have the flexibility to drop, mark and transmit, or transmit packets that have exceeded or violated a traffic profile.

For example, a common deployment scenario is one where the enterprise customer polices traffic exiting the network towards the service provider and marks the conforming, exceeding and violating packets with different DSCP values. The service provider could then choose to drop the packets marked with the exceeded and violated DSCP values under cases of congestion, but may choose to transmit them when bandwidth is available.
The Layer 2 fields can be marked to include the CoS fields, and the Layer 3 fields can be marked to include the precedence and the DSCP fields.

One useful feature is the ability to associate multiple actions with an event. For example, you could set the precedence bit and the CoS for all conforming packets. A submode for an action configuration could then be provided by the policing feature.

This is an example of a policing action configuration:

```
Device# configure terminal
Device(config)# policy-map police
Device(config-pmap)# class class-default
Device(config-pmap-c)# police cir 1000000 pir 2000000
Device(config-pmap-c-police)# conform-action transmit
Device(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Device(config-pmap-c-police)# violate-action set-dscp-transmit dscp table violate-markdown-table
Device(config-pmap-c-police)# end
```

In this example, the exceed-markdown-table and violate-mark-down-table are table maps.

Note
Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the device.

Examples: Policing Units

The following examples display the various units of policing that are supported for QoS. The policing unit is the basis on which the token bucket works.

The following units of policing are supported:

- CIR and PIR are specified in bits per second. The burst parameters are specified in bytes. This is the default mode; it is the unit that is assumed when no units are specified. The CIR and PIR can also be configured in percent, in which case the burst parameters have to be configured in milliseconds.

- CIR and PIR are specified in packets per second. In this case, the burst parameters are configured in packets as well.

The following is an example of a policer configuration in bits per second:

```plaintext
Device(config)# policy-map bps-policer
Device(config-pmap)# class class-default
Device(config-pmap-c) # police rate 256000 bps burst 1000 bytes
conform-action transmit exceed-action drop
```

The following is an example of a policer configuration in packets per second. In this configuration, a dual-rate three-color policer is configured where the units of measurement is packet. The burst and peak burst are all specified in packets.

```plaintext
Device(config)# policy-map pps-policer
Device(config-pmap)# class class-default
Device(config-pmap-c)# police rate 5000 pps burst 100 packets
peak-rate 10000 pps peak-burst 200 packets conform-action transmit
exceed-action drop violate-action drop
```

Examples: Single-Rate Two-Color Policing Configuration

The following example shows how to configure a single-rate two-color policer:

```plaintext
Device(config)# class-map match-any prec1
Device(config-cmap)# match ip precedence 1
Device(config-cmap)# exit
Device(config)# policy-map policer
Device(config-pmap)# class prec1
Device(config-pmap-c)# police cir 256000 conform-action transmit exceed-action drop
Device(config-pmap-c-police)# exit
Device(config-pmap-c)#
```

Related Topics
- Configuring Police (CLI), on page 1244
- Single-Rate Two-Color Policing, on page 1190
Examples: Dual-Rate Three-Color Policing Configuration

The following example shows how to configure a dual-rate three-color policer:

```
Device# configure terminal
Device(config)# policy-Map dual-rate-3color-policer
Device(config-pmap)# class class-default
Device(config-pmap-c)# police cir 64000 bc 2000 pir 128000 be 2000
Device(config-pmap-c-policy)# conform-action transmit
Device(config-pmap-c-policy)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Device(config-pmap-c-policy)# violate-action set-dscp-transmit dscp table violate-markdown-table
Device(config-pmap-c-policy)# exit
Device(config-pmap-c)#
```

In this example, the exceed-markdown-table and violate-markdown-table are table maps.

---

**Note**

Policer based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the device.

Examples: Table Map Marking Configuration

The following steps and examples show how to use table map marking for your QoS configuration:

1. Define the table map.

   Define the table-map using the `table-map` command and indicate the mapping of the values. This table does not know of the policies or classes within which it will be used. The default command in the table map indicates the value to be copied into the ‘to’ field when there is no matching ‘from’ field. In the example, a table map named table-map1 is created. The mapping defined is to convert the value from 0 to 1 and from 2 to 3, while setting the default value to 4.

   ```
   Device(config)# table-map table-map1
   Device(config-tablemap)# map from 0 to 1
   Device(config-tablemap)# map from 2 to 3
   Device(config-tablemap)# default 4
   Device(config-tablemap)# exit
   ```

2. Define the policy map where the table map will be used.

   In the example, the incoming CoS is mapped to the DSCP based on the mapping specified in the table table-map1. For this example, if the incoming packet has a DSCP of 0, the CoS in the packet is set 1. If no table map name is specified the command assumes a default behavior where the value is copied as is from the ‘from’ field (DSCP in this case) to the ‘to’ field (CoS in this case). Note however, that while the CoS is a 3-bit field, the DSCP is a 6-bit field, which implies that the CoS is copied to the first three bits in the DSCP.
3. Associate the policy to an interface.

```
Device(config)# policy map policy1
Device(config-pmap)# class class-default
Device(config-pmap-c)# set cos dscp table table-map1
Device(config-pmap-c)# exit
```

**Example: Table Map Configuration to Retain CoS Markings**

The following example shows how to use table maps to retain CoS markings on an interface for your QoS configuration.

The cos-trust-policy policy (configured in the example) is enabled in the ingress direction to retain the CoS marking coming into the interface. If the policy is not enabled, only the DSCP is trusted by default. If a pure Layer 2 packet arrives at the interface, then the CoS value will be rewritten to 0 when there is no such policy in the ingress port for CoS.

```
Device(config)# configure terminal
Device(config)# table-map cos2cos
Device(config-tablemap)# default copy
Device(config-tablemap)# exit

Device(config)# policy map cos-trust-policy
Device(config-pmap)# class class-default
Device(config-pmap-c)# set cos table cos2cos
Device(config-pmap-c)# exit

Device(config)# interface GigabitEthernet1/0/2
Device(config-if)# service-policy input cos-trust-policy
Device(config-if)# exit
```

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Radio Resource Management

The device should be configured as a mobility controller and not a mobility anchor to configure Radio Resource Management. It may require dynamic channel assignment functionality for the home APs to be supported.

The new mobility architecture that involves mobility controller and mobility agent must be configured on the switch or controllers for RRM to work.

Note

Refer Mobility Configuration Guide for configuring mobility controller and mobility agent.
Restrictions for Radio Resource Management

The number of APs in a RF-group is limited to 500.

If an AP tries to join the RF-group that already holds the maximum number of APs it can support, the device rejects the application and throws an error.

To enable Airtime Fairness mode for APs, you should disable enforce-policy mode and reapply it again. This will change the airtime fairness configuration for all the APs. You can also use the `ap name <ap-name>` dot11 24ghz airtime-fairness mode enforce-policy command to change airtime fairness mode for individual APs.

Information About Radio Resource Management

The Radio Resource Management (RRM) software embedded in the device acts as a built-in RF engineer to consistently provide real-time RF management of your wireless network. RRM enables devices to continually monitor their associated lightweight access points for the following information:

- Traffic load—The total bandwidth used for transmitting and receiving traffic. It enables wireless LAN managers to track and plan network growth ahead of client demand.
- Interference—The amount of traffic coming from other 802.11 sources.
- Noise—The amount of non-802.11 traffic that is interfering with the currently assigned channel.
- Coverage—The Received Signal Strength (RSSI) and signal-to-noise ratio (SNR) for all connected clients.
- Other —The number of nearby access points.

RRM performs these functions:
- Radio resource monitoring
- Transmit power control
- Dynamic channel assignment
- Coverage hole detection and correction
- RF grouping

Note

RRM grouping will not happen, since AP operates in a static channel which is not in the DCA channel list. NDP is sent only on DCA channels and when radio operates on a non-DCA channel it will not receive NDA on-channel.
Radio Resource Monitoring

Radio Resource Monitoring automatically detects and configures new devices and lightweight access points as they are added to the network. It then automatically adjusts associated and nearby lightweight access points to optimize coverage and capacity.

Lightweight access points can scan all valid channels for the country of operation as well as for channels available in other locations. The access points in local mode go “off-channel” for a period not greater than 60 ms to monitor these channels for noise and interference. Packets collected during this time are analyzed to detect rogue access points, rogue clients, ad-hoc clients, and interfering access points.

In the presence of voice traffic or other critical traffic (in the last 100 ms), the access points can defer off-channel measurements. It also defers based on WLAN scan defer priority configurations.

Each access point spends only 0.2 percent of its time off-channel. This activity is distributed across all access points so that adjacent access points are not scanning at the same time, which could adversely affect wireless LAN performance.

RRM supports new mobility architecture for RF grouping that involves Mobility Controller (MC) and Mobility Agent (MA).

- Mobility Controller (MC)—The Cisco WLC 5700 Series Controllers, Cisco Catalyst 3850 Switch, or Cisco Unified Wireless Networking Solution controller can act as MC. The MC has MC functionality and MA functionality that is running internally into it.

- Mobility Agent (MA)—The Mobility Agent is the component that maintains client mobility state machine for a mobile client.

Information About RF Groups

An RF group is a logical collection of Cisco WLCs that coordinate to perform RRM in a globally optimized manner to perform network calculations on a per-radio basis. An RF group exists for each 802.11 network type. Clustering Cisco WLCs into a single RF group enable the RRM algorithms to scale beyond the capabilities of a single Cisco WLC.

RF group is created based on following parameters:

- User-configured RF network name.
- Neighbor discovery performed at the radio level.
- Country list configured on MC.

RF grouping runs between MCs.

Lightweight access points periodically send out neighbor messages over the air. Access points using the the same RF group name validate messages from each other.

When access points on different Cisco WLCs hear validated neighbor messages at a signal strength of ~80 dBm or stronger, the Cisco WLCs dynamically form an RF neighborhood in auto mode. In static mode, the leader is manually selected and the members are added to the RF Group. To know more about RF Group modes, RF Group Leader.
RF groups and mobility groups are similar in that they both define clusters of Cisco WLCs, but they are different in terms of their use. An RF group facilitates scalable, system-wide dynamic RF management while a mobility group facilitates scalable, system-wide mobility and Cisco WLC redundancy.

**RF Group Leader**

Starting in the 7.0.116.0 release, the RF Group Leader can be configured in two ways as follows:

- **Auto Mode**—In this mode, the members of an RF group elect an RF group leader to maintain a “master” power and channel scheme for the group. The RF grouping algorithm dynamically chooses the RF group leader and ensures that an RF group leader is always present. Group leader assignments can and do change (for instance, if the current RF group leader becomes inoperable or if RF group members experience major changes).

- **Static Mode**—In this mode, the user selects a Cisco WLC as an RF group leader manually. In this mode, the leader and the members are manually configured and are therefore fixed. If the members are unable to join the RF group, the reason is indicated. The leader tries to establish a connection with a member every 1 minute if the member has not joined in the previous attempt.

The RF group leader analyzes real-time radio data collected by the system, calculates the power and channel assignments, and sends them to each of the Cisco WLCs in the RF group. The RRM algorithms ensure system-wide stability and restrain channel and power scheme changes to the appropriate local RF neighborhoods.

In Cisco WLC software releases prior to 6.0, the dynamic channel assignment (DCA) search algorithm attempts to find a good channel plan for the radios associated to Cisco WLCs in the RF group, but it does not adopt a new channel plan unless it is considerably better than the current plan. The channel metric of the worst radio in both plans determines which plan is adopted. Using the worst-performing radio as the single criterion for adopting a new channel plan can result in pinning or cascading problems.

Pinning occurs when the algorithm could find a better channel plan for some of the radios in an RF group but is prevented from pursuing such a channel plan change because the worst radio in the network does not have any better channel options. The worst radio in the RF group could potentially prevent other radios in the group from seeking better channel plans. The larger the network, the more likely pinning becomes.

Cascading occurs when one radio’s channel change results in successive channel changes to optimize the remaining radios in the RF neighborhood. Optimizing these radios could lead to their neighbors and their neighbors’ neighbors having a suboptimal channel plan and triggering their channel optimization. This effect could propagate across multiple floors or even multiple buildings, if all the access point radios belong to the same RF group. This change results in considerable client confusion and network instability.

The main cause of both pinning and cascading is the way in which the search for a new channel plan is performed and that any potential channel plan changes are controlled by the RF circumstances of a single radio. In Cisco WLC software release 6.0, the DCA algorithm has been redesigned to prevent both pinning and cascading. The following changes have been implemented:

- **Multiple local searches**—The DCA search algorithm performs multiple local searches initiated by different radios within the same DCA run rather than performing a single global search driven by a single radio. This change addresses both pinning and cascading while maintaining the desired flexibility and adaptability of DCA and without jeopardizing stability.
• Multiple channel plan change initiators (CPCIs)—Previously, the single worst radio was the sole initiator of a channel plan change. Now each radio within the RF group is evaluated and prioritized as a potential initiator. Intelligent randomization of the resulting list ensures that every radio is eventually evaluated, which eliminates the potential for pinning.

• Limiting the propagation of channel plan changes (Localization)—For each CPC radio, the DCA algorithm performs a local search for a better channel plan, but only the CPC radio itself and its one-hop neighboring access points are actually allowed to change their current transmit channels. The impact of an access point triggering a channel plan change is felt only to within two RF hops from that access point, and the actual channel plan changes are confined to within a one-hop RF neighborhood. Because this limitation applies across all CPC radios, cascading cannot occur.

• Non-RSSI-based cumulative cost metric—A cumulative cost metric measures how well an entire region, neighborhood, or network performs with respect to a given channel plan. The individual cost metrics of all access points in that area are considered in order to provide an overall understanding of the channel plan’s quality. These metrics ensure that the improvement or deterioration of each single radio is factored into any channel plan change. The objective is to prevent channel plan changes in which a single radio improves but at the expense of multiple other radios experiencing a considerable performance decline.

The RRM algorithms run at a specified updated interval, which is 600 seconds by default. Between update intervals, the RF group leader sends keepalive messages to each of the RF group members and collects real-time RF data.

---

**Note**

Several monitoring intervals are also available. See the Configuring RRM section for details.

---

**RF Group Name**

A Cisco WLC is configured with an RF group name, which is sent to all access points joined to the Cisco WLC and used by the access points as the shared secret for generating the hashed MIC in the neighbor messages. To create an RF group, you configure all of the Cisco WLCs to be included in the group with the same RF group name.

If there is any possibility that an access point joined to a Cisco WLC may hear RF transmissions from an access point on a different Cisco WLC, you should configure the Cisco WLCs with the same RF group name. If RF transmissions between access points can be heard, then system-wide RRM is recommended to avoid 802.11 interference and contention as much as possible.

**Mobility Controller**

An MC can either be a group leader or a group member. One of the MCs can act as a RF group leader based on RF grouping and RF group election with other MCs. The order of priority to elect the RF leader is based on the maximum number of APs the controller or switch can support. The highest priority being 1 and the least being 5.

1. WiSM 2 Controllers
2. Cisco WLC 5700 Series Controllers
3. WiSM 1 Controllers
4. Catalyst 3850 Series Switches
5. Catalyst 3650 Series Switches
When one of the MCs becomes the RRM group leader, the remaining MCs become RRM group members. RRM group members send their RF information to the Group Leader. The group leader determines a channel and Tx power plan for the network and passes the information back to the RF group members. The MCs push the power plan to MA for the radios that belong to MA. These channel and power plans are ultimately pushed down to individual radios.

---

**Note**

MC has MA functionality within it.

### Mobility Agent

The MA communicates with the MC. The MC includes MAC or IP address of the switch/controller while communicating with the MA.

The MA provides the following information when polled by the MC:

- Interference or noise data.
- Neighbor data.
- Radio capabilities (supported channels, power levels).
- Radio configuration (power, channel, channel width).
- Radar data.

The MC exchanges the following information with the switch/controller (MA). The message includes:

- Configurations (channel/power/channel width) for individual radios.
- Polling requests for current configurations and RF measurements for individual radios
- Group Leader Update

In turn, the MA communicates the following messages with the MC:

- RF measurements from radios (e.g. load, noise and neighbor information)
- RF capabilities and configurations of individual radios

The MA sets channel, power, and channel width on the radios when directed by the MC. The DFS, coverage hole detection/mitigation, static channel/power configurations are performed by the MA.

### Information About Rogue Access Point Detection in RF Groups

After you have created an RF group of Cisco WLCs, you need to configure the access points connected to the Cisco WLCs to detect rogue access points. The access points will then select the beacon/probe-response frames in neighboring access point messages to see if they contain an authentication information element (IE) that matches that of the RF group. If the select is successful, the frames are authenticated. Otherwise, the authorized access point reports the neighboring access point as a rogue, records its BSSID in a rogue table, and sends the table to the Cisco WLC.
**Transmit Power Control**

The device dynamically controls access point transmit power based on real-time wireless LAN conditions. The Transmit Power Control (TPC) algorithm both increases and decreases an access point’s power in response to changes in the RF environment. In most instances, TPC seeks to lower an access point’s power to reduce interference, but in the case of a sudden change in the RF coverage—for example, if an access point fails or becomes disabled—TPC can also increase power on surrounding access points. This feature is different from coverage hole detection, which is primarily concerned with clients. TPC provides enough RF power to achieve desired coverage levels while avoiding channel interference between access points.

**Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings**

The TPC algorithm balances RF power in many diverse RF environments. However, it is possible that automatic power control will not be able to resolve some scenarios in which an adequate RF design was not possible to implement due to architectural restrictions or site restrictions—for example, when all access points must be mounted in a central hallway, placing the access points close together, but requiring coverage out to the edge of the building.

In these scenarios, you can configure maximum and minimum transmit power limits to override TPC recommendations. The maximum and minimum TPC power settings apply to all access points through RF profiles in a RF network.

To set the Maximum Power Level Assignment and Minimum Power Level Assignment, enter the maximum and minimum transmit power used by RRM in the text boxes in the Tx Power Control page. The range for these parameters is -10 to 30 dBm. The minimum value cannot be greater than the maximum value; the maximum value cannot be less than the minimum value.

If you configure a maximum transmit power, RRM does not allow any access point attached to the device to exceed this transmit power level (whether the power is set by RRM TPC or by coverage hole detection). For example, if you configure a maximum transmit power of 11 dBm, then no access point would transmit above 11 dBm, unless the access point is configured manually.

**Dynamic Channel Assignment**

Two adjacent access points on the same channel can cause either signal contention or signal collision. In a collision, data is not received by the access point. This functionality can become a problem, for example, when someone reading e-mail in a café affects the performance of the access point in a neighboring business. Even though these are completely separate networks, someone sending traffic to the café on channel 1 can disrupt communication in an enterprise using the same channel. Devices can dynamically allocate access point channel assignments to avoid conflict and to increase capacity and performance. Channels are “reused” to avoid wasting scarce RF resources. In other words, channel 1 is allocated to a different access point far from the café, which is more effective than not using channel 1 altogether.

The device’s Dynamic Channel Assignment (DCA) capabilities are also useful in minimizing adjacent channel interference between access points. For example, two overlapping channels in the 802.11b/g band, such as 1 and 2, cannot both simultaneously use 11/54 Mbps. By effectively reassigning channels, the device keeps adjacent channels separated.
We recommend that you use only non-overlapping channels (1, 6, 11, and so on).

The device examines a variety of real-time RF characteristics to efficiently handle channel assignments as follows:

- **Access point received energy**—The received signal strength measured between each access point and its nearby neighboring access points. Channels are optimized for the highest network capacity.

- **Noise**—Noise can limit signal quality at the client and access point. An increase in noise reduces the effective cell size and degrades user experience. By optimizing channels to avoid noise sources, the device can optimize coverage while maintaining system capacity. If a channel is unusable due to excessive noise, that channel can be avoided.

- **802.11 Interference**—Interference is any 802.11 traffic that is not part of your wireless LAN, including rogue access points and neighboring wireless networks. Lightweight access points constantly scan all channels looking for sources of interference. If the amount of 802.11 interference exceeds a predefined configurable threshold (the default is 10 percent), the access point sends an alert to the device. Using the RRM algorithms, the device may then dynamically rearrange channel assignments to increase system performance in the presence of the interference. Such an adjustment could result in adjacent lightweight access points being on the same channel, but this setup is preferable to having the access points remain on a channel that is unusable due to an interfering foreign access point.

In addition, if other wireless networks are present, the device shifts the usage of channels to complement the other networks. For example, if one network is on channel 6, an adjacent wireless LAN is assigned to channel 1 or 11. This arrangement increases the capacity of the network by limiting the sharing of frequencies. If a channel has virtually no capacity remaining, the device may choose to avoid this channel. In very dense deployments in which all nonoverlapping channels are occupied, the device does its best, but you must consider RF density when setting expectations.

- **Load and utilization**—When utilization monitoring is enabled, capacity calculations can consider that some access points are deployed in ways that carry more traffic than other access points (for example, a lobby versus an engineering area). The device can then assign channels to improve the access point with the worst performance reported. The load is taken into account when changing the channel structure to minimize the impact on clients currently in the wireless LAN. This metric keeps track of every access point's transmitted and received packet counts to determine how busy the access points are. New clients avoid an overloaded access point and associate to a new access point. This parameter is disabled by default.

The device combines this RF characteristic information with RRM algorithms to make system-wide decisions. Conflicting demands are resolved using soft-decision metrics that guarantee the best choice for minimizing network interference. The end result is optimal channel configuration in a three-dimensional space, where access points on the floor above and below play a major factor in an overall wireless LAN configuration.

**Note**

Radios using 40-MHz channels in the 2.4-GHz band or or 80MHz channels are not supported by DCA.

The RRM startup mode is invoked in the following conditions:

- In a single-device environment, the RRM startup mode is invoked after the device is upgraded and rebooted.
In a multiple-device environment, the RRM startup mode is invoked after an RF Group leader is elected. You can trigger RRM startup mode from CLI. RRM startup mode runs for 100 minutes (10 iterations at 10-minute intervals). The duration of the RRM startup mode is independent of the DCA interval, sensitivity, and network size. The startup mode consists of 10 DCA runs with high sensitivity (making channel changes easy and sensitive to the environment) to converge to a steady state channel plan. After the startup mode is finished, DCA continues to run at the specified interval and sensitivity.

DCA algorithm interval is set to one hour, but DCA algorithm always runs in default interval of 10min, channel allocation happens for every 10min interval for the first 10 cycles, and channel changes as per DCA algorithm for every 10min. After that it goes back to the configured time interval. This is common for both DCA interval and Anchor time since it follows the steady state.

If DCA/TPC is turned off on the RF-group member, and auto is set on RF-group leader, the channel/TX power on member gets changed as per the algorithm run on the RF-group leader.

Coverage Hole Detection and Correction

The RRM coverage hole detection algorithm can detect areas of radio coverage in a wireless LAN that are below the level needed for robust radio performance. This feature can alert you to the need for an additional (or relocated) lightweight access point.

If clients on a lightweight access point are detected at threshold levels (RSSI, failed client count, percentage of failed packets, and number of failed packets) lower than those specified in the RRM configuration, the access point sends a “coverage hole” alert to the device. The alert indicates the existence of an area where clients are continually experiencing poor signal coverage, without having a viable access point to which to roam. The device discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the device mitigates the coverage hole by increasing the transmit power level for that specific access point. The device does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level because increasing their downstream transmit power might increase interference in the network.

How to Configure RRM

Configuring Advanced RRM CCX Parameters (CLI)

SUMMARY STEPS

1. configure terminal
2. ap dot11 24ghz | 5ghz rrm ccx location-measurement interval
3. end
### Configuring Neighbor Discovery Type (CLI)

**SUMMARY STEPS**

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm ndp-type {protected | transparent}`
3. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Configures the neighbor discovery type. By default, the mode is set to “transparent”.</td>
</tr>
<tr>
<td>`ap dot11 24ghz</td>
<td>5ghz rrm ndp-type {protected</td>
</tr>

</table>
Configuring RF Groups

This section describes how to configure RF groups through either the GUI or the CLI.

Note
The RF group name is generally set at deployment time through the Startup Wizard. However, you can change it as necessary.

Note
When the multiple-country feature is being used, all Cisco WLCs intended to join the same RF group must be configured with the same set of countries, configured in the same order.

Note
You can also configure RF groups using the Cisco Prime Infrastructure.

Note
In Auto mode, RF group leader will skip TPC and DCA for first three runs of grouping cycle in order to stabilize the RF-group.

Configuring RF Group Selection Mode (CLI)

SUMMARY STEPS

1. configure terminal
2. ap dot11 24ghz | 5ghz rrm group-mode {auto | leader | off}
3. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>

</tbody>
</table>
Configuring an RF Group Name (CLI)

SUMMARY STEPS

1. configure terminal
2. wireless rf-network name
3. end
4. show network profile profile_number

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> wireless rf-network name</td>
<td>Creates an RF group. The group name should be ASCII String up to 19 characters and is case sensitive.</td>
</tr>
<tr>
<td>Example: Device (config)# wireless rf-network test1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> show network profile profile_number</td>
<td>Displays the RF group.</td>
</tr>
<tr>
<td><strong>Note</strong> You can view the network profile number from 1 to 4294967295.</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Members in a 802.11 Static RF Group (CLI)

SUMMARY STEPS

1. configure terminal
2. ap dot11 24ghz | 5ghz rrm group-member group_name ip_addr
3. end
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 | ap dot11 24ghz | 5ghz rrm group-member group_name ip_addr | Configures members in a 802.11 static RF group. The group mode should be set as leader for the group member to be active. |
| **Example:** Device(config)# ap dot11 24ghz rrm group-member Grpmem01 10.1.1.1 | |

| Step 3 | end | Returns to privileged EXEC mode. Alternatively, you can also press `Ctrl-Z` to exit global configuration mode. |
| **Example:** Device(config)# end | |

### Configuring Transmit Power Control

#### Configuring the Tx-Power Control Threshold (CLI)

**SUMMARY STEPS**

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm tpc-threshold threshold_value`
3. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

</tbody>
</table>
### Command or Action | Purpose
--- | ---
**Step 5** | 
```plaintext
Device(config)# ap dot11 24ghz rrm channel device
```
| Configures the persistent non-Wi-Fi device avoidance in the 802.11 channel assignment. |
**Step 6** | 
```plaintext
Device(config)# ap dot11 24ghz rrm channel foreign
```
| Configures the foreign AP 802.11 interference avoidance in the channel assignment. |
**Step 7** | 
```plaintext
Device(config)# ap dot11 24ghz rrm channel load
```
| Configures the Cisco AP 802.11 load avoidance in the channel assignment. |
**Step 8** | 
```plaintext
Device(config)# ap dot11 24ghz rrm channel noise
```
| Configures the 802.11 noise avoidance in the channel assignment. |
**Step 9** | 
```plaintext
Device(config)# end
```
| Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |

### Configuring 802.11 Coverage Hole Detection (CLI)

#### SUMMARY STEPS

1. configure terminal
2. ap dot11 24ghz | 5ghz rrm coverage data {fail-percentage | packet-count | rssi-threshold}
3. ap dot11 24ghz | 5ghz rrm coverage exception global exception level
4. ap dot11 24ghz | 5ghz rrm coverage level global cli_min exception level
5. ap dot11 24ghz | 5ghz rrm coverage voice {fail-percentage | packet-count | rssi-threshold}
6. end

#### DETAILED STEPS

| Command or Action | Purpose |
--- | --- |
**Step 1** | 
```plaintext
Device# configure terminal
```
| Enters global configuration mode. |

| Device(config)# | `ap dot11 24ghz rrm profile clients 20` |

| **Step 3** | ap dot11 24ghz | 5ghz rrm profile foreign int_threshold_value |
| Example: | Sets the threshold value for 802.11 foreign interference that ranges between 0 and 100%. |
| Device(config)# | `ap dot11 24ghz rrm profile foreign 50` |

| **Step 4** | ap dot11 24ghz | 5ghz rrm profile noise for_noise_threshold_value |
| Example: | Sets the threshold value for 802.11 foreign noise ranges between $-127$ and 0 dBm. |
| Device(config)# | `ap dot11 24ghz rrm profile noise -65` |

| **Step 5** | ap dot11 24ghz | 5ghz rrm profile throughput throughput_threshold_value |
| Example: | Sets the threshold value for 802.11 Cisco AP throughput that ranges between 1000 and 10000000 bytes per second. |
| Device(config)# | `ap dot11 24ghz rrm profile throughput 10000` |
### Configuring Rogue Access Point Detection in RF Groups

#### Configuring Rogue Access Point Detection in RF Groups (CLI)

**Before you begin**

Ensure that each Cisco WLC in the RF group has been configured with the same RF group name.

**Note**

The name is used to verify the authentication IE in all beacon frames. If the Cisco WLCs have different names, false alarms will occur.

#### SUMMARY STEPS

1. `ap name Cisco_AP mode {local | monitor}
2. end
3. configure terminal
4. wireless wps ap-authentication
5. wireless wps ap-authentication threshold value

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>`ap name Cisco_AP mode {local</td>
<td>monitor}`</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# ap name ap1 mode local</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Monitoring RRM Parameters and RF Group Status

#### Monitoring RRM Parameters

**Table 97: Commands for monitoring Radio Resource Management**

<table>
<thead>
<tr>
<th>Commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ap dot11 24ghz ccx</td>
<td>Displays the 802.11b CCX information for all Cisco APs.</td>
</tr>
<tr>
<td>show ap dot11 24ghz channel</td>
<td>Displays the configuration and statistics of the 802.11b channel assignment.</td>
</tr>
<tr>
<td>show ap dot11 24ghz coverage</td>
<td>Displays the configuration and statistics of the 802.11b coverage.</td>
</tr>
<tr>
<td>show ap dot11 24ghz group</td>
<td>Displays the configuration and statistics of the 802.11b grouping.</td>
</tr>
<tr>
<td>show ap dot11 24ghz l2roam</td>
<td>Displays 802.11b l2roam information.</td>
</tr>
<tr>
<td>show ap dot11 24ghz logging</td>
<td>Displays the configuration and statistics of the 802.11b event logging.</td>
</tr>
<tr>
<td>show ap dot11 24ghz monitor</td>
<td>Displays the configuration and statistics of the 802.11b monitoring.</td>
</tr>
</tbody>
</table>
### Monitoring RF Group Status (CLI)

This section describes the new commands for RF group status.

The following commands can be used to monitor RF group status on the.

#### Table 98: Monitoring Aggressive Load Balancing Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ap dot11 5ghz group</td>
<td>Displays the Cisco WLC name which is the RF group leader for the 802.11a RF network.</td>
</tr>
<tr>
<td>show ap dot11 24ghz group</td>
<td>Displays the Cisco WLC name which is the RF group leader for the 802.11b/g RF network.</td>
</tr>
</tbody>
</table>
Examples: RF Group Configuration

This example shows how to configure RF group name:

Device# configure terminal
Device(config)# wireless rf-network test1
Device(config)# ap dot11 24ghz shutdown
Device(config)# end
Device # show network profile 5

This example shows how to configure rogue access point detection in RF groups:

Device# ap name ap1 mode local
Device# end
Device# configure terminal
Device(config)# wireless wps ap-authentication
Device(config)# wireless wps ap-authentication threshold 50
Device(config)# end

Information About ED-RRM

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a threshold for air quality (AQ) that, if exceeded, triggers an immediate channel change for the affected access point. Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an access point detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active. Cisco CleanAir also identifies and locates the source of interference so that more permanent mitigation of the device can be performed at a later time.

Configuring ED-RRM on the Cisco Wireless LAN Controller (CLI)

Step 1
Trigger spectrum event-driven radio resource management (RRM) to run when a Cisco CleanAir-enabled access point detects a significant level of interference by entering these commands:

```
ap dot11 {24ghz | 5ghz} rrm channel cleanair-event —Configures CleanAir driven RRM parameters for the 802.11 Cisco lightweight access points.
ap dot11 {24ghz | 5ghz} rrm channel cleanair-event sensitivity {low | medium | high | custom} —Configures CleanAir driven RRM sensitivity for the 802.11 Cisco lightweight access points. Default selection is Medium.
ap dot11 {24ghz | 5ghz} rrm channel cleanair-event rogue-contribution—Enables rogue contribution.
ap dot11 {24ghz | 5ghz} rrm channel cleanair-event rogue-contribution duty-cycle thresholdvalue—Configures threshold value for rogue contribution. The valid range is from 1 to 99, with 80 as the default.
```

Step 2
Save your changes by entering this command:

```
write memory
```
Step 3  
See the CleanAir configuration for the 802.11a/n/ac or 802.11b/g/n network by entering this command:

```
show ap dot11 {24ghz | 5ghz} cleanair config
```

Information similar to the following appears:

```
Additional Clean Air Settings:
CleanAir Event-driven RRM State................ : Enabled
CleanAir Driven RRM Sensitivity.............. : LOW
CleanAir Event-driven RRM Rogue Option...... : Enabled
CleanAir Event-driven RRM Rogue Duty Cycle... : 80
CleanAir Persistent Devices State............ : Disabled
CleanAir Persistent Device Propagation....... : Disabled
```

CHAPTER 70

Configuring Optimized Roaming

- Information About Optimized Roaming, on page 1307
- Restrictions for Optimized Roaming, on page 1307
- Configuring Optimized Roaming (CLI), on page 1308

Information About Optimized Roaming

Optimized roaming resolves the problem of sticky clients that remain associated to access points that are far away and outbound clients that attempt to connect to a Wi-Fi network without having a stable connection. This feature disassociates clients based on the RSSI of the client data packets and data rate. The client is disassociated if the RSSI alarm condition is met and the current data rate of the client is lower than the optimized roaming data rate threshold. You can disable the data rate option so that only RSSI is used for disassociating clients.

Optimized roaming also prevents client association when the client's RSSI is low. This feature checks the RSSI of the incoming client against the RSSI threshold. This check prevents the clients from connecting to a Wi-Fi network unless the client has a viable connection. In many scenarios, even though clients can hear beacons and connect to a Wi-Fi network, the signal might not be strong enough to support a stable connection.

You can also configure the client coverage reporting interval for a radio by using optimized roaming. The client coverage statistics include data packet RSSIs, Coverage Hole Detection and Mitigation (CHDM) pre-alarm failures, retransmission requests, and current data rates.

Optimized Roaming is implemented in the following scenarios:

- Addresses the sticky client challenge by pro-actively disconnecting clients.
- Actively monitors Data RSSI packets.
- Disassociates client when the RSSI is lower than the set threshold.

Restrictions for Optimized Roaming

- You cannot configure the optimized roaming interval until you disable the 802.11a/b network.
Configuring Optimized Roaming (CLI)

Step 1
Enable or disable optimized roaming by entering this command:
```
config advanced {802.11a | 802.11b} optimized-roaming {enable | disable}
```
By default, optimized roaming is disabled.

Step 2
Configure the client coverage reporting interval for 802.11a/b networks by entering this command:
```
config advanced {802.11a | 802.11b} optimized-roaming interval seconds
```
The range is from 5 to 90 seconds. The default value is 90 seconds.

**Note** You must disable the 802.11a/b network before you configure the optimized roaming reporting interval.

Step 3
Configure the threshold data rate for 802.11a/b networks by entering this command:
```
config advanced {802.11a | 802.11b} optimized-roaming datarate mbps
```
For 802.11a, the configurable data rates are 6, 9, 12, 18, 24, 36, 48, and 54. For 802.11b, the configurable data rates are 1, 2, 5.5, 11, 6, 9, 12, 18, 24, 36, 48, and 54. You can configure 0 to disable the data rate.

Step 4
View information about optimized roaming for each band by entering this command:
```
show advanced {802.11a | 802.11b} optimized-roaming
```
(Cisco Controller) > show advanced 802.11a optimized-roaming
```
OptimizedRoaming
  802.11a OptimizedRoaming Mode.................. Enabled
  802.11a OptimizedRoaming Reporting Interval.... 20 seconds
  802.11a OptimizedRoaming Rate Threshold....... disabled
```

Step 5
View information about optimized roaming statistics by entering this command:
```
show advanced {802.11a | 802.11b} optimized-roaming stats
```
(Cisco Controller) > show advanced 802.11a optimized-roaming stats
```
OptimizedRoaming Stats
  802.11a OptimizedRoaming Disassociations........ 0
  802.11a OptimizedRoaming Rejections............ 0
```
CHAPTER 71

Configuring Rx SOP

- Information About Rx-SOP, on page 1309
- Configuring Rx SOP (CLI), on page 1309

Information About Rx-SOP

Receiver Start of Packet Detection Threshold (Rx SOP) determines the Wi-Fi signal level in dBm at which an access point's radio demodulates and decodes a packet. As the Wi-Fi level increases, the radio sensitivity decreases and the receiver cell size becomes smaller. Reduction of the cell size affects the distribution of clients in the network.

Rx SOP is used to address clients with weak RF links, sticky clients, and client load balancing across access points. Rx SOP helps to optimize the network performance at high-density deployments such as stadiums and auditoriums where access points need to optimize the nearest and strongest clients.

Configuring Rx SOP (CLI)

**Step 1** Configure the Rx SOP mode by entering this command:

```
ap dot11 {24ghz | 5ghz} rx-sop threshold {auto | high | low | medium}
```

**Step 2** Verify Rx SOP high-density parameters:

```
show ap dot11 24ghz high-density
```

Controller# show ap dot11 24ghz high-density
Receiver Start-of-Packet threshold: auto
Multicast Data Rate: auto
AP Name : AP5475.d064.0552
Receiver Start-of-Packet threshold: auto
Multicast Data Rate: auto 2:33 PM
Configuring Rx SOP (CLI)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring MSDP

This section describes how to configure the Multicast Source Discovery Protocol (MSDP on the switch. The MSDP connects multiple Protocol-Independent Multicast sparse-mode (PIM-SM) domains.

MSDP is not fully supported in this software release because of a lack of support for Multicast Border Gateway Protocol (MBGP), which works closely with MSDP. However, it is possible to create default peers that MSDP can operate with if MBGP is not running.

Note

To use this feature, the active switch must be running the IP services feature set.
MSDP Overview

MSDP allows multicast sources for a group to be known to all rendezvous points (RPs) in different domains. Each PIM-SM domain uses its own RPs and does not depend on RPs in other domains. An RP runs MSDP over the Transmission Control Protocol (TCP) to discover multicast sources in other domains.

An RP in a PIM-SM domain has an MSDP peering relationship with MSDP-enabled devices in another domain. The peering relationship occurs over a TCP connection, primarily exchanging a list of sources sending to multicast groups. The TCP connections between RPs are achieved by the underlying routing system. The receiving RP uses the source lists to establish a source path.

The purpose of this topology is to have domains discover multicast sources in other domains. If the multicast sources are of interest to a domain that has receivers, multicast data is delivered over the normal, source-tree building mechanism in PIM-SM. MSDP is also used to announce sources sending to a group. These announcements must originate at the domain’s RP.

MSDP depends heavily on the Border Gateway Protocol (BGP) or MBGP for interdomain operation. We recommend that you run MSDP in RPs in your domain that are RPs for sources sending to global groups to be announced to the Internet.

MSDP Operation

When a source sends its first multicast packet, the first-hop router (designated router or RP) directly connected to the source sends a PIM register message to the RP. The RP uses the register message to register the active source and to forward the multicast packet down the shared tree in the local domain. With MSDP configured, the RP also forwards a source-active (SA) message to all MSDP peers. The SA message identifies the source, the group the source is sending to, and the address of the RP or the originator ID (the IP address of the interface used as the RP address), if configured.

Each MSDP peer receives and forwards the SA message away from the originating RP to achieve peer reverse-path flooding (RPF). The MSDP device examines the BGP or MBGP routing table to discover which peer is the next hop toward the originating RP of the SA message. Such a peer is called an RPF peer (reverse-path forwarding peer). The MSDP device forwards the message to all MSDP peers other than the RPF peer. For information on how to configure an MSDP peer when BGP and MBGP are not supported, see the Configuring a Default MSDP Peer, on page 1316.

If the MSDP peer receives the same SA message from a non-RPF peer toward the originating RP, it drops the message. Otherwise, it forwards the message to all its MSDP peers.

The RP for a domain receives the SA message from an MSDP peer. If the RP has any join requests for the group the SA message describes and if the (*,G) entry exists with a nonempty outgoing interface list, the domain is interested in the group, and the RP triggers an (S,G) join toward the source. After the (S,G) join reaches the source’s DR, a branch of the source tree has been built from the source to the RP in the remote domain. Multicast traffic can now flow from the source across the source tree to the RP and then down the shared tree in the remote domain to the receiver.
This figure shows MSDP operating between two MSDP peers. PIM uses MSDP as the standard mechanism to register a source with the RP of a domain. When MSDP is configured, this sequence occurs.

By default, the switch does not cache source or group pairs from received SA messages. When the switch forwards the MSDP SA information, it does not store it in memory. Therefore, if a member joins a group soon after an SA message is received by the local RP, that member needs to wait until the next SA message to hear about the source. This delay is known as join latency.

Local RPs can send SA requests and get immediate responses for all active sources for a given group. By default, the switch does not send any SA request messages to its MSDP peers when a new member joins a group and wants to receive multicast traffic. The new member waits to receive the next periodic SA message.

If you want a new member of a group to learn the active multicast sources in a connected PIM sparse-mode domain that are sending to a group, configure the switch to send SA request messages to the specified MSDP peer when a new member joins a group.

**MSDP Benefits**

MSDP has these benefits:

- It breaks up the shared multicast distribution tree. You can make the shared tree local to your domain. Your local members join the local tree, and join messages for the shared tree never need to leave your domain.

- PIM sparse-mode domains can rely only on their own RPs, decreasing reliance on RPs in another domain. This increases security because you can prevent your sources from being known outside your domain.

- Domains with only receivers can receive data without globally advertising group membership.

- Global source multicast routing table state is not required, saving memory.
How to Configure MSDP

Default MSDP Configuration

MSDP is not enabled, and no default MSDP peer exists.

Configuring a Default MSDP Peer

Before you begin
Configure an MSDP peer.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip msdp default-peer ip-address</td>
<td>Defines a default peer from which to accept all MSDP SA messages.</td>
</tr>
<tr>
<td>name [prefix-list list]</td>
<td>Example:</td>
</tr>
<tr>
<td>Router(config)# ip msdp default-peer 10.1.1.1 prefix-list site-a</td>
<td></td>
</tr>
<tr>
<td>• For <strong>ip-address</strong></td>
<td>name, enter the IP address or Domain Name System (DNS) server name of the MSDP default peer.</td>
</tr>
<tr>
<td>• (Optional) For <strong>prefix-list list</strong>, enter the list name that specifies the peer to be the default peer only for the listed prefixes. You can have multiple active default peers when you have a prefix list associated with each.</td>
<td></td>
</tr>
<tr>
<td>When you enter multiple <strong>ip msdp default-peer</strong> commands with the <strong>prefix-list</strong> keyword, you use all the default peers at the same time for different RP prefixes. This syntax is typically used in a service provider cloud that connects stub site clouds.</td>
<td></td>
</tr>
<tr>
<td>When you enter multiple <strong>ip msdp default-peer</strong> commands without the <strong>prefix-list</strong> keyword, a single active peer accepts all SA messages. If that peer fails,</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a Default MSDP Peer

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>the next configured default peer accepts all SA messages. This syntax is typically used at a stub site.</td>
</tr>
<tr>
<td>ip prefix-list name [description string]</td>
<td>(Optional) Creates a prefix list using the name specified in Step 2.</td>
</tr>
<tr>
<td>seq number</td>
<td>- (Optional) For <strong>description string</strong>, enter a description of up to 80 characters to describe this prefix list.</td>
</tr>
<tr>
<td>{permit</td>
<td>deny} network length</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>- The <strong>deny</strong> keyword denies access to matching conditions.</td>
</tr>
<tr>
<td>Router(config)# prefix-list site-a seq 3 permit 12 network length 128</td>
<td>- The <strong>permit</strong> keyword permits access to matching conditions.</td>
</tr>
<tr>
<td></td>
<td>- For <strong>network length</strong>, specify the network number and length (in bits) of the network mask that is permitted or denied.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>(Optional) Configures a description for the specified peer to make it easier to identify in a configuration or in <strong>show</strong> command output.</td>
</tr>
<tr>
<td>ip msdp description {peer-name</td>
<td>peer-address} text</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Step 6</strong></td>
</tr>
<tr>
<td>Router(config)# ip msdp description peer-name site-b</td>
<td><strong>Step 7</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Step 8</strong></td>
</tr>
<tr>
<td>show running-config</td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Device# copy running-config startup-config</strong></td>
</tr>
</tbody>
</table>
Caching Source-Active State

If you want to sacrifice some memory in exchange for reducing the latency of the source information, you can configure the Device to cache SA messages. Perform the following steps to enable the caching of source/group pairs:

Follow these steps to enable the caching of source/group pairs:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>ip msdp cache-sa-state [list access-list-number]</td>
<td>Enables the caching of source/group pairs (create an SA state). Those pairs that pass the access list are cached. For list access-list-number, the range is 100 to 199.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ip msdp cache-sa-state 100</td>
<td>Note An alternative to this command is the ip msdp sa-request global configuration command, which causes the Device to send an SA request message to the MSDP peer when a new member for a group becomes active.</td>
</tr>
<tr>
<td>Step 4</td>
<td>access-list access-list-number (deny</td>
<td>permit) protocol source source-wildcard destination destination-wildcard</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# access-list 100 permit ip 171.69.0.0 0.0.255.255 224.2.0.0 0.0.255.255</td>
<td>• For access-list-number, the range is 100 to 199. Enter the same number created in Step 2. • The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. • For protocol, enter ip as the protocol name. • For source, enter the number of the network or host from which the packet is being sent. • For source-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</td>
</tr>
</tbody>
</table>
### Requesting Source Information from an MSDP Peer

If you want a new member of a group to learn the active multicast sources in a connected PIM sparse-mode domain that are sending to a group, perform this task for the Device to send SA request messages to the specified MSDP peer when a new member joins a group. The peer replies with the information in its SA cache. If the peer does not have a cache configured, this command has no result. Configuring this feature reduces join latency but sacrifices memory.

Follow these steps to configure the Device to send SA request messages to the MSDP peer when a new member joins a group and wants to receive multicast traffic:

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

| Step 5 | `end` | Returns to privileged EXEC mode. |
| Example: | Device(config)# `end` |

| Step 6 | `show running-config` | Verifies your entries. |
| Example: | Device# `show running-config` |

| Step 7 | `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
| Example: | Device# `copy running-config startup-config` |

---

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• For destination, enter the number of the network or host to which the packet is being sent.</td>
<td></td>
</tr>
<tr>
<td>• For destination-wildcard, enter the wildcard bits in dotted decimal notation to be applied to the destination. Place ones in the bit positions that you want to ignore.</td>
<td></td>
</tr>
</tbody>
</table>

Recall that the access list is always terminated by an implicit deny statement for everything.
### Command or Action | Purpose
--- | ---
**Step 2** | enter the global configuration mode.
- **configure terminal**
  
  **Example:**
  
  Device# configure terminal

**Step 3** | Configure the Device to send SA request messages to the specified MSDP peer.
- **ip msdp sa-request** `{ip-address | name}`
  
  **Example:**
  
  Device(config)# ip msdp sa-request 171.69.1.1

**Step 4** | Returns to privileged EXEC mode.
- **end**
  
  **Example:**
  
  Device(config)# end

**Step 5** | Verifies your entries.
- **show running-config**
  
  **Example:**
  
  Device# show running-config

**Step 6** | (Optional) Saves your entries in the configuration file.
- **copy running-config startup-config**
  
  **Example:**
  
  Device# copy running-config startup-config

---

**Controlling Source Information that Your Switch Originates**

You can control the multicast source information that originates with your Device:

- Sources you advertise (based on your sources)
- Receivers of source information (based on knowing the requestor)

For more information, see the [Redistributing Sources](#) on page 1320 and the [Filtering Source-Active Request Messages](#) on page 1322.

**Redistributing Sources**

SA messages originate on RPs to which sources have registered. By default, any source that registers with an RP is advertised. The **A** flag is set in the RP when a source is registered, which means the source is advertised in an SA unless it is filtered.

---

**Table:**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td>enter the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Configure the Device to send SA request messages to the specified MSDP peer.</td>
</tr>
<tr>
<td>ip msdp sa-request `{ip-address</td>
<td>name}`</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip msdp sa-request 171.69.1.1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
Follow these steps to further restrict which registered sources are advertised:

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>ip msdp redistribute [list access-list-name] [asn aspath-access-list-number] [route-map map]</td>
<td>Configures which (S,G) entries from the multicast routing table are advertised in SA messages.</td>
</tr>
<tr>
<td>Example:</td>
<td>ip msdp redistribute list 21</td>
<td>By default, only sources within the local domain are advertised.</td>
</tr>
<tr>
<td>Example:</td>
<td>Use one of the following:</td>
<td>Creates an IP standard access list, repeating the command as many times as necessary.</td>
</tr>
<tr>
<td>Example:</td>
<td>• access-list access-list-number</td>
<td>or</td>
</tr>
<tr>
<td>Example:</td>
<td>• access-list access-list-number</td>
<td>Creates an IP extended access list, repeating the command as many times as necessary.</td>
</tr>
<tr>
<td>Example:</td>
<td>protocol source source-wildcard destination destination-wildcard</td>
<td>• access-list-number—Enters the same number created in Step 2. The range is 1 to 99 for standard access lists and 100 to 199 for extended lists.</td>
</tr>
</tbody>
</table>
Filtering Source-Active Request Messages

By default, only Device that are caching SA information can respond to SA requests. By default, such a Device honors all SA request messages from its MSDP peers and supplies the IP addresses of the active sources.

However, you can configure the Device to ignore all SA requests from an MSDP peer. You can also honor only those SA request messages from a peer for groups described by a standard access list. If the groups in the access list pass, SA request messages are accepted. All other such messages from the peer for other groups are ignored.
To return to the default setting, use the `no ip msdp filter-sa-request {ip-address|name}` global configuration command.

Follow these steps to configure one of these options:

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example: Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Use one of the following: * `ip msdp filter-sa-request {ip-address</td>
<td>name}<code>\*</code>ip msdp filter-sa-request {ip-address</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config)# <code>ip msdp filter sa-request 171.69.2.2</code></td>
<td></td>
</tr>
</tbody>
</table>
| 4    | `access-list access-list-number {deny | permit} source [source-wildcard]` | Creates an IP standard access list, repeating the command as many times as necessary.  
  \* For `access-list-number`, the range is 1 to 99.  
  \* The `deny` keyword denies access if the conditions are matched. The `permit` keyword permits access if the conditions are matched.  
  \* For `source`, enter the number of the network or host from which the packet is being sent.  
  \* (Optional) For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.  
  Recall that the access list is always terminated by an implicit `deny` statement for everything. |
|      | Example: Device(config)# `access-list 1 permit 192.4.22.0 0.0.0.255` | |
Controlling Source Information that Your Switch Forwards

By default, the Device forwards all SA messages it receives to all its MSDP peers. However, you can prevent outgoing messages from being forwarded to a peer by using a filter or by setting a time-to-live (TTL) value.

Using a Filter

By creating a filter, you can perform one of these actions:

- Filter all source/group pairs
- Specify an IP extended access list to pass only certain source/group pairs
- Filter based on match criteria in a route map

Follow these steps to apply a filter:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

**Step 3**

Use one of the following:

- `ip msdp sa-filter out {ip-address name}`
- `ip msdp sa-filter out`  
  `{ip-address name}`  
  `list access-list-number`
- `ip msdp sa-filter out`
  `{ip-address name}`  
  `route-map map-tag`

**Example:**

Device(config)# ip msdp sa-filter out switch.cisco.com

or

Device(config)# ip msdp sa-filter out list 100

or

Device(config)# ip msdp sa-filter out switch.cisco.com route-map 22

**Step 4**

`access-list access-list-number {deny | permit} protocol source source-wildcard destination destination-wildcard`

**(Optional)** Creates an IP extended access list, repeating the command as many times as necessary.

- For `access-list-number`, enter the number specified in Step 2.
- The `deny` keyword denies access if the conditions are matched. The `permit` keyword permits access if the conditions are matched.
- For `protocol`, enter `ip` as the protocol name.
- For `source`, enter the number of the network or host from which the packet is being sent.
- For `source-wildcard`, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.
- For `destination`, enter the number of the network or host to which the packet is being sent.
### Using TTL to Limit the Multicast Data Sent in SA Messages

You can use a TTL value to control what data is encapsulated in the first SA message for every source. Only multicast packets with an IP-header TTL greater than or equal to the `ttl` argument are sent to the specified MSDP peer. For example, you can limit internal traffic to a TTL of 8. If you want other groups to go to external locations, you must send those packets with a TTL greater than 8.

Follow these steps to establish a TTL threshold:

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Controlling Source Information that Your Switch Receives

By default, the Device receives all SA messages that its MSDP RPF peers send to it. However, you can control the source information that you receive from MSDP peers by filtering incoming SA messages. In other words, you can configure the Device to not accept them.

You can perform one of these actions:

- Filter all incoming SA messages from an MSDP peer
- Specify an IP extended access list to pass certain source/group pairs
- Filter based on match criteria in a route map

Follow these steps to apply a filter:

<table>
<thead>
<tr>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
</tr>
<tr>
<td>enable</td>
</tr>
</tbody>
</table>

---

**Purpose**

**Command or Action** | **Step 3** | **Step 4** | **Step 5** | **Step 6**
---|---|---|---|---
**Purpose** | Limits which multicast data is encapsulated in the first SA message to the specified MSDP peer. | Returns to privileged EXEC mode. | Verifies your entries. | (Optional) Saves your entries in the configuration file.
**Command or Action** | ip msdp ttl-threshold \( \text{ip-address | name} \) \( \text{ttl} \) | end | show running-config | copy running-config startup-config
**Example:** | Device(config)# ip msdp ttl-threshold switch.cisco.com 0 | Device(config)# end | Device# show running-config | Device# copy running-config startup-config
## Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Device&gt; enable</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>

### Step 2

**Example:**

```
Device# configure terminal
```

### Step 3

Use one of the following:

- **ip msdp sa-filter in**
  
  `{ip-address name}`

- **ip msdp sa-filter in**
  
  `{ip-address name}
list access-list-number`

- **ip msdp sa-filter in**
  
  `{ip-address name}
route-map map-tag`

**Example:**

```
Device(config)# ip msdp sa-filter in switch.cisco.com
```

or

```
Device(config)# ip msdp sa-filter in list 100
```

or

```
Device(config)# ip msdp sa-filter in switch.cisco.com route-map 22
```

### Step 4

**access-list access-list-number {deny | permit} protocol source source-wildcard destination destination-wildcard**

**Example:**

```
Device(config)# access list 100 permit ip 194.1.22.0 1.1.1.1 194.3.44.0 1.1.1.1
```

(Optional) Creates an IP extended access list, repeating the command as many times as necessary.

- **access-list-number**, enter the number specified in Step 2.

- The `deny` keyword denies access if the conditions are matched. The `permit` keyword permits access if the conditions are matched.

- For `protocol`, enter `ip` as the protocol name.

- For `source`, enter the number of the network or host from which the packet is being sent.
### Configuring an MSDP Mesh Group

An MSDP mesh group is a group of MSDP speakers that have fully meshed MSDP connectivity among one another. Any SA messages received from a peer in a mesh group are not forwarded to other peers in the same mesh group. Thus, you reduce SA message flooding and simplify peer-RPF flooding. Use the `ip msdp mesh-group` global configuration command when there are multiple RPs within a domain. It is especially used to send SA messages across a domain. You can configure multiple mesh groups (with different names) in a single Device.

Follow these steps to create a mesh group:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.
### Shutting Down an MSDP Peer

If you want to configure many MSDP commands for the same peer and you do not want the peer to become active, you can shut down the peer, configure it, and later bring it up. When a peer is shut down, the TCP connection is terminated and is not restarted. You can also shut down an MSDP session without losing configuration information for the peer.

Follow these steps to shut down a peer:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>ip msdp mesh-group name {ip-address</td>
<td>name}</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip msdp mesh-group 2 switch.cisco.com</td>
<td>By default, the MSDP peers do not belong to a mesh group.</td>
</tr>
<tr>
<td></td>
<td>• For name, enter the name of the mesh group.</td>
</tr>
<tr>
<td></td>
<td>• For ip-address</td>
</tr>
<tr>
<td></td>
<td>Repeat this procedure on each MSDP peer in the group.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td></td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
**Including a Bordering PIM Dense-Mode Region in MSDP**

You can configure MSDP on a Device that borders a PIM sparse-mode region with a dense-mode region. By default, active sources in the dense-mode region do not participate in MSDP.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td> </td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td> </td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ip msdp shutdown {peer-name</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ip msdp shutdown switch.cisco.com</td>
</tr>
<tr>
<td> </td>
<td>Shuts down the specified MSDP peer without losing configuration information. For peer-name</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
</tr>
<tr>
<td> </td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show running-config</td>
</tr>
<tr>
<td> </td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>copy running-config startup-config</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# copy running-config startup-config</td>
</tr>
<tr>
<td> </td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
We do not recommend using the `ip msdp border sa-address` global configuration command. It is better to configure the border router in the sparse-mode domain to proxy-register sources in the dense-mode domain to the RP of the sparse-domain and have the sparse-mode domain use standard MSDP procedures to advertise these sources.

The `ip msdp originator-id` global configuration command also identifies an interface to be used as the RP address. If both the `ip msdp border sa-address` and the `ip msdp originator-id` global configuration commands are configured, the address derived from the `ip msdp originator-id` command specifies the RP address.

Follow these steps to configure the border router to send SA messages for sources active in the dense-mode region to the MSDP peers:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Configures the switch on the border between a dense-mode and sparse-mode region to send SA messages about active sources in the dense-mode region.</td>
</tr>
<tr>
<td><code>ip msdp border sa-address interface-id</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ip msdp border sa-address 0/1</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Configures which (S,G) entries from the multicast routing table are advertised in SA messages. For more information, see the Redistributing Sources, on page 1320.</td>
</tr>
<tr>
<td><code>ip msdp redistribute [list access-list-name] [asn aspath-access-list-number] [route-map map]</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# ip msdp redistribute list 100</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# end</td>
</tr>
</tbody>
</table>
### Configuring an Originating Address other than the RP Address

You can allow an MSDP speaker that originates an SA message to use the IP address of the interface as the RP address in the SA message by changing the Originator ID. You might change the Originator ID in one of these cases:

- If you configure a logical RP on multiple Device in an MSDP mesh group.
- If you have a Device that borders a PIM sparse-mode domain and a dense-mode domain. If a Device borders a dense-mode domain for a site, and sparse-mode is being used externally, you might want dense-mode sources to be known to the outside world. Because this Device is not an RP, it would not have an RP address to use in an SA message. Therefore, this command provides the RP address by specifying the address of the interface.

If both the `ip msdp border sa-address` and the `ip msdp originator-id` global configuration commands are configured, the address derived from the `ip msdp originator-id` command specifies the address of the RP.

Follow these steps to allow an MSDP speaker that originates an SA message to use the IP address on the interface as the RP address in the SA message:

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>
### Monitoring and Maintaining MSDP

Commands that monitor MSDP SA messages, peers, state, and peer status:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>debug ip msdp</strong> [peer-address</td>
<td>name] [detail] [routes]</td>
</tr>
<tr>
<td><strong>debug ip msdp resets</strong></td>
<td>Debugs MSDP peer reset reasons.</td>
</tr>
<tr>
<td><strong>show ip msdp count</strong> [autonomous-system-number]</td>
<td>Displays the number of sources and groups originated in SA messages from each autonomous system. The <strong>ip msdp cache-sa-state</strong> command must be configured for this command to produce any output.</td>
</tr>
<tr>
<td><strong>show ip msdp peer</strong> [peer-address</td>
<td>name]</td>
</tr>
<tr>
<td><strong>show ip msdp sa-cache</strong> [group-address</td>
<td>source-address</td>
</tr>
</tbody>
</table>
Commands that clear MSDP connections, statistics, and SA cache entries:

**Table 100: Commands for Clearing MSDP Connections, Statistics, or SA Cache Entries**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`clear ip msdp peer peer-address</td>
<td>name`</td>
</tr>
<tr>
<td>`clear ip msdp statistics [peer-address</td>
<td>name]`</td>
</tr>
<tr>
<td>`clear ip msdp sa-cache [group-address</td>
<td>name]`</td>
</tr>
</tbody>
</table>

### Configuration Examples for Configuring MSDP

#### Configuring a Default MSDP Peer: Example

This example shows a partial configuration of Router A and Router C in . Each of these ISPs have more than one customer (like the customer in ) who use default peering (no BGP or MBGP). In that case, they might have similar configurations. That is, they accept SAs only from a default peer if the SA is permitted by the corresponding prefix list.

**Router A**

```
Router(config)# ip msdp default-peer 10.1.1.1
Router(config)# ip msdp default-peer 10.1.1.1 prefix-list site-a
Router(config)# ip prefix-list site-b permit 10.0.0.0/1
```

**Router C**

```
Router(config)# ip msdp default-peer 10.1.1.1 prefix-list site-a
Router(config)# ip prefix-list site-b permit 10.0.0.0/1
```

#### Caching Source-Active State: Example

This example shows how to enable the cache state for all sources in 171.69.0.0/16 sending to groups 224.2.0.0/16:

```
Device(config)# ip msdp cache-sa-state 100
Device(config)# access-list 100 permit ip 171.69.0.0 0.0.255.255 224.2.0.0 0.0.255.255
```
Requesting Source Information from an MSDP Peer: Example

This example shows how to configure the switch to send SA request messages to the MSDP peer at 171.69.1.1:

Device(config)# ip msdp sa-request 171.69.1.1

Controlling Source Information that Your Switch Originates: Example

This example shows how to configure the switch to filter SA request messages from the MSDP peer at 171.69.2.2. SA request messages from sources on network 192.4.22.0 pass access list 1 and are accepted; all others are ignored.

Device(config)# ip msdp filter sa-request 171.69.2.2 list 1
Device(config)# access-list 1 permit 192.4.22.0 0.0.0.255

Controlling Source Information that Your Switch Forwards: Example

This example shows how to allow only (S,G) pairs that pass access list 100 to be forwarded in an SA message to the peer named switch.cisco.com:

Device(config)# ip msdp peer switch.cisco.com connect-source gigabitethernet1/0/1
Device(config)# ip msdp sa-filter out switch.cisco.com list 100
Device(config)# access-list 100 permit ip 171.69.0.0 0.0.255.255 224.20 0 0.0.255.255

Controlling Source Information that Your Switch Receives: Example

This example shows how to filter all SA messages from the peer named switch.cisco.com:

Device(config)# ip msdp peer switch.cisco.com connect-source gigabitethernet1/0/1
Device(config)# ip msdp sa-filter in switch.cisco.com

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring IP Unicast Routing

This module describes how to configure IP Version 4 (IPv4) unicast routing on the switch.

On switches running the LAN base feature, static routing on VLANs is supported only with this release.

A switch stack operates and appears as a single router to the rest of the routers in the network. Basic routing functions like static routing and the Routing Information Protocol (RIP), are available with both the IP Base feature set and the IP Services feature set. To use advanced routing features and other routing protocols, you must have the IP Services feature set enabled on the standalone switch or on the active switch.

In addition to IPv4 traffic, you can also enable IP Version 6 (IPv6) unicast routing and configure interfaces to forward IPv6 traffic if the switch or switch stack is running the IP Base or IP Services feature set.

Information About IP Routing

In some network environments, VLANs are associated with individual networks or subnetworks. In an IP network, each subnetwork is mapped to an individual VLAN. Configuring VLANs helps control the size of the broadcast domain and keeps local traffic local. However, network devices in different VLANs cannot communicate with one another without a Layer 3 device (router) to route traffic between the VLAN, referred to as inter-VLAN routing. You configure one or more routers to route traffic to the appropriate destination VLAN.

**Figure 82: Routing Topology Example**

This figure shows a basic routing topology. Switch A is in VLAN 10, and Switch B is in VLAN 20. The router has an interface in each VLAN.
When Host A in VLAN 10 needs to communicate with Host B in VLAN 10, it sends a packet addressed to that host. Switch A forwards the packet directly to Host B, without sending it to the router.

When Host A sends a packet to Host C in VLAN 20, Switch A forwards the packet to the router, which receives the traffic on the VLAN 10 interface. The router checks the routing table, finds the correct outgoing interface, and forwards the packet on the VLAN 20 interface to Switch B. Switch B receives the packet and forwards it to Host C.

**Types of Routing**

Routers and Layer 3 switches can route packets in these ways:

- By using default routing
- By using preprogrammed static routes for the traffic
- By dynamically calculating routes by using a routing protocol

Default routing refers to sending traffic with a destination unknown to the router to a default outlet or destination.

Static unicast routing forwards packets from predetermined ports through a single path into and out of a network. Static routing is secure and uses little bandwidth, but does not automatically respond to changes in the network, such as link failures, and therefore, might result in unreachable destinations. As networks grow, static routing becomes a labor-intensive liability.

Switches running the LAN base feature set support 16 user-configured static routes, in addition to any default routes used for the management interface. The LAN base image supports static routing only on SVIs.

Dynamic routing protocols are used by routers to dynamically calculate the best route for forwarding traffic. There are two types of dynamic routing protocols:

- Routers using distance-vector protocols maintain routing tables with distance values of networked resources, and periodically pass these tables to their neighbors. Distance-vector protocols use one or a series of metrics for calculating the best routes. These protocols are easy to configure and use.
- Routers using link-state protocols maintain a complex database of network topology, based on the exchange of link-state advertisements (LSAs) between routers. LSAs are triggered by an event in the network, which speeds up the convergence time or time required to respond to these changes. Link-state protocols respond quickly to topology changes, but require greater bandwidth and more resources than distance-vector protocols.

Distance-vector protocols supported by the switch are Routing Information Protocol (RIP), which uses a single distance metric (cost) to determine the best path and Border Gateway Protocol (BGP), which adds a path vector mechanism. The switch also supports the Open Shortest Path First (OSPF) link-state protocol and Enhanced IGRP (EIGRP), which adds some link-state routing features to traditional Interior Gateway Routing Protocol (IGRP) to improve efficiency.

**Note**

On a switch or switch stack, the supported protocols are determined by the software running on the active switch. If the active switch is running the IP base feature set, only default routing, static routing and RIP are supported. If the switch is running the LAN base feature set, you can configure 16 static routes on SVIs. All other routing protocols require the IP services feature set.
IP Routing and Switch Stacks

A switch stack appears to the network as a single switch, regardless of which switch in the stack is connected to a routing peer.

The active switch performs these functions:

- It initializes and configures the routing protocols.
- It sends routing protocol messages and updates to other routers.
- It processes routing protocol messages and updates received from peer routers.
- It generates, maintains, and distributes the distributed Cisco Express Forwarding (dCEF) database to all stack members. The routes are programmed on all switches in the stack bases on this database.
- The MAC address of the active switch is used as the router MAC address for the whole stack, and all outside devices use this address to send IP packets to the stack.
- All IP packets that require software forwarding or processing go through the CPU of the active switch.

Stack members perform these functions:

- They act as routing standby switches, ready to take over in case they are elected as the new active switch if the active switch fails.
- They program the routes into hardware.

If a active switch fails, the stack detects that the active switch is down and elects one of the stack members to be the new active switch. During this period, except for a momentary interruption, the hardware continues to forward packets with no active protocols.

However, even though the switch stack maintains the hardware identification after a failure, the routing protocols on the router neighbors might flap during the brief interruption before the active switch restarts. Routing protocols such as OSPF and EIGRP need to recognize neighbor transitions. The router uses two levels of nonstop forwarding (NSF) to detect a switchover, to continue forwarding network traffic, and to recover route information from peer devices:

- NSF-aware routers tolerate neighboring router failures. After the neighbor router restarts, an NSF-aware router supplies information about its state and route adjacencies on request.
- NSF-capable routers support NSF. When they detect a active switch change, they rebuild routing information from NSF-aware or NSF-capable neighbors and do not wait for a restart.

The switch stack supports NSF-capable routing for OSPF and EIGRP.

Upon election, the new active switch performs these functions:

- It starts generating, receiving, and processing routing updates.
- It builds routing tables, generates the CEF database, and distributes it to stack members.
- It uses its MAC address as the router MAC address. To notify its network peers of the new MAC address, it periodically (every few seconds for 5 minutes) sends a gratuitous ARP reply with the new router MAC address.
If you configure the persistent MAC address feature on the stack and the active switch changes, the stack MAC address does not change for the configured time period. If the previous active switch rejoins the stack as a member switch during that time period, the stack MAC address remains the MAC address of the previous active switch.

Note

- It attempts to determine the reachability of every proxy ARP entry by sending an ARP request to the proxy ARP IP address and receiving an ARP reply. For each reachable proxy ARP IP address, it generates a gratuitous ARP reply with the new router MAC address. This process is repeated for 5 minutes after a new active switch election.

Note

When a active switch is running the IP services feature set, the stack can run all supported protocols, including Open Shortest Path First (OSPF), and Enhanced IGRP (EIGRP) and Border Gateway Protocol (BGP). If the active switch fails and the new elected active switch is running the IP base or LAN base feature set, these protocols will no longer run in the stack.

Caution

Partitioning of the switch stack into two or more stacks might lead to undesirable behavior in the network.

If the switch is reloaded, then all the ports on that switch go down and there is a loss of traffic for the interfaces involved in routing, despite NSF/SSO capability.

**Classless Routing**

By default, classless routing behavior is enabled on the Device when it is configured to route. With classless routing, if a router receives packets for a subnet of a network with no default route, the router forwards the packet to the best supernet route. A supernet consists of contiguous blocks of Class C address spaces used to simulate a single, larger address space and is designed to relieve the pressure on the rapidly depleting Class B address space.

In the figure, classless routing is enabled. When the host sends a packet to 120.20.4.1, instead of discarding the packet, the router forwards it to the best supernet route. If you disable classless routing and a router receives packets destined for a subnet of a network with no network default route, the router discards the packet.
In the figure, the router in network 128.20.0.0 is connected to subnets 128.20.1.0, 128.20.2.0, and 128.20.3.0. If the host sends a packet to 120.20.4.1, because there is no network default route, the router discards the packet.

To prevent the Device from forwarding packets destined for unrecognized subnets to the best supernet route possible, you can disable classless routing behavior.

**Address Resolution**

You can control interface-specific handling of IP by using address resolution. A device using IP can have both a local address or MAC address, which uniquely defines the device on its local segment or LAN, and a network address, which identifies the network to which the device belongs.
In a switch stack, network communication uses a single MAC address and the IP address of the stack.

The local address or MAC address is known as a data link address because it is contained in the data link layer (Layer 2) section of the packet header and is read by data link (Layer 2) devices. To communicate with a device on Ethernet, the software must learn the MAC address of the device. The process of learning the MAC address from an IP address is called address resolution. The process of learning the IP address from the MAC address is called reverse address resolution.

The Device can use these forms of address resolution:

- Address Resolution Protocol (ARP) is used to associate IP address with MAC addresses. Taking an IP address as input, ARP learns the associated MAC address and then stores the IP address/MAC address association in an ARP cache for rapid retrieval. Then the IP datagram is encapsulated in a link-layer frame and sent over the network. Encapsulation of IP datagrams and ARP requests or replies on IEEE 802 networks other than Ethernet is specified by the Subnetwork Access Protocol (SNAP).

- Proxy ARP helps hosts with no routing tables learn the MAC addresses of hosts on other networks or subnets. If the Device (router) receives an ARP request for a host that is not on the same interface as the ARP request sender, and if the router has all of its routes to the host through other interfaces, it generates a proxy ARP packet giving its own local data link address. The host that sent the ARP request then sends its packets to the router, which forwards them to the intended host.

The Device also uses the Reverse Address Resolution Protocol (RARP), which functions the same as ARP does, except that the RARP packets request an IP address instead of a local MAC address. Using RARP requires a RARP server on the same network segment as the router interface. Use the `ip rarp-server address` interface configuration command to identify the server.

For more information on RARP, see the Cisco IOS Configuration Fundamentals Configuration Guide

**Proxy ARP**

Proxy ARP, the most common method for learning about other routes, enables an Ethernet host with no routing information to communicate with hosts on other networks or subnets. The host assumes that all hosts are on the same local Ethernet and that they can use ARP to learn their MAC addresses. If a Device receives an ARP request for a host that is not on the same network as the sender, the Device evaluates whether it has the best route to that host. If it does, it sends an ARP reply packet with its own Ethernet MAC address, and the host that sent the request sends the packet to the Device, which forwards it to the intended host. Proxy ARP treats all networks as if they are local and performs ARP requests for every IP address.

**ICMP Router Discovery Protocol**

Router discovery allows the Device to dynamically learn about routes to other networks using ICMP router discovery protocol (IRDP). IRDP allows hosts to locate routers. When operating as a client, the Device generates router discovery packets. When operating as a host, the Device receives router discovery packets. The Device can also listen to Routing Information Protocol (RIP) routing updates and use this information to infer locations of routers. The Device does not actually store the routing tables sent by routing devices; it merely keeps track of which systems are sending the data. The advantage of using IRDP is that it allows each router to specify both a priority and the time after which a device is assumed to be down if no further packets are received.
Each device discovered becomes a candidate for the default router, and a new highest-priority router is selected when a higher priority router is discovered, when the current default router is declared down, or when a TCP connection is about to time out because of excessive retransmissions.

**UDP Broadcast Packets and Protocols**

User Datagram Protocol (UDP) is an IP host-to-host layer protocol, as is TCP. UDP provides a low-overhead, connectionless session between two end systems and does not provide for acknowledgment of received datagrams. Network hosts occasionally use UDP broadcasts to find address, configuration, and name information. If such a host is on a network segment that does not include a server, UDP broadcasts are normally not forwarded. You can remedy this situation by configuring an interface on a router to forward certain classes of broadcasts to a helper address. You can use more than one helper address per interface.

You can specify a UDP destination port to control which UDP services are forwarded. You can specify multiple UDP protocols. You can also specify the Network Disk (ND) protocol, which is used by older diskless Sun workstations and the network security protocol SDNS.

By default, both UDP and ND forwarding are enabled if a helper address has been defined for an interface. The description for the `ip forward-protocol` interface configuration command in the *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services* lists the ports that are forwarded by default if you do not specify any UDP ports.

**Broadcast Packet Handling**

After configuring an IP interface address, you can enable routing and configure one or more routing protocols, or you can configure the way the Device responds to network broadcasts. A broadcast is a data packet destined for all hosts on a physical network. The Device supports two kinds of broadcasting:

- A directed broadcast packet is sent to a specific network or series of networks. A directed broadcast address includes the network or subnet fields.
- A flooded broadcast packet is sent to every network.

**Note**

You can also limit broadcast, unicast, and multicast traffic on Layer 2 interfaces by using the `storm-control` interface configuration command to set traffic suppression levels.

Routers provide some protection from broadcast storms by limiting their extent to the local cable. Bridges (including intelligent bridges), because they are Layer 2 devices, forward broadcasts to all network segments, thus propagating broadcast storms. The best solution to the broadcast storm problem is to use a single broadcast address scheme on a network. In most modern IP implementations, you can set the address to be used as the broadcast address. Many implementations, including the one in the Device, support several addressing schemes for forwarding broadcast messages.

**IP Broadcast Flooding**

You can allow IP broadcasts to be flooded throughout your internetwork in a controlled fashion by using the database created by the bridging STP. Using this feature also prevents loops. To support this capability, bridging must be configured on each interface that is to participate in the flooding. If bridging is not configured
on an interface, it still can receive broadcasts. However, the interface never forwards broadcasts it receives, and the router never uses that interface to send broadcasts received on a different interface.

Packets that are forwarded to a single network address using the IP helper-address mechanism can be flooded. Only one copy of the packet is sent on each network segment.

To be considered for flooding, packets must meet these criteria. (Note that these are the same conditions used to consider packet forwarding using IP helper addresses.)

- The packet must be a MAC-level broadcast.
- The packet must be an IP-level broadcast.
- The packet must be a TFTP, DNS, Time, NetBIOS, ND, or BOOTP packet, or a UDP specified by the `ip forward-protocol udp` global configuration command.
- The time-to-live (TTL) value of the packet must be at least two.

A flooded UDP datagram is given the destination address specified with the `ip broadcast-address` interface configuration command on the output interface. The destination address can be set to any address. Thus, the destination address might change as the datagram propagates through the network. The source address is never changed. The TTL value is decremented.

When a flooded UDP datagram is sent out an interface (and the destination address possibly changed), the datagram is handed to the normal IP output routines and is, therefore, subject to access lists, if they are present on the output interface.

In the Device, the majority of packets are forwarded in hardware; most packets do not go through the Device CPU. For those packets that do go to the CPU, you can speed up spanning tree-based UDP flooding by a factor of about four to five times by using turbo-flooding. This feature is supported over Ethernet interfaces configured for ARP encapsulation.

## How to Configure IP Routing

By default, IP routing is disabled on the Device, and you must enable it before routing can take place. For detailed IP routing configuration information, see the *Cisco IOS IP Configuration Guide*.

In the following procedures, the specified interface must be one of these Layer 3 interfaces:

- A routed port: a physical port configured as a Layer 3 port by using the `no switchport` interface configuration command.
- A switch virtual interface (SVI): a VLAN interface created by using the `interface vlan vlan_id` global configuration command and by default a Layer 3 interface.
- An EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the `interface port-channel port-channel-number` global configuration command and binding the Ethernet interface into the channel group. For more information, see the “Configuring Layer 3 EtherChannels” chapter in the Layer 2 Configuration Guide.

Note: The switch does not support tunnel interfaces for unicast routed traffic.

All Layer 3 interfaces on which routing will occur must have IP addresses assigned to them.
A Layer 3 switch can have an IP address assigned to each routed port and SVI.

The number of routed ports and SVIs that you can configure is limited to 128, exceeding the recommended number and volume of features being implemented might impact CPU utilization because of hardware limitations.

Configuring routing consists of several main procedures:

- To support VLAN interfaces, create and configure VLANs on the Device or switch stack, and assign VLAN membership to Layer 2 interfaces. For more information, see the “Configuring VLANs” chapter in the VLAN Configuration Guide.
- Configure Layer 3 interfaces.
- Enable IP routing on the switch.
- Assign IP addresses to the Layer 3 interfaces.
- Enable selected routing protocols on the switch.
- Configure routing protocol parameters (optional).

How to Configure IP Addressing

A required task for configuring IP routing is to assign IP addresses to Layer 3 network interfaces to enable the interfaces and allow communication with the hosts on those interfaces that use IP. The following sections describe how to configure various IP addressing features. Assigning IP addresses to the interface is required; the other procedures are optional.

- Default Addressing Configuration
- Assigning IP Addresses to Network Interfaces
- Configuring Address Resolution Methods
- Routing Assistance When IP Routing is Disabled
- Configuring Broadcast Packet Handling
- Monitoring and Maintaining IP Addressing

Default IP Addressing Configuration

Assigning IP Addresses to Network Interfaces

An IP address identifies a location to which IP packets can be sent. Some IP addresses are reserved for special uses and cannot be used for host, subnet, or network addresses. RFC 1166, “Internet Numbers,” contains the official description of IP addresses.

An interface can have one primary IP address. A mask identifies the bits that denote the network number in an IP address. When you use the mask to subnet a network, the mask is referred to as a subnet mask. To receive an assigned network number, contact your Internet service provider.

Procedure

<table>
<thead>
<tr>
<th>Step</th>

<td>Device(config-if)# no shutdown</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Using Subnet Zero

Subnetting with a subnet address of zero is strongly discouraged because of the problems that can arise if a network and a subnet have the same addresses. For example, if network 131.108.0.0 is subnetted as 255.255.255.0, subnet zero would be written as 131.108.0.0, which is the same as the network address.

You can use the all ones subnet (131.108.255.0) and even though it is discouraged, you can enable the use of subnet zero if you need the entire subnet space for your IP address.

Use the `no ip subnet-zero` global configuration command to restore the default and disable the use of subnet zero.

### Procedure

<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device# configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
Device# configure terminal
```
### Configuring Address Resolution Methods

You can perform the following tasks to configure address resolution.

#### Defining a Static ARP Cache

ARP and other address resolution protocols provide dynamic mapping between IP addresses and MAC addresses. Because most hosts support dynamic address resolution, you usually do not need to specify static ARP cache entries. If you must define a static ARP cache entry, you can do so globally, which installs a permanent entry in the ARP cache that the Device uses to translate IP addresses into MAC addresses. Optionally, you can also specify that the Device respond to ARP requests as if it were the owner of the specified IP address. If you do not want the ARP entry to be permanent, you can specify a timeout period for the ARP entry.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Defining a Static ARP Cache

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Device# configure terminal | associates an IP address with a MAC (hardware) address in the ARP cache, and specifies encapsulation type as one of these:  
  - **arpa**—ARP encapsulation for Ethernet interfaces  
  - **snap**—Subnetwork Address Protocol encapsulation for Token Ring and FDDI interfaces  
  - **sap**—HP’s ARP type |

**Step 3**

`arp ip-address hardware-address type`

**Example:**

Device(config)# ip 10.1.5.1 c2f3.220a.12f4 arpa

- **arpa**—ARP encapsulation for Ethernet interfaces
- **snap**—Subnetwork Address Protocol encapsulation for Token Ring and FDDI interfaces
- **sap**—HP’s ARP type

**Step 4**

`arp ip-address hardware-address type [alias]`

**Example:**

Device(config)# ip 10.1.5.3 d7f3.220d.12f5 arpa alias

(Optional) Specifies that the switch respond to ARP requests as if it were the owner of the specified IP address.

**Step 5**

`interface interface-id`

**Example:**

Device(config)# interface gigabitethernet 1/0/1

Enters interface configuration mode, and specifies the interface to configure.

**Step 6**

`arp timeout seconds`

**Example:**

Device(config-if)# arp 20000

(Optional) Sets the length of time an ARP cache entry will stay in the cache. The default is 14400 seconds (4 hours). The range is 0 to 2147483 seconds.

**Step 7**

`end`

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 8**

`show interfaces [interface-id]`

**Example:**

Device# show interfaces gigabitethernet 1/0/1

Verifies the type of ARP and the timeout value used on all interfaces or a specific interface.

**Step 9**

`show arp`

**Example:**

Device# show arp

Views the contents of the ARP cache.

**Step 10**

`show ip arp`

**Example:**

Views the contents of the ARP cache.
### Setting ARP Encapsulation

By default, Ethernet ARP encapsulation (represented by the `arpa` keyword) is enabled on an IP interface. You can change the encapsulation methods to SNAP if required by your network.

To disable an encapsulation type, use the `no arp arpa` or `no arp snap` interface configuration command.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode. Enter your password if prompted. Example:  
`Device>` `enable` |
| **Step 2** | `configure terminal` | Enters the global configuration mode.  
Example:  
`Device# configure terminal` |
| **Step 3** | `interface interface-id` | Enters interface configuration mode, and specifies the Layer 3 interface to configure.  
Example:  
`Device(config)# interface gigabitethernet 1/0/2` |
| **Step 4** | `arp {arpa | snap}` | Specifies the ARP encapsulation method:  
• `arpa`—Address Resolution Protocol  
• `snap`—Subnetwork Address Protocol  
Example:  
`Device(config-if)# arp arpa` |
| **Step 5** | `end` | Returns to privileged EXEC mode.  
Example:  
`Device(config)# end` |
Enabling Proxy ARP

By default, the Device uses proxy ARP to help hosts learn MAC addresses of hosts on other networks or subnets.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
Routing Assistance When IP Routing is Disabled

These mechanisms allow the Device to learn about routes to other networks when it does not have IP routing enabled:

- Proxy ARP
- Default Gateway
- ICMP Router Discovery Protocol (IRDP)

Proxy ARP

Proxy ARP is enabled by default. To enable it after it has been disabled, see the “Enabling Proxy ARP” section. Proxy ARP works as long as other routers support it.

Default Gateway

Another method for locating routes is to define a default router or default gateway. All non-local packets are sent to this router, which either routes them appropriately or sends an IP Control Message Protocol (ICMP) redirect message back, defining which local router the host should use. The Device caches the redirect messages and forwards each packet as efficiently as possible. A limitation of this method is that there is no means of detecting when the default router has gone down or is unavailable.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

## Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
</tr>
</tbody>
</table>

### Step 3

**Command or Action:**

```
Device(config)# ip default-gateway ip-address
```

**Example:**

```
Device(config)# ip default gateway 10.1.5.1
```

**Purpose:** Sets up a default gateway (router).

### Step 4

**Command or Action:**

```
Device(config)# end
```

**Example:**

```
Device(config)# end
```

**Purpose:** Returns to privileged EXEC mode.

### Step 5

**Command or Action:**

```
Device# show ip redirects
```

**Example:**

```
Device# show ip redirects
```

**Purpose:** Displays the address of the default gateway router to verify the setting.

### Step 6

**Command or Action:**

```
Device# copy running-config startup-config
```

**Example:**

```
Device# copy running-config startup-config
```

**Purpose:** (Optional) Saves your entries in the configuration file.

---

### ICMP Router Discovery Protocol (IRDP)

The only required task for IRDP routing on an interface is to enable IRDP processing on that interface. When enabled, the default parameters apply.

You can optionally change any of these parameters. If you change the `maxadvertinterval` value, the `holdtime` and `minadvertinterval` values also change, so it is important to first change the `maxadvertinterval` value, before manually changing either the `holdtime` or `minadvertinterval` values.

#### Procedure

<table>

Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
**Step 4** | **ip irdp**  
Example:  
Device(config-if)# ip irdp  
Enables IRDP processing on the interface. |
**Step 5** | **ip irdp multicast**  
Example:  
Device(config-if)# ip irdp multicast  
(Optional) Sends IRDP advertisements to the multicast address (224.0.0.1) instead of IP broadcasts.  
**Note**  
This command allows for compatibility with Sun Microsystems Solaris, which requires IRDP packets to be sent out as multicasts. Many implementations cannot receive these multicasts; ensure end-host ability before using this command. |
**Step 6** | **ip irdp holdtime** *seconds***  
Example:  
Device(config-if)# ip irdp holdtime 1000  
(Optional) Sets the IRDP period for which advertisements are valid. The default is three times the `maxadvertinterval` value. It must be greater than `maxadvertinterval` and cannot be greater than 9000 seconds. If you change the `maxadvertinterval` value, this value also changes. |
**Step 7** | **ip irdp maxadvertinterval** *seconds***  
Example:  
Device(config-if)# ip irdp maxadvertinterval 650  
(Optional) Sets the IRDP maximum interval between advertisements. The default is 600 seconds. |
**Step 8** | **ip irdp minadvertinterval** *seconds***  
Example:  
Device(config-if)# ip irdp minadvertinterval 500  
(Optional) Sets the IRDP minimum interval between advertisements. The default is 0.75 times the `maxadvertinterval`. If you change the `maxadvertinterval`, this value changes to the new default (0.75 of `maxadvertinterval`). |
**Step 9** | **ip irdp preference** *number***  
Example:  
Device(config-if)# ip irdp preference 2  
(Optional) Sets a device IRDP preference level. The allowed range is –231 to 231. The default is 0. A higher value increases the router preference level. |
**Step 10** | **ip irdp address** *address* [number]*  
Example:  
Device(config-if)# ip irdp address 10.1.10.10  
(Optional) Specifies an IRDP address and preference to proxy-advertise.
Configuring Broadcast Packet Handling

Perform the tasks in these sections to enable these schemes:

- Enabling Directed Broadcast-to-Physical Broadcast Translation
- Forwarding UDP Broadcast Packets and Protocols
- Establishing an IP Broadcast Address
- Flooding IP Broadcasts

Enabling Directed Broadcast-to-Physical Broadcast Translation

By default, IP directed broadcasts are dropped; they are not forwarded. Dropping IP-directed broadcasts makes routers less susceptible to denial-of-service attacks.

You can enable forwarding of IP-directed broadcasts on an interface where the broadcast becomes a physical (MAC-layer) broadcast. Only those protocols configured by using the `ip forward-protocol` global configuration command are forwarded.

You can specify an access list to control which broadcasts are forwarded. When an access list is specified, only those IP packets permitted by the access list are eligible to be translated from directed broadcasts to physical broadcasts. For more information on access lists, see the “Information about Network Security with ACLs” section in the Security Configuration Guide.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

VerifiessettingsbydisplayingIRDPvalues.

Example:

Step 12 show ip irdp

Example:

Device# show ip irdp

(Optional) Saves your entries in the configuration file.

Example:

Step 13 copy running-config startup-config

Example:

Device# copy running-config startup-config
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; <code>enable</code></td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>

**Step 2**
configure terminal

**Example:**
Device# `configure terminal`

**Step 3**
`interface interface-id`

**Example:**
Device(config)# `interface gigabitethernet 1/0/2`

**Step 4**
`ip directed-broadcast [access-list-number]`

**Example:**
Device(config-if)# `ip directed-broadcast 103`

<table>
<thead>
<tr>
<th>Note</th>
<th>Enables directed broadcast-to-physical broadcast translation on the interface. You can include an access list to control which broadcasts are forwarded. When an access list, only IP packets permitted by the access list can be translated. The <code>ip directed-broadcast</code> interface configuration command can be configured on a VPN routing/forwarding (VRF) interface and is VRF aware. Directed broadcast traffic is routed only within the VRF.</th>
</tr>
</thead>
</table>

**Step 5**
`exit`

**Example:**
Device(config-if)# `exit`

**Step 6**
`ip forward-protocol {udp [port] | nd | sdns}`

**Example:**
Device(config)# `ip forward-protocol nd`

<table>
<thead>
<tr>
<th>Specifies which protocols and ports the router forwards when forwarding broadcast packets.</th>
</tr>
</thead>
<tbody>
<tr>
<td>- <code>udp</code>—Forward UDP datagrams.</td>
</tr>
<tr>
<td>- <code>nd</code>—Forward ND datagrams.</td>
</tr>
<tr>
<td>- <code>sdns</code>—Forward SDNS datagrams.</td>
</tr>
</tbody>
</table>

**Step 7**
`end`

**Example:**
Device(config)# `end`

| Returns to privileged EXEC mode. | --- |
|---|

**Forwarding UDP Broadcast Packets and Protocols**

If you do not specify any UDP ports when you configure the forwarding of UDP broadcasts, you are configuring the router to act as a BOOTP forwarding agent. BOOTP packets carry DHCP information.

### Procedure

<table>
<thead>
<tr>

</tbody>
</table>

**Establishing an IP Broadcast Address**

The most popular IP broadcast address (and the default) is an address consisting of all ones (255.255.255.255). However, the Device can be configured to generate any form of IP broadcast address.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action** | **Purpose**
---|---
**Step 2** configure terminal | Enters the global configuration mode.
Example: Device# configure terminal

**Step 3** interface interface-id | Enters interface configuration mode, and specifies the interface to configure.
Example: Device(config)# interface gigabitethernet 1/0/1

**Step 4** ip broadcast-address ip-address | Enters a broadcast address different from the default, for example 128.1.255.255.
Example: Device(config-if)# ip broadcast-address 128.1.255.255

**Step 5** end | Returns to privileged EXEC mode.
Example: Device(config)# end

**Step 6** show ip interface [interface-id] | Verifies the broadcast address on the interface or all interfaces.
Example: Device# show ip interface

**Step 7** copy running-config startup-config | (Optional) Saves your entries in the configuration file.
Example: Device# copy running-config startup-config

---

### Flooding IP Broadcasts

#### Procedure

**Command or Action** | **Purpose**
---|---
**Step 1** enable | Enables privileged EXEC mode. Enter your password if prompted.
Example: Device> enable

**Step 2** configure terminal | Enters the global configuration mode.
Example:
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip forward-protocol spanning-tree</td>
<td>Uses the bridging spanning-tree database to flood UDP datagrams.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip forward-protocol spanning-tree</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> ip forward-protocol turbo-flood</td>
<td>Uses the spanning-tree database to speed up flooding of UDP datagrams.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip forward-protocol turbo-flood</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
</tbody>
</table>
Monitoring and Maintaining IP Addressing

When the contents of a particular cache, table, or database have become or are suspected to be invalid, you can remove all its contents by using the `clear` privileged EXEC commands. The Table lists the commands for clearing contents.

**Table 102: Commands to Clear Caches, Tables, and Databases**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear arp-cache</td>
<td>Clears the IP ARP cache and the fast-switching cache.</td>
</tr>
<tr>
<td>clear host {name</td>
<td>Removes one or all entries from the hostname and the address cache.</td>
</tr>
<tr>
<td>*}</td>
<td></td>
</tr>
<tr>
<td>clear ip route {network [mask]</td>
<td>Removes one or more routes from the IP routing table.</td>
</tr>
<tr>
<td>*}</td>
<td></td>
</tr>
</tbody>
</table>

You can display specific statistics, such as the contents of IP routing tables, caches, and databases; the reachability of nodes; and the routing path that packets are taking through the network. The Table lists the privileged EXEC commands for displaying IP statistics.

**Table 103: Commands to Display Caches, Tables, and Databases**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show arp</td>
<td>Displays the entries in the ARP table.</td>
</tr>
<tr>
<td>show hosts</td>
<td>Displays the default domain name, style of lookup service, name server hosts, and the cached list of hostnames and addresses.</td>
</tr>
<tr>
<td>show ip aliases</td>
<td>Displays IP addresses mapped to TCP ports (aliases).</td>
</tr>
<tr>
<td>show ip arp</td>
<td>Displays the IP ARP cache.</td>
</tr>
<tr>
<td>show ip interface [interface-id]</td>
<td>Displays the IP status of interfaces.</td>
</tr>
<tr>
<td>show ip irdp</td>
<td>Displays IRDP values.</td>
</tr>
<tr>
<td>show ip masks address</td>
<td>Displays the masks used for network addresses and the number of subnets using each mask.</td>
</tr>
<tr>
<td>show ip redirects</td>
<td>Displays the address of a default gateway.</td>
</tr>
<tr>
<td>show ip route [address [mask]]</td>
<td>Displays the current state of the routing table.</td>
</tr>
</tbody>
</table>

Step 11

**copy running-config startup-config**

Example:

```plaintext
Device# copy running-config startup-config
```
How to Configure IP Unicast Routing

Enabling IP Unicast Routing

By default, the Device is in Layer 2 switching mode and IP routing is disabled. To use the Layer 3 capabilities of the Device, you must enable IP routing.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip routing</td>
<td>Enables IP routing.</td>
</tr>
<tr>
<td>Example: Device(config)# ip routing</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example: Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

show ip route summary

Displays the current state of the routing table in summary form.
### Example of Enabling IP Routing

This example shows how to enable IP routing using RIP as the routing protocol:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# ip routing
Device(config)# router rip
Device(config-router)# network 10.0.0.0
Device(config-router)# end
```

### What to Do Next

You can now set up parameters for the selected routing protocols as described in these sections:

- RIP
- OSPF
- EIGRP
- BGP
- Unicast Reverse Path Forwarding
- Protocol-Independent Features (optional)

### Information About RIP

The Routing Information Protocol (RIP) is an interior gateway protocol (IGP) created for use in small, homogeneous networks. It is a distance-vector routing protocol that uses broadcast User Datagram Protocol (UDP) data packets to exchange routing information. The protocol is documented in RFC 1058. You can find detailed information about RIP in *IP Routing Fundamentals*, published by Cisco Press.

**Note**

RIP is supported in the IP Base.

Using RIP, the Device sends routing information updates (advertisements) every 30 seconds. If a router does not receive an update from another router for 180 seconds or more, it marks the routes served by that router as unusable. If there is still no update after 240 seconds, the router removes all routing table entries for the non-updating router.

RIP uses hop counts to rate the value of different routes. The hop count is the number of routers that can be traversed in a route. A directly connected network has a hop count of zero; a network with a hop count of 16 is unreachable. This small range (0 to 15) makes RIP unsuitable for large networks.
If the router has a default network path, RIP advertises a route that links the router to the pseudonetwork 0.0.0.0. The 0.0.0.0 network does not exist; it is treated by RIP as a network to implement the default routing feature. The Device advertises the default network if a default was learned by RIP or if the router has a gateway of last resort and RIP is configured with a default metric. RIP sends updates to the interfaces in specified networks. If an interface’s network is not specified, it is not advertised in any RIP update.

**Summary Addresses and Split Horizon**

Routers connected to broadcast-type IP networks and using distance-vector routing protocols normally use the split-horizon mechanism to reduce the possibility of routing loops. Split horizon blocks information about routes from being advertised by a router on any interface from which that information originated. This feature usually optimizes communication among multiple routers, especially when links are broken.

**How to Configure RIP**

**Default RIP Configuration**

<table>
<thead>
<tr>
<th>Feature</th>

<td></td>
<td>• Hold-down: 180 seconds.</td>
</tr>
<tr>
<td></td>
<td>• Flush: 240 seconds.</td>
</tr>
</tbody>
</table>
## Configuring Basic RIP Parameters

To configure RIP, you enable RIP routing for a network and optionally configure other parameters. On the Device, RIP configuration commands are ignored until you configure the network number.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable&lt;br&gt;Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal&lt;br&gt;Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>ip routing</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ip routing&lt;br&gt;Enables IP routing. (Required only if IP routing is disabled.)</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>router rip</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# router rip&lt;br&gt;Enables a RIP routing process, and enter router configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>network network-number</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# network 12&lt;br&gt;Associates a network with a RIP routing process. You can specify multiple network commands. RIP routing updates are sent and received through interfaces only on these networks.&lt;br&gt;<strong>Note</strong> You must configure a network number for the RIP commands to take effect.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>neighbor ip-address</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# neighbor 10.2.5.1&lt;br&gt;(Optional) Defines a neighboring router with which to exchange routing information. This step allows routing updates from RIP (normally a broadcast protocol) to reach nonbroadcast networks.</td>
</tr>
</tbody>
</table>
### Configuring Basic RIP Parameters

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 7</strong></td>
<td>(Optional) Applies an offset list to routing metrics to increase incoming and outgoing metrics to routes learned through RIP. You can limit the offset list with an access list or an interface.</td>
</tr>
<tr>
<td>offset-list [access-list number</td>
<td>name] [in</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# offset-list 103 in 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>(Optional) Adjusts routing protocol timers. Valid ranges for all timers are 0 to 4294967295 seconds.</td>
</tr>
<tr>
<td>timers basic update invalid holddown flush</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# timers basic 45 360 400 300</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>(Optional) Configures the switch to receive and send only RIP Version 1 or RIP Version 2 packets. By default, the switch receives Version 1 and 2 but sends only Version 1. You can also use the interface commands ip rip {send</td>
</tr>
<tr>
<td>version {1</td>
<td>2}</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# version 2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>(Optional) Disables automatic summarization. By default, the switch summarizes subprefixes when crossing classful network boundaries. Disable summarization (RIP Version 2 only) to advertise subnet and host routing information to classful network boundaries.</td>
</tr>
<tr>
<td>no auto summary</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# no auto summary</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>(Optional) Disables validation of the source IP address of incoming RIP routing updates. By default, the switch validates the source IP address of incoming RIP routing updates and discards the update if the source address is not valid. Under normal circumstances, disabling this feature is not recommended. However, if you have a router that is off-network and you want to receive its updates, you can use this command.</td>
</tr>
<tr>
<td>no validate-update-source</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# no validate-update-source</td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong></td>
<td>(Optional) Adds interpacket delay for RIP updates sent. By default, packets in a multiple-packet RIP update have no delay added between packets. If you are sending packets to a lower-speed device, you can add an interpacket delay in the range of 8 to 50 milliseconds.</td>
</tr>
<tr>
<td>output-delay delay</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# output-delay 8</td>
<td></td>
</tr>
<tr>
<td><strong>Step 13</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring RIP Authentication

RIP Version 1 does not support authentication. If you are sending and receiving RIP Version 2 packets, you can enable RIP authentication on an interface. The key chain specifies the set of keys that can be used on the interface. If a key chain is not configured, no authentication is performed, not even the default.

The Device supports two modes of authentication on interfaces for which RIP authentication is enabled: plain text and MD5. The default is plain text.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>interface interface-id</td>
<td>Enters interface configuration mode, and specifies the interface to configure.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>ip rip authentication key-chain name-of-chain</td>
<td>Enables RIP authentication.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Summary Addresses and Split Horizon

**Purpose**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-if)# ip rip authentication key-chain trees</td>
<td>Configures the interface to use plain text authentication (the default) or MD5 digest authentication.</td>
</tr>
<tr>
<td>Step 5 ip rip authentication mode {text</td>
<td>md5}</td>
</tr>
<tr>
<td>Example: Device(config-if)# ip rip authentication mode md5</td>
<td></td>
</tr>
<tr>
<td>Step 6 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>Step 7 show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example: Device# show running-config</td>
<td></td>
</tr>
<tr>
<td>Step 8 copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example: Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring Summary Addresses and Split Horizon

**Note**

In general, disabling split horizon is not recommended unless you are certain that your application requires it to properly advertise routes.

If you want to configure an interface running RIP to advertise a summarized local IP address pool on a network access server for dial-up clients, use the **ip summary-address rip** interface configuration command.

**Note**

If split horizon is enabled, neither autosummary nor interface IP summary addresses are advertised.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>
| **Step 2** configure terminal  
Example:  
`Device# configure terminal` | Enters the global configuration mode. |
| **Step 3** `interface interface-id`  
Example:  
`Device(config)# interface gigabitethernet 1/0/1` | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| **Step 4** `ip address ip-address subnet-mask`  
Example:  
`Device(config-if)# ip address 10.1.1.10 255.255.255.0` | Configures the IP address and IP subnet. |
| **Step 5** `ip summary-address rip ip address ip-network mask`  
Example:  
`Device(config-if)# ip summary-address rip ip address 10.1.1.30 255.255.255.0` | Configures the IP address to be summarized and the IP network mask. |
| **Step 6** `no ip split horizon`  
Example:  
`Device(config-if)# no ip split horizon` | Disables split horizon on the interface. |
| **Step 7** `end`  
Example:  
`Device(config)# end` | Returns to privileged EXEC mode. |
| **Step 8** `show ip interface interface-id`  
Example:  
`Device# show ip interface gigabitethernet 1/0/1` | Verifies your entries. |
| **Step 9** `copy running-config startup-config`  
Example:  
`Device# copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
Configuring Split Horizon

Routers connected to broadcast-type IP networks and using distance-vector routing protocols normally use the split-horizon mechanism to reduce the possibility of routing loops. Split horizon blocks information about routes from being advertised by a router on any interface from which that information originated. This feature can optimize communication among multiple routers, especially when links are broken.

Note

In general, we do not recommend disabling split horizon unless you are certain that your application requires it to properly advertise routes.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  enable                                    | Enables privileged EXEC mode. Enter your password if prompted.          |
  Example:
  Device> enable                             |                                                                         |

| **Step 2**
  configure terminal                         | Enters the global configuration mode.                                   |
  Example:
  Device# configure terminal                 |                                                                         |

| **Step 3**
  interface interface-id                    | Enters interface configuration mode, and specifies the interface to configure. |
  Example:
  Device(config)# interface gigabitethernet 1/0/1 |

| **Step 4**
  ip address ip-address subnet-mask         | Configures the IP address and IP subnet.                               |
  Example:
  Device(config-if)# ip address 10.1.1.10 255.255.255.0 |

| **Step 5**
  no ip split-horizon                       | Disables split horizon on the interface.                               |
  Example:
  Device(config-if)# no ip split-horizon    |

| **Step 6**
  end                                        | Returns to privileged EXEC mode.                                        |
  Example:
  Device(config)# end                        |
<table>

### Configuration Example for Summary Addresses and Split Horizon

In this example, the major net is 10.0.0.0. The summary address 10.2.0.0 overrides the autosummary address of 10.0.0.0 so that 10.2.0.0 is advertised out interface Gigabit Ethernet port 2, and 10.0.0.0 is not advertised. In the example, if the interface is still in Layer 2 mode (the default), you must enter a **no switchport** interface configuration command before entering the **ip address** interface configuration command.

---

**Note**

If split horizon is enabled, neither autosummary nor interface summary addresses (those configured with the **ip summary-address rip** router configuration command) are advertised.

```plaintext
Device(config)# router rip
Device(config-router)# interface gigabitethernet1/0/2
Device(config-if)# ip address 10.1.5.1 255.255.255.0
Device(config-if)# ip summary-address rip 10.2.0.0 255.255.0.0
Device(config-if)# no ip split-horizon
Device(config-if)# exit
Device(config)# router rip
Device(config-router)# network 10.0.0.0
Device(config-router)# neighbor 2.2.2.2 peer-group mygroup
Device(config-router)# end
```

### Information About OSPF

OSPF is an Interior Gateway Protocol (IGP) designed expressly for IP networks, supporting IP subnetting and tagging of externally derived routing information. OSPF also allows packet authentication and uses IP multicast when sending and receiving packets. The Cisco implementation supports RFC 1253, OSPF management information base (MIB).

---

**Note**

OSPF is supported in IP Base.

The Cisco implementation conforms to the OSPF Version 2 specifications with these key features:
• Definition of stub areas is supported.

• Routes learned through any IP routing protocol can be redistributed into another IP routing protocol. At
the intradomain level, this means that OSPF can import routes learned through EIGRP and RIP. OSPF
routes can also be exported into RIP.

• Plain text and MD5 authentication among neighboring routers within an area is supported.

• Configurable routing interface parameters include interface output cost, retransmission interval, interface
transmit delay, router priority, router dead and hello intervals, and authentication key.

• Virtual links are supported.

• Not-so-stubby-areas (NSSAs) per RFC 1587 are supported.

OSPF typically requires coordination among many internal routers, area border routers (ABRs) connected to
multiple areas, and autonomous system boundary routers (ASBRs). The minimum configuration would use
all default parameter values, no authentication, and interfaces assigned to areas. If you customize your
environment, you must ensure coordinated configuration of all routers.

**OSPF Nonstop Forwarding**

The Device or switch stack supports two levels of nonstop forwarding (NSF):

- OSPF NSF Awareness, on page 1375
- OSPF NSF Capability, on page 1375

**OSPF NSF Awareness**

The IP-services feature set supports OSPF NSF Awareness supported for IPv4. When the neighboring router
is NSF-capable, the Layer 3 Device continues to forward packets from the neighboring router during the
interval between the primary Route Processor (RP) in a router crashing and the backup RP taking over, or
while the primary RP is manually reloaded for a non-disruptive software upgrade.

This feature cannot be disabled.

**OSPF NSF Capability**

The IP services feature set supports the OSPFv2 NSF IETF format in addition to the OSPFv2 NSF Cisco
format that is supported in earlier releases. For information about this feature, see: NSF—OSPF (RFC 3623
OSPF Graceful Restart).

The IP-services feature set also supports OSPF NSF-capable routing for IPv4 for better convergence and
lower traffic loss following a stack master change. When a stack master change occurs in an OSPF NSF-capable
stack, the new stack master must do two things to resynchronize its link-state database with its OSPF neighbors:

- Release the available OSPF neighbors on the network without resetting the neighbor relationship.
- Reacquire the contents of the link-state database for the network.

After a stack master change, the new master sends an OSPF NSF signal to neighboring NSF-aware devices.
A device recognizes this signal to mean that it should not reset the neighbor relationship with the stack. As
the NSF-capable stack master receives signals from other routes on the network, it begins to rebuild its neighbor
list.
When the neighbor relationships are reestablished, the NSF-capable stack master resynchronizes its database with its NSF-aware neighbors, and routing information is exchanged between the OSPF neighbors. The new stack master uses this routing information to remove stale routes, to update the routing information database (RIB), and to update the forwarding information base (FIB) with the new information. The OSPF protocols then fully converge.

**Note**

OSPF NSF requires that all neighbor networking devices be NSF-aware. If an NSF-capable router discovers non-NSF aware neighbors on a network segment, it disables NSF capabilities for that segment. Other network segments where all devices are NSF-aware or NSF-capable continue to provide NSF capabilities.

Use the `nsf` OSPF routing configuration command to enable OSPF NSF routing. Use the `show ip ospf` privileged EXEC command to verify that it is enabled.

For more information, see *Cisco Nonstop Forwarding:*

**OSPF Area Parameters**

You can optionally configure several OSPF area parameters. These parameters include authentication for password-based protection against unauthorized access to an area, stub areas, and not-so-stubby-areas (NSSAs). Stub areas are areas into which information on external routes is not sent. Instead, the area border router (ABR) generates a default external route into the stub area for destinations outside the autonomous system (AS). An NSSA does not flood all LSAs from the core into the area, but can import AS external routes within the area by redistribution.

Route summarization is the consolidation of advertised addresses into a single summary route to be advertised by other areas. If network numbers are contiguous, you can use the `area range` router configuration command to configure the ABR to advertise a summary route that covers all networks in the range.

**Other OSPF Parameters**

You can optionally configure other OSPF parameters in router configuration mode.

- **Route summarization:** When redistributing routes from other protocols. Each route is advertised individually in an external LSA. To help decrease the size of the OSPF link state database, you can use the `summary-address` router configuration command to advertise a single router for all the redistributed routes included in a specified network address and mask.

- **Virtual links:** In OSPF, all areas must be connected to a backbone area. You can establish a virtual link in case of a backbone-continuity break by configuring two Area Border Routers as endpoints of a virtual link. Configuration information includes the identity of the other virtual endpoint (the other ABR) and the nonbackbone link that the two routers have in common (the transit area). Virtual links cannot be configured through a stub area.

- **Default route:** When you specifically configure redistribution of routes into an OSPF routing domain, the route automatically becomes an autonomous system boundary router (ASBR). You can force the ASBR to generate a default route into the OSPF routing domain.

- **Domain Name Server (DNS) names for use in all OSPF `show` privileged EXEC command displays makes it easier to identify a router than displaying it by router ID or neighbor ID.
• Default Metrics: OSPF calculates the OSPF metric for an interface according to the bandwidth of the interface. The metric is calculated as $\text{ref-bw}$ divided by bandwidth, where $\text{ref}$ is 10 by default, and bandwidth ($\text{bw}$) is specified by the `bandwidth` interface configuration command. For multiple links with high bandwidth, you can specify a larger number to differentiate the cost on those links.

• Administrative distance is a rating of the trustworthiness of a routing information source, an integer between 0 and 255, with a higher value meaning a lower trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored. OSPF uses three different administrative distances: routes within an area (interarea), routes to another area (interarea), and routes from another routing domain learned through redistribution (external). You can change any of the distance values.

• Passive interfaces: Because interfaces between two devices on an Ethernet represent only one network segment, to prevent OSPF from sending hello packets for the sending interface, you must configure the sending device to be a passive interface. Both devices can identify each other through the hello packet for the receiving interface.

• Route calculation timers: You can configure the delay time between when OSPF receives a topology change and when it starts the shortest path first (SPF) calculation and the hold time between two SPF calculations.

• Log neighbor changes: You can configure the router to send a syslog message when an OSPF neighbor state changes, providing a high-level view of changes in the router.

**LSA Group Pacing**

The OSPF LSA group pacing feature allows the router to group OSPF LSAs and pace the refreshing, check-summing, and aging functions for more efficient router use. This feature is enabled by default with a 4-minute default pacing interval, and you will not usually need to modify this parameter. The optimum group pacing interval is inversely proportional to the number of LSAs the router is refreshing, check-summing, and aging. For example, if you have approximately 10,000 LSAs in the database, decreasing the pacing interval would benefit you. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might benefit you slightly.

**Loopback Interfaces**

OSPF uses the highest IP address configured on the interfaces as its router ID. If this interface is down or removed, the OSPF process must recalculate a new router ID and resend all its routing information out its interfaces. If a loopback interface is configured with an IP address, OSPF uses this IP address as its router ID, even if other interfaces have higher IP addresses. Because loopback interfaces never fail, this provides greater stability. OSPF automatically prefers a loopback interface over other interfaces, and it chooses the highest IP address among all loopback interfaces.

### Configuring Basic OSPF Parameters

To enable OSPF, create an OSPF routing process, specify the range of IP addresses to associate with the routing process, and assign area IDs to be associated with that range. For switches running the IP services image, you can configure either the Cisco OSPFv2 NSF format or the IETF OSPFv2 NSF format.

#### Procedure

<table>

</tbody>
</table>
## Configuring OSPF Interfaces

You can use the `ip ospf` interface configuration commands to modify interface-specific OSPF parameters. You are not required to modify any of these parameters, but some interface parameters (hello interval, dead interval, and authentication key) must be consistent across all routers in an attached network. If you modify these parameters, be sure all routers in the network have compatible values.

The `ip ospf` interface configuration commands are all optional.

### Procedure

<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip ospf [process-id]</code></td>
<td>Displays general information about OSPF routing processes.</td>
</tr>
</tbody>
</table>
Configuration Examples for OSPF

Example: Configuring Basic OSPF Parameters

This example shows how to configure an OSPF routing process and assign it a process number of 109:

```
Device(config)# router ospf 109
Device(config-router)# network 131.108.0.0 255.255.255.0 area 24
```

Information About EIGRP

Enhanced IGRP (EIGRP) is a Cisco proprietary enhanced version of the IGRP. EIGRP uses the same distance vector algorithm and distance information as IGRP; however, the convergence properties and the operating efficiency of EIGRP are significantly improved.

The convergence technology employs an algorithm referred to as the Diffusing Update Algorithm (DUAL), which guarantees loop-free operation at every instant throughout a route computation and allows all devices...
involved in a topology change to synchronize at the same time. Routers that are not affected by topology changes are not involved in recomputations.

IP EIGRP provides increased network width. With RIP, the largest possible width of your network is 15 hops. Because the EIGRP metric is large enough to support thousands of hops, the only barrier to expanding the network is the transport-layer hop counter. EIGRP increments the transport control field only when an IP packet has traversed 15 routers and the next hop to the destination was learned through EIGRP. When a RIP route is used as the next hop to the destination, the transport control field is incremented as usual.

**EIGRP Features**

EIGRP offers these features:

- Fast convergence.
- Incremental updates when the state of a destination changes, instead of sending the entire contents of the routing table, minimizing the bandwidth required for EIGRP packets.
- Less CPU usage because full update packets need not be processed each time they are received.
- Protocol-independent neighbor discovery mechanism to learn about neighboring routers.
- Variable-length subnet masks (VLSMs).
- Arbitrary route summarization.
- EIGRP scales to large networks.

**EIGRP Components**

EIGRP has these four basic components:

- Neighbor discovery and recovery is the process that routers use to dynamically learn of other routers on their directly attached networks. Routers must also discover when their neighbors become unreachable or inoperative. Neighbor discovery and recovery is achieved with low overhead by periodically sending small hello packets. As long as hello packets are received, the Cisco IOS software can learn that a neighbor is alive and functioning. When this status is determined, the neighboring routers can exchange routing information.

- The reliable transport protocol is responsible for guaranteed, ordered delivery of EIGRP packets to all neighbors. It supports intermixed transmission of multicast and unicast packets. Some EIGRP packets must be sent reliably, and others need not be. For efficiency, reliability is provided only when necessary. For example, on a multiaccess network that has multicast capabilities (such as Ethernet), it is not necessary to send hellos reliably to all neighbors individually. Therefore, EIGRP sends a single multicast hello with an indication in the packet informing the receivers that the packet need not be acknowledged. Other types of packets (such as updates) require acknowledgment, which is shown in the packet. The reliable transport has a provision to send multicast packets quickly when there are unacknowledged packets pending. Doing so helps ensure that convergence time remains low in the presence of varying speed links.

- The DUAL finite state machine embodies the decision process for all route computations. It tracks all routes advertised by all neighbors. DUAL uses the distance information (known as a metric) to select efficient, loop-free paths. DUAL selects routes to be inserted into a routing table based on feasible successors. A successor is a neighboring router used for packet forwarding that has a least-cost path to
a destination that is guaranteed not to be part of a routing loop. When there are no feasible successors, but there are neighbors advertising the destination, a recomputation must occur. This is the process whereby a new successor is determined. The amount of time it takes to recompute the route affects the convergence time. Recomputation is processor-intensive; it is advantageous to avoid recomputation if it is not necessary. When a topology change occurs, DUAL tests for feasible successors. If there are feasible successors, it uses any it finds to avoid unnecessary recomputation.

• The protocol-dependent modules are responsible for network layer protocol-specific tasks. An example is the IP EIGRP module, which is responsible for sending and receiving EIGRP packets that are encapsulated in IP. It is also responsible for parsing EIGRP packets and informing DUAL of the new information received. EIGRP asks DUAL to make routing decisions, but the results are stored in the IP routing table. EIGRP is also responsible for redistributing routes learned by other IP routing protocols.

Note
To enable EIGRP, the Device or stack master must be running the IP services feature set.

EIGRP Nonstop Forwarding

The Device stack supports two levels of EIGRP nonstop forwarding:

• EIGRP NSF Awareness

• EIGRP NSF Capability

EIGRP NSF Awareness

The IP-services feature set supports EIGRP NSF Awareness for IPv4. When the neighboring router is NSF-capable, the Layer 3 Device continues to forward packets from the neighboring router during the interval between the primary Route Processor (RP) in a router failing and the backup RP taking over, or while the primary RP is manually reloaded for a nondisruptive software upgrade.

This feature cannot be disabled. For more information on this feature, see the “EIGRP Nonstop Forwarding (NSF) Awareness” section of the Cisco IOS IP Routing Protocols Configuration Guide, Release 12.4.

EIGRP NSF Capability

The IP services feature set supports EIGRP Cisco NSF routing to speed up convergence and to eliminate traffic loss after a stack master change. For details about this NSF capability, see the “Configuring Nonstop Forwarding” chapter in the High Availability Configuration Guide, Cisco IOS XE Release 3S.

The IP-services feature set also supports EIGRP NSF-capable routing for IPv4 for better convergence and lower traffic loss following a stack master change. When an EIGRP NSF-capable stack master restarts or a new stack master starts up and NSF restarts, the Device has no neighbors, and the topology table is empty. The Device must bring up the interfaces, reacquire neighbors, and rebuild the topology and routing tables without interrupting the traffic directed toward the Device stack. EIGRP peer routers maintain the routes learned from the new stack master and continue forwarding traffic through the NSF restart process.

To prevent an adjacency reset by the neighbors, the new stack master uses a new Restart (RS) bit in the EIGRP packet header to show the restart. When the neighbor receives this, it synchronizes the stack in its peer list
and maintains the adjacency with the stack. The neighbor then sends its topology table to the stack master with the RS bit set to show that it is NSF-aware and is aiding the new stack master.

If at least one of the stack peer neighbors is NSF-aware, the stack master receives updates and rebuilds its database. Each NSF-aware neighbor sends an end of table (EOT) marker in the last update packet to mark the end of the table content. The stack master recognizes the convergence when it receives the EOT marker, and it then begins sending updates. When the stack master has received all EOT markers from its neighbors or when the NSF converge timer expires, EIGRP notifies the routing information database (RIB) of convergence and floods its topology table to all NSF-aware peers.

**EIGRP Stub Routing**

The EIGRP stub routing feature, available in all feature sets, reduces resource utilization by moving routed traffic closer to the end user.

---

**Note**

The IP Base feature set contains EIGRP stub routing capability, which only advertises connected or summary routes from the routing tables to other Devices in the network. The Device uses EIGRP stub routing at the access layer to eliminate the need for other types of routing advertisements. For enhanced capability and complete EIGRP routing, the Device must be running the IP Base feature set. On a Device running the IP base feature set, if you try to configure multi-VRF-CE and EIGRP stub routing at the same time, the configuration is not allowed. IPv6 EIGRP stub routing is not supported with the IP base feature set.

In a network using EIGRP stub routing, the only allowable route for IP traffic to the user is through a Device that is configured with EIGRP stub routing. The Device sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRP stub routing, you need to configure the distribution and remote routers to use EIGRP and to configure only the Device as a stub. Only specified routes are propagated from the Device. The Device responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In the figure given below, Device B is configured as an EIGRP stub router. Devices A and C are connected to the rest of the WAN. Device B advertises connected, static, redistribution, and summary routes to Device A and C. Device B does not advertise any routes learned from Device A (and the reverse).
How to Configure EIGRP

To create an EIGRP routing process, you must enable EIGRP and associate networks. EIGRP sends updates to the interfaces in the specified networks. If you do not specify an interface network, it is not advertised in any EIGRP update.

**Note**

If you have routers on your network that are configured for IGRP, and you want to change to EIGRP, you must designate transition routers that have both IGRP and EIGRP configured. In these cases, perform Steps 1 through 3 in the next section and also see the “Configuring Split Horizon” section. You must use the same AS number for routes to be automatically redistributed.

## Default EIGRP Configuration

### Configuring Basic EIGRP Parameters

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| **Step 2**
router eigrp autonomous-system  
Example:  
Device(config)# router eigrp 10 | Enables an EIGRP routing process, and enter router configuration mode. The AS number identifies the routes to other EIGRP routers and is used to tag routing information. |
| **Step 3**
nsf  
Example:  
Device(config)# nsf | (Optional) Enables EIGRP NSF. Enter this command on the stack master and on all of its peers. |
| **Step 4**
network network-number  
Example:  
Device(config)# network 192.168.0.0 | Associate networks with an EIGRP routing process. EIGRP sends updates to the interfaces in the specified networks. |
| **Step 5**
eigrp log-neighbor-changes  
Example:  
Device(config)# eigrp log-neighbor-changes | (Optional) Enables logging of EIGRP neighbor changes to monitor routing system stability. |
| **Step 6**
metric weights tos k1 k2 k3 k4 k5  
Example:  
Device(config)# metric weights 0 2 0 2 0 0 | (Optional) Adjust the EIGRP metric. Although the defaults have been carefully set to provide excellent operation in most networks, you can adjust them. |

#### Default Setting

</table>
| 6    | `ip hold-time eigrp autonomous-system-number seconds` | (Optional) Change the hold time interval for an EIGRP routing process. The range is 1 to 65535 seconds. The default is 180 seconds for low-speed NBMA networks and 15 seconds for all other networks.  
**Caution** Do not adjust the hold time without consulting Cisco technical support. |
|      | **Example:** `Device(config-if)# ip hold-time eigrp 109 40` | |
| 7    | `no ip split-horizon eigrp autonomous-system-number` | (Optional) Disables split horizon to allow route information to be advertised by a router out any interface from which that information originated. |
|      | **Example:** `Device(config-if)# no ip split-horizon eigrp 109` | |
| 8    | `end` | Returns to privileged EXEC mode. |
|      | **Example:** | |
### Configuring EIGRP Route Authentication

EIGRP route authentication provides MD5 authentication of routing updates from the EIGRP routing protocol to prevent the introduction of unauthorized or false routing messages from unapproved sources.

**Procedure**

### Monitoring and Maintaining EIGRP

You can delete neighbors from the neighbor table. You can also display various EIGRP routing statistics. The table given below lists the privileged EXEC commands for deleting neighbors and displaying statistics. For explanations of fields in the resulting display, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

### Information About BGP

The Border Gateway Protocol (BGP) is an exterior gateway protocol used to set up an interdomain routing system that guarantees the loop-free exchange of routing information between autonomous systems. Autonomous systems are made up of routers that operate under the same administration and that run Interior Gateway Protocols (IGPs), such as RIP or OSPF, within their boundaries and that interconnect by using an Exterior Gateway Protocol (EGP). BGP Version 4 is the standard EGP for interdomain routing in the Internet. The protocol is defined in RFCs 1163, 1267, and 1771. You can find detailed information about BGP in *Internet Routing Architectures*, published by Cisco Press, and in the “Configuring BGP” chapter in the *Cisco IP and IP Routing Configuration Guide*.

For details about BGP commands and keywords, see the “IP Routing Protocols” part of the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols*.

### BGP Network Topology

Routers that belong to the same autonomous system (AS) and that exchange BGP updates run internal BGP (IBGP), and routers that belong to different autonomous systems and that exchange BGP updates run external
BGP (EBGP). Most configuration commands are the same for configuring EBGP and IBGP. The difference is that the routing updates are exchanged either between autonomous systems (EBGP) or within an AS (IBGP). The figure given below shows a network that is running both EBGP and IBGP.

**Figure 86: EBGP, IBGP, and Multiple Autonomous Systems**

Before exchanging information with an external AS, BGP ensures that networks within the AS can be reached by defining internal BGP peering among routers within the AS and by redistributing BGP routing information to IGPs that run within the AS, such as IGRP and OSPF.

Routers that run a BGP routing process are often referred to as BGP speakers. BGP uses the Transmission Control Protocol (TCP) as its transport protocol (specifically port 179). Two BGP speakers that have a TCP connection to each other for exchanging routing information are known as peers or neighbors. In the above figure, Routers A and B are EBGP peers, as are Routers B and C and Routers C and D. The routing information is a series of AS numbers that describe the full path to the destination network. BGP uses this information to construct a loop-free map of autonomous systems.

The network has these characteristics:

- Routers A and B are running EBGP, and Routers B and C are running IBGP. Note that the EBGP peers are directly connected and that the IBGP peers are not. As long as there is an IGP running that allows the two neighbors to reach one another, IBGP peers do not have to be directly connected.

- All BGP speakers within an AS must establish a peer relationship with each other. That is, the BGP speakers within an AS must be fully meshed logically. BGP4 provides two techniques that reduce the requirement for a logical full mesh: confederations and route reflectors.

- AS 200 is a transit AS for AS 100 and AS 300—that is, AS 200 is used to transfer packets between AS 100 and AS 300.

BGP peers initially exchange their full BGP routing tables and then send only incremental updates. BGP peers also exchange keepalive messages (to ensure that the connection is up) and notification messages (in response to errors or special conditions).

In BGP, each route consists of a network number, a list of autonomous systems that information has passed through (the autonomous system path), and a list of other path attributes. The primary function of a BGP system is to exchange network reachability information, including information about the list of AS paths, with other BGP systems. This information can be used to determine AS connectivity, to prune routing loops, and to enforce AS-level policy decisions.
A router or Device running Cisco IOS does not select or use an IBGP route unless it has a route available to the next-hop router and it has received synchronization from an IGP (unless IGP synchronization is disabled). When multiple routes are available, BGP bases its path selection on attribute values. See the “Configuring BGP Decision Attributes” section for information about BGP attributes.

BGP Version 4 supports classless interdomain routing (CIDR) so you can reduce the size of your routing tables by creating aggregate routes, resulting in supernets. CIDR eliminates the concept of network classes within BGP and supports the advertising of IP prefixes.

Nonstop ForwardingAwareness

The BGP NSF Awareness feature is supported for IPv4 in the IP services feature set. To enable this feature with BGP routing, you need to enable Graceful Restart. When the neighboring router is NSF-capable, and this feature is enabled, the Layer 3 Device continues to forward packets from the neighboring router during the interval between the primary Route Processor (RP) in a router failing and the backup RP taking over, or while the primary RP is manually reloaded for a nondisruptive software upgrade.

For more information, see the “BGP Nonstop Forwarding (NSF) Awareness” section of theCisco IOS IP Routing Protocols Configuration Guide, Release 12.4.

Information About BGP Routing

To enable BGP routing, you establish a BGP routing process and define the local network. Because BGP must completely recognize the relationships with its neighbors, you must also specify a BGP neighbor.

BGP supports two kinds of neighbors: internal and external. Internal neighbors are in the same AS; external neighbors are in different autonomous systems. External neighbors are usually adjacent to each other and share a subnet, but internal neighbors can be anywhere in the same AS.

The switch supports the use of private AS numbers, usually assigned by service providers and given to systems whose routes are not advertised to external neighbors. The private AS numbers are from 64512 to 65535. You can configure external neighbors to remove private AS numbers from the AS path by using the neighbor remove-private-as router configuration command. Then when an update is passed to an external neighbor, if the AS path includes private AS numbers, these numbers are dropped.

If your AS will be passing traffic through it from another AS to a third AS, it is important to be consistent about the routes it advertises. If BGP advertised a route before all routers in the network had learned about the route through the IGP, the AS might receive traffic that some routers could not yet route. To prevent this from happening, BGP must wait until the IGP has propagated information across the AS so that BGP is synchronized with the IGP. Synchronization is enabled by default. If your AS does not pass traffic from one AS to another AS, or if all routers in your autonomous systems are running BGP, you can disable synchronization, which allows your network to carry fewer routes in the IGP and allows BGP to converge more quickly.

Routing Policy Changes

Routing policies for a peer include all the configurations that might affect inbound or outbound routing table updates. When you have defined two routers as BGP neighbors, they form a BGP connection and exchange routing information. If you later change a BGP filter, weight, distance, version, or timer, or make a similar configuration change, you must reset the BGP sessions so that the configuration changes take effect.
There are two types of reset, hard reset and soft reset. Cisco IOS Releases 12.1 and later support a soft reset without any prior configuration. To use a soft reset without preconfiguration, both BGP peers must support the soft route refresh capability, which is advertised in the OPEN message sent when the peers establish a TCP session. A soft reset allows the dynamic exchange of route refresh requests and routing information between BGP routers and the subsequent re-advertisement of the respective outbound routing table.

- When soft reset generates inbound updates from a neighbor, it is called dynamic inbound soft reset.
- When soft reset sends a set of updates to a neighbor, it is called outbound soft reset.

A soft inbound reset causes the new inbound policy to take effect. A soft outbound reset causes the new local outbound policy to take effect without resetting the BGP session. As a new set of updates is sent during outbound policy reset, a new inbound policy can also take effect.

The table given below lists the advantages and disadvantages hard reset and soft reset.

<table>
<thead>
<tr>
<th>Type of Reset</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hard reset</td>
<td>No memory overhead</td>
<td>The prefixes in the BGP, IP, and FIB tables provided by the neighbor are lost. Not recommended.</td>
</tr>
<tr>
<td>Outbound soft reset</td>
<td>No configuration, no storing of routing table updates</td>
<td>Does not reset inbound routing table updates.</td>
</tr>
<tr>
<td>Dynamic inbound soft reset</td>
<td>Does not clear the BGP session and cache Does not require storing of routing table updates and has no memory overhead</td>
<td>Both BGP routers must support the route refresh capability (in Cisco IOS Release 12.1 and later).</td>
</tr>
</tbody>
</table>

**BGP Decision Attributes**

When a BGP speaker receives updates from multiple autonomous systems that describe different paths to the same destination, it must choose the single best path for reaching that destination. When chosen, the selected path is entered into the BGP routing table and propagated to its neighbors. The decision is based on the value of attributes that the update contains and other BGP-configurable factors.

When a BGP peer learns two EBGP paths for a prefix from a neighboring AS, it chooses the best path and inserts that path in the IP routing table. If BGP multipath support is enabled and the EBGP paths are learned from the same neighboring autonomous systems, instead of a single best path, multiple paths are installed in the IP routing table. Then, during packet switching, per-packet or per-destination load-balancing is performed among the multiple paths. The `maximum-paths` router configuration command controls the number of paths allowed.

These factors summarize the order in which BGP evaluates the attributes for choosing the best path:

1. If the path specifies a next hop that is inaccessible, drop the update. The BGP next-hop attribute, automatically determined by the software, is the IP address of the next hop that is going to be used to reach a destination. For EBGP, this is usually the IP address of the neighbor specified by the `neighbor`
remote-as router configuration command. You can disable next-hop processing by using route maps or the neighbor next-hop-self router configuration command.

2. Prefer the path with the largest weight (a Cisco proprietary parameter). The weight attribute is local to the router and not propagated in routing updates. By default, the weight attribute is 32768 for paths that the router originates and zero for other paths. Routes with the largest weight are preferred. You can use access lists, route maps, or the neighbor weight router configuration command to set weights.

3. Prefer the route with the highest local preference. Local preference is part of the routing update and exchanged among routers in the same AS. The default value of the local preference attribute is 100. You can set local preference by using the bgp default local-preference router configuration command or by using a route map.

4. Prefer the route that was originated by BGP running on the local router.

5. Prefer the route with the shortest AS path.

6. Prefer the route with the lowest origin type. An interior route or IGP is lower than a route learned by EGP, and an EGP-learned route is lower than one of unknown origin or learned in another way.

7. Prefer the route with the lowest multi -exit discriminator (MED) metric attribute if the neighboring AS is the same for all routes considered. You can configure the MED by using route maps or by using the default-metric router configuration command. When an update is sent to an IBGP peer, the MED is included.

8. Prefer the external (EBGP) path over the internal (IBGP) path.

9. Prefer the route that can be reached through the closest IGP neighbor (the lowest IGP metric). This means that the router will prefer the shortest internal path within the AS to reach the destination (the shortest path to the BGP next-hop).

10. If the following conditions are all true, insert the route for this path into the IP routing table:

Both the best route and this route are external.

Both the best route and this route are from the same neighboring autonomous system.

Maximum-paths is enabled.

11. If multipath is not enabled, prefer the route with the lowest IP address value for the BGP router ID. The router ID is usually the highest IP address on the router or the loopback (virtual) address, but might be implementation-specific.

---

**Route Maps**

Within BGP, route maps can be used to control and to modify routing information and to define the conditions by which routes are redistributed between routing domains. See the “Using Route Maps to Redistribute Routing Information” section for more information about route maps. Each route map has a name that identifies the route map (map tag) and an optional sequence number.

**BGP Filtering**

You can filter BGP advertisements by using AS-path filters, such as the as-path access-list global configuration command and the neighbor filter-list router configuration command. You can also use access lists with the neighbor distribute-list router configuration command. Distribute-list filters are applied to network numbers.
See the “Controlling Advertising and Processing in Routing Updates” section for information about the `distribute-list` command.

You can use route maps on a per-neighbor basis to filter updates and to modify various attributes. A route map can be applied to either inbound or outbound updates. Only the routes that pass the route map are sent or accepted in updates. On both inbound and outbound updates, matching is supported based on AS path, community, and network numbers. Autonomous system path matching requires the `match as-path access-list` route-map command, community based matching requires the `match community-list` route-map command, and network-based matching requires the `ip access-list` global configuration command.

**Prefix List for BGP Filtering**

You can use prefix lists as an alternative to access lists in many BGP route filtering commands, including the `neighbor distribute-list` router configuration command. The advantages of using prefix lists include performance improvements in loading and lookup of large lists, incremental update support, easier CLI configuration, and greater flexibility.

Filtering by a prefix list involves matching the prefixes of routes with those listed in the prefix list, as when matching access lists. When there is a match, the route is used. Whether a prefix is permitted or denied is based upon these rules:

- An empty prefix list permits all prefixes.
- An implicit deny is assumed if a given prefix does not match any entries in a prefix list.
- When multiple entries of a prefix list match a given prefix, the sequence number of a prefix list entry identifies the entry with the lowest sequence number.

By default, sequence numbers are generated automatically and incremented in units of five. If you disable the automatic generation of sequence numbers, you must specify the sequence number for each entry. You can specify sequence values in any increment. If you specify increments of one, you cannot insert additional entries into the list; if you choose very large increments, you might run out of values.

**BGP Community Filtering**

One way that BGP controls the distribution of routing information based on the value of the COMMUNITIES attribute. The attribute is a way to groups destinations into communities and to apply routing decisions based on the communities. This method simplifies configuration of a BGP speaker to control distribution of routing information.

A community is a group of destinations that share some common attribute. Each destination can belong to multiple communities. AS administrators can define to which communities a destination belongs. By default, all destinations belong to the general Internet community. The community is identified by the COMMUNITIES attribute, an optional, transitive, global attribute in the numerical range from 1 to 4294967200. These are some predefined, well-known communities:

- **internet**—Advertise this route to the Internet community. All routers belong to it.
- **no-export**—Do not advertise this route to EBGP peers.
- **no-advertise**—Do not advertise this route to any peer (internal or external).
- **local-as**—Do not advertise this route to peers outside the local autonomous system.
Based on the community, you can control which routing information to accept, prefer, or distribute to other neighbors. A BGP speaker can set, append, or modify the community of a route when learning, advertising, or redistributing routes. When routes are aggregated, the resulting aggregate has a COMMUNITIES attribute that contains all communities from all the initial routes.

You can use community lists to create groups of communities to use in a match clause of a route map. As with an access list, a series of community lists can be created. Statements are checked until a match is found. As soon as one statement is satisfied, the test is concluded.

To set the COMMUNITIES attribute and match clauses based on communities, see the `match community-list` and `set community` route-map configuration commands in the “Using Route Maps to Redistribute Routing Information” section.

**BGP Neighbors and Peer Groups**

Often many BGP neighbors are configured with the same update policies (that is, the same outbound route maps, distribute lists, filter lists, update source, and so on). Neighbors with the same update policies can be grouped into peer groups to simplify configuration and to make updating more efficient. When you have configured many peers, we recommend this approach.

To configure a BGP peer group, you create the peer group, assign options to the peer group, and add neighbors as peer group members. You configure the peer group by using the `neighbor` router configuration commands. By default, peer group members inherit all the configuration options of the peer group, including the remote-as (if configured), version, update-source, out-route-map, out-filter-list, out-dist-list, minimum-advertisement-interval, and next-hop-self. All peer group members also inherit changes made to the peer group. Members can also be configured to override the options that do not affect outbound updates.

**Aggregate Routes**

Classless interdomain routing (CIDR) enables you to create aggregate routes (or supernets) to minimize the size of routing tables. You can configure aggregate routes in BGP either by redistributing an aggregate route into BGP or by creating an aggregate entry in the BGP routing table. An aggregate address is added to the BGP table when there is at least one more specific entry in the BGP table.

**Routing Domain Confederations**

One way to reduce the IBGP mesh is to divide an autonomous system into multiple subautonomous systems and to group them into a single confederation that appears as a single autonomous system. Each autonomous system is fully meshed within itself and has a few connections to other autonomous systems in the same confederation. Even though the peers in different autonomous systems have EBGP sessions, they exchange routing information as if they were IBGP peers. Specifically, the next hop, MED, and local preference information is preserved. You can then use a single IGP for all of the autonomous systems.

**BGP Route Reflectors**

BGP requires that all of the IBGP speakers be fully meshed. When a router receives a route from an external neighbor, it must advertise it to all internal neighbors. To prevent a routing information loop, all IBGP speakers must be connected. The internal neighbors do not send routes learned from internal neighbors to other internal neighbors.
With route reflectors, all IBGP speakers need not be fully meshed because another method is used to pass learned routes to neighbors. When you configure an internal BGP peer to be a route reflector, it is responsible for passing IBGP learned routes to a set of IBGP neighbors. The internal peers of the route reflector are divided into two groups: client peers and nonclient peers (all the other routers in the autonomous system). A route reflector reflects routes between these two groups. The route reflector and its client peers form a cluster. The nonclient peers must be fully meshed with each other, but the client peers need not be fully meshed. The clients in the cluster do not communicate with IBGP speakers outside their cluster.

When the route reflector receives an advertised route, it takes one of these actions, depending on the neighbor:

- A route from an external BGP speaker is advertised to all clients and nonclient peers.
- A route from a nonclient peer is advertised to all clients.
- A route from a client is advertised to all clients and nonclient peers. Hence, the clients need not be fully meshed.

Usually a cluster of clients have a single route reflector, and the cluster is identified by the route reflector router ID. To increase redundancy and to avoid a single point of failure, a cluster might have more than one route reflector. In this case, all route reflectors in the cluster must be configured with the same 4-byte cluster ID so that a route reflector can recognize updates from route reflectors in the same cluster. All the route reflectors serving a cluster should be fully meshed and should have identical sets of client and nonclient peers.

**Route Dampening**

Route flap dampening is a BGP feature designed to minimize the propagation of flapping routes across an internetwork. A route is considered to be flapping when it is repeatedly available, then unavailable, then available, then unavailable, and so on. When route dampening is enabled, a numeric penalty value is assigned to a route when it flaps. When a route’s accumulated penalties reach a configurable limit, BGP suppresses advertisements of the route, even if the route is running. The reuse limit is a configurable value that is compared with the penalty. If the penalty is less than the reuse limit, a suppressed route that is up is advertised again.

Dampening is not applied to routes that are learned by IBGP. This policy prevents the IBGP peers from having a higher penalty for routes external to the AS.

**More BGP Information**

For detailed descriptions of BGP configuration, see the “Configuring BGP” chapter in the “IP Routing Protocols” part of the *Cisco IOS IP Configuration Guide, Release 12.4*. For details about specific commands, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

**How to Configure BGP**

**Default BGP Configuration**

The table given below shows the basic default BGP configuration. For the defaults for all characteristics, see the specific commands in the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*. 
Table 110: Default BGP Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate address</td>
<td>Disabled: None defined.</td>
</tr>
<tr>
<td>AS path access list</td>
<td>None defined.</td>
</tr>
<tr>
<td>Auto summary</td>
<td>Disabled.</td>
</tr>
</tbody>
</table>
| Best path                                         | • The router considers *as-path* in choosing a route and does not compare similar routes from external BGP peers.  
|                                                    | • Compare router ID: Disabled.                                                  |
| BGP community list                                | • Number: None defined. When you permit a value for the community number, the list defaults to an implicit deny for everything else that has not been permitted.  
|                                                    | • Format: Cisco default format (32-bit number).                                |
| BGP confederation identifier/peers                | • Identifier: None configured.                                                 |
|                                                    | • Peers: None identified.                                                      |
| BGP Fast external fallover                        | Enabled.                                                                       |
| BGP local preference                              | 100. The range is 0 to 4294967295 with the higher value preferred.             |
| BGP network                                       | None specified; no backdoor route advertised.                                  |
| BGP route dampening                               | Disabled by default. When enabled:  
<p>|                                                    | • Half-life is 15 minutes.                                                      |
|                                                    | • Re-use is 750 (10-second increments).                                         |
|                                                    | • Suppress is 2000 (10-second increments).                                     |
|                                                    | • Max-suppress-time is 4 times half-life; 60 minutes.                           |
| BGP router ID                                     | The IP address of a loopback interface if one is configured or the highest IP address configured for a physical interface on the router. |
| Default information originate (protocol or network redistribution) | Disabled.                                                                       |
| Default metric                                    | Built-in, automatic metric translations.                                       |</p>

                          • Private AS number removal: Disabled.  
                          • Route maps: None applied to a peer.  
                          • Send community attributes: None sent to neighbors.  
                          • Shutdown or soft reconfiguration: Not enabled.  
                          • Timers: keepalive: 60 seconds; holdtime: 180 seconds.  
                          • Update source: Best local address.  
                          • Weight: Routes learned through BGP peer: 0; routes sourced by the local router: 32768. |
| NSF Awareness         | Disabled\(^2\). If enabled, allows Layer 3 switches to continue forwarding packets from a neighboring NSF-capable router during hardware or software changes. |
### Enabling BGP Routing

#### Before you begin

To enable BGP, the switch or stack master must be running the IP services feature set.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal Example: Device# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>ip routing        Example: Device(config)# ip routing</td>
<td>Enables IP routing.</td>
</tr>
<tr>
<td>Step 3</td>
<td>router bgp autonomous-system Example: Device(config)# router bgp 45000</td>
<td>Enables a BGP routing process, assign it an AS number, and enter router configuration mode. The AS number can be from 1 to 65535, with 64512 to 65535 designated as private autonomous numbers.</td>
</tr>
<tr>
<td>Step 4</td>
<td>network network-number [mask network-mask] [route-map route-map-name] Example: Device(config)# network 10.108.0.0</td>
<td>Configures a network as local to this AS, and enter it in the BGP table.</td>
</tr>
</tbody>
</table>

---

6. Nonstop Forwarding
7. NSF Awareness can be enabled for IPv4 on switches with the IP services feature set by enabling Graceful Restart.

### Feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Route reflector</td>
<td>None configured.</td>
</tr>
<tr>
<td>Synchronization (BGP and IGP)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Table map update</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Timers</td>
<td>Keepalive: 60 seconds; holdtime: 180 seconds.</td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
</tr>
</tbody>
</table>
| **Step 5** | `neighbor {ip-address | peer-group-name} remote-as number` | Adds an entry to the BGP neighbor table specifying that the neighbor identified by the IP address belongs to the specified AS.  
For EBGP, neighbors are usually directly connected, and the IP address is the address of the interface at the other end of the connection.  
For IBGP, the IP address can be the address of any of the router interfaces. |
| **Example:** | `Device(config)# neighbor 10.108.1.2 remote-as 65200` | |
| **Step 6** | `neighbor {ip-address | peer-group-name} remove-private-as` | (Optional) Removes private AS numbers from the AS-path in outbound routing updates. |
| **Example:** | `Device(config)# neighbor 172.16.2.33 remove-private-as` | |
| **Step 7** | `synchronization` | (Optional) Enables synchronization between BGP and an IGP. |
| **Example:** | `Device(config)# synchronization` | |
| **Step 8** | `auto-summary` | (Optional) Enables automatic network summarization. When a subnet is redistributed from an IGP into BGP, only the network route is inserted into the BGP table. |
| **Example:** | `Device(config)# auto-summary` | |
| **Step 9** | `bgp graceful-restart` | (Optional) Enables NSF awareness on switch. By default, NSF awareness is disabled. |
| **Example:** | `Device(config)# bgp graceful-start` | |
| **Step 10** | `end` | Returns to privileged EXEC mode. |
| **Example:** | `Device(config)# end` | |
| **Step 11** | `show ip bgp network network-number` | Verifies the configuration. |
| **Example:** | `Device# show ip bgp network 10.108.0.0` | |
| **Step 12** | `show ip bgp neighbor` | Verifies that NSF awareness (Graceful Restart) is enabled on the neighbor.  
If NSF awareness is enabled on the switch and the neighbor, this message appears:  
*Graceful Restart Capability: advertised and received* |
| **Example:** | `Device# show ip bgp neighbor` | |
Purpose

If NSF awareness is enabled on the switch, but not on the neighbor, this message appears:

Graceful Restart Capability: advertised

Step 13

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

Managing Routing Policy Changes

To learn if a BGP peer supports the route refresh capability and to reset the BGP session:

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Displays whether a neighbor supports the route refresh capability. When supported, this message appears for the router:</td>
</tr>
<tr>
<td>show ip bgp neighbors</td>
<td>Received route refresh capability from peer.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ip bgp neighbors</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Resets the routing table on the specified connection.</td>
</tr>
<tr>
<td>clear ip bgp {*</td>
<td>address</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# clear ip bgp *</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>(Optional) Performs an outbound soft reset to reset the inbound routing table on the specified connection. Use this command if route refresh is supported.</td>
</tr>
<tr>
<td>clear ip bgp {*</td>
<td>address</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# clear ip bgp * soft out</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>Verifies the reset by checking information about the routing table and about BGP neighbors.</td>
</tr>
<tr>
<td>show ip bgp</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ip bgp</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring BGP Decision Attributes

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> router bgp autonomous-system</td>
<td>Enables a BGP routing process, assign it an AS number, and enter router configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# router bgp 4500</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> bgp best-path as-path ignore</td>
<td>(Optional) Configures the router to ignore AS path length in selecting a route.</td>
</tr>
<tr>
<td>Example: Device(config-router)# bgp bestpath as-path ignore</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> neighbor {ip-address</td>
<td>peer-group-name} next-hop-self</td>
</tr>
<tr>
<td>Example: Device(config-router)# neighbor 10.108.1.1 next-hop-self</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> neighbor {ip-address</td>
<td>peer-group-name} weight weight</td>
</tr>
<tr>
<td>Example: Device(config-router)# neighbor 172.16.12.1 weight 50</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> default-metric number</td>
<td>(Optional) Sets a MED metric to set preferred paths to external neighbors. All routes without a MED will also be set to this value. The range is 1 to 4294967295. The lowest value is the most desirable.</td>
</tr>
<tr>
<td>Example: Device(config-router)# default-metric 300</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

```text
show ip bgp neighbors
```

Example:

```
Device# show ip bgp neighbors
```

Verifies the reset by checking information about the routing table and about BGP neighbors.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 7** bgp bestpath med missing-as-worst  
Example:  
Device(config-router)# bgp bestpath med missing-as-worst | (Optional) Configures the switch to consider a missing MED as having a value of infinity, making the path without a MED value the least desirable path. |
| **Step 8** bgp always-compare med  
Example:  
Device(config-router)# bgp always-compare-med | (Optional) Configures the switch to compare MEDs for paths from neighbors in different autonomous systems. By default, MED comparison is only done among paths in the same AS. |
| **Step 9** bgp bestpath med confed  
Example:  
Device(config-router)# bgp bestpath med confed | (Optional) Configures the switch to consider the MED in choosing a path from among those advertised by different subautonomous systems within a confederation. |
| **Step 10** bgp deterministic med  
Example:  
Device(config-router)# bgp deterministic med | (Optional) Configures the switch to consider the MED variable when choosing among routes advertised by different peers in the same AS. |
| **Step 11** bgp default local-preference value  
Example:  
Device(config-router)# bgp default local-preference 200 | (Optional) Change the default local preference value. The range is 0 to 4294967295; the default value is 100. The highest local preference value is preferred. |
| **Step 12** maximum-paths number  
Example:  
Device(config-router)# maximum-paths 8 | (Optional) Configures the number of paths to be added to the IP routing table. The default is to only enter the best path in the routing table. The range is from 1 to 16. Having multiple paths allows load-balancing among the paths. (Although the switch software allows a maximum of 32 equal-cost routes, the switch hardware will never use more than 16 paths per route.) |
| **Step 13** end  
Example:  
Device(config)# end | Returns to privileged EXEC mode. |
| **Step 14** show ip bgp  
Example:  
Device# show ip bgp | Verifies the reset by checking information about the routing table and about BGP neighbors. |
| **Step 15** show ip bgp neighbors  
Example: | Verifies the reset by checking information about the routing table and about BGP neighbors. |
### Configuring BGP Filtering with Route Maps

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 | route-map map-tag [permit | deny] [sequence-number] | Creates a route map, and enter route-map configuration mode. |
|---------|-------------------------|----------------------------------------------------------|
| Example: |                         |                                                         |
| `Device(config)# route-map set-peer-address permit 10` |                                                         |

<table>
<thead>
<tr>
<th>Step 3</th>
<th>set ip next-hop ip-address [...ip-address] [peer-address]</th>
<th>(Optional) Sets a route map to disable next-hop processing</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# set ip next-hop 10.1.1.3</code></td>
<td></td>
<td>In an inbound route map, set the next hop of matching routes to be the neighbor peering address, overriding third-party next hops.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In an outbound route map of a BGP peer, set the next hop to the peering address of the local router, disabling the next-hop calculation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 4</th>
<th>end</th>
<th>Returns to privileged EXEC mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 5</th>
<th>show route-map [map-name]</th>
<th>Displays all route maps configured or only the one specified to verify configuration.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>Device# show route-map</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring BGP Filtering by Neighbor

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;&lt;br&gt;Device# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>router bgp [autonomous-system]</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;&lt;br&gt;Device{config}# router bgp 109</td>
<td>Enables a BGP routing process, assign it an AS number, and enter router configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>**neighbor {ip-address</td>
<td>peer-group name} distribute-list {access-list-number</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>**neighbor {ip-address</td>
<td>peer-group name} route-map map-tag {in</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>end</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong>&lt;br&gt;&lt;br&gt;Device{config}# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>show ip bgp neighbors</strong>&lt;br&gt;&lt;br&gt;<strong>Example:</strong></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device# show ip bgp neighbors</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 7**

**copy running-config startup-config**

Example:

```
Device# copy running-config startup-config
```

### Configuring BGP Filtering by Access Lists and Neighbors

Another method of filtering is to specify an access list filter on both incoming and outbound updates, based on the BGP autonomous system paths. Each filter is an access list based on regular expressions. (See the “Regular Expressions” appendix in the Cisco IOS Dial Technologies Command Reference, Release 12.4 for more information on forming regular expressions.) To use this method, define an autonomous system path access list, and apply it to updates to and from particular neighbors.

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

```
configure terminal
```

Example:

```
Device# configure terminal
```

Enters the global configuration mode.

**Step 2**

```
ip as-path access-list access-list-number {permit | deny} as-regular-expressions
```

Example:

```
Device(config)# ip as-path access-list 1 deny _65535_
```

Defines a BGP-related access list.

**Step 3**

```
router bgp autonomous-system
```

Example:

```
Device(config)# router bgp 110
```

Enters BGP router configuration mode.

**Step 4**

```
neighbor {ip-address | peer-group name} filter-list {access-list-number | name} {in | out | weight weight}
```

Example:

```
Device(config-router)# neighbor 172.16.1.1 filter-list 1 out
```

Establishes a BGP filter based on an access list.

**Step 5**

```
end
```

Example:

```
```

Returns to privileged EXEC mode.
### Configuring Prefix Lists for BGP Filtering

You do not need to specify a sequence number when removing a configuration entry. Show commands include the sequence numbers in their output.

Before using a prefix list in a command, you must set up the prefix list.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
configure terminal
Example:
Device# configure terminal
| Enters the global configuration mode. |
| **Step 2**
ip prefix-list list-name [seq seq-value] deny | permit network/len [ge ge-value] [le le-value]
Example:
Device(config)# ip prefix-list BLUE permit 172.16.1.0/24
| Creates a prefix list with an optional sequence number to deny or permit access for matching conditions. You must enter at least one permit or deny clause.
- network/len is the network number and length (in bits) of the network mask.
- (Optional) ge and le values specify the range of the prefix length to be matched. The specified ge-value and le-value must satisfy this condition: len < ge-value < le-value < 32 |
| **Step 3**
ip prefix-list list-name seq seq-value deny | permit network/len [ge ge-value] [le le-value]
Example:
Device(config)# ip prefix-list BLUE seq 10 permit 172.24.1.0/24
| (Optional) Adds an entry to a prefix list, and assign a sequence number to the entry. |
### Configuring BGP Community Filtering

By default, no COMMUNITIES attribute is sent to a neighbor. You can specify that the COMMUNITIES attribute be sent to the neighbor at an IP address by using the `neighbor send-community` router configuration command.

#### SUMMARY STEPS

1. configure terminal
2. ip community-list community-list-number {permit | deny} community-number
3. router bgp autonomous-system
4. neighbor {ip-address | peer-group-name} send-community
5. set comm-list list-num delete
6. exit
7. ip bgp-community new-format
8. end
9. show ip bgp community
10. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
Device# configure terminal
```
| Step 2 | **ip community-list community-list-number {permit | deny} community-number** | **Purpose** | Creates a community list, and assigns it a number.  
• The *community-list-number* is an integer from 1 to 99 that identifies one or more permit or deny groups of communities.  
• The *community-number* is the number configured by a set community route-map configuration command. |
| Step 3 | **router bgp autonomous-system** | **Example:** | Enters BGP router configuration mode. |
| Step 4 | **neighbor {ip-address | peer-group name} send-community** | **Example:** | Specifies that the COMMUNITIES attribute be sent to the neighbor at this IP address. |
| Step 5 | **set comm-list list-num delete** | **Example:** | (Optional) Removes communities from the community attribute of an inbound or outbound update that match a standard or extended community list specified by a route map. |
| Step 6 | **exit** | **Example:** | Returns to global configuration mode. |
| Step 7 | **ip bgp-community new-format** | **Example:** | (Optional) Displays and parses BGP communities in the format AA:NN.  
A BGP community is displayed in a two-part format 2 bytes long. The Cisco default community format is in the format NNAA. In the most recent RFC for BGP, a community takes the form AA:NN, where the first part is the AS number and the second part is a 2-byte number. |
| Step 8 | **end** | **Example:** | Returns to privileged EXEC mode. |
| Step 9 | **show ip bgp community** | **Example:** | Verifies the configuration. |
### Configuring BGP Neighbors and Peer Groups

To assign configuration options to an individual neighbor, specify any of these router configuration commands by using the neighbor IP address. To assign the options to a peer group, specify any of the commands by using the peer group name. You can disable a BGP peer or peer group without removing all the configuration information by using the `neighbor shutdown` router configuration command.

### Procedure

<td><strong>Step 11</strong> neighbor {ip-address</td>
<td>peer-group-name} local-as number</td>
<td>(Optional) Specifies an AS number to use as the local AS. The range is 1 to 65535.</td>
</tr>
<tr>
<td><strong>Step 12</strong> neighbor {ip-address</td>
<td>peer-group-name} advertisement-interval seconds</td>
<td>(Optional) Sets the minimum interval between sending BGP routing updates.</td>
</tr>
<tr>
<td><strong>Step 13</strong> neighbor {ip-address</td>
<td>peer-group-name} maximum-prefix maximum [threshold]</td>
<td>(Optional) Controls how many prefixes can be received from a neighbor. The range is 1 to 4294967295. The threshold (optional) is the percentage of maximum at which a warning message is generated. The default is 75 percent.</td>
</tr>
<tr>
<td><strong>Step 14</strong> neighbor {ip-address</td>
<td>peer-group-name} next-hop-self</td>
<td>(Optional) Disables next-hop processing on the BGP updates to a neighbor.</td>
</tr>
<tr>
<td><strong>Step 15</strong> neighbor {ip-address</td>
<td>peer-group-name} password string</td>
<td>(Optional) Sets MD5 authentication on a TCP connection to a BGP peer. The same password must be configured on both BGP peers, or the connection between them is not made.</td>
</tr>
<tr>
<td><strong>Step 16</strong> neighbor {ip-address</td>
<td>peer-group-name} route-map map-name {in</td>
<td>out}</td>
</tr>
<tr>
<td><strong>Step 17</strong> neighbor {ip-address</td>
<td>peer-group-name} send-community</td>
<td>(Optional) Specifies that the COMMUNITIES attribute be sent to the neighbor at this IP address.</td>
</tr>
<tr>
<td><strong>Step 18</strong> neighbor {ip-address</td>
<td>peer-group-name} timers keepalive holdtime</td>
<td>(Optional) Sets timers for the neighbor or peer group.</td>
</tr>
<tr>
<td></td>
<td>• The keepalive interval is the time within which keepalive messages are sent to peers. The range is 1 to 4294967295 seconds; the default is 60.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The holdtime is the interval after which a peer is declared inactive after not receiving a keepalive message from it. The range is 1 to 4294967295 seconds; the default is 180.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 19</strong> neighbor {ip-address</td>
<td>peer-group-name} weight weight</td>
<td>(Optional) Specifies a weight for all routes from a neighbor.</td>
</tr>
<tr>
<td><strong>Step 20</strong> neighbor {ip-address</td>
<td>peer-group-name} distribute-list {access-list-number</td>
<td>name} {in</td>
</tr>
<tr>
<td><strong>Step 21</strong> neighbor {ip-address</td>
<td>peer-group-name} filter-list access-list-number {in</td>
<td>out</td>
</tr>
<tr>
<td><strong>Step 22</strong> neighbor {ip-address</td>
<td>peer-group-name} version value</td>
<td>(Optional) Specifies the BGP version to use when communicating with a neighbor.</td>
</tr>
<tr>
<td><strong>Step 23</strong> neighbor {ip-address</td>
<td>peer-group-name} soft-reconfiguration inbound</td>
<td>(Optional) Configures the software to start storing received updates.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 24</th>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
</tr>
</tbody>
</table>

Returns to privileged EXEC mode.

**Step 25**

**Command or Action**

| show ip bgp neighbors |

Verifies the configuration.

**Step 26**

**Command or Action**

| copy running-config startup-config |

(Optional) Saves your entries in the configuration file.

---

## Configuring Aggregate Addresses in a Routing Table

### Procedure

**Command or Action**

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
</tr>
<tr>
<td>Example:</td>
</tr>
</tbody>
</table>

Enters the global configuration mode.

| Step 2 | router bgp autonomous-system |
| Example: | Device(config)# router bgp 106 |

Enters BGP router configuration mode.

| Step 3 | aggregate-address address mask |
| Example: | Device(config-router)# aggregate-address 10.0.0.0 255.0.0.0 |

Creates an aggregate entry in the BGP routing table. The aggregate route is advertised as coming from the AS, and the atomic aggregate attribute is set to indicate that information might be missing.

| Step 4 | aggregate-address address mask as-set |
| Example: | Device(config-router)# aggregate-address 10.0.0.0 255.0.0.0 as-set |

(Optional) Generates AS set path information. This command creates an aggregate entry following the same rules as the previous command, but the advertised path will be an AS_SET consisting of all elements contained in all paths. Do not use this keyword when aggregating many paths because this route must be continually withdrawn and updated.

<p>| Step 5 | aggregate-address address-mask summary-only |
| Example: | (Optional) Advertises summary addresses only. |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-router)# aggregate-address 10.0.0.0 255.0.0.0 summary-only</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> aggregate-address address mask suppress-map map-name</td>
<td>(Optional) Suppresses selected, more specific routes.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# aggregate-address 10.0.0.0 255.0.0.0 suppress-map map1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> aggregate-address address mask advertise-map map-name</td>
<td>(Optional) Generates an aggregate based on conditions specified by the route map.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# aggregate-address 10.0.0.0 255.0.0.0 advertise-map map2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> aggregate-address address mask attribute-map map-name</td>
<td>(Optional) Generates an aggregate with attributes specified in the route map.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# aggregate-address 10.0.0.0 255.0.0.0 attribute-map map3</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> show ip bgp neighbors [advertised-routes]</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ip bgp neighbors</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring Routing Domain Confederations**

You must specify a confederation identifier that acts as the autonomous system number for the group of autonomous systems.
### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>&lt;br&gt;configure terminal  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong>&lt;br&gt;router bgp autonomous-system  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device(config)# router bgp 100</td>
<td>Enters BGP router configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong>&lt;br&gt;bgp confederation identifier autonomous-system  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device(config)# bgp confederation identifier 50007</td>
<td>Configures a BGP confederation identifier.</td>
</tr>
<tr>
<td><strong>Step 4</strong>&lt;br&gt;bgp confederation peers autonomous-system  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device(config)# bgp confederation peers 51000 51001 51002</td>
<td>Specifies the autonomous systems that belong to the confederation and that will be treated as special EBGP peers.</td>
</tr>
<tr>
<td><strong>Step 5</strong>&lt;br&gt;end  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong>&lt;br&gt;show ip bgp neighbor  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device# show ip bgp neighbor</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td><strong>Step 7</strong>&lt;br&gt;show ip bgp network  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device# show ip bgp network</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td><strong>Step 8</strong>&lt;br&gt;copy running-config startup-config  &lt;br&gt;<strong>Example:</strong>  &lt;br&gt;Device# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
## Configuring BGP Route Reflectors

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> router bgp autonomous-system</td>
<td>Enters BGP router configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# router bgp 101</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> neighbor {ip-address</td>
<td>peer-group-name} route-reflector-client</td>
</tr>
<tr>
<td>Example: Device(config-router)# neighbor 172.16.70.24 route-reflector-client</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> bgp cluster-id cluster-id</td>
<td>(Optional) Configures the cluster ID if the cluster has more than one route reflector.</td>
</tr>
<tr>
<td>Example: Device(config-router)# bgp cluster-id 10.0.1.2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> no bgp client-to-client reflection</td>
<td>(Optional) Disables client-to-client route reflection. By default, the routes from a route reflector client are reflected to other clients. However, if the clients are fully meshed, the route reflector does not need to reflect routes to clients.</td>
</tr>
<tr>
<td>Example: Device(config-router)# no bgp client-to-client reflection</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> show ip bgp</td>
<td>Verifies the configuration. Displays the originator ID and the cluster-list attributes.</td>
</tr>
<tr>
<td>Example: Device# show ip bgp</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Route Dampening

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-router)# bgp dampening</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>bgp dampening half-life reuse suppress max-suppress [route-map map]</td>
<td>(Optional) Changes the default values of route dampening factors.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-router)# bgp dampening 30 1500 10000 120</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>show ip bgp flap-statistics [{regexp regexp}</td>
<td>(Optional) Monitors the flaps of all paths that are flapping. The statistics are deleted when the route is not suppressed and is stable.</td>
</tr>
<tr>
<td></td>
<td>{filter-list list}</td>
<td></td>
</tr>
<tr>
<td></td>
<td>{address mask {longer-prefix}}]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# show ip bgp flap-statistics</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>show ip bgp dampened-paths</td>
<td>(Optional) Displays the dampened routes, including the time remaining before they are suppressed.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Monitoring and Maintaining BGP

Monitoring and Maintaining BGP

You can remove all contents of a particular cache, table, or database. This might be necessary when the contents of the particular structure have become or are suspected to be invalid.

You can display specific statistics, such as the contents of BGP routing tables, caches, and databases. You can use the information to get resource utilization and solve network problems. You can also display information about node reachability and discover the routing path your device’s packets are taking through the network.

The table given below lists the privileged EXEC commands for clearing and displaying BGP. For explanations of the display fields, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4.*

**Table 111: IP BGP Clear and Show Commands**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clear ip bgp address</code></td>
<td>Resets a particular BGP connection.</td>
</tr>
<tr>
<td><code>clear ip bgp *</code></td>
<td>Resets all BGP connections.</td>
</tr>
<tr>
<td><code>clear ip bgp peer-group tag</code></td>
<td>Removes all members of a BGP peer group.</td>
</tr>
<tr>
<td><code>show ip bgp prefix</code></td>
<td>Displays peer groups and peers not in peer groups to which the prefix has been advertised. Also displays prefix attributes such as the next hop and the local prefix.</td>
</tr>
<tr>
<td><code>show ip bgp cidr-only</code></td>
<td>Displays all BGP routes that contain subnet and supernet network masks.</td>
</tr>
<tr>
<td><code>show ip bgp community [community-number] [exact]</code></td>
<td>Displays routes that belong to the specified communities.</td>
</tr>
</tbody>
</table>
**Configuration Examples for BGP**

**Example: Configuring BGP on Routers**

These examples show how to configure BGP on the routers in the figure below,
Figure 87: EBGP, IBGP, and Multiple Autonomous Systems

Router A:

Device(config)# router bgp 100
Device(config-router)# neighbor 129.213.1.1 remote-as 200

Router B:

Device(config)# router bgp 200
Device(config-router)# neighbor 129.213.1.2 remote-as 100
Device(config-router)# neighbor 175.220.1.2 remote-as 200

Router C:

Device(config)# router bgp 200
Device(config-router)# neighbor 175.220.212.1 remote-as 200
Device(config-router)# neighbor 192.208.10.1 remote-as 300

Router D:

Device(config)# router bgp 300
Device(config-router)# neighbor 192.208.10.2 remote-as 200

To verify that BGP peers are running, use the show ip bgp neighbors privileged EXEC command. This is the output of this command on Router A:

Device# show ip bgp neighbors

BGP neighbor is 129.213.1.1, remote AS 200, external link
BGP version 4, remote router ID 175.220.212.1
BGP state = established, table version = 3, up for 0:10:59
Last read 0:00:29, hold time is 180, keepalive interval is 60 seconds
Minimum time between advertisement runs is 30 seconds
Received 2828 messages, 0 notifications, 0 in queue
Sent 2826 messages, 0 notifications, 0 in queue
Connections established 11; dropped 10

Anything other than state = established means that the peers are not running. The remote router ID is the highest IP address on that router (or the highest loopback interface). Each time the table is updated with new information, the table version number increments. A table version number that continually increments means that a route is flapping, causing continual routing updates.
For exterior protocols, a reference to an IP network from the `network` router configuration command controls only which networks are advertised. This is in contrast to Interior Gateway Protocols (IGPs), such as EIGRP, which also use the `network` command to specify where to send updates.

For detailed descriptions of BGP configuration, see the “IP Routing Protocols” part of the *Cisco IOS IP Configuration Guide, Release 12.4*. For details about specific commands, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

### Information About ISO CLNS Routing

#### Connectionless Routing

The International Organization for Standardization (ISO) Connectionless Network Service (CLNS) protocol is a standard for the network layer of the Open System Interconnection (OSI) model. Addresses in the ISO network architecture are referred to as network service access point (NSAP) addresses and network entity titles (NETs). Each node in an OSI network has one or more NETs. In addition, each node has many NSAP addresses.

When you enable connectionless routing on the Device by using the `clns routing` global configuration command, the Device makes only forwarding decisions, with no routing-related functionality. For dynamic routing, you must also enable a routing protocol. The Device supports the Intermediate System-to-Intermediate System (IS-IS) dynamic routing protocol that is based on the OSI routing protocol for ISO CLNS networks.

When dynamically routing, you use IS-IS. This routing protocol supports the concept of areas. Within an area, all routers know how to reach all the system IDs. Between areas, routers know how to reach the proper area. IS-IS supports two levels of routing: station routing (within an area) and area routing (between areas).

The key difference between the ISO IGRP and IS-IS NSAP addressing schemes is in the definition of area addresses. Both use the system ID for Level 1 routing (routing within an area). However, they differ in the way addresses are specified for area routing. An ISO IGRP NSAP address includes three separate fields for routing: the domain, area, and system ID. An IS-IS address includes two fields: a single continuous area field (comprising the domain and area fields) and the system ID.

**Note**

For more detailed information about ISO CLNS, see the *Cisco IOS Apollo Domain, Banyan VINES, DECnet, ISO CLNS and XNS Configuration Guide, Release 12.4*. For complete syntax and usage information for the commands used in this chapter, see the *Cisco IOS Apollo Domain, Banyan VINES, DECnet, ISO CLNS and XNS Command Reference, Release 12.4*, use the IOS command reference master index, or search online.

### Information About IS-IS Routing

IS-IS is an ISO dynamic routing protocol (described in ISO 105890). Compared to other routing protocols, to enable IS-IS you need to create an IS-IS routing process and assign it to a specific interface, rather than to a network. You can specify more than one IS-IS routing process per Layer 3 device by using the multiarea IS-IS configuration syntax. You then need to configure the parameters for each instance of the IS-IS routing process.

Small IS-IS networks are built as a single area that includes all the devices in the network. As the network grows larger, the network reorganizes itself into a backbone area made up of all the connected set of Level 2
devices still connected to their local areas. Within a local area, devices know how to reach all system IDs. Between areas, devices know how to reach the backbone, and the backbone devices know how to reach other areas.

Devices establish Level 1 adjacencies to perform routing within a local area (station routing). Devices establish Level 2 adjacencies to perform routing between Level 1 areas (area routing).

A single Cisco device can participate in routing in up to 29 areas and can perform Level 2 routing in the backbone. In general, each routing process corresponds to an area. By default, the first instance of the routing process that is configured performs both Level 1 and Level 2 routing. You can configure additional device instances, which are automatically treated as Level 1 areas. You must configure the parameters for each instance of the IS-IS routing process individually.

For IS-IS multiarea routing, you can configure only one process to perform Level 2 routing, although you can define up to 29 Level 1 areas for each Cisco unit. If Level 2 routing is configured on any process, all additional processes are automatically configured as Level 1 routing at the same time. If Level 2 routing is not desired for a device instance, remove the Level 2 capability using the `is-type` command in global configuration mode. Use the `is-type` command also to configure a different device instance as a Level 2 device.

Nonstop Forwarding Awareness

The integrated IS-IS Nonstop Forwarding (NSF) Awareness feature is supported for IPv4G. The feature allows customer premises equipment (CPE) devices that are NSF-aware to help NSF-capable devices perform nonstop forwarding of packets. The local device is not necessarily performing NSF, but its NSF awareness capability allows the integrity and accuracy of the routing database and the link-state database on the neighboring NSF-capable device to be maintained during the switchover process.

The integrated IS-IS Nonstop Forwarding (NSF) Awareness feature is automatically enabled and requires no configuration.

IS-IS Global Parameters

The following are the optional IS-IS global parameters that you can configure:

- You can force a default route into an IS-IS routing domain by configuring a default route that is controlled by a route map. You can also specify the other filtering options that are configurable under a route map.
- You can configure the device to ignore IS-IS link-state packets (LSPs) that are received with internal checksum errors, or to purge corrupted LSPs, and cause the initiator of the LSP to regenerate it.
- You can assign passwords to areas and domains.
- You can create aggregate addresses that are represented in the routing table by a summary address (based on route summarization). Routes learned from other routing protocols can also be summarized. The metric used to advertise the summary is the smallest metric of all the specific routes.
- You can set an overload bit.
- You can configure the LSP refresh interval and the maximum time that an LSP can remain in the device database without a refresh.
- You can set the throttling timers for LSP generation, shortest path first computation, and partial route computation.
• You can configure the device to generate a log message when an IS-IS adjacency changes state (Up or Down).

• If a link in the network has a maximum transmission unit (MTU) size of less than 1500 bytes, you can lower the LSP MTU so that routing still occurs.

• You can use the partition avoidance device configuration command to prevent an area from becoming partitioned when full connectivity is lost among a Level 1-2 border device, adjacent Level 1 devices, and end hosts.

IS-IS Interface Parameters

You can optionally configure certain interface-specific IS-IS parameters independently from other attached devices. However, if you change default value, such as multipliers and time intervals, it makes sense to also change them on multiple devices and interfaces. Most of the interface parameters can be configured for level 1, level 2, or both.

The following are the interface-level parameters that you can configure:

• The default metric on the interface that is used as a value for the IS-IS metric and assigned when quality of service (QoS) routing is not performed.

• The hello interval (length of time between hello packets sent on the interface) or the default hello packet multiplier used on the interface to determine the hold time sent in IS-IS hello packets. The hold time determines how long a neighbor waits for another hello packet before declaring the neighbor down. This determines how quickly a failed link or neighbor is detected so that routes can be recalculated. Change the hello multiplier in circumstances where hello packets are lost frequently and IS-IS adjacencies are failing unnecessarily. You can raise the hello multiplier and lower the hello interval correspondingly to make the hello protocol more reliable, without increasing the time required to detect a link failure.

• Other time intervals:
  • Complete sequence number PDU (CSNP) interval—CSNPs are sent by the designated device to maintain database synchronization.
  • Retransmission interval—This is the time between retransmission of IS-IS LSPs for point-to-point links.
  • IS-IS LSP retransmission throttle interval—This is the maximum rate (number of milliseconds between packets) at which IS-IS LSPs are resent on point-to-point links. This interval is different from the retransmission interval, which is the time between successive retransmissions of the same LSP.

• Designated device-election priority, which allows you to reduce the number of adjacencies required on a multiaccess network, which in turn reduces the amount of routing protocol traffic and the size of the topology database.

• The interface circuit type, which is the type of adjacency required for neighbors on the specified interface.

• Password authentication for the interface.
# How to Configure ISO CLNS Routing

## Default IS-IS Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore link-state PDU (LSP) errors</td>
<td>Enabled.</td>
</tr>
</tbody>
</table>
| IS-IS type               | Conventional IS-IS—The router acts as both a Level 1 (station) and a Level 2 (area) router.  
                           | Multiarea IS-IS—The first instance of the IS-IS routing process is a Level 1-2 router. Remaining instances are Level 1 routers. |
| Default-information originate | Disabled.                                                                 |
| Log IS-IS adjacency state changes. | Disabled.                                                                     |
| LSP generation throttling timers | Maximum interval between two consecutive occurrences—5 seconds.  
                               | Initial LSP generation delay—50 ms.  
                               | Hold time between the first and second LSP generation—5000 ms. |
| LSP maximum lifetime (without a refresh) | 1200 seconds (20 minutes) before the LSP packet is deleted.               |
| LSP refresh interval     | Every 900 seconds (15 minutes).                                              |
| Maximum LSP packet size  | 1497 bytes.                                                                   |
| NSF Awareness            | Enabled. Allows Layer 3 devices to continue forwarding packets from a neighboring Nonstop Forwarding-capable router during hardware or software changes. |
| Partial route computation (PRC) throttling timers | Maximum PRC wait interval—5 seconds.  
                                           | Initial PRC calculation delay after a topology change—2000 ms.  
                                           | Hold time between the first and second PRC calculation—5000 ms. |
| Partition avoidance      | Disabled.                                                                     |
| Password                 | No area or domain password is defined, and authentication is disabled.       |
### Default Setting

<table>
<thead>

</table>
| Shortest path first (SPF) throttling timers  | Maximum interval between consecutive SFPs—10 seconds.  
Initial SFP calculation after a topology change—5500 ms.  
Hold time between the first and second SFP calculation—5500 ms. |
| Summary-address                              | Disabled.                                                                       |

### Enabling IS-IS Routing

To enable IS-IS, you specify a name and NET for each routing process. You then enable IS-IS routing on the interface and specify the area for each instance of the routing process.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>clns routing</code></td>
<td>Enables ISO connectionless routing on the switch.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device(config)# clns routing</code></td>
<td></td>
</tr>
</tbody>
</table>
| Step 3 | `router isis [area tag]` | Enables the IS-IS routing for the specified routing process and enter IS-IS routing configuration mode.  
(Optional) Use the *area tag* argument to identify the area to which the IS-IS router is assigned. You must enter a value if you are configuring multiple IS-IS areas.  
The first IS-IS instance configured is Level 1-2 by default. Later instances are automatically Level 1. You can change the level of routing by using the `is-type` global configuration command. |
<p>|       | Example: <code>Device(config)# router isis tag1</code> | |
| Step 4 | <code>net network-entity-title</code> | Configures the NETs for the routing process. If you are configuring multiarea IS-IS, specify a NET for each routing process. You can specify a name for a NET and for an address. |
|       | Example: | |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Device(config-router)# net 47.0004.004d.0001.0001.0c11.1111.00 | (Optional) Configures the router to act as a Level 1 (station) router, a Level 2 (area) router for multi-area routing, or both (the default):  
  - **level-1**—act as a station router only  
  - **level-1-2**—act as both a station router and an area router  
  - **level 2**—act as an area router only |
| **Step 5** is-type {level-1 | level-1-2 | level-2-only} | Returns to global configuration mode. |
| Example: Device(config-router)# is-type level-2-only | Step 6 exit  
  Example: Device(config-router)# end | Specifies an interface to route IS-IS, and enter interface configuration mode. If the interface is not already configured as a Layer 3 interface, enter the no switchport command to put it into Layer 3 mode. |
| **Step 7** interface interface-id | Configures an IS-IS routing process for ISO CLNS on the interface and attach an area designator to the routing process. |
| Example: Device(config)# interface gigabitethernet 1/0/1 | **Step 8** ip router isis [area tag]  
  Example: Device(config-if)# ip router isis tag1 | Enables ISO CLNS on the interface. |
| **Step 9** clns router isis [area tag] | **Step 10** ip address ip-address-mask  
  Example: Device(config-if)# ip address 10.0.0.5 255.255.255.0 | Define the IP address for the interface. An IP address is required on all interfaces in an area enabled for IS-IS if any one interface is configured for IS-IS routing. |
| Example: Device(config-if)# end | **Step 11** end  
  Example: Device(config)# end | Returns to privileged EXEC mode. |
| **Step 12** show isis [area tag] database detail  
  Example: | Verifies your entries. |

### Configuring IS-IS Interface Parameters

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td>Specifies the interface to be configured and enter interface configuration mode. If the interface is not already configured as a Layer 3 interface, enter the <code>no switchport</code> command to put it into Layer 3 mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> isis metric default-metric</td>
<td>(Optional) Configures the metric (or cost) for the specified interface.</td>
</tr>
<tr>
<td>[level-1</td>
<td>level-2]</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# isis metric 15</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> isis hello-interval [seconds</td>
<td>(Optional) Specifies the length of time between hello packets sent by</td>
</tr>
<tr>
<td>minimal] [level-1</td>
<td>level-2]</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| Device(config-if)# isis hello-interval minimal | the hello packets sent. With smaller hello intervals, topological changes are detected faster, but there is more routing traffic.  
- **minimal**—causes the system to compute the hello interval based on the hello multiplier so that the resulting hold time is 1 second.  
- **seconds**—the range is from 1 to 65535. The default is 10 seconds. |

**Step 5**  
isis hello-multiplier multiplier [level-1 | level-2]  
Example:  
Device(config-if)# isis hello-multiplier 5  
(Optional) Specifies the number of IS-IS hello packets a neighbor must miss before the router should declare the adjacency as down. The range is from 3 to 1000. The default is 3. Using a smaller hello-multiplier causes fast convergence, but can result in more routing instability. |

**Step 6**  
isis csnp-interval seconds [level-1 | level-2]  
Example:  
Device(config-if)# isis csnp-interval 15  
(Optional) Configures the IS-IS complete sequence number PDU (CSNP) interval for the interface. The range is from 0 to 65535. The default is 10 seconds. |

**Step 7**  
isis retransmit-interval seconds  
Example:  
Device(config-if)# isis retransmit-interval 7  
(Optional) Configures the number of seconds between retransmission of IS-IS LSPs for point-to-point links. The value you specify should be an integer greater than the expected round-trip delay between any two routers on the network. The range is from 0 to 65535. The default is 5 seconds. |

**Step 8**  
isis retransmit-throttle-interval milliseconds  
Example:  
Device(config-if)# isis retransmit-throttle-interval 4000  
(Optional) Configures the IS-IS LSP retransmission throttle interval, which is the maximum rate (number of milliseconds between packets) at which IS-IS LSPs will be re-sent on point-to-point links. The range is from 0 to 65535. The default is determined by the **isis lsp-interval** command. |

**Step 9**  
isis priority value [level-1 | level-2]  
Example:  
Device(config-if)# isis priority 50  
(Optional) Configures the priority to use for designated router election. The range is from 0 to 127. The default is 64. |

**Step 10**  
isis circuit-type {level-1 | level-1-2 | level-2-only}  
Example:  
Device(config-if)# isis circuit-type level-1-2  
(Optional) Configures the type of adjacency desired for neighbors on the specified interface (specify the interface circuit type).  
- **level-1**—a Level 1 adjacency is established if there is at least one area address common to both this node and its neighbors.  
- **level-1-2**—a Level 1 and 2 adjacency is established if the neighbor is also configured as both Level 1 and...

### Monitoring and Maintaining ISO IGRP and IS-IS

You can remove all contents of a CLNS cache or remove information for a particular neighbor or route. You can display specific CLNS or IS-IS statistics, such as the contents of routing tables, caches, and databases. You can also display information about specific interfaces, filters, or neighbors.

The following table lists the privileged EXEC commands for clearing and displaying ISO CLNS and IS-IS routing. For explanations of the display fields, see the *Cisco IOS Apollo Domain, Banyan VINES, DECnet, ISO CLNS and XNS Command Reference*, use the Cisco IOS command reference master index, or search online.

### Table 113: ISO CLNS and IS-IS Clear and Show Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear clns cache</td>
<td>Clears and reinitializes the CLNS routing cache.</td>
</tr>
</tbody>
</table>
### Command | Purpose
--- | ---
`clear clns es-neighbors` | Removes end system (ES) neighbor information from the adjacency database.
`clear clns is-neighbors` | Removes intermediate system (IS) neighbor information from the adjacency database.
`clear clns neighbors` | Removes CLNS neighbor information from the adjacency database.
`clear clns route` | Removes dynamically derived CLNS routing information.
`show clns` | Displays information about the CLNS network.
`show clns cache` | Displays the entries in the CLNS routing cache.
`show clns es-neighbors` | Displays ES neighbor entries, including the associated areas.
`show clns filter-expr` | Displays filter expressions.
`show clns filter-set` | Displays filter sets.
`show clns interface [interface-id]` | Displays the CLNS-specific or ES-IS information about each interface.
`show clns neighbor` | Displays information about IS-IS neighbors.
`show clns protocol` | List the protocol-specific information for each IS-IS or ISO IGRP routing process in this router.
`show clns route` | Displays all the destinations to which this router knows how to route CLNS packets.
`show clns traffic` | Displays information about the CLNS packets this router has seen.
`show ip route isis` | Displays the current state of the ISIS IP routing table.
`show isis database` | Displays the IS-IS link-state database.
`show isis routes` | Displays the IS-IS Level 1 routing table.
`show isis spf-log` | Displays a history of the shortest path first (SPF) calculations for IS-IS.
`show isis topology` | Displays a list of all connected routers in all areas.
`show route-map` | Displays all route maps configured or only the one specified.
`trace clns destination` | Discover the paths taken to a specified destination by packets in the network.

### Configuration Examples for ISO CLNS Routing

#### Example: Configuring IS-IS Routing

This example shows how to configure three routers to run conventional IS-IS as an IP routing protocol. In conventional IS-IS, all routers act as Level 1 and Level 2 routers (by default).

**Router A:**

```
Device(config)# clns routing
Device(config)# router isis
Device(config-router)# net 49.0001.0000.0000.000a.00
Device(config-router)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip router isis
Device(config-if)# clns router isis
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip router isis
Device(config-if)# clns router isis
Device(config-router)# exit
```

**Router B:**

```
Device(config)# clns routing
Device(config)# router isis
Device(config-router)# net 49.0001.0000.0000.000b.00
Device(config-router)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip router isis
Device(config-if)# clns router isis
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip router isis
Device(config-if)# clns router isis
Device(config-router)# exit
```

**Router C:**

```
Device(config)# clns routing
Device(config)# router isis
Device(config-router)# net 49.0001.0000.0000.000c.00
Device(config-router)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip router isis
Device(config-if)# clns router isis
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip router isis
Device(config-if)# clns router isis
Device(config-router)# exit
```
**Information About Multi-VRF CE**

Virtual Private Networks (VPNs) provide a secure way for customers to share bandwidth over an ISP backbone network. A VPN is a collection of sites sharing a common routing table. A customer site is connected to the service-provider network by one or more interfaces, and the service provider associates each interface with a VPN routing table, called a VPN routing/forwarding (VRF) table.

The switch supports multiple VPN routing/forwarding (multi-VRF) instances in customer edge (CE) devices (multi-VRF CE) when the it is running the IP services or advanced IP Services feature set. Multi-VRF CE allows a service provider to support two or more VPNs with overlapping IP addresses.

---

**Note**

The switch does not use Multiprotocol Label Switching (MPLS) to support VPNs.

---

**Understanding Multi-VRF CE**

Multi-VRF CE is a feature that allows a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs. Multi-VRF CE uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF. Interfaces in a VRF can be either physical, such as Ethernet ports, or logical, such as VLAN SVIs, but an interface cannot belong to more than one VRF at any time.

---

**Note**

Multi-VRF CE interfaces must be Layer 3 interfaces.

Multi-VRF CE includes these devices:

- Customer edge (CE) devices provide customers access to the service-provider network over a data link to one or more provider edge routers. The CE device advertises the site’s local routes to the router and learns the remote VPN routes from it. A switch can be a CE.

- Provider edge (PE) routers exchange routing information with CE devices by using static routing or a routing protocol such as BGP, RIPv2, OSPF, or EIGRP. The PE is only required to maintain VPN routes for those VPNs to which it is directly attached, eliminating the need for the PE to maintain all of the service-provider VPN routes. Each PE router maintains a VRF for each of its directly connected sites. Multiple interfaces on a PE router can be associated with a single VRF if all of these sites participate in the same VPN. Each VPN is mapped to a specified VRF. After learning local VPN routes from CEs, a PE router exchanges VPN routing information with other PE routers by using internal BGP (IBPG).

- Provider routers or core routers are any routers in the service provider network that do not attach to CE devices.

With multi-VRF CE, multiple customers can share one CE, and only one physical link is used between the CE and the PE. The shared CE maintains separate VRF tables for each customer and switches or routes packets for each customer based on its own routing table. Multi-VRF CE extends limited PE functionality to a CE device, giving it the ability to maintain separate VRF tables to extend the privacy and security of a VPN to the branch office.
Network Topology

The figure shows a configuration using switches as multiple virtual CEs. This scenario is suited for customers who have low bandwidth requirements for their VPN service, for example, small companies. In this case, multi-VRF CE support is required in the switches. Because multi-VRF CE is a Layer 3 feature, each interface in a VRF must be a Layer 3 interface.

*Figure 88: Switches Acting as Multiple Virtual CEs*

When the CE switch receives a command to add a Layer 3 interface to a VRF, it sets up the appropriate mapping between the VLAN ID and the policy label (PL) in multi-VRF-CE-related data structures and adds the VLAN ID and PL to the VLAN database.

When multi-VRF CE is configured, the Layer 3 forwarding table is conceptually partitioned into two sections:

- The multi-VRF CE routing section contains the routes from different VPNs.
- The global routing section contains routes to non-VPN networks, such as the Internet.

VLAN IDs from different VRFs are mapped into different policy labels, which are used to distinguish the VRFs during processing. For each new VPN route learned, the Layer 3 setup function retrieves the policy label by using the VLAN ID of the ingress port and inserts the policy label and new route to the multi-VRF CE routing section. If the packet is received from a routed port, the port internal VLAN ID number is used; if the packet is received from an SVI, the VLAN number is used.

Packet-Forwarding Process

This is the packet-forwarding process in a multi-VRF-CE-enabled network:

- When the switch receives a packet from a VPN, the switch looks up the routing table based on the input policy label number. When a route is found, the switch forwards the packet to the PE.
- When the ingress PE receives a packet from the CE, it performs a VRF lookup. When a route is found, the router adds a corresponding MPLS label to the packet and sends it to the MPLS network.
- When an egress PE receives a packet from the network, it strips the label and uses the label to identify the correct VPN routing table. Then it performs the normal route lookup. When a route is found, it forwards the packet to the correct adjacency.
- When a CE receives a packet from an egress PE, it uses the input policy label to look up the correct VPN routing table. If a route is found, it forwards the packet within the VPN.
Network Components

To configure VRF, you create a VRF table and specify the Layer 3 interface associated with the VRF. Then configure the routing protocols in the VPN and between the CE and the PE. BGP is the preferred routing protocol used to distribute VPN routing information across the provider’s backbone. The multi-VRF CE network has three major components:

- VPN route target communities—lists of all other members of a VPN community. You need to configure VPN route targets for each VPN community member.

- Multiprotocol BGP peering of VPN community PE routers—propagates VRF reachability information to all members of a VPN community. You need to configure BGP peering in all PE routers within a VPN community.

- VPN forwarding—transports all traffic between all VPN community members across a VPN service-provider network.

VRF-Aware Services

IP services can be configured on global interfaces, and these services run within the global routing instance. IP services are enhanced to run on multiple routing instances; they are VRF-aware. Any configured VRF in the system can be specified for a VRF-aware service.

VRF-Aware services are implemented in platform-independent modules. VRF means multiple routing instances in Cisco IOS. Each platform has its own limit on the number of VRFs it supports.

VRF-aware services have the following characteristics:

- The user can ping a host in a user-specified VRF.

- ARP entries are learned in separate VRFs. The user can display Address Resolution Protocol (ARP) entries for specific VRFs.

How to Configure Multi-VRF CE

Default Multi-VRF CE Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>VRF</td>
<td>Disabled. No VRFs are defined.</td>
</tr>
<tr>
<td>Maps</td>
<td>No import maps, export maps, or route maps are defined.</td>
</tr>
<tr>
<td>VRF maximum routes</td>
<td>Fast Ethernet switches: 8000 Gigabit Ethernet switches: 12000.</td>
</tr>
<tr>
<td>Forwarding table</td>
<td>The default for an interface is the global routing table.</td>
</tr>
</tbody>
</table>
Multi-VRF CE Configuration Guidelines

Note

To use multi-VRF CE, you must have the IP services or advanced IP services feature set enabled on your switch.

- A switch with multi-VRF CE is shared by multiple customers, and each customer has its own routing table.
- Because customers use different VRF tables, the same IP addresses can be reused. Overlapped IP addresses are allowed in different VPNs.
- Multi-VRF CE lets multiple customers share the same physical link between the PE and the CE. Trunk ports with multiple VLANs separate packets among customers. Each customer has its own VLAN.
- Multi-VRF CE does not support all MPLS-VRF functionality. It does not support label exchange, LDP adjacency, or labeled packets.
- For the PE router, there is no difference between using multi-VRF CE or using multiple CEs. In Figure 41-6, multiple virtual Layer 3 interfaces are connected to the multi-VRF CE device.
- The switch supports configuring VRF by using physical ports, VLAN SVIs, or a combination of both. The SVIs can be connected through an access port or a trunk port.
- A customer can use multiple VLANs as long as they do not overlap with those of other customers. A customer’s VLANs are mapped to a specific routing table ID that is used to identify the appropriate routing tables stored on the switch.
- The switch supports one global network and up to 26 VRFs.
- Most routing protocols (BGP, OSPF, RIP, and static routing) can be used between the CE and the PE. However, we recommend using external BGP (EBGP) for these reasons:
  - BGP does not require multiple algorithms to communicate with multiple CEs.
  - BGP is designed for passing routing information between systems run by different administrations.
  - BGP makes it easy to pass attributes of the routes to the CE.
- Multi-VRF CE does not affect the packet switching rate.
- VPN multicast is not supported.
- You can enable VRF on a private VLAN, and the reverse.
- You cannot enable VRF when policy-based routing (PBR) is enabled on an interface, and the reverse.
- You cannot enable VRF when Web Cache Communication Protocol (WCCP) is enabled on an interface, and the reverse.

Configuring VRFs

For complete syntax and usage information for the commands, see the switch command reference for this release and the Cisco IOS Switching Services Command Reference.
## Configuring VRFs

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ip routing</td>
<td>Enables IP routing.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ip routing</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip vrf vrf-name</td>
<td>Names the VRF, and enter VRF configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ip vrf vpn1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> rd route-distinguisher</td>
<td>Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and arbitrary number (A.B.C.D:y).</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-vrf)# rd 100:2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> route-target {export</td>
<td>import</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-vrf)# route-target both 100:2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> import map route-map</td>
<td>(Optional) Associates a route map with the VRF.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-vrf)# import map importmap1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> interface interface-id</td>
<td>Specifies the Layer 3 interface to be associated with the VRF, and enter interface configuration mode. The interface can be a routed port or SVI.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-vrf)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> ip vrf forwarding vrf-name</td>
<td>Associates the VRF with the Layer 3 interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ip vrf forwarding vpn1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring VRF-Aware Services

These services are VRF-Aware:

- ARP
- Ping
- Simple Network Management Protocol (SNMP)
- Unicast Reverse Path Forwarding (uRPF)
- Syslog
- Traceroute
- FTP and TFTP

**Note**

The switch does not support VRF-aware services for Unicast Reverse Path Forwarding (uRPF) or Network Time Protocol (NTP).

### Configuring VRF-Aware Services for ARP

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>show ip arp vrf vrf-name</code></td>
<td>Displays the ARP table in the specified VRF.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show ip arp vrf vpn1</td>
<td></td>
</tr>
</tbody>
</table>
Configuring VRF-Aware Services for Ping

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> ping vrf vrf-name ip-host</td>
<td>Displays the ARP table in the specified VRF.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# ping vrf vpn1 ip-host</td>
<td></td>
</tr>
</tbody>
</table>

Configuring VRF-Aware Services for SNMP

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> snmp-server trap authentication vrf</td>
<td>Enables SNMP traps for packets on a VRF.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# snmp-server trap authentication vrf</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> snmp-server engineID remote host vrf vpn-instance engine-id string</td>
<td>Configures a name for the remote SNMP engine on a switch.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# snmp-server engineID remote 172.16.20.3 vrf vpn1 80000009030000B064EFE100</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> snmp-server host host vrf vpn-instance traps community</td>
<td>Specifies the recipient of an SNMP trap operation and specifies the VRF table to be used for sending SNMP traps.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# snmp-server host 172.16.20.3 vrf vpn1 traps comaccess</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring VRF-Aware Services for uRPF

uRPF can be configured on an interface assigned to a VRF, and source lookup is done in the VRF table.

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

#### Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>interface interface-id</code></td>
<td>Enters interface configuration mode, and specifies the Layer 3 interface to configure.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# interface gigabitethernet 1/0/1</code></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>no switchport</code></td>
<td>Removes the interface from Layer 2 configuration mode if it is a physical interface.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config-if)# no switchport</code></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>ip vrf forwarding vrf-name</code></td>
<td>Configures VRF on the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Configuring VRF-Aware RADIUS

To configure VRF-Aware RADIUS, you must first enable AAA on a RADIUS server. The switch supports the `ip vrf forwarding vrf-name` server-group configuration and the `ip radius source-interface` global configuration commands, as described in the Per VRF AAA Feature Guide.

### Configuring VRF-Aware Services for Syslog

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enables or temporarily disables logging of storage router event message. |
| logging on        |                     |
| Example:          |                     |
| Device(config)# logging on |     |

| **Step 3**        | Specifies the host address of the syslog server where logging messages are to be sent. |
| logging host ip-address vrf vrf-name |                     |
| Example:          |                     |
| Device(config)# logging host 10.10.1.0 vrf vpn1 |     |
Configuring VRF-Aware Services for Traceroute

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the Cisco IOS Switching Services Command Reference, Release 12.4.

Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>traceroute vrf vrf-name ipaddress</td>
<td>Specifies the name of a VPN VRF in which to find the destination address.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# traceroute vrf vpn2 10.10.1.1</td>
<td></td>
</tr>
</tbody>
</table>

Configuring VRF-Aware Services for FTP and TFTP

So that FTP and TFTP are VRF-aware, you must configure some FTP/TFTP CLIs. For example, if you want to use a VRF table that is attached to an interface, say E1/0, you need to configure the ip tftp source-interface E1/0 or the ip ftp source-interface E1/0 command to inform TFTP or FTP server to use a specific routing table. In this example, the VRF table is used to look up the destination IP address. These changes are backward-compatible and do not affect existing behavior. That is, you can use the source-interface CLI to send packets out a particular interface even if no VRF is configured on that interface.
**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ip ftp source-interface interface-type interface-number</td>
<td>Specifies the source IP address for FTP connections.</td>
</tr>
<tr>
<td>Example: Device(config)# ip ftp source-interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ip tftp source-interface interface-type interface-number</td>
<td>Specifies the source IP address for TFTP connections.</td>
</tr>
<tr>
<td>Example: Device(config)# ip tftp source-interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring Multicast VRFs**

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS IP Multicast Command Reference*.

For more information about configuring a multicast within a Multi-VRF CE, see the *IP Routing: Protocol-Independent Configuration Guide, Cisco IOS Release 15S*. 
## Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> ip routing</td>
<td>Enables IP routing mode.</td>
</tr>
<tr>
<td>Example: Device(config)# ip routing</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip vrf vrf-name</td>
<td>Names the VRF, and enter VRF configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# ip vrf vpn1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> rd route-distinguisher</td>
<td>Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y)</td>
</tr>
<tr>
<td>Example: Device(config-vrf)# rd 100:2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> route-target import</td>
<td>Creates a list of import, export, or import and export route target communities for the specified VRF. Enter either an AS system number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y). The route-target-ext-community should be the same as the route-distinguisher entered in Step 4.</td>
</tr>
<tr>
<td>Example: Device(config-vrf)# route-target import 100:2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> import map route-map</td>
<td>(Optional) Associates a route map with the VRF.</td>
</tr>
<tr>
<td>Example: Device(config-vrf)# import map importmap1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> ip multicast-routing vrf vrf-name distributed</td>
<td>(Optional) Enables global multicast routing for VRF table.</td>
</tr>
<tr>
<td>Example: Device(config-vrf)# ip multicast-routing vrf vpn1 distributed</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> interface interface-id</td>
<td>Specifies the Layer 3 interface to be associated with the VRF, and enter interface configuration mode. The interface can be a routed port or an SVI.</td>
</tr>
<tr>
<td>Example: Device(config-vrf)# interface gigabitethernet 1/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> ip vrf forwarding vrf-name</td>
<td>Associates the VRF with the Layer 3 interface.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a VPN Routing Session

Routing within the VPN can be configured with any supported routing protocol (RIP, OSPF, EIGRP, or BGP) or with static routing. The configuration shown here is for OSPF, but the process is the same for other protocols.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)#</code></td>
<td></td>
</tr>
</tbody>
</table>

**Note**

To configure an EIGRP routing process to run within a VRF instance, you must configure an autonomous-system number by entering the `autonomous-system autonomous-system-number address-family` configuration mode command.

### Configuring a VPN Routing Session

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 10</strong></td>
<td>Configures IP address for the Layer 3 interface.</td>
</tr>
<tr>
<td><code>ip address ip-address mask</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)#</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Device(config-if)# ip address 10.1.5.1 255.255.255.0</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 11**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enables PIM on the VRF-associated Layer 3 interface.</td>
<td></td>
</tr>
<tr>
<td><code>ip pim sparse-dense mode</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-if)#</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Device(config-if)# ip pim sparse-dense mode</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 12**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)#</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Device(config)# end</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 13**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verifies the configuration. Displays information about the configured VRFs.</td>
<td></td>
</tr>
<tr>
<td>`show ip vrf [brief</td>
<td>detail</td>
</tr>
<tr>
<td><code>Device#</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Device# show ip vrf detail vpn1</code></td>
<td></td>
</tr>
</tbody>
</table>

**Step 14**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) Saves your entries in the configuration file.</td>
<td></td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td><code>Device#</code></td>
<td></td>
</tr>
<tr>
<td>Example: <code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td>Enables OSPF routing, specifies a VPN forwarding table, and enter router configuration mode.</td>
</tr>
<tr>
<td>Step 2 router ospf process-id vrf vrf-name</td>
<td>(Optional) Logs changes in the adjacency state. This is the default state.</td>
</tr>
<tr>
<td>Device(config)# router ospf 1 vrf vpn1</td>
<td></td>
</tr>
<tr>
<td>Step 3 log-adjacency-changes</td>
<td>Sets the switch to redistribute information from the BGP network to the OSPF network.</td>
</tr>
<tr>
<td>Device(config-router)# log-adjacency-changes</td>
<td></td>
</tr>
<tr>
<td>Step 4 redistribute bgp autonomous-system-number subnets</td>
<td>Defines a network address and mask on which OSPF runs and the area ID for that network address.</td>
</tr>
<tr>
<td>Device(config-router)# redistribute bgp 10 subnets</td>
<td></td>
</tr>
<tr>
<td>Step 5 network network-number area area-id</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Device(config-router)# network 1 area 2</td>
<td></td>
</tr>
<tr>
<td>Step 6 end</td>
<td>Verifies the configuration of the OSPF network.</td>
</tr>
<tr>
<td>Device(config-router)# end</td>
<td></td>
</tr>
<tr>
<td>Step 7 show ip ospf process-id</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Device# show ip ospf 1</td>
<td></td>
</tr>
<tr>
<td>Step 8 copy running-config startup-config</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring BGP PE to CE Routing Sessions

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>----------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> router bgp autonomous-system-number</td>
<td>Configures the BGP routing process with the AS number passed to other BGP routers, and enter router configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# router bgp 2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> network network-number mask network-mask</td>
<td>Specifies a network and mask to announce using BGP.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# network 5 mask 255.255.255.0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> redistribute ospf process-id match internal</td>
<td>Sets the switch to redistribute OSPF internal routes.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# redistribute ospf 1 match internal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> network network-number area area-id</td>
<td>Defines a network address and mask on which OSPF runs and the area ID for that network address.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# network 5 area 2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> address-family ipv4 vrf vrf-name</td>
<td>Defines BGP parameters for PE to CE routing sessions, and enter VRF address-family mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# address-family ipv4 vrf vpn1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> neighbor address remote-as as-number</td>
<td>Defines a BGP session between PE and CE routers.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# neighbor 10.1.1.2 remote-as 2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> neighbor address activate</td>
<td>Activates the advertisement of the IPv4 address family.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# neighbor 10.2.1.1 activate</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-router)# end</td>
<td></td>
</tr>
<tr>
<td>Step 10</td>
<td>Command or Action</td>
</tr>
<tr>
<td>---------</td>
<td>-------------------</td>
</tr>
<tr>
<td>show ip bgp [ipv4] [neighbors]</td>
<td>Verifies BGP configuration.</td>
</tr>
<tr>
<td>Device# show ip bgp ipv4 neighbors</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 11</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

## Monitoring Multi-VRF CE

### Table 115: Commands for Displaying Multi-VRF CE Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip protocols vrf vrf-name</td>
<td>Displays routing protocol information associated with a VRF.</td>
</tr>
<tr>
<td>show ip route vrf vrf-name [connected] [protocol [as-number]] [list] [mobile] [odr] [profile] [static] [summary] [supernets-only]</td>
<td>Displays IP routing table information associated with a VRF.</td>
</tr>
<tr>
<td>show ip vrf [brief</td>
<td>detail</td>
</tr>
</tbody>
</table>

For more information about the information in the displays, see the *Cisco IOS Switching Services Command Reference, Release 12.4*.

## Configuration Examples for Multi-VRF CE

### Multi-VRF CE Configuration Example

OSPF is the protocol used in VPN1, VPN2, and the global network. BGP is used in the CE to PE connections. The examples following the illustration show how to configure a switch as CE Switch A, and the VRF configuration for customer switches D and F. Commands for configuring CE Switch C and the other customer switches are not included but would be similar. The example also includes commands for configuring traffic to Switch A for a Catalyst 6000 or Catalyst 6500 switch acting as a PE router.
On Switch A, enable routing and configure VRF.

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# ip routing
Device(config)# ip vrf v11
Device(config-vrf)# rd 800:1
Device(config-vrf)# route-target export 800:1
Device(config-vrf)# route-target import 800:1
Device(config-vrf)# exit
Device(config)# ip vrf v12
Device(config-vrf)# rd 800:2
Device(config-vrf)# route-target export 800:2
Device(config-vrf)# route-target import 800:2
Device(config-vrf)# exit
```

Configure the loopback and physical interfaces on Switch A. Gigabit Ethernet port 1 is a trunk connection to the PE. Gigabit Ethernet ports 8 and 11 connect to VPNs:

```
Device(config)# interface loopback1
Device(config-if)# ip vrf forwarding v11
Device(config-if)# ip address 8.8.1.8 255.255.255.0
Device(config-if)# exit

Device(config)# interface loopback2
Device(config-if)# ip vrf forwarding v12
Device(config-if)# ip address 8.8.2.8 255.255.255.0
Device(config-if)# exit

Device(config)# interface gigabitethernet1/0/5
Device(config-if)# switchport trunk encapsulation dot1q
```
Device(config-if)# switchport mode trunk
Device(config-if)# no ip address
Device(config-if)# exit
Device(config)# interface gigabitethernet1/0/8
Device(config-if)# switchport access vlan 208
Device(config-if)# no ip address
Device(config-if)# exit
Device(config)# interface gigabitethernet1/0/11
Device(config-if)# switchport trunk encapsulation dot1q
Device(config-if)# switchport mode trunk
Device(config-if)# no ip address
Device(config-if)# exit

Configure the VLANs used on Switch A. VLAN 10 is used by VRF 11 between the CE and the PE. VLAN 20 is used by VRF 12 between the CE and the PE. VLANs 118 and 208 are used for the VPNs that include Switch F and Switch D, respectively:

Device(config)# interface vlan10
Device(config-if)# ip vrf forwarding v11
Device(config-if)# ip address 38.0.0.8 255.255.255.0
Device(config-if)# exit
Device(config)# interface vlan20
Device(config-if)# ip vrf forwarding v12
Device(config-if)# ip address 83.0.0.8 255.255.255.0
Device(config-if)# exit
Device(config)# interface vlan118
Device(config-if)# ip vrf forwarding v12
Device(config-if)# ip address 118.0.0.8 255.255.255.0
Device(config-if)# exit
Device(config)# interface vlan208
Device(config-if)# ip vrf forwarding v11
Device(config-if)# ip address 208.0.0.8 255.255.255.0
Device(config-if)# exit

Configure OSPF routing in VPN1 and VPN2.

Device(config)# router ospf 1 vrf vl1
Device(config-router)# redistribute bgp 800 subnets
Device(config-router)# network 208.0.0.0 0.0.0.255 area 0
Device(config-router)# exit
Device(config)# router ospf 2 vrf vl2
Device(config-router)# redistribute bgp 800 subnets
Device(config-router)# network 118.0.0.0 0.0.0.255 area 0
Device(config-router)# exit

Configure BGP for CE to PE routing.

Device(config)# router bgp 800
Device(config-router)# address-family ipv4 vrf vl2
Device(config-router-af)# redistribute ospf 2 match internal
Device(config-router-af)# neighbor 83.0.0.3 remote-as 100
Device(config-router-af)# neighbor 83.0.0.3 activate
Device(config-router-af)# network 8.8.2.0 mask 255.255.255.0
Device(config-router-af)# exit
Device(config-router)# address-family ipv4 vrf vl1
Device(config-router-af)# redistribute ospf 1 match internal
Device(config-router-af)# neighbor 38.0.0.3 remote-as 100
Device(config-router-af)# neighbor 38.0.0.3 activate
Device(config-router-af)# network 8.8.1.0 mask 255.255.255.0
Device(config-router-af)# end

Switch D belongs to VPN 1. Configure the connection to Switch A by using these commands.
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# ip routing
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 208.0.0.20 255.255.255.0
Device(config-if)# exit

Device(config)# router ospf 101
Device(config-router)# network 208.0.0.0 0.0.0.255 area 0
Device(config-router)# end

Switch F belongs to VPN 2. Configure the connection to Switch A by using these commands.

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# ip routing
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# switchport trunk encapsulation dot1q
Device(config-if)# switchport mode trunk
Device(config-if)# no ip address
Device(config-if)# exit

Device(config)# interface vlan118
Device(config-if)# ip address 118.0.0.11 255.255.255.0
Device(config-if)# exit

Device(config)# router ospf 101
Device(config-router)# network 118.0.0.0 0.0.0.255 area 0
Device(config-router)# end

When used on switch B (the PE router), these commands configure only the connections to the CE device, Switch A.

Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip vrf v1
Router(config-vrf)# rd 100:1
Router(config-vrf)# route-target export 100:1
Router(config-vrf)# route-target import 100:1
Router(config-vrf)# exit

Router(config)# ip vrf v2
Router(config-vrf)# rd 100:2
Router(config-vrf)# route-target export 100:2
Router(config-vrf)# route-target import 100:2
Router(config-vrf)# exit

Router(config)# ip cef
Router(config)# interface Loopback1
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 3.3.1.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Loopback2
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 3.3.2.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface gigabitethernet1/1/0.10
Router(config-if)# encapsulation dot1q 10
Router(config-if)# ip vrf forwarding v1

Router (config-if)# exit

Router(config)# interface gigabitethernet1/1/0.20
Router(config-if)# encapsulation dot1q 20
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 83.0.0.3 255.255.255.0
Router(config-if)# exit

Router(config)# router bgp 100
Router(config-router)# address-family ipv4 vrf v2
Router(config-router-af)# neighbor 83.0.0.8 remote-as 800
Router(config-router-af)# neighbor 83.0.0.8 activate
Router(config-router-af)# network 3.3.2.0 mask 255.255.255.0
Router(config-router-af)# exit
Router(config-router)# address-family ipv4 vrf vl
Router(config-router-af)# neighbor 38.0.0.8 remote-as 800
Router(config-router-af)# neighbor 38.0.0.8 activate
Router(config-router-af)# network 3.3.1.0 mask 255.255.255.0
Router(config-router-af)# end

Configuring Unicast Reverse Path Forwarding

The unicast reverse path forwarding (unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

Note

- Unicast RPF is supported in IP Services.
- Do not configure unicast RPF if the switch is in a mixed hardware stack combining more than one switch type. For example, Catalyst 3750-X, Catalyst 3750-E, and Catalyst 3750 switches.

For detailed IP unicast RPF configuration information, see the Other Security Features chapter in the Cisco IOS Security Configuration Guide.

Protocol-Independent Features

This section describes IP routing protocol-independent features that are available on switches running the IP Base or the IP Services feature set. Except that with the IP Base feature set, protocol-related features are available only for RIP. For a complete description of the IP routing protocol-independent commands in this chapter, see the “IP Routing Protocol-Independent Commands” chapter of the Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols.
Distributed Cisco Express Forwarding

Information About Cisco Express Forwarding

Cisco Express Forwarding (CEF) is a Layer 3 IP switching technology used to optimize network performance. CEF implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. CEF is less CPU-intensive than fast switching route caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed CEF (dCEF) in the stack. In dynamic networks, fast switching cache entries are frequently invalidated because of routing changes, which can cause traffic to be process switched using the routing table, instead of fast switched using the route cache. CEF and dCEF use the Forwarding Information Base (FIB) lookup table to perform destination-based switching of IP packets.

The two main components in CEF and dCEF are the distributed FIB and the distributed adjacency tables.

- The FIB is similar to a routing table or information base and maintains a mirror image of the forwarding information in the IP routing table. When routing or topology changes occur in the network, the IP routing table is updated, and those changes are reflected in the FIB. The FIB maintains next-hop address information based on the information in the IP routing table. Because the FIB contains all known routes that exist in the routing table, CEF eliminates route cache maintenance, is more efficient for switching traffic, and is not affected by traffic patterns.

- Nodes in the network are said to be adjacent if they can reach each other with a single hop across a link layer. CEF uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all FIB entries.

Because the switch or switch stack uses Application Specific Integrated Circuits (ASICs) to achieve Gigabit-speed line rate IP traffic, CEF or dCEF forwarding applies only to the software-forwarding path, that is, traffic that is forwarded by the CPU.

How to Configure Cisco Express Forwarding

CEF or distributed CEF is enabled globally by default. If for some reason it is disabled, you can re-enable it by using the `ip cef` or `ip cef distributed` global configuration command.

The default configuration is CEF or dCEF enabled on all Layer 3 interfaces. Entering the `no ip route-cache cef` interface configuration command disables CEF for traffic that is being forwarded by software. This command does not affect the hardware forwarding path. Disabling CEF and using the `debug ip packet detail` privileged EXEC command can be useful to debug software-forwarded traffic. To enable CEF on an interface for the software-forwarding path, use the `ip route-cache cef` interface configuration command.

Caution

Although the `no ip route-cache cef` interface configuration command to disable CEF on an interface is visible in the CLI, we strongly recommend that you do not disable CEF or dCEF on interfaces except for debugging purposes.

To enable CEF or dCEF globally and on an interface for software-forwarded traffic if it has been disabled:

**SUMMARY STEPS**

1. `configure terminal`
2. `ip cef`
### DETAILED STEPS

<table>

**Number of Equal-Cost Routing Paths**

**Information About Equal-Cost Routing Paths**

When a router has two or more routes to the same network with the same metrics, these routes can be thought of as having an equal cost. The term parallel path is another way to see occurrences of equal-cost routes in a routing table. If a router has two or more equal-cost paths to a network, it can use them concurrently. Parallel paths provide redundancy in case of a circuit failure and also enable a router to load balance packets over the available paths for more efficient use of available bandwidth. Equal-cost routes are supported across switches in a stack.

Even though the router automatically learns about and configures equal-cost routes, you can control the maximum number of parallel paths supported by an IP routing protocol in its routing table. Although the switch software allows a maximum of 32 equal-cost routes, the switch hardware will never use more than 16 paths per route.
# How to Configure Equal-Cost Routing Paths

## Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
|      | *Example:*  
Device# configure terminal |         |
| 2    | `router {bgp | rip | ospf | eigrp}` | Enters router configuration mode. |
|      | *Example:*  
Device(config)# router eigrp |         |
| 3    | `maximum-paths maximum` | Sets the maximum number of parallel paths for the protocol routing table. The range is from 1 to 16; the default is 4 for most IP routing protocols, but only 1 for BGP. |
|      | *Example:*  
Device(config-router)# maximum-paths 2 |         |
| 4    | `end` | Returns to privileged EXEC mode. |
|      | *Example:*  
Device(config-router)# end |         |
| 5    | `show ip protocols` | Verifies the setting in the Maximum path field. |
|      | *Example:*  
Device# show ip protocols |         |
| 6    | `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
|      | *Example:*  
Device# copy running-config startup-config |         |

## Static Unicast Routes

### Information About Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

The switch retains static routes until you remove them. However, you can override static routes with dynamic routing information by assigning administrative distance values. Each dynamic routing protocol has a default administrative distance, as listed in Table 41-16. If you want a static route to be overridden by information from a dynamic routing protocol, set the administrative distance of the static route higher than that of the dynamic protocol.
### Configuring Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

Follow these steps to configure a static route:

### Default Routes and Networks

#### Information About Default Routes and Networks

A router might not be able to learn the routes to all other networks. To provide complete routing capability, you can use some routers as smart routers and give the remaining routers default routes to the smart router. (Smart routers have routing table information for the entire internetwork.) These default routes can be dynamically learned or can be configured in the individual routers. Most dynamic interior routing protocols include a mechanism for causing a smart router to generate dynamic default information that is then forwarded to other routers.

If a router has a directly connected interface to the specified default network, the dynamic routing protocols running on that device generate a default route. In RIP, it advertises the pseudonetwork 0.0.0.0.

A router that is generating the default for a network also might need a default of its own. One way a router can generate its own default is to specify a static route to the network 0.0.0.0 through the appropriate device.
When default information is passed through a dynamic routing protocol, no further configuration is required. The system periodically scans its routing table to choose the optimal default network as its default route. In IGRP networks, there might be several candidate networks for the system default. Cisco routers use administrative distance and metric information to set the default route or the gateway of last resort.

If dynamic default information is not being passed to the system, candidates for the default route are specified with the `ip default-network` global configuration command. If this network appears in the routing table from any source, it is flagged as a possible choice for the default route. If the router has no interface on the default network, but does have a path to it, the network is considered as a possible candidate, and the gateway to the best default path becomes the gateway of last resort.

### How to Configure Default Routes and Networks

### Route Maps to Redistribute Routing Information

#### Information About Route Maps

The switch can run multiple routing protocols simultaneously, and it can redistribute information from one routing protocol to another. Redistributing information from one routing protocol to another applies to all supported IP-based routing protocols.
You can also conditionally control the redistribution of routes between routing domains by defining enhanced packet filters or route maps between the two domains. The `match` and `set` route-map configuration commands define the condition portion of a route map. The `match` command specifies that a criterion must be matched. The `set` command specifies an action to be taken if the routing update meets the conditions defined by the `match` command. Although redistribution is a protocol-independent feature, some of the `match` and `set` route-map configuration commands are specific to a particular protocol.

One or more `match` commands and one or more `set` commands follow a `route-map` command. If there are no `match` commands, everything matches. If there are no `set` commands, nothing is done, other than the match. Therefore, you need at least one `match` or `set` command.

---

**Note**

A route map with no `set` route-map configuration commands is sent to the CPU, which causes high CPU utilization.

You can also identify route-map statements as `permit` or `deny`. If the statement is marked as a deny, the packets meeting the match criteria are sent back through the normal forwarding channels (destination-based routing). If the statement is marked as permit, set clauses are applied to packets meeting the match criteria. Packets that do not meet the match criteria are forwarded through the normal routing channel.

## How to Configure a Route Map

Although each of Steps 3 through 14 in the following section is optional, you must enter at least one `match` route-map configuration command and one `set` route-map configuration command.

---

**Note**

The keywords are the same as defined in the procedure to control the route distribution.

### Procedure

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# route-map rip-to-ospf permit 4</td>
<td>Defines any route maps used to control redistribution and enter route-map configuration mode.</td>
</tr>
</tbody>
</table>

`map-tag`—A meaningful name for the route map. The `redistribute` router configuration command uses this name to reference this route map. Multiple route maps might share the same map tag name.

(Optional) If `permit` is specified and the match criteria are met for this route map, the route is redistributed as controlled by the set actions. If `deny` is specified, the route is not redistributed.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3** match as-path *path-list-number*  
Example:  
Device(config-route-map)#match as-path 10 | Matches a BGP AS path access list. |
| **Step 4** match community-list *community-list-number* [exact]  
Example:  
Device(config-route-map)# match community-list 150 | Matches a BGP community list. |
| **Step 5** match ip address *access-list-number* | Matches a standard access list by specifying the name or number. It can be an integer from 1 to 199. |
| Example:  
Device(config-route-map)# match ip address 5 80 | |
| **Step 6** match metric *metric-value*  
Example:  
Device(config-route-map)# match metric 2000 | Matches the specified route metric. The *metric-value* can be an EIGRP metric with a specified value from 0 to 4294967295. |
| **Step 7** match ip next-hop *access-list-number* | Matches a next-hop router address passed by one of the access lists specified (numbered from 1 to 199). |
| Example:  
Device(config-route-map)# match ip next-hop 8 45 | |
| **Step 8** match tag *tag value*  
Example:  
Device(config-route-map)# match tag 3500 | Matches the specified tag value in a list of one or more route tag values. Each can be an integer from 0 to 4294967295. |
| **Step 9** match interface *type number*  
Example:  
Device(config-route-map)# match interface gigabitethernet 1/0/1 | Matches the specified next hop route out one of the specified interfaces. |
| **Step 10** match ip route-source *access-list-number* | Matches the address specified by the specified advertised access lists.  
Example:  
Device(config-route-map)# match ip route-source 192.168.1.0 255.255.255.0 |
<table>
<thead>

</table>
How to Control Route Distribution

Although each of Steps 3 through 14 in the following section is optional, you must enter at least one **match** route-map configuration command and one **set** route-map configuration command.

**Note**
The keywords are the same as defined in the procedure to configure the route map for redistribution.

The metrics of one routing protocol do not necessarily translate into the metrics of another. For example, the RIP metric is a hop count, and the IGRP metric is a combination of five qualities. In these situations, an artificial metric is assigned to the redistributed route. Uncontrolled exchanging of routing information between different routing protocols can create routing loops and seriously degrade network operation.

If you have not defined a default redistribution metric that replaces metric conversion, some automatic metric translations occur between routing protocols:

- RIP can automatically redistribute static routes. It assigns static routes a metric of 1 (directly connected).
- Any protocol can redistribute other routing protocols if a default mode is in effect.

### Policy-Based Routing

#### Information About Policy-Based Routing

You can use policy-based routing (PBR) to configure a defined policy for traffic flows. By using PBR, you can have more control over routing by reducing the reliance on routes derived from routing protocols. PBR can specify and implement routing policies that allow or deny paths based on:

- Identity of a particular end system
- Application
- Protocol

You can use PBR to provide equal-access and source-sensitive routing, routing based on interactive versus batch traffic, or routing based on dedicated links. For example, you could transfer stock records to a corporate office on a high-bandwidth, high-cost link for a short time while transmitting routine application data such as e-mail over a low-bandwidth, low-cost link.

With PBR, you classify traffic using access control lists (ACLs) and then make traffic go through a different path. PBR is applied to incoming packets. All packets received on an interface with PBR enabled are passed through route maps. Based on the criteria defined in the route maps, packets are forwarded (routed) to the appropriate next hop.

- Route map statement marked as permit is processed as follows:
  - A match command can match on length or multiple ACLs. A route map statement can contain multiple match commands. Logical or algorithm function is performed across all the match commands to reach a permit or deny decision.

For example:

match length A B

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-router)# default-metric 1000 100 250 100 1500</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-router)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> show route-map</td>
<td>Displays all route maps configured or only the one specified to verify configuration.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show route-map</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
match ip address acl1 acl2
match ip address acl3

A packet is permitted if it is permitted by match length A B or acl1 or acl2 or acl3

• If the decision reached is permit, then the action specified by the set command is applied on the packet.
• If the decision reached is deny, then the PBR action (specified in the set command) is not applied. Instead the processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.

• For PBR, route-map statements marked as deny are not supported.

You can use standard IP ACLs to specify match criteria for a source address or extended IP ACLs to specify match criteria based on an application, a protocol type, or an end station. The process proceeds through the route map until a match is found. If no match is found, normal destination-based routing occurs. There is an implicit deny at the end of the list of match statements.

If match clauses are satisfied, you can use a set clause to specify the IP addresses identifying the next hop router in the path.

For details about PBR commands and keywords, see Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols.

How to Configure PBR

• To use PBR, you must have the IP Base feature set enabled on the switch or stack master.
• Multicast traffic is not policy-routed. PBR applies only to unicast traffic.
• You can enable PBR on a routed port or an SVI.
• The switch supports PBR based on match length.
• You can apply a policy route map to an EtherChannel port channel in Layer 3 mode, but you cannot apply a policy route map to a physical interface that is a member of the EtherChannel. If you try to do so, the command is rejected. When a policy route map is applied to a physical interface, that interface cannot become a member of an EtherChannel.
• You can define a maximum of 128 IP policy route maps on the switch or switch stack.
• You can define a maximum of 512 access control entries (ACEs) for PBR on the switch or switch stack.
• When configuring match criteria in a route map, follow these guidelines:
  • Do not match ACLs that permit packets destined for a local address.

• VRF and PBR are mutually exclusive on a switch interface. You cannot enable VRF when PBR is enabled on an interface. The reverse is also true, you cannot enable PBR when VRF is enabled on an interface.
• Web Cache Communication Protocol (WCCP) and PBR are mutually exclusive on a switch interface. You cannot enable WCCP when PBR is enabled on an interface. The reverse is also true, you cannot enable PBR when WCCP is enabled on an interface.
• The number of hardware entries used by PBR depends on the route map itself, the ACLs used, and the order of the ACLs and route-map entries.
• PBR based on TOS, DSCP and IP Precedence are not supported.

• Set interface, set default next-hop and set default interface are not supported.

• ip next-hop recursive and ip next-hop verify availability features are not available and the next-hop should be directly connected.

• Policy-maps with no set actions are supported. Matching packets are routed normally.

• Policy-maps with no match clauses are supported. Set actions are applied to all packets.

By default, PBR is disabled on the switch. To enable PBR, you must create a route map that specifies the match criteria and the resulting action. Then, you must enable PBR for that route map on an interface. All packets arriving on the specified interface matching the match clauses are subject to PBR.

Packets that are generated by the switch, or local packets, are not normally policy-routed. When you globally enable local PBR on the switch, all packets that originate on the switch are subject to local PBR. Local PBR is disabled by default.

SUMMARY STEPS

1. configure terminal
2. route-map map-tag [permit] [sequence number]
3. match ip address {access-list-number | access-list-name} [access-list-number |...access-list-name]
4. match length min max
5. set ip next-hop ip-address [...ip-address]
6. exit
7. interface interface-id
8. ip policy route-map map-tag
9. ip route-cache policy
10. exit
11. ip local policy route-map map-tag
12. end
13. show route-map [map-name]
14. show ip policy
15. show ip local policy

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

Example:

Device# configure terminal

Step 2 route-map map-tag [permit] [sequence number]

Example:

Device(config)# route-map pbr-map permit

Purpose

Defines route maps that are used to control where packets are output, and enters route-map configuration mode.

*map-tag — A meaningful name for the route map.*

The ip policy route-map interface configuration command uses this name to reference the route map.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Purpose</strong></td>
<td>Multiple route-map statements with the same map tag define a single route map.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) <code>permit</code> — If <code>permit</code> is specified and the match criteria are met for this route map, the route is policy routed as defined by the set actions.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) <code>sequence number</code> — The sequence number shows the position of the route-map statement in the given route map.</td>
</tr>
<tr>
<td><strong>Step 3</strong> match ip address `{access-list-number</td>
<td>access-list-name}<code> </code>{access-list-number</td>
</tr>
<tr>
<td>Example:</td>
<td>If you do not specify a <code>match</code> command, the route map is applicable to all packets.</td>
</tr>
<tr>
<td>Device(config-route-map)# match ip address 110 140</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> match length min max</td>
<td>Matches the length of the packet.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Device(config-if)# exit</td>
<td></td>
</tr>
</tbody>
</table>
### Filtering Routing Information

You can filter routing protocol information by performing the tasks described in this section.

**Note** When routes are redistributed between OSPF processes, no OSPF metrics are preserved.

### Setting Passive Interfaces

To prevent other routers on a local network from dynamically learning about routes, you can use the `passive-interface` router configuration command to keep routing update messages from being sent through a router interface. When you use this command in the OSPF protocol, the interface address you specify as passive appears as a stub network in the OSPF domain. OSPF routing information is neither sent nor received through the specified router interface.

In networks with many interfaces, to avoid having to manually set them as passive, you can set all interfaces to be passive by default by using the `passive-interface default` router configuration command and manually setting interfaces where adjacencies are desired.

Use a network monitoring privileged EXEC command such as `show ip ospf interface` to verify the interfaces that you enabled as passive, or use the `show ip interface` privileged EXEC command to verify the interfaces that you enabled as active.

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
### Setting Passive Interfaces

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | configure terminal  
   Example:  
   Device# configure terminal | Enters global configuration mode. |
| **Step 2** | router { rip | ospf | eigrp}  
   Example:  
   Device(config)# router ospf | Enters router configuration mode. |
| **Step 3** | passive-interface interface-id  
   Example:  
   Device(config-router)# passive-interface gigabitethernet 1/0/1 | Suppresses sending routing updates through the specified Layer 3 interface. |
| **Step 4** | passive-interface default  
   Example:  
   Device(config-router)# passive-interface default | (Optional) Sets all interfaces as passive by default. |
| **Step 5** | no passive-interface interface type  
   Example:  
   Device(config-router)# no passive-interface gigabitethernet 1/0/3 gigabitethernet 1/0/5 | (Optional) Activates only those interfaces that need to have adjacencies sent. |
| **Step 6** | network network-address  
   Example:  
   Device(config-router)# network 10.1.1.1 | (Optional) Specifies the list of networks for the routing process. The network-address is an IP address. |
| **Step 7** | end  
   Example:  
   Device(config-router)# end | Returns to privileged EXEC mode. |
| **Step 8** | copy running-config startup-config  
   Example:  
   Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
Controlling Advertising and Processing in Routing Updates

You can use the `distribute-list` router configuration command with access control lists to suppress routes from being advertised in routing updates and to prevent other routers from learning one or more routes. When used in OSPF, this feature applies to only external routes, and you cannot specify an interface name.

You can also use a `distribute-list` router configuration command to avoid processing certain routes listed in incoming updates. (This feature does not apply to OSPF.)

### Procedure

<table>

<td><strong>Example:</strong> <code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

Filtering Sources of Routing Information

Because some routing information might be more accurate than others, you can use filtering to prioritize information coming from different sources. An administrative distance is a rating of the trustworthiness of a
routing information source, such as a router or group of routers. In a large network, some routing protocols
can be more reliable than others. By specifying administrative distance values, you enable the router to
intelligently discriminate between sources of routing information. The router always picks the route whose
routing protocol has the lowest administrative distance.

Because each network has its own requirements, there are no general guidelines for assigning administrative
distances.

**Procedure**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>

<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
Managing Authentication Keys

Key management is a method of controlling authentication keys used by routing protocols. Not all protocols can use key management. Authentication keys are available for EIGRP and RIP Version 2.

Prerequisites

Before you manage authentication keys, you must enable authentication. See the appropriate protocol section to see how to enable authentication for that protocol. To manage authentication keys, define a key chain, identify the keys that belong to the key chain, and specify how long each key is valid. Each key has its own key identifier (specified with the `key number` key chain configuration command), which is stored locally. The combination of the key identifier and the interface associated with the message uniquely identifies the authentication algorithm and Message Digest 5 (MD5) authentication key in use.

How to Configure Authentication Keys

You can configure multiple keys with life times. Only one authentication packet is sent, regardless of how many valid keys exist. The software examines the key numbers in order from lowest to highest, and uses the first valid key it encounters. The lifetimes allow for overlap during key changes. Note that the router must know these lifetimes.

<table>
<thead>
<tr>
<th>Command or Action</th>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Preventing Unauthorized Access

You can prevent unauthorized users from reconfiguring your switch and viewing configuration information. Typically, you want network administrators to have access to your switch while you restrict access to users who dial from outside the network through an asynchronous port, connect from outside the network through a serial port, or connect through a terminal or workstation from within the local network.

To prevent unauthorized access into your switch, you should configure one or more of these security features:

- At a minimum, you should configure passwords and privileges at each switch port. These passwords are locally stored on the switch. When users attempt to access the switch through a port or line, they must enter the password specified for the port or line before they can access the switch.

- For an additional layer of security, you can also configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

- If you want to use username and password pairs, but you want to store them centrally on a server instead of locally, you can store them in a database on a security server. Multiple networking devices can then use the same database to obtain user authentication (and, if necessary, authorization) information.
• You can also enable the login enhancements feature, which logs both failed and unsuccessful login attempts. Login enhancements can also be configured to block future login attempts after a set number of unsuccessful attempts are made. For more information, see the Cisco IOS Login Enhancements documentation.

Restrictions for Controlling Switch Access with Passwords and Privileges

The following are the restrictions for controlling switch access with passwords and privileges:

• Disabling password recovery will not work if you have set the switch to boot up manually by using the boot manual global configuration command. This command produces the boot loader prompt (switch:) after the switch is power cycled.

Information About Passwords and Privilege Levels

Default Password and Privilege Level Configuration

A simple way of providing terminal access control in your network is to use passwords and assign privilege levels. Password protection restricts access to a network or network device. Privilege levels define what commands users can enter after they have logged into a network device.

This table shows the default password and privilege level configuration.

Table 118: Default Password and Privilege Levels

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable password and privilege level</td>
<td>No password is defined. The default is level 15 (privileged EXEC level). The password is not encrypted in the configuration file.</td>
</tr>
<tr>
<td>Enable secret password and privilege level</td>
<td>No password is defined. The default is level 15 (privileged EXEC level). The password is encrypted before it is written to the configuration file.</td>
</tr>
<tr>
<td>Line password</td>
<td>No password is defined.</td>
</tr>
</tbody>
</table>

Additional Password Security

To provide an additional layer of security, particularly for passwords that cross the network or that are stored on a Trivial File Transfer Protocol (TFTP) server, you can use either the `enable password` or `enable secret` global configuration commands. Both commands accomplish the same thing; that is, you can establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify.

We recommend that you use the `enable secret` command because it uses an improved encryption algorithm.

If you configure the `enable secret` command, it takes precedence over the `enable password` command; the two commands cannot be in effect simultaneously.

If you enable password encryption, it applies to all passwords including username passwords, authentication key passwords, the privileged command password, and console and virtual terminal line passwords.

- Example: Protecting Enable and Enable Secret Passwords with Encryption, on page 1508

Password Recovery

By default, any end user with physical access to the switch can recover from a lost password by interrupting the boot process while the switch is powering on and then by entering a new password.

The password-recovery disable feature protects access to the switch password by disabling part of this functionality. When this feature is enabled, the end user can interrupt the boot process only by agreeing to set
the system back to the default configuration. With password recovery disabled, you can still interrupt the boot process and change the password, but the configuration file (config.text) and the VLAN database file (vlan.dat) are deleted.

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

To re-enable password recovery, use the `service password-recovery` global configuration command.

Terminal Line Telnet Configuration

When you power-up your switch for the first time, an automatic setup program runs to assign IP information and to create a default configuration for continued use. The setup program also prompts you to configure your switch for Telnet access through a password. If you did not configure this password during the setup program, you can configure it when you set a Telnet password for a terminal line.

Related Topics
- Setting a Telnet Password for a Terminal Line, on page 1501
- Example: Setting a Telnet Password for a Terminal Line, on page 1508

Username and Password Pairs

You can configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

Related Topics
- Configuring Username and Password Pairs, on page 1502

Privilege Levels

Cisco switches (and other devices) use privilege levels to provide password security for different levels of switch operation. By default, the Cisco IOS software operates in two modes (privilege levels) of password security: user EXEC (Level 1) and privileged EXEC (Level 15). You can configure up to 16 hierarchical levels of commands for each mode. By configuring multiple passwords, you can allow different sets of users to have access to specified commands.

Privilege Levels on Lines

Users can override the privilege level you set using the `privilege level` line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the `disable` command. If users know the password to a higher privilege level, they can use that password to enable the
higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

For example, if you want many users to have access to the `clear line` command, you can assign it level 2 security and distribute the level 2 password fairly widely. But if you want more restricted access to the `configure` command, you can assign it level 3 security and distribute that password to a more restricted group of users.

**Command Privilege Levels**

When you set a command to a privilege level, all commands whose syntax is a subset of that command are also set to that level. For example, if you set the `show ip traffic` command to level 15, the `show` commands and `show ip` commands are automatically set to privilege level 15 unless you set them individually to different levels.

**How to Control Switch Access with Passwords and Privilege Levels**

**Setting or Changing a Static Enable Password**

The enable password controls access to the privileged EXEC mode. Follow these steps to set or change a static enable password:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `enable password password`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>

Protecting Enable and Enable Secret Passwords with Encryption

Follow these steps to establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify:

SUMMARY STEPS

1. enable
2. configure terminal
3. Use one of the following:
   - `enable password [level level] {password encryption-type encrypted-password}`
   - `enable secret [level level] {password encryption-type encrypted-password}`
4. service password-encryption
5. end
6. show running-config
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> Use one of the following:</td>
<td></td>
</tr>
<tr>
<td>- <code>enable password [level level] {password encryption-type encrypted-password}</code></td>
<td></td>
</tr>
<tr>
<td>- <code>enable secret [level level] {password encryption-type encrypted-password}</code></td>
<td></td>
</tr>
<tr>
<td>Example: Device(config)# enable password example102 or Device(config)# enable secret level 1 password secret123sample</td>
<td></td>
</tr>
<tr>
<td>• Defines a new password or changes an existing password for access to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td>• Defines a secret password, which is saved using a nonreversible encryption method.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) For level, the range is from 0 to 15. Level 1 is normal user EXEC mode privileges. The default level is 15 (privileged EXEC mode privileges).</td>
<td></td>
</tr>
<tr>
<td>• For password, specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined.</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• (Optional) For encryption-type, only type 5, a Cisco proprietary encryption algorithm, is available. If you specify an encryption type, you must provide an encrypted password—an encrypted password that you copy from another switch configuration.</td>
<td>Note: If you specify an encryption type and then enter a clear text password, you cannot re-enter privileged EXEC mode. You cannot recover a lost encrypted password by any method.</td>
</tr>
</tbody>
</table>

**Step 4**

service password-encryption

**Example:**

Device(config)# service password-encryption

(Optional) Encrypts the password when the password is defined or when the configuration is written.

Encryption prevents the password from being readable in the configuration file.

**Step 5**

end

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 6**

show running-config

**Example:**

Device# show running-config

Verifies your entries.

**Step 7**

copy running-config startup-config

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

**Disabling Password Recovery**

Follow these steps to disable password recovery to protect the security of your switch:
Before you begin

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

SUMMARY STEPS

1. enable
2. configure terminal
3. no service password-recovery
4. end
5. show running-config
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>

</tr>
</tbody>
</table>
Setting a Telnet Password for a Terminal Line

Beginning in user EXEC mode, follow these steps to set a Telnet password for the connected terminal line:

**Before you begin**
- Attach a PC or workstation with emulation software to the switch console port, or attach a PC to the Ethernet management port.
- The default data characteristics of the console port are 9600, 8, 1, no parity. You might need to press the Return key several times to see the command-line prompt.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. line vty 0 15
4. password *password*
5. end
6. show running-config
7. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step 1</th>

Configuration Examples for Setting Passwords and Privilege Levels

Example: Setting or Changing a Static Enable Password

This example shows how to change the enable password to 11u2c3k4y5. The password is not encrypted and provides access to level 15 (traditional privileged EXEC mode access):

```
Device(config)# enable password 11u2c3k4y5
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for TACACS+

The following are the prerequisites for set up and configuration of switch access with TACACS+ (must be performed in the order presented):

1. Configure the switches with the TACACS+ server addresses.
2. Set an authentication key.
3. Configure the key from Step 2 on the TACACS+ servers.
4. Enable authentication, authorization, and accounting (AAA).
5. Create a login authentication method list.
6. Apply the list to the terminal lines.
7. Create an authorization and accounting method list.

The following are the prerequisites for controlling switch access with TACACS+: 
You must have access to a configured TACACS+ server to configure TACACS+ features on your switch. Also, you must have access to TACACS+ services maintained in a database on a TACACS+ daemon typically running on a LINUX or Windows workstation.

We recommend a redundant connection between a switch stack and the TACACS+ server. This is to help ensure that the TACACS+ server remains accessible in case one of the connected stack members is removed from the switch stack.

You need a system running the TACACS+ daemon software to use TACACS+ on your switch.

To use TACACS+, it must be enabled.

Authorization must be enabled on the switch to be used.

Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

To use any of the AAA commands listed in this section or elsewhere, you must first enable AAA with the **aaa new-model** command.

At a minimum, you must identify the host or hosts maintaining the TACACS+ daemon and define the method lists for TACACS+ authentication. You can optionally define method lists for TACACS+ authorization and accounting.

The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list (which, by coincidence, is named `default`). The default method list is automatically applied to all ports except those that have a named method list explicitly defined. A defined method list overrides the default method list.

Use TACACS+ for privileged EXEC access authorization if authentication was performed by using TACACS+.

Use the local database if authentication was not performed by using TACACS+.

Information About TACACS+

TACACS+ and Switch Access

This section describes TACACS+. TACACS+ provides detailed accounting information and flexible administrative control over the authentication and authorization processes. It is facilitated through authentication, authorization, accounting (AAA) and can be enabled only through AAA commands.

TACACS+ Overview

TACACS+ is a security application that provides centralized validation of users attempting to gain access to your switch.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a method for managing multiple network access points from a single management service. Your switch can be a network access server along with other Cisco routers and access servers.

Figure 90: Typical TACACS+ Network Configuration
TACACS+, administered through the AAA security services, can provide these services:

- **Authentication**—Provides complete control of authentication through login and password dialog, challenge and response, and messaging support.
  
  The authentication facility can conduct a dialog with the user (for example, after a username and password are provided, to challenge a user with several questions, such as home address, mother’s maiden name, service type, and social security number). The TACACS+ authentication service can also send messages to user screens. For example, a message could notify users that their passwords must be changed because of the company’s password aging policy.

- **Authorization**—Provides fine-grained control over user capabilities for the duration of the user’s session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user can execute with the TACACS+ authorization feature.

- **Accounting**—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the switch and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between the switch and the TACACS+ daemon are encrypted.

**Related Topics**

[Prerequisites for TACACS+, on page 1511](#)

**TACACS+ Operation**

When a user attempts a simple ASCII login by authenticating to a switch using TACACS+, this process occurs:

1. When the connection is established, the switch contacts the TACACS+ daemon to obtain a username prompt to show to the user. The user enters a username, and the switch then contacts the TACACS+ daemon to obtain a password prompt. The switch displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

   TACACS+ allows a dialog between the daemon and the user until the daemon receives enough information to authenticate the user. The daemon prompts for a username and password combination, but can include other items, such as the user’s mother’s maiden name.

2. The switch eventually receives one of these responses from the TACACS+ daemon:
   - **ACCEPT**—The user is authenticated and service can begin. If the switch is configured to require authorization, authorization begins at this time.
   - **REJECT**—The user is not authenticated. The user can be denied access or is prompted to retry the login sequence, depending on the TACACS+ daemon.
   - **ERROR**—An error occurred at some time during authentication with the daemon or in the network connection between the daemon and the switch. If an ERROR response is received, the switch typically tries to use an alternative method for authenticating the user.
   - **CONTINUE**—The user is prompted for additional authentication information.
After authentication, the user undergoes an additional authorization phase if authorization has been enabled on the switch. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

3. If TACACS+ authorization is required, the TACACS+ daemon is again contacted, and it returns an ACCEPT or REJECT authorization response. If an ACCEPT response is returned, the response contains data in the form of attributes that direct the EXEC or NETWORK session for that user and the services that the user can access:
   • Telnet, Secure Shell (SSH), rlogin, or privileged EXEC services
   • Connection parameters, including the host or client IP address, access list, and user timeouts

Method List

A method list defines the sequence and methods to be used to authenticate, to authorize, or to keep accounts on a user. You can use method lists to designate one or more security protocols to be used, thus ensuring a backup system if the initial method fails. The software uses the first method listed to authenticate, to authorize, or to keep accounts on users; if that method does not respond, the software selects the next method in the list. This process continues until there is successful communication with a listed method or the method list is exhausted.

Related Topics
How to Configure TACACS+, on page 1516
Prerequisites for TACACS+, on page 1511

TACACS+ Configuration Options

You can configure the switch to use a single server or AAA server groups to group existing server hosts for authentication. You can group servers to select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list and contains the list of IP addresses of the selected server hosts.

Related Topics
Identifying the TACACS+ Server Host and Setting the Authentication Key, on page 1517

TACACS+ Login Authentication

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

## TACACS+ Authorization for Privileged EXEC Access and Network Services

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user’s profile, which is located either in the local user database or on the security server, to configure the user’s session. The user is granted access to a requested service only if the information in the user profile allows it.

Related Topics
- Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services, on page 1521
- Prerequisites for TACACS+, on page 1511

## TACACS+ Accounting

The AAA accounting feature tracks the services that users are accessing and the amount of network resources that they are consuming. When AAA accounting is enabled, the switch reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, or auditing.

Related Topics
- Starting TACACS+ Accounting, on page 1523

## Default TACACS+ Configuration

TACACS+ and AAA are disabled by default.

To prevent a lapse in security, you cannot configure TACACS+ through a network management application. When enabled, TACACS+ can authenticate users accessing the switch through the CLI.

**Note**
Although TACACS+ configuration is performed through the CLI, the TACACS+ server authenticates HTTP connections that have been configured with a privilege level of 15.

## How to Configure TACACS+

This section describes how to configure your switch to support TACACS+.

Identifying the TACACS+ Server Host and Setting the Authentication Key

Follow these steps to identify the TACACS+ server host and set the authentication key:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `tacacs server server-name`
4. `address {ipv4 | ipv6} ip address`
5. `exit`
6. `aaa new-model`
7. `aaa group server tacacs+ group-name`
8. `server ip-address`
9. `end`
10. `show running-config`
11. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>tacacs server server-name</code></td>
<td>Identifies the IP host or hosts maintaining a TACACS+ server. Enter this command multiple times to create a list of preferred hosts. The software searches for hosts in the order in which you specify them. For <code>server-name</code>, specify the server name.</td>
</tr>
<tr>

### Configuring TACACS+ Login Authentication

Follow these steps to configure TACACS+ login authentication:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-server-tacacs)# exit</td>
<td>Enables AAA.</td>
</tr>
</tbody>
</table>
| **Step 6** aaa new-model  
  Example:  
  Device(config)# aaa new-model | |
| **Step 7** aaa group server tacacs+ group-name  
  Example:  
  Device(config)# aaa group server tacacs+ your_server_group | (Optional) Defines the AAA server-group with a group name. This command puts the Device in a server group subconfiguration mode. |
| **Step 8** server ip-address  
  Example:  
  Device(config)# server 10.1.2.3 | (Optional) Associates a particular TACACS+ server with the defined server group. Repeat this step for each TACACS+ server in the AAA server group. Each server in the group must be previously defined in Step 3. |
| **Step 9** end  
  Example:  
  Device(config)# end | Returns to privileged EXEC mode. |
| **Step 10** show running-config  
  Example:  
  Device# show running-config | Verifies your entries. |
| **Step 11** copy running-config startup-config  
  Example:  
  Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

---

**Configuring TACACS+ Login Authentication**

Follow these steps to configure TACACS+ login authentication:
Before you begin

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports.

To secure the for HTTP access by using AAA methods, you must configure the with the `ip http authentication aaa` global configuration command. Configuring AAA authentication does not secure the for HTTP access by using AAA methods.

For more information about the `ip http authentication` command, see the *Cisco IOS Security Command Reference, Release 12.4*.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `aaa new-model`
4. `aaa authentication login {default | list-name} method1 [method2...]
5. `line [console | tty | vty] line-number [ending-line-number]
6. `login authentication {default | list-name}
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>

</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables AAA.</td>
</tr>
<tr>
<td><code>aaa new-model</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# aaa new-model</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Creates a login authentication method list.</td>
</tr>
</tbody>
</table>
| `aaa authentication login {default | list-name} method1 [method2...]
**Example:** | |
| *To create a default list that is used when a named list is not specified in the login authentication command,
### Purpose

**Command or Action**

```
Device(config)# aaa authentication login default
tacacs+ local
```

**Purpose**

use the `default` keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all ports.

- For `list-name`, specify a character string to name the list you are creating.
- For `method1...`, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails.

Select one of these methods:

- **enable**—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the `enable password` global configuration command.
- **group tacacs+**—Uses TACACS+ authentication. Before you can use this authentication method, you must configure the TACACS+ server.
- **line**—Use the line password for authentication. Before you can use this authentication method, you must define a line password. Use the `password password` line configuration command.
- **local**—Use the local username database for authentication. You must enter username information in the database. Use the `username password` global configuration command.
- **local-case**—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the `username name password` global configuration command.
- **none**—Do not use any authentication for login.

### Step 5

**line [console | tty | vty] line-number [ending-line-number]**

**Example:**

```
Device(config)# line 2 4
```

Enters line configuration mode, and configures the lines to which you want to apply the authentication list.

### Step 6

**login authentication {default | list-name}**

**Example:**

```
Device(config-line)# login authentication default
```

Applies the authentication list to a line or set of lines.

- If you specify `default`, use the default list created with the `aaa authentication login` command.
- For `list-name`, specify the list created with the `aaa authentication login` command.
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 7</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>

### Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services

You can use the `aaa authorization` global configuration command with the `tacacs+` keyword to set parameters that restrict a user’s network access to privileged EXEC mode.

---

**Note**

Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

---

Follow these steps to specify TACACS+ authorization for privileged EXEC access and network services:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. aaa authorization network tacacs+
4. aaa authorization exec tacacs+
5. end
6. show running-config
7. copy running-config startup-config
# Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>

### Establishing a Session with a Router if the AAA Server is Unreachable

To establish a session with a router if the AAA server is unreachable, use the **aaa accounting system guarantee-first** command. It guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

### What to do next

To establish a session with a router if the AAA server is unreachable, use the **aaa accounting system guarantee-first** command. It guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring RADIUS

This section lists the prerequisites for controlling Device access with RADIUS.

General:

- RADIUS and Authentication, Authorization, and Accounting (AAA) must be enabled to use any of the configuration commands in this chapter.
- RADIUS is facilitated through AAA and can be enabled only through AAA commands.
- Use the `aaa new-model` global configuration command to enable AAA.
- Use the `aaa authentication` global configuration command to define method lists for RADIUS authentication.
- Use `line` and `interface` commands to enable the defined method lists to be used.
At a minimum, you must identify the host or hosts that run the RADIUS server software and define the method lists for RADIUS authentication. You can optionally define method lists for RADIUS authorization and accounting.

You should have access to and should configure a RADIUS server before configuring RADIUS features on your Device.

The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (Cisco Secure Access Control Server Version 3.0), Livingston, Merit, Microsoft, or another software provider. For more information, see the RADIUS server documentation.

To use the Change-of-Authorization (CoA) interface, a session must already exist on the switch. CoA can be used to identify a session and enforce a disconnect request. The update affects only the specified session.

A redundant connection between a switch stack and the RADIUS server is recommended. This is to help ensure that the RADIUS server remains accessible in case one of the connected stack members is removed from the switch stack.

For RADIUS operation:

- Users must first successfully complete RADIUS authentication before proceeding to RADIUS authorization, if it is enabled.

Restrictions for Configuring RADIUS

This topic covers restrictions for controlling Device access with RADIUS.

General:

- To prevent a lapse in security, you cannot configure RADIUS through a network management application.

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support AppleTalk Remote Access (ARA), NetBIOS Frame Control Protocol (NBFCP), NetWare Asynchronous Services Interface (NASI), or X.25 PAD connections.

- Switch-to-switch or router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one device to a non-Cisco device if the non-Cisco device requires authentication.

- Networks using a variety of services. RADIUS generally binds a user to one service model.

RADIUS Overview

RADIUS is a distributed client/server system that secures networks against unauthorized access. RADIUS clients run on supported Cisco routers and switches. Clients send authentication requests to a central RADIUS server, which contains all user authentication and network service access information.

Use RADIUS in these network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors’ access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.

- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a smart card access control system. In one case, RADIUS has been used with Enigma’s security cards to validate users and to grant access to network resources.

- Networks already using RADIUS. You can add a Cisco Device containing a RADIUS client to the network. This might be the first step when you make a transition to a TACACS+ server. See Figure 2: Transitioning from RADIUS to TACACS+ Services below.

- Network in which the user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to the network through a protocol such as IEEE 802.1x. For more information about this protocol, see Chapter 11, “Configuring IEEE 802.1x Port-Based Authentication.”

- Networks that require resource accounting. You can use RADIUS accounting independently of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, showing the amount of resources (such as time, packets, bytes, and so forth) used during the session. An Internet service provider might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.
Figure 91: Transitioning from RADIUS to TACACS+ Services

RADIUS Operation

When a user attempts to log in and authenticate to a Device that is access controlled by a RADIUS server, these events occur:

1. The user is prompted to enter a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.
3. The user receives one of the following responses from the RADIUS server:
   - ACCEPT—The user is authenticated.
   - REJECT—The user is either not authenticated and is prompted to re-enter the username and password, or access is denied.
   - CHALLENGE—A challenge requires additional data from the user.
   - CHALLENGE PASSWORD—A response requests the user to select a new password.

The ACCEPT or REJECT response is bundled with additional data that is used for privileged EXEC or network authorization. The additional data included with the ACCEPT or REJECT packets includes these items:

- Telnet, SSH, rlogin, or privileged EXEC services
- Connection parameters, including the host or client IP address, access list, and user timeouts

RADIUS Change of Authorization

The RADIUS Change of Authorization (CoA) provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is authenticated. When a policy changes for a user or user group in AAA, administrators can send RADIUS CoA packets from the AAA server such as a Cisco Secure Access Control Server (ACS) to reinitialize authentication and apply the new policy. This section provides an overview of the RADIUS interface including available primitives and how they are used during a CoA.

- Change-of-Authorization Requests
- CoA Request Response Code
- CoA Request Commands
- Session Reauthentication
- Stacking Guidelines for Session Termination

A standard RADIUS interface is typically used in a pulled model where the request originates from a network attached device and the response come from the queried servers. Catalyst supports the RADIUS CoA extensions defined in RFC 5176 that are typically used in a pushed model and allow for the dynamic reconfiguring of sessions from external AAA or policy servers.

The supports these per-session CoA requests:

- Session reauthentication
- Session termination
- Session termination with port shutdown
- Session termination with port bounce

This feature is integrated with Cisco Secure Access Control Server (ACS) 5.1.

The RADIUS interface is enabled by default on Catalyst. However, some basic configuration is required for the following attributes:

- Security and Password—refer to the “Preventing Unauthorized Access to Your Switch” section in this guide.
- Accounting—refer to the “Starting RADIUS Accounting” section in the Configuring Switch-Based Authentication chapter in this guide.

Cisco IOS software supports the RADIUS CoA extensions defined in RFC 5176 that are typically used in a push model to allow the dynamic reconfiguring of sessions from external AAA or policy servers. Per-session CoA requests are supported for session identification, session termination, host reauthentication, port shutdown, and port bounce. This model comprises one request (CoA-Request) and two possible response codes:

- CoA acknowledgement (ACK) [CoA-ACK]
- CoA nonacknowledgement (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a AAA or policy server) and directed to the device that acts as a listener.
The table below shows the RADIUS CoA commands and vendor-specific attributes (VSAs) supported by Identity-Based Networking Services. All CoA commands must include the session identifier between the device and the CoA client.

**Change-of-Authorization Requests**

Change of Authorization (CoA) requests, as described in RFC 5176, are used in a push model to allow for session identification, host reauthentication, and session termination. The model is comprised of one request (CoA-Request) and two possible response codes:

- CoA acknowledgment (ACK) [CoA-ACK]
- CoA non-acknowledgment (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a RADIUS or policy server) and directed to the switch that acts as a listener.

**RFC 5176 Compliance**

The Disconnect Request message, which is also referred to as Packet of Disconnect (POD), is supported by the switch for session termination.
This table shows the IETF attributes are supported for this feature.

CoA Request Response Code

The CoA Request response code can be used to convey a command to the switch.

The packet format for a CoA Request Response code as defined in RFC 5176 consists of the following fields: Code, Identifier, Length, Authenticator, and Attributes in the Type:Length:Value (TLV) format. The Attributes field is used to carry Cisco vendor-specific attributes (VSAs).

**Related Topics**

CoA Request Commands, on page 1533

Session Identification

For disconnect and CoA requests targeted at a particular session, the switch locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)
- Audit-Session-Id (Cisco VSA)
- Calling-Station-Id (IETF attribute #31 which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
  - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
  - Framed-IPv6-Address
- Plain IP Address (IETF attribute #8)

Unless all session identification attributes included in the CoA message match the session, the switch returns a Disconnect-NAK or CoA-NAK with the “Invalid Attribute Value” error-code attribute.

If more than one session identification attribute is included in the message, all the attributes must match the session or the switch returns a Disconnect- negative acknowledgment (NAK) or CoA-NAK with the error code “Invalid Attribute Value.”

The packet format for a CoA Request code as defined in RFC 5176 consists of the fields: Code, Identifier, Length, Authenticator, and Attributes in Type:Length:Value (TLV) format.

```
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
| Code | Identifier | Length |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
| Authenticator |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
| Attributes ... |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

The attributes field is used to carry Cisco vendor-specific attributes (VSAs).

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code “Invalid Attribute Value” if any of the above session identification attributes are included in the message.
CoA ACK Response Code

If the authorization state is changed successfully, a positive acknowledgment (ACK) is sent. The attributes returned within CoA ACK will vary based on the CoA Request and are discussed in individual CoA Commands.

CoA NAK Response Code

A negative acknowledgment (NAK) indicates a failure to change the authorization state and can include attributes that indicate the reason for the failure. Use `show` commands to verify a successful CoA.

Session Reauthentication

The AAA server typically generates a session reauthentication request when a host with an unknown identity or posture joins the network and is associated with a restricted access authorization profile (such as a guest VLAN). A reauthentication request allows the host to be placed in the appropriate authorization group when its credentials are known.

To initiate session authentication, the AAA server sends a standard CoA-Request message which contains a Cisco VSA in this form: `Cisco:Avpair="subscriber:command=reauthenticate"` and one or more session identification attributes.

The current session state determines the switch response to the message. If the session is currently authenticated by IEEE 802.1x, the switch responds by sending an EAPoL (Extensible Authentication Protocol over Lan) -RequestId message to the server.

If the session is currently authenticated by MAC authentication bypass (MAB), the switch sends an access-request to the server, passing the same identity attributes used for the initial successful authentication.

If session authentication is in progress when the switch receives the command, the switch terminates the process, and restarts the authentication sequence, starting with the method configured to be attempted first.
If the session is not yet authorized, or is authorized via guest VLAN, or critical VLAN, or similar policies, the reauthentication message restarts the access control methods, beginning with the method configured to be attempted first. The current authorization of the session is maintained until the reauthentication leads to a different authorization result.

**Session Reauthentication in a Switch Stack**

When a switch stack receives a session reauthentication message:

- It checkpoints the need for a re-authentication before returning an acknowledgment (ACK).
- It initiates reauthentication for the appropriate session.
- If authentication completes with either success or failure, the signal that triggered the reauthentication is removed from the stack member.
- If the stack master fails before authentication completes, reauthentication is initiated after stack master switch-over based on the original command (which is subsequently removed).
- If the stack master fails before sending an ACK, the new stack master treats the re-transmitted command as a new command.

**Session Termination**

There are three types of CoA requests that can trigger session termination. A CoA Disconnect-Request terminates the session, without disabling the host port. This command causes re-initialization of the authenticator state machine for the specified host, but does not restrict that host access to the network.

To restrict a host’s access to the network, use a CoA Request with the Cisco:Avpair="subscriber:command=disable-host-port" VSA. This command is useful when a host is known to be causing problems on the network, and you need to immediately block network access for the host. When you want to restore network access on the port, re-enable it using a non-RADIUS mechanism.

When a device with no supplicant, such as a printer, needs to acquire a new IP address (for example, after a VLAN change), terminate the session on the host port with port-bounce (temporarily disable and then re-enable the port).

**CoA Disconnect-Request**

This command is a standard Disconnect-Request. If the session cannot be located, the switch returns a Disconnect-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch terminates the session. After the session has been completely removed, the switch returns a Disconnect-ACK.

If the switch fails-over to a standby switch before returning a Disconnect-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the session is not found following re-sending, a Disconnect-ACK is sent with the “Session Context Not Found” error-code attribute.

**Related Topics**

- [Session Identification](#), on page 1532

**CoA Request: Disable Host Port**

The RADIUS server CoA disable port command administratively shuts down the authentication port that is hosting a session, resulting in session termination. This command is useful when a host is known to cause problems on the network and network access needs to be immediately blocked for the host. To restore network
access on the port, reenable it using a non-RADIUS mechanism. This command is carried in a standard CoA-Request message that has this new vendor-specific attribute (VSA):

Cisco:Avpair="subscriber:command=disable-host-port"

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the “Session Identification” section. If the session cannot be located, the switch returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch disables the hosting port and returns a CoA-ACK message.

If the switch fails before returning a CoA-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the switch fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is restarted on the new active switch.

**Note**
A Disconnect-Request failure following command re-sending could be the result of either a successful session termination before change-over (if the Disconnect-ACK was not sent) or a session termination by other means (for example, a link failure) that occurred after the original command was issued and before the standby switch became active.

**Related Topics**

- [Session Identification](#), on page 1532

**CoA Request: Bounce-Port**

A RADIUS server CoA bounce port sent from a RADIUS server can cause a link flap on an authentication port, which triggers DHCP renegotiation from one or more hosts connected to this port. This incident can occur when there is a VLAN change and the endpoint is a device (such as a printer) that does not have a mechanism to detect a change on this authentication port. The CoA bounce port is carried in a standard CoA-Request message that contains the following VSA:

Cisco:Avpair="subscriber:command=bounce-host-port"

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes. If the session cannot be located, the switch returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch disables the hosting port for a period of 10 seconds, re-enables it (port-bounce), and returns a CoA-ACK.

If the switch fails before returning a CoA-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the switch fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is re-started on the new active switch.

**Related Topics**

- [Session Identification](#), on page 1532

**Stacking Guidelines for Session Termination**

No special handling is required for CoA Disconnect-Request messages in a switch stack.

**Stacking Guidelines for CoA-Request Bounce-Port**

Because the `bounce-port` command is targeted at a session, not a port, if the session is not found, the command cannot be executed.
When the Auth Manager command handler on the stack master receives a valid bounce-port command, it checkpoints the following information before returning a CoA-ACK message:

- the need for a port-bounce
- the port-id (found in the local session context)

The switch initiates a port-bounce (disables the port for 10 seconds, then re-enables it).

If the port-bounce is successful, the signal that triggered the port-bounce is removed from the standby stack master.

If the stack master fails before the port-bounce completes, a port-bounce is initiated after stack master change-over based on the original command (which is subsequently removed).

If the stack master fails before sending a CoA-ACK message, the new stack master treats the re-sent command as a new command.

### Stacking Guidelines for CoA-Request Disable-Port

Because the disable-port command is targeted at a session, not a port, if the session is not found, the command cannot be executed.

When the Auth Manager command handler on the stack master receives a valid disable-port command, it verifies this information before returning a CoA-ACK message:

- the need for a port-disable
- the port-id (found in the local session context)

The switch attempts to disable the port.

If the port-disable operation is successful, the signal that triggered the port-disable is removed from the standby stack master.

If the stack master fails before the port-disable operation completes, the port is disabled after stack master change-over based on the original command (which is subsequently removed).

If the stack master fails before sending a CoA-ACK message, the new stack master treats the re-sent command as a new command.

### Default RADIUS Configuration

RADIUS and AAA are disabled by default.

To prevent a lapse in security, you cannot configure RADIUS through a network management application. When enabled, RADIUS can authenticate users accessing the switch through the CLI.

### RADIUS Server Host

Switch-to-RADIUS-server communication involves several components:

- Hostname or IP address
- Authentication destination port
- Accounting destination port
You identify RADIUS security servers by their hostname or IP address, hostname and specific UDP port numbers, or their IP address and specific UDP port numbers. The combination of the IP address and the UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address.

If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as a fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the %RADIUS-4-RADIUS_DEAD message appears, and then the switch tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order that they are configured.)

A RADIUS server and the switch use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the switch.

The timeout, retransmission, and encryption key values can be configured globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings.

**Related Topics**
- Identifying the RADIUS Server Host
- Defining AAA Server Groups, on page 1555
- Configuring Settings for All RADIUS Servers, on page 1560
- Configuring RADIUS Login Authentication, on page 1553

### RADIUS Login Authentication

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports. The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list. The default method list is automatically applied to all ports except those that have a named method list explicitly defined.

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

**Related Topics**
- Configuring RADIUS Login Authentication, on page 1553
AAA Server Groups

You can configure the switch to use AAA server groups to group existing server hosts for authentication. You select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list, which lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server if each entry has a unique identifier (the combination of the IP address and UDP port number), allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If you configure two different host entries on the same RADIUS server for the same service, (for example, accounting), the second configured host entry acts as a fail-over backup to the first one. If the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

Related Topics
- Defining AAA Server Groups, on page 1555

AAA Authorization

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user’s profile, which is in the local user database or on the security server, to configure the user’s session. The user is granted access to a requested service only if the information in the user profile allows it.

Related Topics
- Configuring RADIUS Authorization for User Privileged Access and Network Services, on page 1557

RADIUS Accounting

The AAA accounting feature tracks the services that users are using and the amount of network resources that they are consuming. When you enable AAA accounting, the switch reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. You can then analyze the data for network management, client billing, or auditing.

Related Topics
- Starting RADIUS Accounting, on page 1558

Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the switch and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option by using the format recommended in the specification. Cisco’s vendor-ID is 9, and the supported option has vendor-type 1, which is named cisco-avpair. The value is a string with this format:

```plaintext
protocol : attribute sep value *
```
Protocol is a value of the Cisco protocol attribute for a particular type of authorization. Attribute and value are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and sep is = for mandatory attributes and is * for optional attributes. The full set of features available for TACACS+ authorization can then be used for RADIUS.

For example, the following AV pair causes Cisco’s “multiple named IP address pools” feature to be activated during IP authorization (during PPP’s Internet Protocol Control Protocol (IPCP) address assignment):

cisco-avpair= "ip:addr-pool=first"

If you insert an “*”, the AV pair “ip:addr-pool=first” becomes optional. Note that any AV pair can be made optional:

cisco-avpair= "ip:addr-pool*first"

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

cisco-avpair= "shell:priv-lvl=15"

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, see RFC 2138, “Remote Authentication Dial-In User Service (RADIUS).”

Attribute 26 contains the following three elements:

• Type

• Length

• String (also known as data)
  • Vendor-Id
  • Vendor-Type
  • Vendor-Length
  • Vendor-Data

The figure below shows the packet format for a VSA encapsulated “behind” attribute 26.

**Figure 92: VSA Encapsulated Behind Attribute 26**

It is up to the vendor to specify the format of their VSA. The Attribute-Specific field (also known as Vendor-Data) is dependent on the vendor's definition of that attribute.

The table below describes significant fields listed in the Vendor-Specific RADIUS IETF Attributes table (second table below), which lists supported vendor-specific RADIUS attributes (IETF attribute 26).
### Table 125: Vendor-Specific Attributes Table Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>All attributes listed in the following table are extensions of IETF attribute 26.</td>
</tr>
<tr>
<td>Vendor-Specific Command Codes</td>
<td>A defined code used to identify a particular vendor. Code 9 defines Cisco VSAs, 311 defines Microsoft VSAs, and 529 defines Ascend VSAs.</td>
</tr>
<tr>
<td>Sub-Type Number</td>
<td>The attribute ID number. This number is much like the ID numbers of IETF attributes, except it is a “second layer” ID number encapsulated behind attribute 26.</td>
</tr>
<tr>
<td>Attribute</td>
<td>The ASCII string name of the attribute.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the attribute.</td>
</tr>
</tbody>
</table>

### Table 126: Vendor-Specific RADIUS IETF Attributes

<table>
<thead>
<tr>
<th>Number</th>
<th>Vendor-Specific Company Code</th>
<th>Sub-Type Number</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>311</td>
<td>1</td>
<td>MSCHAP-Response</td>
<td>Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier. (RFC 2548)</td>
</tr>
<tr>
<td>26</td>
<td>311</td>
<td>11</td>
<td>MSCHAP-Challenge</td>
<td>Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets. (RFC 2548)</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>l2tp-cm-local-window-size</td>
<td>Specifies the maximum receive window size for L2TP control messages. This value is advertised to the peer during tunnel establishment.</td>
</tr>
<tr>
<td>Number</td>
<td>Vendor-Specific Company Code</td>
<td>Sub-Type Number</td>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>

<td>-----------------</td>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>12tp-drop-out-of-order</td>
<td>Respects sequence numbers on data packets by dropping those that are received out of order. This does not ensure that sequence numbers will be sent on data packets, just how to handle them if they are received.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>12tp-hello-interval</td>
<td>Specifies the number of seconds for the hello keepalive interval. Hello packets are sent when no data has been sent on a tunnel for the number of seconds configured here.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>12tp-hidden-avp</td>
<td>When enabled, sensitive AVPs in L2TP control messages are scrambled or hidden.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>12tp-nosession-timeout</td>
<td>Specifies the number of seconds that a tunnel will stay active with no sessions before timing out and shutting down.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>tunnel-tos-reflect</td>
<td>Copies the IP ToS field from the IP header of each payload packet to the IP header of the tunnel packet for packets entering the tunnel at the LNS.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>12tp-tunnel-authen</td>
<td>If this attribute is set, it performs L2TP tunnel authentication.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>12tp-tunnel-password</td>
<td>Shared secret used for L2TP tunnel authentication and AVP hiding.</td>
</tr>
</tbody>
</table>
### Vendor-Specific RADIUS Attributes

<table>
<thead>

<td>This is an authorization attribute and defines whether L2TP should perform UDP checksums for data packets. Valid values are “yes” and “no.” The default is no.</td>
</tr>
</tbody>
</table>

**Store and Forward Fax Attributes**

- **Fax-Account-Id-Origin**
  - Indicates the account ID origin as defined by system administrator for the `mmoip aaa receive-id` or the `mmoip aaa send-id` commands.

- **Fax-Msg-Id**
  - Indicates a unique fax message identification number assigned by Store and Forward Fax.

- **Fax-Pages**
  - Indicates the number of pages transmitted or received during this fax session. This page count includes cover pages.

- **Fax-Coverpage-Flag**
  - Indicates whether or not a cover page was generated by the off-ramp gateway for this fax session. True indicates that a cover page was generated; false means that a cover page was not generated.

- **Fax-Modem-Time**
  - Indicates the amount of time in seconds the modem sent fax data (x) and the amount of time in seconds of the total fax session (y), which includes both fax-mail and PSTN time, in the form x/y. For example, 10/15 means that the transfer time took 10 seconds, and the total fax session took 15 seconds.
<table>
<thead>
<tr>
<th>Number</th>
<th>Vendor-Specific Company Code</th>
<th>Sub-Type Number</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>9</td>
<td>8</td>
<td>Fax-Connect-Speed</td>
<td>Indicates the modem speed at which this fax-mail was initially transmitted or received. Possible values are 1200, 4800, 9600, and 14400.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>9</td>
<td>Fax-Recipient-Count</td>
<td>Indicates the number of recipients for this fax transmission. Until e-mail servers support Session mode, the number should be 1.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>10</td>
<td>Fax-Process-Abort-Flag</td>
<td>Indicates that the fax session was aborted or successful. True means that the session was aborted; false means that the session was successful.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>11</td>
<td>Fax-Dsn-Address</td>
<td>Indicates the address to which DSNs will be sent.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>12</td>
<td>Fax-Dsn-Flag</td>
<td>Indicates whether or not DSN has been enabled. True indicates that DSN has been enabled; false means that DSN has not been enabled.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>13</td>
<td>Fax-Mdn-Address</td>
<td>Indicates the address to which MDNs will be sent.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>14</td>
<td>Fax-Mdn-Flag</td>
<td>Indicates whether or not message delivery notification (MDN) has been enabled. True indicates that MDN had been enabled; false means that MDN had not been enabled.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>15</td>
<td>Fax-Auth-Status</td>
<td>Indicates whether or not authentication for this fax session was successful. Possible values for this field are success, failed, bypassed, or unknown.</td>
</tr>
<tr>
<td>Number</td>
<td>Vendor-Specific Company Code</td>
<td>Sub-Type Number</td>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------</td>
<td>----------------</td>
<td>-------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>16</td>
<td>Email-Server-Address</td>
<td>Indicates the IP address of the e-mail server handling the on-ramp fax-mail message.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>17</td>
<td>Email-Server-Ack-Flag</td>
<td>Indicates that the on-ramp gateway has received a positive acknowledgment from the e-mail server accepting the fax-mail message.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>18</td>
<td>Gateway-Id</td>
<td>Indicates the name of the gateway that processed the fax session. The name appears in the following format: hostname.domain-name.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>19</td>
<td>Call-Type</td>
<td>Describes the type of fax activity: fax receive or fax send.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>20</td>
<td>Port-Used</td>
<td>Indicates the slot/port number of the Cisco AS5300 used to either transmit or receive this fax-mail.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>21</td>
<td>Abort-Cause</td>
<td>If the fax session aborts, indicates the system component that signaled the abort. Examples of system components that could trigger an abort are FAP (Fax Application Process), TIFF (the TIFF reader or the TIFF writer), fax-mail client, fax-mail server, ESMTP client, or ESMTP server.</td>
</tr>
</tbody>
</table>

**H323 Attributes**

<table>
<thead>
<tr>
<th>Number</th>
<th>Vendor-Specific Company Code</th>
<th>Sub-Type Number</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>9</td>
<td>23</td>
<td>Remote-Gateway-ID (h323-remote-address)</td>
<td>Indicates the IP address of the remote gateway.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>24</td>
<td>Connection-ID (h323-conf-id)</td>
<td>Identifies the conference ID.</td>
</tr>
<tr>
<td>Number</td>
<td>Vendor-Specific Company Code</td>
<td>Sub-Type Number</td>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------</td>
<td>----------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>25</td>
<td>Setup-Time (h323-setup-time)</td>
<td>Indicates the setup time for this connection in Coordinated Universal Time (UTC) formerly known as Greenwich Mean Time (GMT) and Zulu time.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>26</td>
<td>Call-Origin (h323-call-origin)</td>
<td>Indicates the origin of the call relative to the gateway. Possible values are originating and terminating (answer).</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>27</td>
<td>Call-Type (h323-call-type)</td>
<td>Indicates call leg type. Possible values are telephony and VoIP.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>28</td>
<td>Connect-Time (h323-connect-time)</td>
<td>Indicates the connection time for this call leg in UTC.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>29</td>
<td>Disconnect-Time (h323-disconnect-time)</td>
<td>Indicates the time this call leg was disconnected in UTC.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>30</td>
<td>Disconnect-Cause (h323-disconnect-cause)</td>
<td>Specifies the reason a connection was taken offline per Q.931 specification.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>31</td>
<td>Voice-Quality (h323-voice-quality)</td>
<td>Specifies the impairment factor (ICPIF) affecting voice quality for a call.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>33</td>
<td>Gateway-ID (h323-gw-id)</td>
<td>Indicates the name of the underlying gateway.</td>
</tr>
</tbody>
</table>

**Large Scale Dialout Attributes**

<table>
<thead>
<tr>
<th>Number</th>
<th>Vendor-Specific Company Code</th>
<th>Sub-Type Number</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>callback-dialstring</td>
<td>Defines a dialing string to be used for callback.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>data-service</td>
<td>No description available.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>dial-number</td>
<td>Defines the number to dial.</td>
</tr>
<tr>
<td>Number</td>
<td>Vendor-Specific Company Code</td>
<td>Sub-Type Number</td>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------</td>
<td>-----------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>force-56</td>
<td>Determines whether the network access server uses only the 56 K portion of a channel, even when all 64 K appear to be available.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>map-class</td>
<td>Allows the user profile to reference information configured in a map class of the same name on the network access server that dials out.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>send-auth</td>
<td>Defines the protocol to use (PAP or CHAP) for username-password authentication following CLID authentication.</td>
</tr>
<tr>
<td>Number</td>
<td>Vendor-Specific Company Code</td>
<td>Sub-Type Number</td>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------</td>
<td>-----------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>send-name</td>
<td>PPP name authentication. To apply for PAP, do not configure the <code>ppp pap sent-name password</code> command on the interface. For PAP, “preauth:send-name” and “preauth:send-secret” will be used as the PAP username and PAP password for outbound authentication. For CHAP, “preauth:send-name” will be used not only for outbound authentication, but also for inbound authentication. For a CHAP inbound case, the NAS will use the name defined in “preauth:send-name” in the challenge packet to the caller box.</td>
</tr>
</tbody>
</table>

**Note** The send-name attribute has changed over time: Initially, it performed the functions now provided by both the send-name and remote-name attributes. Because the remote-name attribute has been added, the send-name attribute is restricted to its current behavior.
### Vendor-Specific RADIUS Attributes

<table>
<thead>
<tr>
<th>Number</th>
<th>Vendor-Specific Company Code</th>
<th>Sub-Type Number</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>send-secret</td>
<td>PPP password authentication. The vendor-specific attributes (VSAs) &quot;preauth:send-name&quot; and &quot;preauth:send-secret&quot; will be used as the PAP username and PAP password for outbound authentication. For a CHAP outbound case, both &quot;preauth:send-name&quot; and &quot;preauth:send-secret&quot; will be used in the response packet.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>remote-name</td>
<td>Provides the name of the remote host for use in large-scale dial-out. Dialer checks that the large-scale dial-out remote name matches the authenticated name, to protect against accidental user RADIUS misconfiguration. (For example, dialing a valid phone number but connecting to the wrong device.)</td>
</tr>
</tbody>
</table>

#### Miscellaneous Attributes
<table>
<thead>
<tr>
<th>Number</th>
<th>Vendor-Specific Company Code</th>
<th>Sub-Type Number</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>9</td>
<td>2</td>
<td>Cisco-NAS-Port</td>
<td>Specifies additional vendor specific attribute (VSA) information for NAS-Port accounting. To specify additional NAS-Port information in the form an Attribute-Value Pair (AVPair) string, use the <code>radius-server vsa send</code> global configuration command.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td><strong>Note</strong> This VSA is typically used in Accounting, but may also be used in Authentication (Access-Request) packets.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>min-links</td>
<td>Sets the minimum number of links for MLP.</td>
</tr>
<tr>
<td>26</td>
<td>9</td>
<td>1</td>
<td>proxyacl#&lt;n&gt;</td>
<td>Allows users to configure the downloadable user profiles (dynamic ACLs) by using the authentication proxy feature so that users can have the configured authorization to permit traffic going through the configured interfaces.</td>
</tr>
</tbody>
</table>
Carries the authentication information needed by the home agent to authenticate a mobile node during registration. The information is in the same syntax as the ip mobile secure host <addr> configuration command. Basically it contains the rest of the configuration command that follows that string, verbatim. It provides the Security Parameter Index (SPI), key, authentication algorithm, authentication mode, and replay protection timestamp range.

Vendor-Proprietary RADIUS Server Communication

Although an IETF draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the switch and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-proprietary or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the switch. You specify the RADIUS host and secret text string by using the radius-server global configuration commands.

How to Configure RADIUS

Identifying the RADIUS Server Host

To apply these settings globally to all RADIUS servers communicating with the Device, use the three unique global configuration commands: radius-server timeout, radius-server retransmit, and key string.

You can configure the Device to use AAA server groups to group existing server hosts for authentication. For more information, see Related Topics below.
You also need to configure some settings on the RADIUS server. These settings include the IP address of the Device and the key string to be shared by both the server and the Device. For more information, see the RADIUS server documentation.

Follow these steps to configure per-server RADIUS server communication.

Before you begin
If you configure both global and per-server functions (timeout, retransmission, and key commands) on the device, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands. For information on configuring these settings on all RADIUS servers, see Related Topics below.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. radius server server name
4. address {ipv4 | ipv6} ip address { auth-port port number | acct-port port number}
5. key string
6. retransmit value
7. timeout seconds
8. exit
9. end
10. show running-config
11. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>radius server server name</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# radius server rsim</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>address {ipv4</td>
<td>ipv6} ip address { auth-port port number</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>For auth-port <code>&lt;port-number&gt;</code>, specify the UDP destination port for authentication requests. The default is 1645. The range is 0 to 65536. For acct-port <code>&lt;port-number&gt;</code>, specify the UDP destination port for authentication requests. The default is 1646.</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-radius-server)# address ipv4 124.2.2.12 auth-port 1612</code></td>
<td>(Optional) For key <code>&lt;string&gt;</code>, specify the authentication and encryption key used between the Device and the RADIUS daemon running on the RADIUS server. <strong>Note</strong> The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius-server command. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> key <code>&lt;string&gt;</code></td>
<td>(Optional) Specifies the number of times a RADIUS request is resent when the server is not responding or responding slowly. The range is 1 to 100. This setting overrides the radius-server retransmit global configuration command setting.</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-radius-server)# key rad123</code></td>
<td>(Optional) Specifies the time interval that the Device waits for the RADIUS server to reply before sending a request again. The range is 1 to 1000. This setting overrides the radius-server timeout global configuration command setting.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> retransmit <code>&lt;value&gt;</code></td>
<td>Exits the RADIUS server mode and enters the global configuration mode.</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-radius-server)# retransmit 10</code></td>
<td>Returns to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> timeout <code>&lt;seconds&gt;</code></td>
<td><strong>Step 9</strong> end</td>
<td></td>
</tr>
<tr>
<td><code>Device(config-radius-server)# timeout 60</code></td>
<td><strong>Step 10</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 8</strong> exit</td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config-radius-server-tacacs)# exit</code></td>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> show running-config</td>
<td><code>Device(config)# exit</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device# show running-config</code></td>
<td></td>
</tr>
</tbody>
</table>
## Configuring RADIUS Login Authentication

Follow these steps to configure RADIUS login authentication:

### Before you begin
To secure the device for HTTP access by using AAA methods, you must configure the device with the `ip http authentication aaa` global configuration command. Configuring AAA authentication does not secure the device for HTTP access by using AAA methods.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `aaa new-model`
4. `aaa authentication login {default | list-name} method1 [method2... ]`
5. `line [console | tty | vty] line-number [ending-line-number]`
6. `login authentication {default | list-name}`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>aaa new-model</code></td>
<td>Enables AAA.</td>
</tr>
<tr>
<td></td>
<td><code>Example:</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Device(config)# aaa new-model</td>
<td>Creates a login authentication method list.</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>aaa authentication login {default</td>
<td>list-name} method1 [method2...]</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# aaa authentication login default local</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

To create a default list that is used when a named list is not specified in the `login authentication` command, use the `default` keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all ports.

- **For list-name**, specify a character string to name the list you are creating.
- **For method1,...**, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails.

Select one of these methods:

- **enable**—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the `enable password` global configuration command.
- **group radius**—Use RADIUS authentication. Before you can use this authentication method, you must configure the RADIUS server.
- **line**—Use the line password for authentication. Before you can use this authentication method, you must define a line password. Use the `password password` line configuration command.
- **local**—Use the local username database for authentication. You must enter username information in the database. Use the `username name password` global configuration command.
- **local-case**—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the `username password` global configuration command.
- **none**—Do not use any authentication for login.

**Step 5**

Enters line configuration mode, and configure the lines to which you want to apply the authentication list.
### Command or Action

Device(config)# line 1 4

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies the authentication list to a line or set of lines.</td>
</tr>
</tbody>
</table>

#### Step 6

**login authentication** {default | list-name}

**Example:**

Device(config)# login authentication default

- If you specify **default**, use the default list created with the `aaa authentication login` command.
- For **list-name**, specify the list created with the `aaa authentication login` command.

#### Step 7

**end**

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

#### Step 8

**show running-config**

**Example:**

Device# show running-config

Verifies your entries.

#### Step 9

**copy running-config startup-config**

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

### Defining AAA Server Groups

You use the `server` group server configuration command to associate a particular server with a defined group server. You can either identify the server by its IP address or identify multiple host instances or entries by using the optional `auth-port` and `acct-port` keywords.

Follow these steps to define AAA server groups:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `radius server name`
4. `address {ipv4 | ipv6} {ip-address | hostname} auth-port port-number acct-port port-number`
5. `end` {{0 | 7} string}string

---

## Configuring RADIUS Authorization for User Privileged Access and Network Services

**Note**
Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

Follow these steps to configure RADIUS authorization for user privileged access and network services:

### SUMMARY STEPS

1. enable
2. configure terminal
3. aaa authorization network radius
4. aaa authorization exec radius
5. end
6. show running-config
7. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>aaa authorization network radius</td>
</tr>
<tr>
<td>Example:</td>
<td>Configures the device for user RADIUS authorization for all network-related service requests.</td>
</tr>
<tr>
<td></td>
<td>Device(config)# aaa authorization network radius</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>aaa authorization exec radius</td>
</tr>
<tr>
<td>Example:</td>
<td>Configures the device for user RADIUS authorization if the user has privileged EXEC access.</td>
</tr>
<tr>
<td></td>
<td>The exec keyword might return user profile information (such as autocommand information).</td>
</tr>
<tr>
<td></td>
<td>Device(config)# aaa authorization exec radius</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Device(config)# end</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td>Example:</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td></td>
<td>Device# show running-config</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>copy running-config startup-config</td>
</tr>
<tr>
<td>Example:</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td></td>
<td>Device# copy running-config startup-config</td>
</tr>
</tbody>
</table>

**What to do next**

You can use the `aaa authorization` global configuration command with the `radius` keyword to set parameters that restrict a user’s network access to privileged EXEC mode.

The `aaa authorization exec radius local` command sets these authorization parameters:

- Use RADIUS for privileged EXEC access authorization if authentication was performed by using RADIUS.
- Use the local database if authentication was not performed by using RADIUS.

**Starting RADIUS Accounting**

Follow these steps to start RADIUS accounting:
SUMMARY STEPS

1. enable
2. configure terminal
3. aaa accounting network start-stop radius
4. aaa accounting exec start-stop radius
5. end
6. show running-config
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>aaa accounting network start-stop radius</td>
<td>Enables RADIUS accounting for all network-related service requests.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# aaa accounting network start-stop radius</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>aaa accounting exec start-stop radius</td>
<td>Enables RADIUS accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# aaa accounting exec start-stop radius</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show running-config</td>
<td></td>
</tr>
</tbody>
</table>
Beginning in privileged EXEC mode, follow these steps to configure settings for all RADIUS servers:

**SUMMARY STEPS**

1. configure terminal  
2. radius-server key *string*  
3. radius-server retranmit *retries*  
4. radius-server timeout *seconds*  
5. radius-server deadtime *minutes*  
6. end  
7. show running-config  
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| **Step 2**  
radius-server key *string*  
Example: | Specifies the shared secret text string used between the switch and all RADIUS servers. |

**What to do next**

To establishing a session with a router if the AAA server is unreachable, use the `aaa accounting system guarantee-first` command. This command guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the `no aaa accounting system guarantee-first` command.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Controlling Switch Access with Kerberos

The following are the prerequisites for controlling switch access with Kerberos.

- So that remote users can authenticate to network services, you must configure the hosts and the KDC in the Kerberos realm to communicate and mutually authenticate users and network services. To do this, you must identify them to each other. You add entries for the hosts to the Kerberos database on the KDC and add KEYTAB files generated by the KDC to all hosts in the Kerberos realm. You also create entries for the users in the KDC database.

- A Kerberos server can be a switch that is configured as a network security server and that can authenticate users by using the Kerberos protocol.

When you add or create entries for the hosts and users, follow these guidelines:

- The Kerberos principal name must be in all lowercase characters.
- The Kerberos instance name must be in all lowercase characters.
• The Kerberos realm name must be in all uppercase characters.

Information about Kerberos

This section provides Kerberos information.

Kerberos and Switch Access

This section describes how to enable and configure the Kerberos security system, which authenticates requests for network resources by using a trusted third party.

Note

In the Kerberos configuration examples, the trusted third party can be any switch that supports Kerberos, that is configured as a network security server, and that can authenticate users by using the Kerberos protocol.

Kerberos Overview

Kerberos is a secret-key network authentication protocol, which was developed at the Massachusetts Institute of Technology (MIT). It uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication and authenticates requests for network resources. Kerberos uses the concept of a trusted third party to perform secure verification of users and services. This trusted third party is called the key distribution center (KDC).

Kerberos verifies that users are who they claim to be and the network services that they use are what the services claim to be. To do this, a KDC or trusted Kerberos server issues tickets to users. These tickets, which have a limited life span, are stored in user credential caches. The Kerberos server uses the tickets instead of user names and passwords to authenticate users and network services.

Note

A Kerberos server can be any switch that is configured as a network security server and that can authenticate users by using the Kerberos protocol.

The Kerberos credential scheme uses a process called single logon. This process authenticates a user once and then allows secure authentication (without encrypting another password) wherever that user credential is accepted.

This software release supports Kerberos 5, which allows organizations that are already using Kerberos 5 to use the same Kerberos authentication database on the KDC that they are already using on their other network hosts (such as UNIX servers and PCs).

Kerberos supports these network services:

• Telnet
• rlogin
• rsh
This table lists the common Kerberos-related terms and definitions.

**Table 129: Kerberos Terms**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication</td>
<td>A process by which a user or service identifies itself to another service. For example, a client can authenticate to a switch or a switch can authenticate to another switch.</td>
</tr>
<tr>
<td>Authorization</td>
<td>A means by which the switch identifies what privileges the user has in a network or on the switch and what actions the user can perform.</td>
</tr>
<tr>
<td>Credential</td>
<td>A general term that refers to authentication tickets, such as TGTs and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of re-entering a username and password. Credentials have a default life span of eight hours.</td>
</tr>
<tr>
<td>Instance</td>
<td>An authorization level label for Kerberos principals. Most Kerberos principals are of the form <code>user@REALM</code> (for example, <a href="mailto:smith@EXAMPLE.COM">smith@EXAMPLE.COM</a>). A Kerberos principal with a Kerberos instance has the form <code>user/instance@REALM</code> (for example, smith/admin@EXAMPLE.COM). The Kerberos instance can be used to specify the authorization level for the user if authentication is successful. The server of each network service might implement and enforce the authorization mappings of Kerberos instances but is not required to do so.</td>
</tr>
<tr>
<td>Note</td>
<td>The Kerberos principal and instance names <em>must</em> be in all lowercase characters.</td>
</tr>
<tr>
<td>Note</td>
<td>The Kerberos realm name <em>must</em> be in all uppercase characters.</td>
</tr>
<tr>
<td>KDC</td>
<td>Key distribution center that consists of a Kerberos server and database program that is running on a network host.</td>
</tr>
<tr>
<td>Kerberized</td>
<td>A term that describes applications and services that have been modified to support the Kerberos credential infrastructure.</td>
</tr>
<tr>
<td>Kerberos realm</td>
<td>A domain consisting of users, hosts, and network services that are registered to a Kerberos server. The Kerberos server is trusted to verify the identity of a user or network service to another user or network service.</td>
</tr>
<tr>
<td>Note</td>
<td>The Kerberos realm name <em>must</em> be in all uppercase characters.</td>
</tr>
<tr>
<td>Kerberos server</td>
<td>A daemon that is running on a network host. Users and network services register their identity with the Kerberos server. Network services query the Kerberos server to authenticate to other network services.</td>
</tr>
<tr>
<td>KEYTAB</td>
<td>A password that a network service shares with the KDC. In Kerberos 5 and later Kerberos versions, the network service authenticates an encrypted service credential by using the KEYTAB to decrypt it. In Kerberos versions earlier than Kerberos 5, KEYTAB is referred to as SRVTAB.</td>
</tr>
<tr>
<td>Principal</td>
<td>Also known as a Kerberos identity, this is who you are or what a service is according to the Kerberos server.</td>
</tr>
<tr>
<td>Note</td>
<td>The Kerberos principal name <em>must</em> be in all lowercase characters.</td>
</tr>
</tbody>
</table>
**Kerberos Operation**

A Kerberos server can be a device that is configured as a network security server and that can authenticate remote users by using the Kerberos protocol. Although you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

To authenticate to network services by using a device as a Kerberos server, remote users must follow these steps:

**Authenticating to a Boundary Switch**

This section describes the first layer of security through which a remote user must pass. The user must first authenticate to the boundary switch. This process then occurs:

1. The user opens an un-Kerberized Telnet connection to the boundary switch.
2. The switch prompts the user for a username and password.
3. The switch requests a TGT from the KDC for this user.
4. The KDC sends an encrypted TGT that includes the user identity to the switch.
5. The switch attempts to decrypt the TGT by using the password that the user entered.
   - If the decryption is successful, the user is authenticated to the switch.
   - If the decryption is not successful, the user repeats Step 2 either by re-entering the username and password (noting if Caps Lock or Num Lock is on or off) or by entering a different username and password.

A remote user who initiates a un-Kerberized Telnet session and authenticates to a boundary switch is inside the firewall, but the user must still authenticate directly to the KDC before getting access to the network services. The user must authenticate to the KDC because the TGT that the KDC issues is stored on the switch and cannot be used for additional authentication until the user logs on to the switch.
Obtaining a TGT from a KDC

This section describes the second layer of security through which a remote user must pass. The user must now authenticate to a KDC and obtain a TGT from the KDC to access network services.

For instructions about how to authenticate to a KDC, see the “Obtaining a TGT from a KDC” section in the “Security Server Protocols” chapter of the Cisco IOS Security Configuration Guide, Release 12.4.

Authenticating to Network Services

This section describes the third layer of security through which a remote user must pass. The user with a TGT must now authenticate to the network services in a Kerberos realm.

For instructions about how to authenticate to a network service, see the “Authenticating to Network Services” section in the “Security Server Protocols” chapter of the Cisco IOS Security Configuration Guide, Release 12.4.

How to Configure Kerberos

To set up a Kerberos-authenticated server-client system, follow these steps:

• Configure the KDC by using Kerberos commands.

• Configure the switch to use the Kerberos protocol.

Monitoring the Kerberos Configuration

To display the Kerberos configuration, use the following commands:

• `show running-config`
• `show kerberos creds`: Lists the credentials in a current user’s credentials cache.
• `clear kerberos creds`: Destroys all credentials in a current user’s credentials cache, including those forwarded.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

How to Configure Local Authentication and Authorization

Configuring the Switch for Local Authentication and Authorization

You can configure AAA to operate without a server by setting the switch to implement AAA in local mode. The switch then handles authentication and authorization. No accounting is available in this configuration.

Note

To secure the switch for HTTP access by using AAA methods, you must configure the switch with the `ip http authentication aaa` global configuration command. Configuring AAA authentication does not secure the switch for HTTP access by using AAA methods.

Follow these steps to configure AAA to operate without a server by setting the switch to implement AAA in local mode:
SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. aaa authentication login default local
5. aaa authorization exec local
6. aaa authorization network local
7. username name [privilege level] [password encryption-type password]
8. end
9. show running-config
10. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | enable  
Example:  
Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| Step 3 | aaa new-model  
Example:  
Device(config)# aaa new-model | Enables AAA. |
| Step 4 | aaa authentication login default local  
Example:  
Device(config)# aaa authentication login default local | Sets the login authentication to use the local username database. The default keyword applies the local user database authentication to all ports. |
| Step 5 | aaa authorization exec local  
Example:  
Device(config)# aaa authorization exec local | Configures user AAA authorization, check the local database, and allow the user to run an EXEC shell. |
| Step 6 | aaa authorization network local  
Example:  
Device(config)# aaa authorization network local | Configures user AAA authorization for all network-related service requests. |
### Command or Action

- **Device(config)# aaa authorization network local**

### Purpose

Enters the local database, and establishes a username-based authentication system.

**Step 7**

**username name [privilege level] {password encryption-type password}**

**Example:**

```
Device(config)# username your_user_name privilege 1 password 7 secret567
```

Repeat this command for each user.

- For **name**, specify the user ID as one word. Spaces and quotation marks are not allowed.
- (Optional) For **level**, specify the privilege level the user has after gaining access. The range is 0 to 15. Level 15 gives privileged EXEC mode access. Level 0 gives user EXEC mode access.
- For **encryption-type**, enter 0 to specify that an unencrypted password follows. Enter 7 to specify that a hidden password follows.
- For **password**, specify the password the user must enter to gain access to the switch. The password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the **username** command.

### Step 8

**end**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

### Step 9

**show running-config**

**Example:**

```
Device# show running-config
```

Verifies your entries.

### Step 10

**copy running-config startup-config**

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

• Additional References, on page 1591

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Secure Shell

The following are the prerequisites for configuring the switch for secure shell (SSH):

• For SSH to work, the switch needs an Rivest, Shamir, and Adleman (RSA) public/private key pair. This is the same with Secure Copy Protocol (SCP), which relies on SSH for its secure transport.

• Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the switch.

• Because SCP relies on SSH for its secure transport, the router must have an Rivest, Shamir, and Adelman (RSA) key pair.

• SCP relies on SSH for security.

• SCP requires that authentication, authorization, and accounting (AAA) authorization be configured so the router can determine whether the user has the correct privilege level.

• A user must have appropriate authorization to use SCP.
Restrictions for Configuring Secure Shell

The following are restrictions for configuring the Device for secure shell.

- The switch supports Rivest, Shamir, and Adelman (RSA) authentication.
- SSH supports only the execution-shell application.
- The SSH server and the SSH client are supported only on Data Encryption Standard (DES) (56-bit) and 3DES (168-bit) data encryption software. In DES software images, DES is the only encryption algorithm available. In 3DES software images, both DES and 3DES encryption algorithms are available.
- The Device supports the Advanced Encryption Standard (AES) encryption algorithm with a 128-bit key, 192-bit key, or 256-bit key. However, symmetric cipher AES to encrypt the keys is not supported.
- This software release does not support IP Security (IPSec).
- When using SCP, you cannot enter the password into the `copy` command. You must enter the password when prompted.
- The login banner is not supported in Secure Shell Version 1. It is supported in Secure Shell Version 2.
- The `-l` keyword and `userid : {number} {ip-address}` delimiter and arguments are mandatory when configuring the alternative method of Reverse SSH for console access.

Related Topics

Secure Copy Protocol, on page 1586

Information about SSH

Secure Shell (SSH) is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated. This software release supports SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2).

SSH and Switch Access

Secure Shell (SSH) is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated. This software release supports SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2).
SSH functions the same in IPv6 as in IPv4. For IPv6, SSH supports IPv6 addresses and enables secure, encrypted connections with remote IPv6 nodes over an IPv6 transport.

**SSH Servers, Integrated Clients, and Supported Versions**

The Secure Shell (SSH) Integrated Client feature is an application that runs over the SSH protocol to provide device authentication and encryption. The SSH client enables a Cisco device to make a secure, encrypted connection to another Cisco device or to any other device running the SSH server. This connection provides functionality similar to that of an outbound Telnet connection except that the connection is encrypted. With authentication and encryption, the SSH client allows for secure communication over an unsecured network.

The SSH server and SSH integrated client are applications that run on the switch. The SSH server works with the SSH client supported in this release and with non-Cisco SSH clients. The SSH client works with publicly and commercially available SSH servers. The SSH client supports the ciphers of Data Encryption Standard (DES), 3DES, and password authentication.

The switch supports an SSHv1 or an SSHv2 server.

The switch supports an SSHv1 client.

---

**Note**

The SSH client functionality is available only when the SSH server is enabled.

User authentication is performed like that in the Telnet session to the device. SSH also supports the following user authentication methods:

- TACACS+
- RADIUS
- Local authentication and authorization

**Related Topics**

- Configuring the Switch for Local Authentication and Authorization, on page 1579
- TACACS+ and Switch Access, on page 1513
- RADIUS and Switch Access, on page 1527

**SSH Configuration Guidelines**

Follow these guidelines when configuring the switch as an SSH server or SSH client:

- An RSA key pair generated by a SSHv1 server can be used by an SSHv2 server, and the reverse.
- If the SSH server is running on a stack master and the stack master fails, the new stack master uses the RSA key pair generated by the previous stack master.
- If you get CLI error messages after entering the `crypto key generate rsa` global configuration command, an RSA key pair has not been generated. Reconfigure the hostname and domain, and then enter the `crypto key generate rsa` command. For more information, see Related Topics below.
- When generating the RSA key pair, the message No host name specified might appear. If it does, you must configure a hostname by using the `hostname` global configuration command.
• When generating the RSA key pair, the message No domain specified might appear. If it does, you must configure an IP domain name by using the `ip domain-name` global configuration command.

• When configuring the local authentication and authorization authentication method, make sure that AAA is disabled on the console.

**Related Topics**

- Configuring the Switch for Local Authentication and Authorization, on page 1579

**Secure Copy Protocol Overview**

The Secure Copy Protocol (SCP) feature provides a secure and authenticated method for copying switch configurations or switch image files. SCP relies on Secure Shell (SSH), an application and a protocol that provides a secure replacement for the Berkeley r-tools.

For SSH to work, the switch needs an RSA public/private key pair. This is the same with SCP, which relies on SSH for its secure transport.

Because SSH also relies on AAA authentication, and SCP relies further on AAA authorization, correct configuration is necessary.

• Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the switch.

• Because SCP relies on SSH for its secure transport, the router must have an Rivest, Shamir, and Adelman (RSA) key pair.

**Note**
When using SCP, you cannot enter the password into the copy command. You must enter the password when prompted.

**Secure Copy Protocol**

The Secure Copy Protocol (SCP) feature provides a secure and authenticated method for copying device configurations or switch image files. The behavior of SCP is similar to that of remote copy (rcp), which comes from the Berkeley r-tools suite, except that SCP relies on SSH for security. SCP also requires that authentication, authorization, and accounting (AAA) authorization be configured so the device can determine whether the user has the correct privilege level. To configure the Secure Copy feature, you should understand the SCP concepts.

How to Configure SSH

Setting Up the Device to Run SSH

Follow these steps to set up your Device to run SSH:

### Before you begin
Configure user authentication for local or remote access. This step is required. For more information, see Related Topics below.

### SUMMARY STEPS

1. enable
2. configure terminal
3. hostname hostname
4. ip domain-name domain_name
5. crypto key generate rsa
6. end
7. show running-config
8. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
### Configuring the SSH Server

Follow these steps to configure the SSH server:

**Note**

This procedure is only required if you are configuring the Device as an SSH server.

**SUMMARY STEPS**

1. **enable**

---

### Command or Action | Purpose
---|---

`Device(config)# ip domain-name your_domain` | Enables the SSH server for local and remote authentication on the Device and generates an RSA key pair. Generating an RSA key pair for the Device automatically enables SSH. We recommend that a minimum modulus size of 1024 bits. When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use. **Note** Follow this procedure only if you are configuring the Device as an SSH server.

**Step 5** `crypto key generate rsa`  
**Example:**

`Device(config)# crypto key generate rsa` | Returns to privileged EXEC mode.

**Step 6** `end`  
**Example:**

`Device(config)# end` | Verifies your entries.

**Step 7** `show running-config`  
**Example:**

`Device# show running-config` | (Optional) Saves your entries in the configuration file.

**Step 8** `copy running-config startup-config`  
**Example:**

`Device# copy running-config startup-config` |  

**Related Topics**

<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip ssh version [1</td>
<td>2]</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip ssh version 1</td>
<td></td>
</tr>
<tr>
<td>• 1—Configure the Device to run SSH Version 1.</td>
<td></td>
</tr>
<tr>
<td>• 2—Configure the Device to run SSH Version 2.</td>
<td></td>
</tr>
<tr>
<td>If you do not enter this command or do not specify a keyword, the SSH server selects the latest SSH version supported by the SSH client. For example, if the SSH client supports SSHv1 and SSHv2, the SSH server selects SSHv2.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip ssh {timeout seconds</td>
<td>authentication-retries number}</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip ssh timeout 90 authentication-retries 2</td>
<td></td>
</tr>
<tr>
<td>• Specify the time-out value in seconds; the default is 120 seconds. The range is 0 to 120 seconds. This parameter applies to the SSH negotiation phase. After the connection is established, the Device uses the default time-out values of the CLI-based sessions.</td>
<td></td>
</tr>
<tr>
<td>By default, up to five simultaneous, encrypted SSH connections for multiple CLI-based sessions over the network are available (session 0 to session 4). After the execution shell starts, the CLI-based session time-out value returns to the default of 10 minutes.</td>
<td></td>
</tr>
</tbody>
</table>
Step 5

Use one or both of the following:
- `line vty line_number[ending_line_number]`
- `transport input ssh`

Example:
Device(config)# line vty 1 10

or
Device(config-line)# transport input ssh

(Optional) Configures the virtual terminal line settings.
- Enters line configuration mode to configure the virtual terminal line settings. For `line_number` and `ending_line_number`, specify a pair of lines. The range is 0 to 15.
- Specifies that the Device prevent non-SSH Telnet connections. This limits the router to only SSH connections.

Step 6

Example:
Device(config-line)# end

Returns to privileged EXEC mode.

Step 7

Example:
Device# show running-config

Verifies your entries.

Step 8

Example:
Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

---

X.509v3 Certificates for SSH Authentication

The X.509v3 Certificates for secure shell (SSH) Authentication feature uses the X.509v3 digital certificates in server and user authentication at the SSH server side.

Prerequisites for Digital Certificates for SSH Authentication

The Digital Certificates for SSH Authentication feature introduces the `ip ssh server algorithm authentication` command to replace the `ip ssh server authenticate user` command. If you use the `ip ssh server authenticate user` command, the following deprecation message is displayed.

Warning: SSH command accepted but this CLI will be deprecated soon. Please move to new CLI "ip ssh server algorithm authentication". Please configure "default ip ssh server authenticate user" to make CLI ineffective.

Use the `default ip ssh server authenticate user` command to remove the `ip ssh server authenticate user` command from effect. The IOS secure shell (SSH) server then starts using the `ip ssh server algorithm authentication` command.

Restrictions for X.509v3 Certificates for SSH Authentication

The following restrictions are applicable for X.509v3 Certificate for SSH Authentication:

- The X.509v3 Certificates for SSH Authentication feature implementation is applicable only on the IOS secure shell (SSH) server side.

- IOS SSH server supports only the x509v3-ssh-rsa algorithm based certificate for server and user authentication on the IOS SSH server side.

The X.509v3 Certificate for SSH Authentication fails in the following conditions:
- When root certification authority is configured as a trustpoint on the device.
- When a client passes a certificate chain that leads to a self-signed root certificate authority that includes a client certificate, sub-ca certificate, and self-signed root certificate authority.
- When a sub-ca certification is configured as a trustpoint on the device but not included as a trustpoint on the user certificate.

### Information About X.509v3 Certificates for SSH Authentication

The following section provides information about digital certificates, and server and user authentication.

#### Digital Certificates

The validity of the authentication depends upon the strength of the linkage between the public signing key and the identity of the signer. Digital certificates in the X.509v3 format (RFC5280) are used to provide identity management. A chain of signatures by a trusted root certification authority and its intermediate certificate authorities binds a given public signing key to a given digital identity.

Public key infrastructure (PKI) trustpoint helps manage the digital certificates. The association between the certificate and the trustpoint helps track the certificate. The trustpoint contains information about the certificate authority (CA), different identity parameters, and the digital certificate. Multiple trustpoints can be created to associate with different certificates.

#### Server and User Authentication using X.509v3

For server authentication, the IOS secure shell (SSH) server sends its own certificate to the SSH client for verification. This server certificate is associated with the trustpoint configured in the server certificate profile (ssh-server-cert-profile-server configuration mode).

For user authentication, the SSH client sends the user's certificate to the IOS SSH server for verification. The SSH server validates the incoming user certificate using public key infrastructure (PKI) trustpoints configured in the server certificate profile (ssh-server-cert-profile-user configuration mode).

By default, certificate-based authentication is enabled for server and user at the IOS SSH server end.

#### How to Configure X.509v3 Certificates for SSH Authentication

The following section provides information about how to configure X.509v3 Certificates for SSH Authentication.

#### Configuring IOS SSH Server to Use Digital Certificates for Sever Authentication

The following section provides information about Configuring IOS SSH Server to Use Digital Certificates for Sever Authentication.

<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip ssh server algorithm authentication publickey</td>
<td>Defines the order of user authentication algorithms. Only the configured algorithm is negotiated with the secure shell (SSH) client.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip ssh server algorithm authentication publickey</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip ssh server algorithm publickey {x509v3-ssh-rsa [ssh-rsa]</td>
<td>Defines the order of public key algorithms. Only the configured algorithm is accepted by the SSH client for user authentication.</td>
</tr>
<tr>
<td>[x509v3-ssh-rsa]}</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip ssh server algorithm publickey x509v3-ssh-rsa</td>
<td></td>
</tr>
</tbody>
</table>

Note

- The IOS SSH server must have at least one configured user authentication algorithm.
- To use the certificate method for user authentication, the **publickey** keyword must be configured.
- The **ip ssh server algorithm authentication** command replaces the **ip ssh server authenticate user** command.

Note

The IOS SSH client must have at least one configured public key algorithm:

- ssh-rsa – public-key-based authentication
- x509v3-ssh-rsa – certificate-based authentication

## Configuration Examples for X.509v3 Certificates for SSH Authentication

The following section provides examples for user and server authentication using digital certificates.

### Example: Configuring IOS SSH Server to Use Digital Certificates for Server Authentication

This example shows how to configure IOS SSH Server to Use Digital Certificates for Server Authentication.

```
Device> enable
Device# configure terminal
Device(config)# ip ssh server algorithm hostkey x509v3-ssh-rsa
Device(config)# ip ssh server certificate profile
Device(ssh-server-cert-profile)# server
Device(ssh-server-cert-profile-server)# trustpoint sign trust1
Device(ssh-server-cert-profile-server)# exit
```

### Example: Configuring IOS SSH Server to Verify User's Digital Certificate for User Authentication

This example shows how to configure IOS SSH Server to Verify User's Digital Certificate for User Authentication.

```
Device> enable
Device# configure terminal
```

Feature Information for X.509v3 Certificates for SSH Authentication

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about Secure Sockets Layer (SSL) HTTP

Secure HTTP Servers and Clients Overview

On a secure HTTP connection, data to and from an HTTP server is encrypted before being sent over the Internet. HTTP with SSL encryption provides a secure connection to allow such functions as configuring a switch from a Web browser. Cisco's implementation of the secure HTTP server and secure HTTP client uses an implementation of SSL Version 3.0 with application-layer encryption. HTTP over SSL is abbreviated as HTTPS; the URL of a secure connection begins with https:// instead of http://.

Note

SSL evolved into Transport Layer Security (TLS) in 1999, but is still used in this particular context.

The primary role of the HTTP secure server (the switch) is to listen for HTTPS requests on a designated port (the default HTTPS port is 443) and pass the request to the HTTP 1.1 Web server. The HTTP 1.1 server
processes requests and passes responses (pages) back to the HTTP secure server, which, in turn, responds to the original request.

The primary role of the HTTP secure client (the web browser) is to respond to Cisco IOS application requests for HTTPS User Agent services, perform HTTPS User Agent services for the application, and pass the response back to the application.

Certificate Authority Trustpoints

Certificate authorities (CAs) manage certificate requests and issue certificates to participating network devices. These services provide centralized security key and certificate management for the participating devices. Specific CA servers are referred to as trustpoints.

When a connection attempt is made, the HTTPS server provides a secure connection by issuing a certified X.509v3 certificate, obtained from a specified CA trustpoint, to the client. The client (usually a Web browser), in turn, has a public key that allows it to authenticate the certificate.

For secure HTTP connections, we highly recommend that you configure a CA trustpoint. If a CA trustpoint is not configured for the device running the HTTPS server, the server certifies itself and generates the needed RSA key pair. Because a self-certified (self-signed) certificate does not provide adequate security, the connecting client generates a notification that the certificate is self-certified, and the user has the opportunity to accept or reject the connection. This option is useful for internal network topologies (such as testing).

If you do not configure a CA trustpoint, when you enable a secure HTTP connection, either a temporary or a persistent self-signed certificate for the secure HTTP server (or client) is automatically generated.

- If the switch is not configured with a hostname and a domain name, a temporary self-signed certificate is generated. If the switch reboots, any temporary self-signed certificate is lost, and a new temporary new self-signed certificate is assigned.

- If the switch has been configured with a host and domain name, a persistent self-signed certificate is generated. This certificate remains active if you reboot the switch or if you disable the secure HTTP server so that it will be there the next time you re-enable a secure HTTP connection.

Note

The certificate authorities and trustpoints must be configured on each device individually. Copying them from other devices makes them invalid on the switch.

When a new certificate is enrolled, the new configuration change is not applied to the HTTPS server until the server is restarted. You can restart the server using either the CLI or by physical reboot. On restarting the server, the switch starts using the new certificate.

If a self-signed certificate has been generated, this information is included in the output of the show running-config privileged EXEC command. This is a partial sample output from that command displaying a self-signed certificate.

```
Device# show running-config
Building configuration...
<output truncated>
crypto pki trustpoint TP=self-signed-3080755072
   enrollment selfsigned
   subject-name cn=IOS-Self-Signed-Certificate-3080755072
```
You can remove this self-signed certificate by disabling the secure HTTP server and entering the `no crypto pki trustpoint TP-self-signed-30890755072` global configuration command. If you later re-enable a secure HTTP server, a new self-signed certificate is generated.

The values that follow `TP self-signed` depend on the serial number of the device.

You can use an optional command (`ip http secure-client-auth`) to allow the HTTPS server to request an X.509v3 certificate from the client. Authenticating the client provides more security than server authentication by itself.

For additional information on Certificate Authorities, see the “Configuring Certification Authority Interoperability” chapter in the *Cisco IOS Security Configuration Guide, Release 12.4*.

**CipherSuites**

A CipherSuite specifies the encryption algorithm and the digest algorithm to use on a SSL connection. When connecting to the HTTPS server, the client Web browser offers a list of supported CipherSuites, and the client and server negotiate the best encryption algorithm to use from those on the list that are supported by both. For example, Netscape Communicator 4.76 supports U.S. security with RSA Public Key Cryptography, MD2, MD5, RC2-CBC, RC4, DES-CBC, and DES-EDE3-CBC.

For the best possible encryption, you should use a client browser that supports 128-bit encryption, such as Microsoft Internet Explorer Version 5.5 (or later) or Netscape Communicator Version 4.76 (or later). The `SSL_RSA_WITH_DES_CBC_SHA` CipherSuite provides less security than the other CipherSuites, as it does not offer 128-bit encryption.

The more secure and more complex CipherSuites require slightly more processing time. This list defines the CipherSuites supported by the switch and ranks them from fastest to slowest in terms of router processing load (speed):

1. `SSL_RSA_WITH_DES_CBC_SHA`—RSA key exchange (RSA Public Key Cryptography) with DES-CBC for message encryption and SHA for message digest
2. `SSL_RSA_WITH_NULL_SHA` key exchange with NULL for message encryption and SHA for message digest (only for SSL 3.0).
3. `SSL_RSA_WITH_NULL_MD5` key exchange with NULL for message encryption and MD5 for message digest (only for SSL 3.0).
4. `SSL_RSA_WITH_RC4_128_MD5`—RSA key exchange with RC4 128-bit encryption and MD5 for message digest
5. SSL_RSA_WITH_RC4_128_SHA—RSA key exchange with RC4 128-bit encryption and SHA for message digest
6. SSL_RSA_WITH_3DES_EDE_CBC_SHA—RSA key exchange with 3DES and DES-EDE3-CBC for message encryption and SHA for message digest
7. SSL_RSA_WITH_AES_128_CBC_SHA—RSA key exchange with AES 128-bit encryption and SHA for message digest (only for SSL 3.0).
8. SSL_RSA_WITH_AES_256_CBC_SHA—RSA key exchange with AES 256-bit encryption and SHA for message digest (only for SSL 3.0).
9. SSL_RSA_WITH_DHE_AES_128_CBC_SHA—RSA key exchange with AES 128-bit encryption and SHA for message digest (only for SSL 3.0).
10. SSL_RSA_WITH_DHE_AES_256_CBC_SHA—RSA key exchange with AES 256-bit encryption and SHA for message digest (only for SSL 3.0).

Note

The latest versions of Chrome do not support the four original cipher suites, thus disallowing access to both web GUI and guest portals.

RSA (in conjunction with the specified encryption and digest algorithm combinations) is used for both key generation and authentication on SSL connections. This usage is independent of whether or not a CA trustpoint is configured.

Default SSL Configuration

The standard HTTP server is enabled.
SSL is enabled.
No CA trustpoints are configured.
No self-signed certificates are generated.

SSL Configuration Guidelines

When SSL is used in a switch cluster, the SSL session terminates at the cluster commander. Cluster member switches must run standard HTTP.

Before you configure a CA trustpoint, you should ensure that the system clock is set. If the clock is not set, the certificate is rejected due to an incorrect date.
In a switch stack, the SSL session terminates at the stack master.
How to Configure Secure HTTP Servers and Clients

Configuring a CA Trustpoint

For secure HTTP connections, we recommend that you configure an official CA trustpoint. A CA trustpoint is more secure than a self-signed certificate.

Beginning in privileged EXEC mode, follow these steps to configure a CA Trustpoint:

**SUMMARY STEPS**

1. `configure terminal`
2. `hostname hostname`
3. `ip domain-name domain-name`
4. `crypto key generate rsa`
5. `crypto ca trustpoint name`
6. `enrollment url url`
7. `enrollment http-proxy host-name port-number`
8. `crl query url`
9. `primary name`
10. `exit`
11. `crypto ca authentication name`
12. `crypto ca enroll name`
13. `end`

**DETAILED STEPS**

</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>crypto key generate rsa</td>
<td>(Optional) Generates an RSA key pair. RSA key pairs are required before you can obtain a certificate for the switch. RSA key pairs are generated automatically. You can use this command to regenerate the keys, if needed.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config)# crypto key generate rsa</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>crypto ca trustpoint name</td>
<td>Specifies a local configuration name for the CA trustpoint and enter CA trustpoint configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config)# crypto ca trustpoint your_trustpoint</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>enrollment url url</td>
<td>Specifies the URL to which the switch should send certificate requests.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(ca-trustpoint)# enrollment url http://your_server:80</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>enrollment http-proxy host-name port-number</td>
<td>(Optional) Configures the switch to obtain certificates from the CA through an HTTP proxy server.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(ca-trustpoint)# enrollment http-proxy your_host 49</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For host-name, specify the proxy server used to get the CA.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For port-number, specify the port number used to access the CA.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>crl query url</td>
<td>Configures the switch to request a certificate revocation list (CRL) to ensure that the certificate of the peer has not been revoked.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(ca-trustpoint)# crl query ldap://your_host:49</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>primary name</td>
<td>(Optional) Specifies that the trustpoint should be used as the primary (default) trustpoint for CA requests.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(ca-trustpoint)# primary your_trustpoint</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For name, specify the trustpoint that you just configured.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>exit</td>
<td>Exits CA trustpoint configuration mode and return to global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(ca-trustpoint)# exit</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>crypto ca authentication name</td>
<td>Authenticates the CA by getting the public key of the CA. Use the same name used in Step 5.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Device(config)# crypto ca authentication</td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
| **your_trustpoint** |  |
| **Step 12** | **crypto ca enroll** *name*  
Example:  
Device(config)# crypto ca enroll your_trustpoint | Obtains the certificate from the specified CA trustpoint. This command requests a signed certificate for each RSA key pair.

| **Step 13** | **end**  
Example:  
Device(config)# end | Returns to privileged EXEC mode.

### Configuring the Secure HTTP Server

Beginning in privileged EXEC mode, follow these steps to configure a secure HTTP server:

**Before you begin**

If you are using a certificate authority for certification, you should use the previous procedure to configure the CA trustpoint on the switch before enabling the HTTP server. If you have not configured a CA trustpoint, a self-signed certificate is generated the first time that you enable the secure HTTP server. After you have configured the server, you can configure options (path, access list to apply, maximum number of connections, or timeout policy) that apply to both standard and secure HTTP servers.

To verify the secure HTTP connection by using a Web browser, enter `https://URL`, where the URL is the IP address or hostname of the server switch. If you configure a port other than the default port, you must also specify the port number after the URL. For example:

```
https://209.165.129:1026
```

or

```
https://host.domain.com:1026
```

### SUMMARY STEPS

1. **show ip http server status**
2. **configure terminal**
3. **ip http secure-server**
4. **ip http secure-port** *port-number*
5. **ip http secure-ciphersuite** `{[3des-ede-cbc-sha] [rc4-128-md5] [rc4-128-sha] [des-cbc-sha]}`
6. **ip http secure-client-auth**
7. **ip http secure-trustpoint** *name*
8. **ip http path** *path-name*
9. **ip http access-class** *access-list-number*
## Configuring the Secure HTTP Server

### 10. `ip http max-connections value`

### 11. `ip http timeout-policy idle seconds life seconds requests value`

### 12. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>show ip http server status</code></td>
<td>(Optional) Displays the status of the HTTP server to determine if the secure HTTP server feature is supported in the software. You should see one of these lines in the output:</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device# show ip http server status</code></td>
<td>HTTP secure server capability: Present</td>
</tr>
<tr>
<td></td>
<td></td>
<td>or</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HTTP secure server capability: Not present</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>ip http secure-server</code></td>
<td>Enables the HTTPS server if it has been disabled. The HTTPS server is enabled by default.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# ip http secure-server</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>ip http secure-port port-number</code></td>
<td>(Optional) Specifies the port number to be used for the HTTPS server. The default port number is 443. Valid options are 443 or any number in the range 1025 to 65535.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# ip http secure-port 443</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>ip http secure-ciphersuite {3des-ede-cbc-sha [rc4-128-md5] [rc4-128-sha] [des-cbc-sha]}</code></td>
<td>(Optional) Specifies the CipherSuites (encryption algorithms) to be used for encryption over the HTTPS connection. If you do not have a reason to specify a particularly CipherSuite, you should allow the server and client to negotiate a CipherSuite that they both support. This is the default.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# ip http secure-ciphersuite rc4-128-md5</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>ip http secure-client-auth</code></td>
<td>(Optional) Configures the HTTP server to request an X.509v3 certificate from the client for authentication during the connection process. The default is for the client to request a certificate from the server, but the server does not attempt to authenticate the client.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Device(config)# ip http secure-client-auth</code></td>
<td></td>
</tr>
</tbody>
</table>
| Step 7 | **ip http secure-trustpoint name**  
**Example:**  
Device(config)# **ip http secure-trustpoint your_trustpoint** | **Purpose**  
Specifies the CA trustpoint to use to get an X.509v3 security certificate and to authenticate the client certificate connection.  
**Note** Use of this command assumes you have already configured a CA trustpoint according to the previous procedure. |
| Step 8 | **ip http path path-name**  
**Example:**  
Device(config)# **ip http path /your_server:80** | *(Optional)* Sets a base HTTP path for HTML files. The path specifies the location of the HTTP server files on the local system (usually located in system flash memory). |
| Step 9 | **ip http access-class access-list-number**  
**Example:**  
Device(config)# **ip http access-class 2** | *(Optional)* Specifies an access list to use to allow access to the HTTP server. |
| Step 10 | **ip http max-connections value**  
**Example:**  
Device(config)# **ip http max-connections 4** | *(Optional)* Sets the maximum number of concurrent connections that are allowed to the HTTP server. We recommend that the value be at least 10 and not less. This is required for the UI to function as expected. |
| Step 11 | **ip http timeout-policy idle seconds life seconds requests requests**  
**Example:**  
Device(config)# **ip http timeout-policy idle 120 life 240 requests 1** | *(Optional)* Specifies how long a connection to the HTTP server can remain open under the defined circumstances:  
- **idle**—the maximum time period when no data is received or response data cannot be sent. The range is 1 to 600 seconds. The default is 180 seconds (3 minutes).  
- **life**—the maximum time period from the time that the connection is established. The range is 1 to 86400 seconds (24 hours). The default is 180 seconds.  
- **requests**—the maximum number of requests processed on a persistent connection. The maximum value is 86400. The default is 1. |
| Step 12 | **end**  
**Example:**  
Device(config)# **end** | Returns to privileged EXEC mode. |
Configuring the Secure HTTP Client

Beginning in privileged EXEC mode, follow these steps to configure a secure HTTP client:

**Before you begin**

The standard HTTP client and secure HTTP client are always enabled. A certificate authority is required for secure HTTP client certification. This procedure assumes that you have previously configured a CA trustpoint on the switch. If a CA trustpoint is not configured and the remote HTTPS server requires client authentication, connections to the secure HTTP client fail.

**SUMMARY STEPS**

1. `configure terminal`
2. `ip http client secure-trustpoint name`
3. `ip http client secure-ciphersuite { [3des-ede-cbc-sha] [rc4-128-md5] [rc4-128-sha] [des-cbc-sha] }`
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring IPv4 Access Control Lists

This section lists the prerequisites for configuring network security with access control lists (ACLs).

- On switches running the LAN base feature set, VLAN maps are not supported.

Restrictions for Configuring IPv4 Access Control Lists

General Network Security

The following are restrictions for configuring network security with ACLs:
• Not all commands that accept a numbered ACL accept a named ACL. ACLs for packet filters and route filters on interfaces can use a name. VLAN maps also accept a name.

• A standard ACL and an extended ACL cannot have the same name.

• Though visible in the command-line help strings, **appletalk** is not supported as a matching condition for the **deny** and **permit** MAC access-list configuration mode commands.

• ACL wildcard is not supported in downstream client policy.

**IPv4 ACL Network Interfaces**

The following restrictions apply to IPv4 ACLs to network interfaces:

• When controlling access to an interface, you can use a named or numbered ACL.

• If you apply an ACL to a Layer 2 interface that is a member of a VLAN, the Layer 2 (port) ACL takes precedence over an input Layer 3 ACL applied to the VLAN interface or a VLAN map applied to the VLAN.

• If you apply an ACL to a Layer 3 interface and routing is not enabled on the switch, the ACL only filters packets that are intended for the CPU, such as SNMP, Telnet, or web traffic.

• If the **preauth_ipv4_acl** ACL is configured to filter packets, the ACL is removed after authentication.

• You do not have to enable routing to apply ACLs to Layer 2 interfaces.

---

**Note**

By default, the router sends Internet Control Message Protocol (ICMP) unreachable messages when a packet is denied by an access group on a Layer 3 interface. These access-group denied packets are not dropped in hardware but are bridged to the switch CPU so that it can generate the ICMP-unreachable message. They do not generate ICMP unreachable messages. ICMP unreachable messages can be disabled on router ACLs with the **no ip unreachables** interface command.

---

**MAC ACLs on a Layer 2 Interface**

After you create a MAC ACL, you can apply it to a Layer 2 interface to filter non-IP traffic coming in that interface. When you apply the MAC ACL, consider these guidelines:

• You can apply no more than one IP access list and one MAC access list to the same Layer 2 interface. The IP access list filters only IP packets, and the MAC access list filters non-IP packets.

• A Layer 2 interface can have only one MAC access list. If you apply a MAC access list to a Layer 2 interface that has a MAC ACL configured, the new ACL replaces the previously configured one.

---

**Note**

The **mac access-group** interface configuration command is only valid when applied to a physical Layer 2 interface. You cannot use the command on EtherChannel port channels.

---

**IP Access List Entry Sequence Numbering**

• This feature does not support dynamic, reflexive, or firewall access lists.
Information about Network Security with ACLs

This chapter describes how to configure network security on the switch by using access control lists (ACLs), which in commands and tables are also referred to as access lists.

ACL Overview

Packet filtering can help limit network traffic and restrict network use by certain users or devices. ACLs filter traffic as it passes through a router or switch and permit or deny packets crossing specified interfaces or VLANs. An ACL is a sequential collection of permit and deny conditions that apply to packets. When a packet is received on an interface, the switch compares the fields in the packet against any applied ACLs to verify that the packet has the required permissions to be forwarded, based on the criteria specified in the access list. One by one, it tests packets against the conditions in an access list. The first match decides whether the switch accepts or rejects the packets. Because the switch stops testing after the first match, the order of conditions in the list is critical. If no conditions match, the switch rejects the packet. If there are no restrictions, the switch forwards the packet; otherwise, the switch drops the packet. The switch can use ACLs on all packets it forwards, including packets bridged within a VLAN.

You configure access lists on a router or Layer 3 switch to provide basic security for your network. If you do not configure ACLs, all packets passing through the switch could be allowed onto all parts of the network. You can use ACLs to control which hosts can access different parts of a network or to decide which types of traffic are forwarded or blocked at router interfaces. For example, you can allow e-mail traffic to be forwarded but not Telnet traffic. ACLs can be configured to block inbound traffic, outbound traffic, or both.

Access Control Entries

An ACL contains an ordered list of access control entries (ACEs). Each ACE specifies permit or deny and a set of conditions the packet must satisfy in order to match the ACE. The meaning of permit or deny depends on the context in which the ACL is used.

ACL Supported Types

The switch supports IP ACLs and Ethernet (MAC) ACLs:

- IP ACLs filter IPv4 traffic, including TCP, User Datagram Protocol (UDP), Internet Group Management Protocol (IGMP), and Internet Control Message Protocol (ICMP).
- Ethernet ACLs filter non-IP traffic.

This switch also supports quality of service (QoS) classification ACLs.

Supported ACLs

The switch supports three types of ACLs to filter traffic:
• Port ACLs access-control traffic entering a Layer 2 interface. You can apply only one IP access list and one MAC access list to a Layer 2 interface.

• Router ACLs access-control routed traffic between VLANs and are applied to Layer 3 interfaces in a specific direction (inbound or outbound).

• VLAN ACLs or VLAN maps access-control all packets (bridged and routed). You can use VLAN maps to filter traffic between devices in the same VLAN. VLAN maps are configured to provide access control based on Layer 3 addresses for IPv4. Unsupported protocols are access-controlled through MAC addresses using Ethernet ACEs. After a VLAN map is applied to a VLAN, all packets (routed or bridged) entering the VLAN are checked against the VLAN map. Packets can either enter the VLAN through a switch port or through a routed port after being routed.

ACL Precedence

When VLAN maps, Port ACLs, and router ACLs are configured on the same switch, the filtering precedence, from greatest to least, is port ACL, router ACL, then VLAN map. The following examples describe simple use cases:

• When both an input port ACL and a VLAN map are applied, incoming packets received on ports with a port ACL applied are filtered by the port ACL. Other packets are filtered by the VLAN map.

• When an input router ACL and input port ACL exist in a switch virtual interface (SVI), incoming packets received on ports to which a port ACL is applied are filtered by the port ACL. Incoming routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.

• When an output router ACL and input port ACL exist in an SVI, incoming packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IP packets are filtered by the router ACL. Other packets are not filtered.

• When a VLAN map, input router ACL, and input port ACL exist in an SVI, incoming packets received on the ports to which a port ACL is applied are only filtered by the port ACL. Incoming routed IP packets received on other ports are filtered by both the VLAN map and the router ACL. Other packets are filtered only by the VLAN map.

• When a VLAN map, output router ACL, and input port ACL exist in an SVI, incoming packets received on the ports to which a port ACL is applied are only filtered by the port ACL. Outgoing routed IP packets are filtered by both the VLAN map and the router ACL. Other packets are filtered only by the VLAN map.

Related Topics

Restrictions for Configuring IPv4 Access Control Lists, on page 1613

Port ACLs

Port ACLs are ACLs that are applied to Layer 2 interfaces on a switch. Port ACLs are supported only on physical interfaces and not on EtherChannel interfaces. Port ACLs can be applied to the interface in outbound and inbound direction. The following access lists are supported:

• Standard IP access lists using source addresses

• Extended IP access lists using source and destination addresses and optional protocol type information

• MAC extended access lists using source and destination MAC addresses and optional protocol type information
The switch examines ACLs on an interface and permits or denies packet forwarding based on how the packet matches the entries in the ACL. In this way, ACLs control access to a network or to part of a network.

**Figure 93: Using ACLs to Control Traffic in a Network**

This is an example of using port ACLs to control access to a network when all workstations are in the same VLAN. ACLs applied at the Layer 2 input would allow Host A to access the Human Resources network, but prevent Host B from accessing the same network. Port ACLs can only be applied to Layer 2 interfaces in the inbound direction.

When you apply a port ACL to a trunk port, the ACL filters traffic on all VLANs present on the trunk port. When you apply a port ACL to a port with voice VLAN, the ACL filters traffic on both data and voice VLANs.

With port ACLs, you can filter IP traffic by using IP access lists and non-IP traffic by using MAC addresses. You can filter both IP and non-IP traffic on the same Layer 2 interface by applying both an IP access list and a MAC access list to the interface.

---

**Note**

You cannot apply more than one IP access list and one MAC access list to a Layer 2 interface. If an IP access list or MAC access list is already configured on a Layer 2 interface and you apply a new IP access list or MAC access list to the interface, the new ACL replaces the previously configured one.

---

**Router ACLs**

You can apply router ACLs on switch virtual interfaces (SVIs), which are Layer 3 interfaces to VLANs; on physical Layer 3 interfaces; and on Layer 3 EtherChannel interfaces. You apply router ACLs on interfaces for specific directions (inbound or outbound). You can apply one router ACL in each direction on an interface.

The switch supports these access lists for IPv4 traffic:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses and optional protocol type information for matching operations.

As with port ACLs, the switch examines ACLs associated with features configured on a given interface. As packets enter the switch on an interface, ACLs associated with all inbound features configured on that interface...
are examined. After packets are routed and before they are forwarded to the next hop, all ACLs associated with outbound features configured on the egress interface are examined.

ACLs permit or deny packet forwarding based on how the packet matches the entries in the ACL, and can be used to control access to a network or to part of a network.

**VLAN Maps**

Use VLAN ACLs or VLAN maps to access-control all traffic. You can apply VLAN maps to all packets that are routed into or out of a VLAN or are bridged within a VLAN in the switch or switch stack.

Use VLAN maps for security packet filtering. VLAN maps are not defined by direction (input or output).

You can configure VLAN maps to match Layer 3 addresses for IPv4 traffic.

All non-IP protocols are access-controlled through MAC addresses and Ethertype using MAC VLAN maps. (IP traffic is not access controlled by MAC VLAN maps.) You can enforce VLAN maps only on packets going through the switch; you cannot enforce VLAN maps on traffic between hosts on a hub or on another switch connected to this switch.

With VLAN maps, forwarding of packets is permitted or denied, based on the action specified in the map.

*Figure 94: Using VLAN Maps to Control Traffic*

This shows how a VLAN map is applied to prevent a specific type of traffic from Host A in VLAN 10 from being forwarded. You can apply only one VLAN map to a VLAN.

**ACEs and Fragmented and Unfragmented Traffic**

IP packets can be fragmented as they cross the network. When this happens, only the fragment containing the beginning of the packet contains the Layer 4 information, such as TCP or UDP port numbers, ICMP type and code, and so on. All other fragments are missing this information.

Some access control entries (ACEs) do not check Layer 4 information and therefore can be applied to all packet fragments. ACEs that do test Layer 4 information cannot be applied in the standard manner to most of the fragments in a fragmented IP packet. When the fragment contains no Layer 4 information and the ACE tests some Layer 4 information, the matching rules are modified:

- Permit ACEs that check the Layer 3 information in the fragment (including protocol type, such as TCP, UDP, and so on) are considered to match the fragment regardless of what the missing Layer 4 information might have been.
- Deny ACEs that check Layer 4 information never match a fragment unless the fragment contains Layer 4 information.
ACES and Fragmented and Unfragmented Traffic Examples

Consider access list 102, configured with these commands, applied to three fragmented packets:

```
Device(config)# access-list 102 permit tcp any host 10.1.1.1 eq smtp
Device(config)# access-list 102 deny tcp any host 10.1.1.2 eq telnet
Device(config)# access-list 102 permit tcp any host 10.1.1.2
Device(config)# access-list 102 deny tcp any any
```

In the first and second Aces in the examples, the `eq` keyword after the destination address means to test for the TCP-destination-port well-known numbers equaling Simple Mail Transfer Protocol (SMTP) and Telnet, respectively.

- Packet A is a TCP packet from host 10.2.2.2, port 65000, going to host 10.1.1.1 on the SMTP port. If this packet is fragmented, the first fragment matches the first ACE (a permit) as if it were a complete packet because all Layer 4 information is present. The remaining fragments also match the first ACE, even though they do not contain the SMTP port information, because the first ACE only checks Layer 3 information when applied to fragments. The information in this example is that the packet is TCP and that the destination is 10.1.1.1.

- Packet B is from host 10.2.2.2, port 65001, going to host 10.1.1.2 on the Telnet port. If this packet is fragmented, the first fragment matches the second ACE (a deny) because all Layer 3 and Layer 4 information is present. The remaining fragments in the packet do not match the second ACE because they are missing Layer 4 information. Instead, they match the third ACE (a permit).

  Because the first fragment was denied, host 10.1.1.2 cannot reassemble a complete packet, so packet B is effectively denied. However, the later fragments that are permitted will consume bandwidth on the network and resources of host 10.1.1.2 as it tries to reassemble the packet.

- Fragmented packet C is from host 10.2.2.2, port 65001, going to host 10.1.1.3, port ftp. If this packet is fragmented, the first fragment matches the fourth ACE (a deny). All other fragments also match the fourth ACE because that ACE does not check any Layer 4 information and because Layer 3 information in all fragments shows that they are being sent to host 10.1.1.3, and the earlier permit ACEs were checking different hosts.

ACLs and Switch Stacks

ACL support is the same for a switch stack as for a standalone switch. ACL configuration information is propagated to all switches in the stack. All switches in the stack, including the active switch, process the information and program their hardware.

Active Switch and ACL Functions

The active switch performs these ACL functions:

- It processes the ACL configuration and propagates the information to all stack members.

- It distributes the ACL information to any switch that joins the stack.

- If packets must be forwarded by software for any reason (for example, not enough hardware resources), the active switch forwards the packets only after applying ACLs on the packets.
It programs its hardware with the ACL information it processes.

**Stack Member and ACL Functions**

Stack members perform these ACL functions:

- They receive the ACL information from the active switch and program their hardware.
- A stack member configured as a standby switch, performs the functions of the active switch in the event the active switch fails.

**Active Switch Failure and ACLs**

Both the active and standby switches have the ACL information. When the active switch fails, the standby takes over. The new active switch distributes the ACL information to all stack members.

**Standard and Extended IPv4 ACLs**

This section describes IP ACLs.

An ACL is a sequential collection of permit and deny conditions. One by one, the switch tests packets against the conditions in an access list. The first match determines whether the switch accepts or rejects the packet. Because the switch stops testing after the first match, the order of the conditions is critical. If no conditions match, the switch denies the packet.

The software supports these types of ACLs or access lists for IPv4:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses for matching operations and optional protocol-type information for finer granularity of control.

**IPv4 ACL Switch Unsupported Features**

Configuring IPv4 ACLs on the switch is the same as configuring IPv4 ACLs on other Cisco switches and routers.

The following ACL-related features are not supported:

- Non-IP protocol ACLs
- IP accounting
- Reflexive ACLs and dynamic ACLs are not supported.

**Access List Numbers**

The number you use to denote your ACL shows the type of access list that you are creating.
This lists the access-list number and corresponding access list type and shows whether or not they are supported in the switch. The switch supports IPv4 standard and extended access lists, numbers 1 to 199 and 1300 to 2699.

Table 133: Access List Numbers

</tr>
</tbody>
</table>

In addition to numbered standard and extended ACLs, you can also create standard and extended named IP ACLs by using the supported numbers. That is, the name of a standard IP ACL can be 1 to 99; the name of an extended IP ACL can be 100 to 199. The advantage of using named ACLs instead of numbered lists is that you can delete individual entries from a named list.

**Numbered Standard IPv4 ACLs**

When creating an ACL, remember that, by default, the end of the ACL contains an implicit deny statement for all packets that it did not find a match for before reaching the end. With standard access lists, if you omit the mask from an associated IP host address ACL specification, 0.0.0.0 is assumed to be the mask.

The switch always rewrites the order of standard access lists so that entries with **host** matches and entries with matches having a **don’t care** mask of 0.0.0.0 are moved to the top of the list, above any entries with
non-zero don’t care masks. Therefore, in show command output and in the configuration file, the ACEs do not necessarily appear in the order in which they were entered.

After creating a numbered standard IPv4 ACL, you can apply it to VLANs, to terminal lines, or to interfaces.

**Numbered Extended IPv4 ACLs**

Although standard ACLs use only source addresses for matching, you can use extended ACL source and destination addresses for matching operations and optional protocol type information for finer granularity of control. When you are creating ACEs in numbered extended access lists, remember that after you create the ACL, any additions are placed at the end of the list. You cannot reorder the list or selectively add or remove ACEs from a numbered list.

The switch does not support dynamic or reflexive access lists. It also does not support filtering based on the type of service (ToS) minimize-monetary-cost bit.

Some protocols also have specific parameters and keywords that apply to that protocol.

You can define an extended TCP, UDP, ICMP, IGMP, or other IP ACL. The switch also supports these IP protocols:

---

**Note**

ICMP echo-reply cannot be filtered. All other ICMP codes or types can be filtered.

These IP protocols are supported:

- Authentication Header Protocol (ahp)
- Encapsulation Security Payload (esp)
- Enhanced Interior Gateway Routing Protocol (eigrp)
- generic routing encapsulation (gre)
- Internet Control Message Protocol (icmp)
- Internet Group Management Protocol (igmp)
- any Interior Protocol (ip)
- IP in IP tunneling (ipinip)
- KA9Q NOS-compatible IP over IP tunneling (nos)
- Open Shortest Path First routing (ospf)
- Payload Compression Protocol (pcp)
- Protocol-Independent Multicast (pim)
- Transmission Control Protocol (tcp)
- User Datagram Protocol (udp)

**Named IPv4 ACLs**

You can identify IPv4 ACLs with an alphanumeric string (a name) rather than a number. You can use named ACLs to configure more IPv4 access lists in a router than if you were to use numbered access lists. If you
identify your access list with a name rather than a number, the mode and command syntax are slightly different. However, not all commands that use IP access lists accept a named access list.

The name you give to a standard or extended ACL can also be a number in the supported range of access list numbers. That is, the name of a standard IP ACL can be 1 to 99 and . The advantage of using named ACLs instead of numbered lists is that you can delete individual entries from a named list.

Consider these guidelines before configuring named ACLs:

- Numbered ACLs are also available.
- A standard ACL and an extended ACL cannot have the same name.
- You can use standard or extended ACLs (named or numbered) in VLAN maps.

**ACL Logging**

The switch software can provide logging messages about packets permitted or denied by a standard IP access list. That is, any packet that matches the ACL causes an informational logging message about the packet to be sent to the console. The level of messages logged to the console is controlled by the `logging console` commands controlling the syslog messages.

**Note**

Because routing is done in hardware and logging is done in software, if a large number of packets match a `permit` or `deny` ACE containing a `log` keyword, the software might not be able to match the hardware processing rate, and not all packets will be logged.

The first packet that triggers the ACL causes a logging message right away, and subsequent packets are collected over 5-minute intervals before they appear or logged. The logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior 5-minute interval.

**Note**

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

**Hardware and Software Treatment of IP ACLs**

ACL processing is performed in hardware. If the hardware reaches its capacity to store ACL configurations, all packets on that interface are dropped.

**Note**

If an ACL configuration cannot be implemented in hardware due to an out-of-resource condition on a switch or stack member, then only the traffic in that VLAN arriving on that switch is affected.
For router ACLs, other factors can cause packets to be sent to the CPU:

- Using the `log` keyword
- Generating ICMP unreachable messages

When you enter the `show ip access-lists` privileged EXEC command, the match count displayed does not account for packets that are access controlled in hardware. Use the `show platform acl counters hardware` privileged EXEC command to obtain some basic hardware ACL statistics for switched and routed packets.

Router ACLs function as follows:

- The hardware controls permit and deny actions of standard and extended ACLs (input and output) for security access control.
- If `log` has not been specified, the flows that match a `deny` statement in a security ACL are dropped by the hardware if `ip unreachables` is disabled. The flows matching a `permit` statement are switched in hardware.
- Adding the `log` keyword to an ACE in a router ACL causes a copy of the packet to be sent to the CPU for logging only. If the ACE is a `permit` statement, the packet is still switched and routed in hardware.

## VLAN Map Configuration Guidelines

VLAN maps are the only way to control filtering within a VLAN. VLAN maps have no direction. To filter traffic in a specific direction by using a VLAN map, you need to include an ACL with specific source or destination addresses. If there is a match clause for that type of packet (IP or MAC) in the VLAN map, the default action is to drop the packet if the packet does not match any of the entries within the map. If there is no match clause for that type of packet, the default is to forward the packet.

The following are the VLAN map configuration guidelines:

- If there is no ACL configured to deny traffic on an interface and no VLAN map is configured, all traffic is permitted.
- Each VLAN map consists of a series of entries. The order of entries in an VLAN map is important. A packet that comes into the switch is tested against the first entry in the VLAN map. If it matches, the action specified for that part of the VLAN map is taken. If there is no match, the packet is tested against the next entry in the map.
- If the VLAN map has at least one match clause for the type of packet (IP or MAC) and the packet does not match any of these match clauses, the default is to drop the packet. If there is no match clause for that type of packet in the VLAN map, the default is to forward the packet.
- Logging is not supported for VLAN maps.
- When a switch has an IP access list or MAC access list applied to a Layer 2 interface, and you apply a VLAN map to a VLAN that the port belongs to, the port ACL takes precedence over the VLAN map.
- If a VLAN map configuration cannot be applied in hardware, all packets in that VLAN are dropped.
**VLAN Maps with Router ACLs**

To access control both bridged and routed traffic, you can use VLAN maps only or a combination of router ACLs and VLAN maps. You can define router ACLs on both input and output routed VLAN interfaces, and you can define a VLAN map to access control the bridged traffic.

If a packet flow matches a VLAN-map deny clause in the ACL, regardless of the router ACL configuration, the packet flow is denied.

---

**Note**

When you use router ACLs with VLAN maps, packets that require logging on the router ACLs are not logged if they are denied by a VLAN map.

If the VLAN map has a match clause for the type of packet (IP or MAC) and the packet does not match the type, the default is to drop the packet. If there is no match clause in the VLAN map, and no action specified, the packet is forwarded if it does not match any VLAN map entry.

---

**VLAN Maps and Router ACL Configuration Guidelines**

These guidelines are for configurations where you need to have an router ACL and a VLAN map on the same VLAN. These guidelines do not apply to configurations where you are mapping router ACLs and VLAN maps on different VLANs.

If you must configure a router ACL and a VLAN map on the same VLAN, use these guidelines for both router ACL and VLAN map configuration:

- You can configure only one VLAN map and one router ACL in each direction (input/output) on a VLAN interface.
- Whenever possible, try to write the ACL with all entries having a single action except for the final, default action of the other type. That is, write the ACL using one of these two forms:
  
  permit... permit... permit... deny ip any any
  
  or
  
  deny... deny... deny... permit ip any any

- To define multiple actions in an ACL (permit, deny), group each action type together to reduce the number of entries.

- Avoid including Layer 4 information in an ACL; adding this information complicates the merging process. The best merge results are obtained if the ACLs are filtered based on IP addresses (source and destination) and not on the full flow (source IP address, destination IP address, protocol, and protocol ports). It is also helpful to use don’t care bits in the IP address, whenever possible.

If you need to specify the full-flow mode and the ACL contains both IP ACEs and TCP/UDP/ICMP ACEs with Layer 4 information, put the Layer 4 ACEs at the end of the list. This gives priority to the filtering of traffic based on IP addresses.

---

**Time Ranges for ACLs**

You can selectively apply extended ACLs based on the time of day and the week by using the `time-range` global configuration command. First, define a time-range name and set the times and the dates or the days of...
the week in the time range. Then enter the time-range name when applying an ACL to set restrictions to the access list. You can use the time range to define when the permit or deny statements in the ACL are in effect, for example, during a specified time period or on specified days of the week. The time-range keyword and argument are referenced in the named and numbered extended ACL task tables.

These are some benefits of using time ranges:

- You have more control over permitting or denying a user access to resources, such as an application (identified by an IP address/mask pair and a port number).
- You can control logging messages. ACL entries can be set to log traffic only at certain times of the day. Therefore, you can simply deny access without needing to analyze many logs generated during peak hours.

Time-based access lists trigger CPU activity because the new configuration of the access list must be merged with other features and the combined configuration loaded into the hardware memory. For this reason, you should be careful not to have several access lists configured to take effect in close succession (within a small number of minutes of each other.)

The time range relies on the switch system clock; therefore, you need a reliable clock source. We recommend that you use Network Time Protocol (NTP) to synchronize the switch clock.

### IPv4 ACL Interface Considerations

When you apply the `ip access-group` interface configuration command to a Layer 3 interface (an SVI, a Layer 3 EtherChannel, or a routed port), the interface must have been configured with an IP address. Layer 3 access groups filter packets that are routed or are received by Layer 3 processes on the CPU. They do not affect packets bridged within a VLAN.

For inbound ACLs, after receiving a packet, the switch checks the packet against the ACL. If the ACL permits the packet, the switch continues to process the packet. If the ACL rejects the packet, the switch discards the packet.

For outbound ACLs, after receiving and routing a packet to a controlled interface, the switch checks the packet against the ACL. If the ACL permits the packet, the switch sends the packet. If the ACL rejects the packet, the switch discards the packet.

By default, the input interface sends ICMP Unreachable messages whenever a packet is discarded, regardless of whether the packet was discarded because of an ACL on the input interface or because of an ACL on the output interface. ICMP Unreachables are normally limited to no more than one every one-half second per input interface, but this can be changed by using the `ip icmp rate-limit unreachable` global configuration command.

When you apply an undefined ACL to an interface, the switch acts as if the ACL has not been applied to the interface and permits all packets. Remember this behavior if you use undefined ACLs for network security.

How to Configure ACLs

Configuring IPv4 ACLs

These are the steps to use IP ACLs on the switch:

**SUMMARY STEPS**

1. Create an ACL by specifying an access list number or name and the access conditions.
2. Apply the ACL to interfaces or terminal lines. You can also apply standard and extended IP ACLs to VLAN maps.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Create an ACL by specifying an access list number or name and the access conditions.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Apply the ACL to interfaces or terminal lines. You can also apply standard and extended IP ACLs to VLAN maps.</td>
</tr>
</tbody>
</table>

Creating a Numbered Standard ACL

Follow these steps to create a numbered standard ACL:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. access-list access-list-number {deny | permit} source source-wildcard [log]
4. end
5. show running-config
6. copy running-config startup-config

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

### Creating a Numbered Standard ACL

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Defines a standard IPv4 access list by using a source address and wildcard.</td>
</tr>
<tr>
<td><strong>Step 3</strong> access-list access-list-number {deny</td>
<td>permit} source source-wildcard [log]</td>
</tr>
</tbody>
</table>
| **Example:** Device(config)# access-list 2 deny your_host | The `source` is the source address of the network or host from which the packet is being sent specified as:  
  - The 32-bit quantity in dotted-decimal format.  
  - The keyword `any` as an abbreviation for `source` and `source-wildcard` of 0.0.0.0 255.255.255.255. You do not need to enter a source-wildcard.  
  - The keyword `host` as an abbreviation for source and `source-wildcard` of source 0.0.0.0.  
(Optional) The `source-wildcard` applies wildcard bits to the source.  
(Optional) Enter `log` to cause an informational logging message about the packet that matches the entry to be sent to the console. |
| **Step 4** end | Returns to privileged EXEC mode. |
| **Example:** Device(config)# end | Verifies your entries. |
| **Step 5** show running-config | |
| **Example:** Device# show running-config | |
| **Step 6** copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| **Example:** Device# copy running-config startup-config | |

---

Note: Logging is supported only on ACLs attached to Layer 3 interfaces.
Creating a Numbered Extended ACL

Follow these steps to create a numbered extended ACL:

**SUMMARY STEPS**

1. configure terminal
2. access-list access-list-number \{deny | permit\} protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]
3. access-list access-list-number \{deny | permit\} tcp source source-wildcard [operator port] destination destination-wildcard [operator port] [established] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp] [flag]
4. access-list access-list-number \{deny | permit\} udp source source-wildcard [operator port] destination destination-wildcard [operator port] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]
5. access-list access-list-number \{deny | permit\} icmp source source-wildcard destination destination-wildcard [icmp-type] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]
6. access-list access-list-number \{deny | permit\} igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]
7. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>access-list access-list-number {deny</td>
<td>permit} protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# access-list 101 permit ip host 10.1.1.2 any precedence 0 tos 0 log</td>
<td></td>
</tr>
</tbody>
</table>

The access-list-number is a decimal number from 100 to 199 or 2000 to 2699.

Enter deny or permit to specify whether to deny or permit the packet if conditions are matched.

For protocol, enter the name or number of an IP protocol: ahp, eigrp, esp, gre, icmp, igmp,igrp,ip,ipinip, ospf, pcp, pim, tcp, or udp, or an integer in the range 0 to 255 representing an IP protocol number. To match any Internet protocol (including ICMP, TCP, and UDP), use the keyword ip.
<table>
<thead>
<tr>

</tbody>
</table>
| 3    | `access-list access-list-number {deny | permit} tcp source source-wildcard [operator port] destination destination-wildcard [operator port] [established] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp] [flag]` | Defines an extended TCP access list and the access conditions. The parameters are the same as those described for an extended IPv4 ACL, with these exceptions: (Optional) Enter an `operator` and `port` to compare source (if positioned after `source source-wildcard`) or destination (if positioned after `destination destination-wildcard`) port. Possible operators include `eq` (equal), `gt` (greater than), `lt` (less than), `neq` (not equal), and `range` (inclusive range). Operators require a port number (range requires two port numbers separated by a space). Enter the `port` number as a decimal number (from 0 to 65535) or the name of a TCP port. Use only TCP port numbers or names when filtering TCP. The other optional keywords have these meanings:  
  - `established`—Enter to match an established connection. This has the same function as matching on the `ack` or `rst` flag.  
  - `flag`—Enter one of these flags to match by the specified TCP header bits: `ack` (acknowledge), `fin` (finish), `psh` (push), `rst` (reset), `syn` (synchronize), or `urg` (urgent). |
| 4    | `access-list access-list-number {deny | permit} udp source source-wildcard [operator port] destination destination-wildcard [operator port] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]` | (Optional) Defines an extended UDP access list and the access conditions. The UDP parameters are the same as those described for TCP except that the `[operator [port]]` port number or name must be a UDP port number or name, and the `flag` and `established` keywords are not valid for UDP. |
| 5    | `access-list access-list-number {deny | permit} icmp source source-wildcard destination destination-wildcard [icmp-type] [icmp-type icmp-code] [icmp-message] [precedence precedence] [tos tos] [fragments] [log [log-input] [time-range time-range-name] [dscp dscp]` | Defines an extended ICMP access list and the access conditions. The ICMP parameters are the same as those described for most IP protocols in an extended IPv4 ACL, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:  
  - `icmp-type`—Enter to filter by ICMP message type, a number from 0 to 255.  
  - `icmp-code`—Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255. |

**Example:**

Device(config)# `access-list 101 permit tcp any any eq 500`
Creating Named Standard ACLs

Follow these steps to create a standard ACL using names:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip access-list standard name`
4. Use one of the following:
   - `deny {source [source-wildcard] | host source | any} [log]`
   - `permit {source [source-wildcard] | host source | any} [log]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

</table>

- **host source**—A source and source wildcard of `source 0.0.0.0`.  
- **host destination**—A destination and destination wildcard of `destination 0.0.0.0`.  
- **any**—A source and source wildcard or destination and destination wildcard of `0.0.0.0 255.255.255.255`.  

---

**Security**

Creating Extended Named ACLs
**Command or Action** | **Purpose**
--- | ---
**Step 5** | end
Example: 
Device(config-ext-nacl)# end
| Returns to privileged EXEC mode.

**Step 6** | show running-config
Example: 
Device# show running-config
| Verifies your entries.

**Step 7** | copy running-config startup-config
Example: 
Device# copy running-config startup-config
| (Optional) Saves your entries in the configuration file.

When you are creating extended ACLs, remember that, by default, the end of the ACL contains an implicit deny statement for everything if it did not find a match before reaching the end. For standard ACLs, if you omit the mask from an associated IP host address access list specification, 0.0.0.0 is assumed to be the mask.

After you create an ACL, any additions are placed at the end of the list. You cannot selectively add ACL entries to a specific ACL. However, you can use **no permit** and **no deny** access-list configuration mode commands to remove entries from a named ACL.

Being able to selectively remove lines from a named ACL is one reason you might use named ACLs instead of numbered ACLs.

**What to do next**

After creating a named ACL, you can apply it to interfaces or to VLANs.

**Configuring Time Ranges for ACLs**

Follow these steps to configure a time-range parameter for an ACL:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. time-range time-range-name
4. Use one of the following:
   - **absolute** [start time date] [end time date]
   - **periodic** day-of-the-week hh:mm to [day-of-the-week] hh:mm
   - **periodic** {weekdays | weekend | daily} hh:mm to hh:mm
5. end
6. show running-config
### 7. copy running-config startup-config

## DETAILED STEPS

### Applying an IPv4 ACL to a Terminal Line

You can use numbered ACLs to control access to one or more terminal lines. You cannot apply named ACLs to lines. You must set identical restrictions on all the virtual terminal lines because a user can attempt to connect to any of them.

Follow these steps to restrict incoming and outgoing connections between a virtual terminal line and the addresses in an ACL:

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `line [console | vty] line-number`
4. `access-class access-list-number {in | out}`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
  - `enable`  
  - **Example:**  
    - `Device(config)# enable` | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2**  
  - `configure terminal`  
  - **Example:** | Enters the global configuration mode. |
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
</tr>
</tbody>
</table>

### Step 3

| line [console | vty] line-number |
|------------------|
| Example: |
| Device(config)# line console 0 |

Identifies a specific line to configure, and enter in-line configuration mode.

- **console**—Specifies the console terminal line. The console port is DCE.
- **vty**—Specifies a virtual terminal for remote console access.

The line-number is the first line number in a contiguous group that you want to configure when the line type is specified. The range is from 0 to 16.

### Step 4

| access-class access-list-number {in | out} |
|-----------------------------------------|
| Example: |
| Device(config-line)# access-class 10 in |

Restricts incoming and outgoing connections between a particular virtual terminal line (into a device) and the addresses in an access list.

### Step 5

<table>
<thead>
<tr>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
</tr>
<tr>
<td>Device(config-line)# end</td>
</tr>
</tbody>
</table>

Returns to privileged EXEC mode.

### Step 6

<table>
<thead>
<tr>
<th>show running-config</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
</tr>
<tr>
<td>Device# show running-config</td>
</tr>
</tbody>
</table>

Verifies your entries.

### Step 7

<table>
<thead>
<tr>
<th>copy running-config startup-config</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
</tr>
</tbody>
</table>

(Optional) Saves your entries in the configuration file.

---

**Applying an IPv4 ACL to an Interface**

This section describes how to apply IPv4 ACLs to network interfaces.

Beginning in privileged EXEC mode, follow these steps to control access to an interface:

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
### Applying an IPv4 ACL to an Interface

3. ip access-group \{access-list-number | name\} \{in | out\}
4. end
5. show running-config
6. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Purpose:</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>

| **Step 2** | interface interface-id |
| **Example:** | Device(config)# interface gigabitethernet1/0/1 |
| **Purpose:** | Identifies a specific interface for configuration, and enter interface configuration mode. The interface can be a Layer 2 interface (port ACL), or a Layer 3 interface (router ACL). |

| **Step 3** | ip access-group \{access-list-number | name\} \{in | out\} |
| **Example:** | Device(config-if)# ip access-group 2 in |
| **Purpose:** | Controls access to the specified interface. The **out** keyword is not supported for Layer 2 interfaces (port ACLs). |

| **Step 4** | end |
| **Example:** | Device(config-if)# end |
| **Purpose:** | Returns to privileged EXEC mode. |

| **Step 5** | show running-config |
| **Example:** | Device# show running-config |
| **Purpose:** | Displays the access list configuration. |

| **Step 6** | copy running-config startup-config |
| **Example:** | Device# copy running-config startup-config |
| **Purpose:** | (Optional) Saves your entries in the configuration file. |

Creating Named MAC Extended ACLs

You can filter non-IPv4 traffic on a VLAN or on a Layer 2 interface by using MAC addresses and named MAC extended ACLs. The procedure is similar to that of configuring other extended named ACLs.

Follow these steps to create a named MAC extended ACL:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `mac access-list extended name`
4. `{deny | permit} {any | host source MAC address | source MAC address mask} {any | host destination MAC address | destination MAC address mask} [type mask | lsap lsap mask | aarp | amber | dec-spanning | decnet-iv | diagnostic | dsm | etype-6000 | etype-8042 | lat | lavc-sca | mop-console | mop-dump | msdos | mumps | netbios | vines-echo | vines-ip | xns-idp | 0-65535] [cos cos]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

**DETAILED STEPS**

<table>

</table>

* type mask—An arbitrary EtherType number of a packet with Ethernet II or SNAP encapsulation in decimal,
### Command or Action

<table>
<thead>
<tr>
<th>Device(config-ext-macl)# deny any any decnet-iv</th>
</tr>
</thead>
<tbody>
<tr>
<td>or</td>
</tr>
<tr>
<td>Device(config-ext-macl)# permit any any</td>
</tr>
</tbody>
</table>

#### Purpose
- hexadecimal, or octal with optional mask of *don’t care* bits applied to the EtherType before testing for a match.
- **lsap lsap mask**—An LSAP number of a packet with IEEE 802.2 encapsulation in decimal, hexadecimal, or octal with optional mask of *don’t care* bits.
- **cos cos**—An IEEE 802.1Q cost of service number from 0 to 7 used to set priority.

### Step 5

**end**

**Example:**

Device(config-ext-macl)# end

**Purpose:** Returns to privileged EXEC mode.

### Step 6

**show running-config**

**Example:**

Device# show running-config

**Purpose:** Verifies your entries.

### Step 7

**copy running-config startup-config**

**Example:**

Device# copy running-config startup-config

**Purpose:** (Optional) Saves your entries in the configuration file.

**Applying a MAC ACL to a Layer 2 Interface**

Follow these steps to apply a MAC access list to control access to a Layer 2 interface:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. mac access-group {name} {in | out}
5. `end`
6. `show mac access-group [interface interface-id]`
7. `show running-config`
8. `copy running-config startup-config`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode. Enter your password if prompted.  
Example:  
Device> enable |
| **Step 2** configure terminal | Enters the global configuration mode.  
Example:  
Device# configure terminal |
| **Step 3** interface interface-id | Identifies a specific interface, and enter interface configuration mode. The interface must be a physical Layer 2 interface (port ACL).  
Example:  
Device(config)# interface gigabitethernet1/0/2 |
| **Step 4** mac access-group \{name\} \{in | out \} | Controls access to the specified interface by using the MAC access list. Port ACLs are supported in the outbound and inbound directions.  
Example:  
Device(config-if)# mac access-group mac1 in |
| **Step 5** end | Returns to privileged EXEC mode.  
Example:  
Device(config-if)# end |
| **Step 6** show mac access-group [interface interface-id] | Displays the MAC access list applied to the interface or all Layer 2 interfaces.  
Example:  
Device# show mac access-group interface gigabitethernet1/0/2 |
| **Step 7** show running-config | Verifies your entries.  
Example:  
Device# show running-config |
### Configuring VLAN Maps

To create a VLAN map and apply it to one or more VLANs, perform these steps:

**Before you begin**

Create the standard or extended IPv4 ACLs or named MAC extended ACLs that you want to apply to the VLAN.

**SUMMARY STEPS**

1. `vlan access-map name [number]`
2. `match {ip | mac} address {name | number} [name | number]`
3. Enter one of the following commands to specify an IP packet or a non-IP packet (with only a known MAC address) and to match the packet against one or more ACLs (standard or extended):
   - `action { forward }`

   ```
   Device(config-access-map)# action forward
   ```

   - `action { drop }`

   ```
   Device(config-access-map)# action drop
   ```
4. `vlan filter mapname vlan-list list`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Creates a VLAN map, and give it a name and (optionally) a number. The number is the sequence number of the entry within the map. When you create VLAN maps with the same name, numbers are assigned sequentially in increments of 10. When modifying or deleting maps, you can enter the number of the map entry that you want to modify or delete. VLAN maps do not use the specific permit or deny keywords. To deny a packet by using VLAN maps, create an ACL that would match the packet, and set the action to drop. A permit in the ACL counts as a match. A deny in the ACL means no match. Entering this command changes to access-map configuration mode.</td>
</tr>
<tr>
<td><code>vlan access-map name [number]</code></td>
<td>Example: <code>Device(config)# vlan access-map map_1 20</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Match the packet (using either the IP or MAC address) against one or more standard or extended access lists. Note that packets are only matched against access lists of the correct protocol type. IP packets are matched against standard or extended IP access lists. Non-IP packets are only matched against named MAC extended access lists. <strong>Note</strong> If the VLAN map is configured with a match clause for a type of packet (IP or MAC) and the map action is drop, all packets that match the type are dropped. If the VLAN map has no match clause, and the configured action is drop, all IP and Layer 2 packets are dropped.</td>
</tr>
<tr>
<td>`match {ip</td>

### Monitoring IPv4 ACLs

You can monitor IPv4 ACLs by displaying the ACLs that are configured on the switch, and displaying the ACLs that have been applied to interfaces and VLANs.
When you use the `ip access-group` interface configuration command to apply ACLs to a Layer 2 or 3 interface, you can display the access groups on the interface. You can also display the MAC ACLs applied to a Layer 2 interface. You can use the privileged EXEC commands as described in this table to display this information.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show access-lists [number</td>
<td>name]`</td>
</tr>
<tr>
<td>`show ip access-lists [number</td>
<td>name]`</td>
</tr>
<tr>
<td><code>show ip interface interface-id</code></td>
<td>Displays detailed configuration and status of an interface. If IP is enabled on the interface and ACLs have been applied by using the <code>ip access-group</code> interface configuration command, the access groups are included in the display.</td>
</tr>
<tr>
<td><code>show running-config [interface interface-id]</code></td>
<td>Displays the contents of the configuration file for the switch or the specified interface, including all configured MAC and IP access lists and which access groups are applied to an interface.</td>
</tr>
<tr>
<td><code>show mac access-group [interface interface-id]</code></td>
<td>Displays MAC access lists applied to all Layer 2 interfaces or the specified Layer 2 interface.</td>
</tr>
</tbody>
</table>

### Configuration Examples for ACLs

#### Examples: Using Time Ranges with ACLs

This example shows how to verify after you configure time ranges for `workhours` and to configure January 1, 2006, as a company holiday.

```
Device# show time-range
time-range entry: new_year_day_2003 (inactive)
    absolute start 00:00 01 January 2006 end 23:59 01 January 2006
time-range entry: workhours (inactive)
    periodic weekdays 8:00 to 12:00
    periodic weekdays 13:00 to 17:00
```

To apply a time range, enter the time-range name in an extended ACL that can implement time ranges. This example shows how to create and verify extended access list 188 that denies TCP traffic from any source to any destination during the defined holiday times and permits all TCP traffic during work hours.

```
Device(config)# access-list 188 deny tcp any any time-range new_year_day_2006
Device(config)# access-list 188 permit tcp any any time-range workhours
```
Device(config)# end
Device# show access-lists
Extended IP access list 188
  10 deny tcp any any time-range new_year_day_2006 (inactive)
  20 permit tcp any any time-range workhours (inactive)

This example uses named ACLs to permit and deny the same traffic.

Device(config)# ip access-list extended deny_access
Device(config-ext-nacl)# deny tcp any any time-range new_year_day_2006
Device(config-ext-nacl)# exit
Device(config)# ip access-list extended may_access
Device(config-ext-nacl)# permit tcp any any time-range workhours
Device(config-ext-nacl)# end
Device# show ip access-lists
Extended IP access list lpip_default
  10 permit ip any any
Extended IP access list deny_access
  10 deny tcp any any time-range new_year_day_2006 (inactive)
Extended IP access list may_access
  10 permit tcp any any time-range workhours (inactive)

Examples: Including Comments in ACLs

You can use the **remark** keyword to include comments (remarks) about entries in any IP standard or extended ACL. The remarks make the ACL easier for you to understand and scan. Each remark line is limited to 100 characters.

The remark can go before or after a permit or deny statement. You should be consistent about where you put the remark so that it is clear which remark describes which permit or deny statement. For example, it would be confusing to have some remarks before the associated permit or deny statements and some remarks after the associated statements.

To include a comment for IP numbered standard or extended ACLs, use the **access-list access-list-number remark** global configuration command. To remove the remark, use the **no** form of this command.

In this example, the workstation that belongs to Jones is allowed access, and the workstation that belongs to Smith is not allowed access:

Device(config)# access-list 1 remark Permit only Jones workstation through
Device(config)# access-list 1 permit 171.69.2.88
Device(config)# access-list 1 remark Do not allow Smith through
Device(config)# access-list 1 deny 171.69.3.13

For an entry in a named IP ACL, use the **remark** access-list configuration command. To remove the remark, use the **no** form of this command.

In this example, the Jones subnet is not allowed to use outbound Telnet:

Device(config)# ip access-list extended telnetting
Device(config-ext-nacl)# remark Do not allow Jones subnet to telnet out
Device(config-ext-nacl)# deny tcp host 171.69.2.88 any eq telnet
IPv4 ACL Configuration Examples

This section provides examples of configuring and applying IPv4 ACLs. For detailed information about compiling ACLs, see the Cisco IOS Security Configuration Guide, Release 12.4 and to the Configuring IP Services’ section in the “IP Addressing and Services” chapter of the Cisco IOS IP Configuration Guide, Release 12.4.

ACLs in a Small Networked Office

Figure 95: Using Router ACLs to Control Traffic

This shows a small networked office environment with routed Port 2 connected to Server A, containing benefits and other information that all employees can access, and routed Port 1 connected to Server B, containing confidential payroll data. All users can access Server A, but Server B has restricted access.

Use router ACLs to do this in one of two ways:

- Create a standard ACL, and filter traffic coming to the server from Port 1.
- Create an extended ACL, and filter traffic coming from the server into Port 1.

Examples: ACLs in a Small Networked Office

This example uses a standard ACL to filter traffic coming into Server B from a port, permitting traffic only from Accounting’s source addresses 172.20.128.64 to 172.20.128.95. The ACL is applied to traffic coming out of routed Port 1 from the specified source address.

Device(config)# access-list 6 permit 172.20.128.64 0.0.0.31
Device(config)# end
Device# how access-lists
Standard IP access list 6
10 permit 172.20.128.64, wildcard bits 0.0.0.31
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 6 out

This example uses an extended ACL to filter traffic coming from Server B into a port, permitting traffic from any source address (in this case Server B) to only the Accounting destination addresses 172.20.128.64 to 172.20.128.95. The ACL is applied to traffic going into routed Port 1, permitting it to go only to the specified destination addresses. Note that with extended ACLs, you must enter the protocol (IP) before the source and destination information.

Device(config)# access-list 106 permit ip any 172.20.128.64 0.0.0.31
Device(config)# end
Device(config)# show access-lists
Extended IP access list 106
10 permit ip any 172.20.128.64 0.0.0.31
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 106 in

Example: Numbered ACLs

In this example, network 36.0.0.0 is a Class A network whose second octet specifies a subnet; that is, its subnet mask is 255.255.0.0. The third and fourth octets of a network 36.0.0.0 address specify a particular host. Using access list 2, the switch accepts one address on subnet 48 and reject all others on that subnet. The last line of the list shows that the switch accepts addresses on all other network 36.0.0.0 subnets. The ACL is applied to packets entering a port.

Device(config)# access-list 2 permit 36.48.0.3
Device(config)# access-list 2 deny 36.48.0.0 0.0.255.255
Device(config)# access-list 2 permit 36.0.0.0 0.255.255.255
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ip access-group 2 in

Examples: Extended ACLs

In this example, the first line permits any incoming TCP connections with destination ports greater than 1023. The second line permits incoming TCP connections to the Simple Mail Transfer Protocol (SMTP) port of host 128.88.1.2. The third line permits incoming ICMP messages for error feedback.

Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 gt 1023
Device(config)# access-list 102 permit tcp any host 128.88.1.2 eq 25
Device(config)# access-list 102 permit icmp any any
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ip access-group 102 in

In this example, suppose that you have a network connected to the Internet, and you want any host on the network to be able to form TCP connections to any host on the Internet. However, you do not want IP hosts to be able to form TCP connections to hosts on your network, except to the mail (SMTP) port of a dedicated mail host.

SMTP uses TCP port 25 on one end of the connection and a random port number on the other end. The same port numbers are used throughout the life of the connection. Mail packets coming in from the Internet have a destination port of 25. Outbound packets have the port numbers reversed. Because the secure system of the network always accepts mail connections on port 25, the incoming and outgoing services are separately
controlled. The ACL must be configured as an input ACL on the outbound interface and an output ACL on the inbound interface.

```
Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 eq 23
Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 eq 25
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 102 in
```

In this example, the network is a Class B network with the address 128.88.0.0, and the mail host address is 128.88.1.2. The `established` keyword is used only for the TCP to show an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which show that the packet belongs to an existing connection. Gigabit Ethernet interface 1 on stack member 1 is the interface that connects the router to the Internet.

```
Device(config)# access-list 102 permit tcp any 128.88.0.0 0.0.255.255 established
Device(config)# access-list 102 permit tcp any host 128.88.1.2 eq 25
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 102 in
```

Examples: Named ACLs

Creating named standard and extended ACLs

This example creates a standard ACL named `internet_filter` and an extended ACL named `marketing_group`. The `internet_filter` ACL allows all traffic from the source address 1.2.3.4.

```
Device(config)# ip access-list standard Internet_filter
Device(config-ext-nacl)# permit 1.2.3.4
Device(config-ext-nacl)# exit
```

The `marketing_group` ACL allows any TCP Telnet traffic to the destination address and wildcard 171.69.0.0 0.0.255.255 and denies any other TCP traffic. It permits ICMP traffic, denies UDP traffic from any source to the destination address range 171.69.0.0 through 179.69.255.255 with a destination port less than 1024, denies any other IP traffic, and provides a log of the result.

```
Device(config)# ip access-list extended marketing_group
Device(config-ext-nacl)# permit tcp any 171.69.0.0 0.0.255.255 eq telnet
Device(config-ext-nacl)# deny tcp any any
Device(config-ext-nacl)# permit icmp any any
Device(config-ext-nacl)# deny udp any 171.69.0.0 0.0.255.255 lt 1024
Device(config-ext-nacl)# deny ip any any log
Device(config-ext-nacl)# exit
```

The `Internet_filter` ACL is applied to outgoing traffic and the `marketing_group` ACL is applied to incoming traffic on a Layer 3 port.

```
Device(config)# interface gigabitethernet3/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 2.0.5.1 255.255.255.0
Device(config-if)# ip access-group Internet_filter out
Device(config-if)# ip access-group marketing_group in
```
Deleting individual ACEs from named ACLs

This example shows how you can delete individual ACEs from the named access list `border-list`:

```
Device(config)# ip access-list extended border-list
Device(config-ext-nacl)# no permit ip host 10.1.1.3 any
```

Examples: Time Range Applied to an IP ACL

This example denies HTTP traffic on IP on Monday through Friday between the hours of 8:00 a.m. and 6:00 p.m (18:00). The example allows UDP traffic only on Saturday and Sunday from noon to 8:00 p.m. (20:00).

```
Device(config)# time-range no-http
Device(config)# periodic weekdays 8:00 to 18:00

Device(config)# time-range udp-yes
Device(config)# periodic weekend 12:00 to 20:00

Device(config)# ip access-list extended strict
Device(config-ext-nacl)# deny tcp any any eq www time-range no-http
Device(config-ext-nacl)# permit udp any any time-range udp-yes

Device(config-ext-nacl)# exit
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ip access-group strict in
```

Examples: Configuring Commented IP ACL Entries

In this example of a numbered ACL, the workstation that belongs to Jones is allowed access, and the workstation that belongs to Smith is not allowed access:

```
Device(config)# access-list 1 remark Permit only Jones workstation through
Device(config)# access-list 1 permit 171.69.2.88
Device(config)# access-list 1 remark Do not allow Smith workstation through
Device(config)# access-list 1 deny 171.69.3.13
```

In this example of a numbered ACL, the Winter and Smith workstations are not allowed to browse the web:

```
Device(config)# access-list 100 remark Do not allow Winter to browse the web
Device(config)# access-list 100 deny host 171.69.3.85 any eq www
Device(config)# access-list 100 remark Do not allow Smith to browse the web
Device(config)# access-list 100 deny host 171.69.3.13 any eq www
```

In this example of a named ACL, the Jones subnet is not allowed access:

```
Device(config)# ip access-list standard prevention
Device(config-std-nacl)# remark Do not allow Jones subnet through
Device(config-std-nacl)# deny 171.69.0.0 0.0.255.255
```

In this example of a named ACL, the Jones subnet is not allowed to use outbound Telnet:

```
Device(config)# ip access-list extended telnetting
Device(config-ext-nacl)# remark Do not allow Jones subnet to telnet out
```
Examples: ACL Logging

Two variations of logging are supported on router ACLs. The `log` keyword sends an informational logging message to the console about the packet that matches the entry; the `log-input` keyword includes the input interface in the log entry.

In this example, standard named access list `stan1` denies traffic from 10.1.1.0 0.0.0.255, allows traffic from all other sources, and includes the `log` keyword.

```plaintext
Device(config)# ip access-list standard stan1
Device(config-standard-nacl)# deny 10.1.1.0 0.0.0.255 log
Device(config-standard-nacl)# permit any log
Device(config-standard-nacl)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group stan1 in
Device(config-if)# end
Device# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
Console logging: level debugging, 37 messages logged
Monitor logging: level debugging, 0 messages logged
Buffer logging: level debugging, 37 messages logged
File logging: disabled
Trap logging: level debugging, 39 message lines logged

Log Buffer (4096 bytes):
00:00:48: NTP: authentication delay calculation problems
(output truncated)
00:09:34:%SEC-6-IPACCESSLOGS:list stan1 permitted 0.0.0.0 1 packet
00:09:59:%SEC-6-IPACCESSLOGS:list stan1 denied 10.1.1.15 1 packet
00:10:11:%SEC-6-IPACCESSLOGS:list stan1 permitted 0.0.0.0 1 packet

This example is a named extended access list `ext1` that permits ICMP packets from any source to 10.1.1.0 0.0.0.255 and denies all UDP packets.

```plaintext
Device(config)# ip access-list extended ext1
Device(config-ext-nacl)# permit icmp any 10.1.1.0 0.0.0.255 log
Device(config-ext-nacl)# deny udp any any log
Device(config-ext-nacl)# exit
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip access-group ext1 in
Device(config-if)# end

This is an example of a log for an extended ACL:

01:24:23:%SEC-6-IPACCESSLOGDP:list ext1 permitted icmp 10.1.1.15 -> 10.1.1.61 (0/0), 1 packet
01:25:14:%SEC-6-IPACCESSLOGDP:list ext1 permitted icmp 10.1.1.15 -> 10.1.1.61 (0/0), 7 packets
01:26:12:%SEC-6-IPACCESSLOGDP:list ext1 denied udp 0.0.0.0(0) -> 255.255.255.255(0), 1 packet
01:31:33:%SEC-6-IPACCESSLOGDP:list ext1 denied udp 0.0.0.0(0) -> 255.255.255.255(0), 8 packets

Note that all logging entries for IP ACLs start with `%SEC-6-IPACCESSLOG` with minor variations in format depending on the kind of ACL and the access entry that has been matched.

This is an example of an output message when the `log-input` keyword is entered:

```
00:04:21:%SEC-6-IPACCESSLOGDP:list inputlog permitted icmp 10.1.1.10 (Vlan 0001.42ef.a400) <-
10.1.1.61 (0/0), 1 packet
```

A log message for the same sort of packet using the `log` keyword does not include the input interface information:

```
00:05:47:%SEC-6-IPACCESSLOGDP:list inputlog permitted icmp 10.1.1.10 -> 10.1.1.61 (0/0), 1 packet
```

### Configuration Examples for ACLs and VLAN Maps

#### Example: Creating an ACL and a VLAN Map to Deny a Packet

This example shows how to create an ACL and a VLAN map to deny a packet. In the first map, any packets that match the `ip1` ACL (TCP packets) would be dropped. You first create the `ip1` ACL to permit any TCP packet and no other packets. Because there is a match clause for IP packets in the VLAN map, the default action is to drop any IP packet that does not match any of the match clauses.

```
Device(config)# ip access-list extended ip1
Device(config-ext-nacl)# permit tcp any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map map_1 10
Device(config-access-map)# match ip address ip1
Device(config-access-map)# action drop
```

#### Example: Creating an ACL and a VLAN Map to Permit a Packet

This example shows how to create a VLAN map to permit a packet. ACL `ip2` permits UDP packets and any packets that match the `ip2` ACL are forwarded. In this map, any IP packets that did not match any of the previous ACLs (that is, packets that are not TCP packets or UDP packets) would get dropped.

```
Device(config)# ip access-list extended ip2
Device(config-ext-nacl)# permit udp any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map map_1 20
Device(config-access-map)# match ip address ip2
Device(config-access-map)# action forward
```

#### Example: Default Action of Dropping IP Packets and Forwarding MAC Packets

In this example, the VLAN map has a default action of drop for IP packets and a default action of forward for MAC packets. Used with standard ACL 101 and extended named access lists `igmp-match` and `tcp-match`, the map will have the following results:

- Forward all UDP packets
- Drop all IGMP packets
- Forward all TCP packets
- Drop all other IP packets
- Forward all non-IP packets

Device(config)# access-list 101 permit udp any any
Device(config)# ip access-list extended igmp-match
Device(config-ext-nacl)# permit igmp any any

Device(config)# action forward
Device(config-ext-nacl)# permit tcp any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map drop-ip-default 10
Device(config-access-map)# match ip address 101
Device(config-access-map)# action forward
Device(config-access-map)# exit
Device(config)# vlan access-map drop-ip-default 20
Device(config-access-map)# match ip address igmp-match
Device(config-access-map)# action drop
Device(config-access-map)# exit
Device(config)# vlan access-map drop-ip-default 30
Device(config-access-map)# match ip address tcp-match
Device(config-access-map)# action forward

Example: Default Action of Dropping MAC Packets and Forwarding IP Packets

In this example, the VLAN map has a default action of drop for MAC packets and a default action of forward for IP packets. Used with MAC extended access lists good-hosts and good-protocols, the map will have the following results:

- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Forward MAC packets with decnet-iv or vines-ip protocols
- Drop all other non-IP packets
- Forward all IP packets

Device(config)# mac access-list extended good-hosts
Device(config-ext-macl)# permit host 0000.0c00.0111 any
Device(config-ext-macl)# permit host 0000.0c00.0211 any
Device(config-ext-nacl)# exit
Device(config)# action forward
Device(config-ext-macl)# mac access-list extended good-protocols
Device(config-ext-macl)# permit any any vines-ip
Device(config-ext-nacl)# exit
Device(config)# vlan access-map drop-mac-default 10
Device(config-access-map)# match mac address good-hosts
Device(config-access-map)# action forward
Device(config-access-map)# exit
Device(config)# vlan access-map drop-mac-default 20
Device(config-access-map)# match mac address good-protocols
Device(config-access-map)# action forward
**Example: Default Action of Dropping All Packets**

In this example, the VLAN map has a default action of drop for all packets (IP and non-IP). Used with access lists `tcp-match` and `good-hosts` from Examples 2 and 3, the map will have the following results:

- Forward all TCP packets
- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Drop all other IP packets
- Drop all other MAC packets

```
Device(config)# vlan access-map drop-all-default 10
Device(config-access-map)# match ip address tcp-match
Device(config-access-map)# action forward
Device(config-access-map)# exit
Device(config)# vlan access-map drop-all-default 20
Device(config-access-map)# match mac address good-hosts
Device(config-access-map)# action forward
```

**Configuration Examples for Using VLAN Maps in Your Network**

**Example: Wiring Closet Configuration**

*Figure 96: Wiring Closet Configuration*

In a wiring closet configuration, routing might not be enabled on the switch. In this configuration, the switch can still support a VLAN map and a QoS classification ACL. Assume that Host X and Host Y are in different VLANs and are connected to wiring closet switches A and C. Traffic from Host X to Host Y is eventually being routed by Switch B, a Layer 3 switch with routing enabled. Traffic from Host X to Host Y can be access-controlled at the traffic entry point,
If you do not want HTTP traffic switched from Host X to Host Y, you can configure a VLAN map on Switch A to drop all HTTP traffic from Host X (IP address 10.1.1.32) to Host Y (IP address 10.1.1.34) at Switch A and not bridge it to Switch B.

First, define the IP access list http that permits (matches) any TCP traffic on the HTTP port.

```
Device(config)# ip access-list extended http
Device(config-ext-nacl)# permit tcp host 10.1.1.32 host 10.1.1.34 eq www
Device(config-ext-nacl)# exit
```

Next, create VLAN access map map2 so that traffic that matches the http access list is dropped and all other IP traffic is forwarded.

```
Device(config)# vlan access-map map2 10
Device(config-access-map)# match ip address http
Device(config-access-map)# action drop
Device(config-access-map)# exit
Device(config)# ip access-list extended match_all
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map map2 20
Device(config-access-map)# match ip address match_all
Device(config-access-map)# action forward
```

Then, apply VLAN access map map2 to VLAN 1.

```
Device(config)# vlan filter map2 vlan 1
```

### Example: Restricting Access to a Server on Another VLAN

**Figure 97: Restricting Access to a Server on Another VLAN**

You can restrict access to a server on another VLAN. For example, server 10.1.1.100 in VLAN 10 needs to have access denied to these hosts:

- Hosts in subnet 10.1.2.0/8 in VLAN 20 should not have access.
- Hosts 10.1.1.4 and 10.1.1.8 in VLAN 10 should not have access.
Example: Denying Access to a Server on Another VLAN

This example shows how to deny access to a server on another VLAN by creating the VLAN map SERVER1 that denies access to hosts in subnet 10.1.2.0, host 10.1.1.4, and host 10.1.1.8 and permits other IP traffic. The final step is to apply the map SERVER1 to VLAN 10.

Define the IP ACL that will match the correct packets.

Device(config)# ip access-list extended SERVER1_ACL
Device(config-ext-nacl)# permit ip 10.1.2.0 0.0.0.255 host 10.1.1.100
Device(config-ext-nacl)# permit ip host 10.1.1.4 host 10.1.1.100
Device(config-ext-nacl)# permit ip host 10.1.1.8 host 10.1.1.100
Device(config-ext-nacl)# exit

Define a VLAN map using this ACL that will drop IP packets that match SERVER1_ACL and forward IP packets that do not match the ACL.

Device(config)# vlan access-map SERVER1_MAP
Device(config-access-map)# match ip address SERVER1_ACL
Device(config-access-map)# action drop
Device(config)# vlan access-map SERVER1_MAP 20
Device(config-access-map)# action forward
Device(config-access-map)# exit

Apply the VLAN map to VLAN 10.

Device(config)# vlan filter SERVER1_MAP vlan-list 10

Configuration Examples of Router ACLs and VLAN Maps Applied to VLANs

This section gives examples of applying router ACLs and VLAN maps to a VLAN for switched, bridged, routed, and multicast packets. Although the following illustrations show packets being forwarded to their destination, each time the packet’s path crosses a line indicating a VLAN map or an ACL, it is also possible that the packet might be dropped, rather than forwarded.

Example: ACLs and Switched Packets

This example shows how an ACL is applied on packets that are switched within a VLAN. Packets switched within the VLAN without being routed or forwarded by fallback bridging are only subject to the VLAN map of the input VLAN.
Example: ACLs and Bridged Packets

Figure 99: Applying ACLs on Bridged Packets

This example shows how an ACL is applied on fallback-bridged packets. For bridged packets, only Layer 2 ACLs are applied to the input VLAN. Only non-IP, non-ARP packets can be fallback-bridged.

Example: ACLs and Routed Packets

Figure 100: Applying ACLs on Routed Packets

This example shows how ACLs are applied on routed packets. The ACLs are applied in this order:

1. VLAN map for input VLAN
2. Input router ACL
3. Output router ACL
4. VLAN map for output VLAN

---

**Example: ACLs and Multicast Packets**

*Figure 101: Applying ACLs on Multicast Packets*

This example shows how ACLs are applied on packets that are replicated for IP multicasting. A multicast packet being routed has two different kinds of filters applied: one for destinations that are other ports in the input VLAN and another for each of the destinations that are in other VLANs to which the packet has been routed. The packet might be routed to more than one output VLAN, in which case a different router output ACL and VLAN map would apply for each destination VLAN. The final result is that the packet might be permitted in some of the output VLANs and not in others. A copy of the packet is forwarded to those destinations where it is permitted. However, if the input VLAN map drops the packet, no destination receives a copy of the packet.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

IPv6 ACLs Overview

You can filter IP Version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP Version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic when the switch is running the IP base and LAN base feature sets.

A switch supports two types of IPv6 ACLs:

- IPv6 router ACLs are supported on outbound or inbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. IPv6 router ACLs apply only to IPv6 packets that are routed.

- IPv6 port ACLs are supported on inbound and outbound Layer 2 interfaces. IPv6 port ACLs are applied to all IPv6 packets entering the interface.
The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.
You can apply both IPv4 and IPv6 ACLs to an interface. As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs.

Switch Stacks and IPv6 ACLs

The active switch supports IPv6 ACLs in hardware and distributes the IPv6 ACLs to the stack members.
If a standby switch takes over as the active switch, it distributes the ACL configuration to all stack members.
The member switches sync up the configuration distributed by the new active switch and flush out entries that are not required.
When an ACL is modified, attached to, or detached from an interface, the active switch distributes the change to all stack members.

Interactions with Other Features and Switches

• If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.
• If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.
• You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.
• You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.
• If the hardware memory is full, packets are dropped on the interface and an unload error message is logged.

Restrictions for IPv6 ACLs

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs.
IPv6 supports only named ACLs.
The switch supports most Cisco IOS-supported IPv6 ACLs with some exceptions:
• The switch does not support matching on these keywords: flowlabel, routing header, and undetermined-transport.
• The switch does not support reflexive ACLs (the reflect keyword).
• This release supports only port ACLs and router ACLs for IPv6; it does not support VLAN ACLs (VLAN maps).
• The switch does not apply MAC-based ACLs on IPv6 frames.
• You cannot apply IPv6 port ACLs to Layer 2 EtherChannels.

• When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the switch checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.

• If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the switch does not allow the ACE to be added to the ACL that is currently attached to the interface.

IPv6 ACLs on the switch have these characteristics:

• Fragmented frames (the fragments keyword as in IPv4) are supported

• The same statistics supported in IPv4 are supported for IPv6 ACLs.

• If the switch runs out of hardware space, the packets associated with the ACL are dropped on the interface.

• Logging is supported for router ACLs, but not for port ACLs.

• The switch supports IPv6 address-matching for a full range of prefix-lengths.

Default Configuration for IPv6 ACLs

The default IPv6 ACL configuration is as follows:

Switch# show access-lists preauth_ipv6_acl
IPv6 access list preauth_ipv6_acl (per-user)
permit udp any any eq domain sequence 10
permit tcp any any eq domain sequence 20
permit icmp any any nd-ns sequence 30
permit icmp any any nd-na sequence 40
permit icmp any any router-solicitation sequence 50
permit icmp any any router-advertisement sequence 60
permit icmp any any redirect sequence 70
permit udp any eq 547 any eq 546 sequence 80
permit udp any eq 546 any eq 547 sequence 90
deny ipv6 any any sequence 100

Configuring IPv6 ACLs

To filter IPv6 traffic, you perform these steps:

SUMMARY STEPS

1. enable
2. configure terminal
3. [no] [ipv6 access-list list-name] [client permit-control-packets] [log-update threshold] [role-based]
4. [no] [deny] [permit] protocol {source-ipv6-prefix/prefix-length|any threshold} [host source-ipv6-address]
[ operator [ port-number ]] [ destination-ipv6-prefix/prefix-length | any ] [ host destination-ipv6-address]
5. `{deny | permit} tcp {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [ack] [dscp value] [established] [fin] [log] [log-input] [neq {port | protocol}] [psh] [range {port | protocol}] [rst] [routing] [sequence value] [syn] [time-range name] [urg]`  

6. `{deny | permit} udp {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dscp value] [log] [log-input] [neq {port | protocol}] [range {port | protocol}] [routing] [sequence value] [time-range name]`  

7. `{deny | permit} icmp {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [icmp-type [icmp-code] | icmp-message] [dscp value] [log] [log-input] [routing] [sequence value] [time-range name]`  

8. `end`  

9. `show ipv6 access-list`  

10. `show running-config`  

11. `copy running-config startup-config`
<table>

<td></td>
</tr>
<tr>
<td>• (Optional) Enter <strong>routing</strong> to specify that IPv6 packets be routed.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Enter <strong>sequence</strong> value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4,294,967,295.</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Step 5** `{deny | permit} tcp {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6- prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [ack] [dscp value] [established] [fin] [log] [log-input] [neq {port | protocol}] [psh] [range {port | protocol}] [rst] [routing] [sequence value] [syn] [time-range name] [urg]` | *(Optional)* Enter **time-range** name to specify the time range that applies to the deny or permit statement. (Optional) Define a TCP access list and the access conditions. Enter **tcp** for Transmission Control Protocol. The parameters are the same as those described in Step 3a, with these additional optional parameters:  
  - **ack**—Acknowledgment bit set.  
  - **established**—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set.  
  - **fin**—Finished bit set; no more data from sender.  
  - **neq** {port | protocol}—Matches only packets that are not on a given port number.  
  - **psh**—Push function bit set.  
  - **range** {port | protocol}—Matches only packets in the port number range.  
  - **rst**—Reset bit set.  
  - **syn**—Synchronize bit set.  
  - **urg**—Urgent pointer bit set. |
| **Step 6** `{deny | permit} udp {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dscp value] [log] [log-input] [neq {port | protocol}] [range {port | protocol}] [routing] [sequence value] [time-range name]` | *(Optional)* Define a UDP access list and the access conditions. Enter **udp** for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the [operator [port]] port number or name must be a UDP port number or name, and the established parameter is not valid for UDP. |
| **Step 7** `{deny | permit} icmp {source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [icmp-type [icmp-code]] [icmp-message] [dscp value] [log] [log-input] [routing] [sequence value] [time-range name]` | *(Optional)* Define an ICMP access list and the access conditions. Enter **icmp** for Internet Control Message Protocol. The ICMP parameters are the same as those described for most IP protocols in Step 1, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:  
  - **icmp-type**—Enter to filter by ICMP message type, a number from 0 to 255. |
### Security

#### Attaching an IPv6 ACL to an Interface

You can apply an ACL to outbound or inbound traffic on Layer 3 interfaces, or to inbound traffic on Layer 2 interfaces. You can also apply ACLs only to inbound management traffic on Layer 3 interfaces.

Follow these steps to control access to an interface:

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface interface-id**
4. **no switchport**
5. **ipv6 address ipv6-address**
6. **ipv6 traffic-filter access-list-name {in | out}**
7. **end**
8. **show running-config**
9. **copy running-config startup-config**

#### What to do next

Attach the IPv6 ACL to an Interface

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Return to privileged EXEC mode.</td>
</tr>
<tr>
<td>show ipv6 access-list</td>
<td>Verify the access list configuration.</td>
</tr>
<tr>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

---

- **icmp-code**—Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255.
- **icmp-message**—Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name. To see a list of ICMP message type names and code names, use the `? key or see command reference for this release.`

---

**Example:**

```
Device# show running-config
```
<table>
<thead>
<tr>
<th>DETAILED STEPS</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>interface interface-id</td>
<td>Identify a Layer 2 interface (for port ACLs) or Layer 3 interface (for router ACLs) on which to apply an access list, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>no switchport</td>
<td>If applying a router ACL, this changes the interface from Layer 2 mode (the default) to Layer 3 mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>ipv6 address ipv6-address</td>
<td>Configure an IPv6 address on a Layer 3 interface (for router ACLs).</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>ipv6 traffic-filter access-list-name {in</td>
<td>out}</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td></td>
<td>Example: Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>
# Monitoring IPv6 ACLs

You can display information about all configured access lists, all IPv6 access lists, or a specific access list by using one or more of the privileged EXEC commands shown in the table below:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show access-lists</code></td>
<td>Displays all access lists configured on the switch.</td>
</tr>
<tr>
<td><code>show ipv6 access-list [access-list-name]</code></td>
<td>Displays all configured IPv6 access lists or the access list specified by name.</td>
</tr>
</tbody>
</table>

This is an example of the output from the `show access-lists` privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

```
Switch # show access-lists
Extended IP access list hello
   10 permit ip any any
IPv6 access list ipv6
   permit ipv6 any any sequence 10
```

This is an example of the output from the `show ipv6 access-list` privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

```
Switch# show ipv6 access-list
IPv6 access list inbound
   permit tcp any any eq bgp (8 matches) sequence 10
   permit tcp any any eq telnet (15 matches) sequence 20
   permit udp any any sequence 30

IPv6 access list outbound
   deny udp any any sequence 10
   deny tcp any any eq telnet sequence 20
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About DHCP

DHCP Server

The DHCP server assigns IP addresses from specified address pools on a switch or router to DHCP clients and manages them. If the DHCP server cannot give the DHCP client the requested configuration parameters from its database, it forwards the request to one or more secondary DHCP servers defined by the network administrator. The switch can act as a DHCP server.

DHCP Relay Agent

A DHCP relay agent is a Layer 3 device that forwards DHCP packets between clients and servers. Relay agents forward requests and replies between clients and servers when they are not on the same physical subnet. Relay agent forwarding is different from the normal Layer 2 forwarding, in which IP datagrams are switched transparently between networks. Relay agents receive DHCP messages and generate new DHCP messages to send on output interfaces.
DHCP Snooping

DHCP snooping is a DHCP security feature that provides network security by filtering untrusted DHCP messages and by building and maintaining a DHCP snooping binding database, also referred to as a DHCP snooping binding table.

DHCP snooping acts like a firewall between untrusted hosts and DHCP servers. You use DHCP snooping to differentiate between untrusted interfaces connected to the end user and trusted interfaces connected to the DHCP server or another switch.

For DHCP snooping to function properly, all DHCP servers must be connected to the switch through trusted interfaces.

An untrusted DHCP message is a message that is received through an untrusted interface. By default, the switch considers all interfaces untrusted. So, the switch must be configured to trust some interfaces to use DHCP Snooping. When you use DHCP snooping in a service-provider environment, an untrusted message is sent from a device that is not in the service-provider network, such as a customer’s switch. Messages from unknown devices are untrusted because they can be sources of traffic attacks.

The DHCP snooping binding database has the MAC address, the IP address, the lease time, the binding type, the VLAN number, and the interface information that corresponds to the local untrusted interfaces of a switch. It does not have information regarding hosts interconnected with a trusted interface.

In a service-provider network, an example of an interface you might configure as trusted is one connected to a port on a device in the same network. An example of an untrusted interface is one that is connected to an untrusted interface in the network or to an interface on a device that is not in the network.

When a switch receives a packet on an untrusted interface and the interface belongs to a VLAN in which DHCP snooping is enabled, the switch compares the source MAC address and the DHCP client hardware address. If the addresses match (the default), the switch forwards the packet. If the addresses do not match, the switch drops the packet.

The switch drops a DHCP packet when one of these situations occurs:

- A packet from a DHCP server, such as a DHCPOFFER, DHCPACK, DHCPNAK, or DHCPELEASEQUERY packet, is received from outside the network or firewall.
- A packet is received on an untrusted interface, and the source MAC address and the DHCP client hardware address do not match.
- The switch receives a DHCPRELEASE or DHCPDECLINE broadcast message that has a MAC address in the DHCP snooping binding database, but the interface information in the binding database does not match the interface on which the message was received.
- A DHCP relay agent forwards a DHCP packet that includes a relay-agent IP address that is not 0.0.0.0, or the relay agent forwards a packet that includes option-82 information to an untrusted port.
- The maximum snooping queue size of 1000 is exceeded when DHCP snooping is enabled.

This is applicable from Cisco IOS XE Denali 16.1.x release onwards.
If the switch is an aggregation switch supporting DHCP snooping and is connected to an edge switch that is inserting DHCP option-82 information, the switch drops packets with option-82 information when packets are received on an untrusted interface. If DHCP snooping is enabled and packets are received on a trusted port, the aggregation switch does not learn the DHCP snooping bindings for connected devices and cannot build a complete DHCP snooping binding database.

When an aggregation switch can be connected to an edge switch through an untrusted interface and you enter the `ip dhcp snooping information option allow-untrusted` global configuration command, the aggregation switch accepts packets with option-82 information from the edge switch. The aggregation switch learns the bindings for hosts connected through an untrusted switch interface. The DHCP security features, such as dynamic ARP inspection or IP source guard, can still be enabled on the aggregation switch while the switch receives packets with option-82 information on untrusted input interfaces to which hosts are connected. The port on the edge switch that connects to the aggregation switch must be configured as a trusted interface.

Normally, it is not desirable to broadcast packets to wireless clients. So, DHCP snooping replaces destination broadcast MAC address (ffff.ffff.ffff) with unicast MAC address for DHCP packets that are going from server to wireless clients. The unicast MAC address is retrieved from CHADDR field in the DHCP payload. This processing is applied for server to client packets such as DHCP OFFER, DHCP ACK, and DHCP NACK messages. The `ip dhcp snooping wireless bootp-broadcast enable` can be used to revert this behavior. When the wireless BOOTP broadcast is enabled, the broadcast DHCP packets from server are forwarded to wireless clients without changing the destination MAC address.

Prerequisites for Configuring DHCP Snooping and Option 82, on page 1687

### Option-82 Data Insertion

In residential, metropolitan Ethernet-access environments, DHCP can centrally manage the IP address assignments for a large number of subscribers. When the DHCP option-82 feature is enabled on the switch, a subscriber device is identified by the switch port through which it connects to the network (in addition to its MAC address). Multiple hosts on the subscriber LAN can be connected to the same port on the access switch and are uniquely identified.

The following illustration shows a metropolitan Ethernet network in which a centralized DHCP server assigns IP addresses to subscribers connected to the switch at the access layer. Because the DHCP clients and their associated DHCP server do not reside on the same IP network or subnet, a DHCP relay agent (the Catalyst switch) is configured with a helper address to enable broadcast forwarding and to transfer DHCP messages between the clients and the server.

---

**Note**

The DHCP option-82 feature is supported only when DHCP snooping is globally enabled on the VLANs to which subscriber devices using option-82 are assigned.
When you enable the DHCP snooping information option 82 on the switch, the following sequence of events occurs:

- The host (DHCP client) generates a DHCP request and broadcasts it on the network.
- When the switch receives the DHCP request, it adds the option-82 information in the packet. By default, the remote-ID suboption is the switch MAC address, and the circuit-ID suboption is the port identifier, `vlan-mod-port`, from which the packet is received. You can configure the remote ID and circuit ID.
- If the IP address of the relay agent is configured, the switch adds this IP address in the DHCP packet.
- The switch forwards the DHCP request that includes the option-82 field to the DHCP server.
- The DHCP server receives the packet. If the server is option-82-capable, it can use the remote ID, the circuit ID, or both to assign IP addresses and implement policies, such as restricting the number of IP addresses that can be assigned to a single remote ID or circuit ID. Then the DHCP server echoes the option-82 field in the DHCP reply.
- The DHCP server unicasts the reply to the switch if the request was relayed to the server by the switch. The switch verifies that it originally inserted the option-82 data by inspecting the remote ID and possibly the circuit ID fields. The switch removes the option-82 field and forwards the packet to the switch port that connects to the DHCP client that sent the DHCP request.

In the default suboption configuration, when the described sequence of events occurs, the values in these fields do not change (see the illustration, *Suboption Packet Formats*):

- Circuit-ID suboption fields
  - Suboption type
  - Length of the suboption type
  - Circuit-ID type
  - Length of the circuit-ID type

- Remote-ID suboption fields
  - Suboption type
  - Length of the suboption type
  - Remote-ID type
• Length of the remote-ID type

In the port field of the circuit ID suboption, the port numbers start at 3. For example, on a switch with 24 10/100/1000 ports and four small form-factor pluggable (SFP) module slots, port 3 is the Gigabit Ethernet 1/0/1 port, port 4 is the Gigabit Ethernet 1/0/2 port, and so forth. Port 27 is the SFP module slot Gigabit Ethernet1/0/25, and so forth.

The illustration, Suboption Packet Formats, shows the packet formats for the remote-ID suboption and the circuit-ID suboption when the default suboption configuration is used. For the circuit-ID suboption, the module number corresponds to the switch number in the stack. The switch uses the packet formats when you globally enable DHCP snooping and enter the ip dhcp snooping information option global configuration command.

![Figure 103: Suboption Packet Formats](image)

The illustration, User-Configured Suboption Packet Formats, shows the packet formats for user-configured remote-ID and circuit-ID suboptions. The switch uses these packet formats when DHCP snooping is globally enabled and when the `ip dhcp snooping information option format remote-id` global configuration command and the `ip dhcp snooping vlan information option format-type circuit-id string` interface configuration command are entered.

The values for these fields in the packets change from the default values when you configure the remote-ID and circuit-ID suboptions:

• Circuit-ID suboption fields
  - The circuit-ID type is 1.
  - The length values are variable, depending on the length of the string that you configure.

• Remote-ID suboption fields
  - The remote-ID type is 1.
  - The length values are variable, depending on the length of the string that you configure.
Cisco IOS DHCP Server Database

During the DHCP-based autoconfiguration process, the designated DHCP server uses the Cisco IOS DHCP server database. It has IP addresses, address bindings, and configuration parameters, such as the boot file.

An address binding is a mapping between an IP address and a MAC address of a host in the Cisco IOS DHCP server database. You can manually assign the client IP address, or the DHCP server can allocate an IP address from a DHCP address pool. For more information about manual and automatic address bindings, see the “Configuring DHCP” chapter of the Cisco IOS IP Configuration Guide, Release 12.4.

For procedures to enable and configure the Cisco IOS DHCP server database, see the “DHCP Configuration Task List” section in the “Configuring DHCP” chapter of the Cisco IOS IP Configuration Guide, Release 12.4.

DHCP Snooping Binding Database

When DHCP snooping is enabled, the switch uses the DHCP snooping binding database to store information about untrusted interfaces. The database can have up to 64,000 bindings.

Each database entry (binding) has an IP address, an associated MAC address, the lease time (in hexadecimal format), the interface to which the binding applies, and the VLAN to which the interface belongs. The database agent stores the bindings in a file at a configured location. At the end of each entry is a checksum that accounts for all the bytes from the start of the file through all the bytes associated with the entry. Each entry is 72 bytes, followed by a space and then the checksum value.

To keep the bindings when the switch reloads, you must use the DHCP snooping database agent. If the agent is disabled, dynamic ARP inspection or IP source guard is enabled, and the DHCP snooping binding database has dynamic bindings, the switch loses its connectivity. If the agent is disabled and only DHCP snooping is enabled, the switch does not lose its connectivity, but DHCP snooping might not prevent DHCP spoofing attacks.

When reloading, the switch reads the binding file to build the DHCP snooping binding database. The switch updates the file when the database changes.

When a switch learns of new bindings or when it loses bindings, the switch immediately updates the entries in the database. The switch also updates the entries in the binding file. The frequency at which the file is
updated is based on a configurable delay, and the updates are batched. If the file is not updated in a specified
time (set by the write-delay and abort-timeout values), the update stops.

This is the format of the file with bindings:

```
<initial-checksum>
TYPE DHCP-SNOOPING
VERSION 1
BEGIN
<entry-1> <checksum-1>
<entry-2> <checksum-1-2>
...
<entry-n> <checksum-1-2-..-n>
END
```

Each entry in the file is tagged with a checksum value that the switch uses to verify the entries when it reads
the file. The initial-checksum entry on the first line distinguishes entries associated with the latest file update
from entries associated with a previous file update.

This is an example of a binding file:

```
2bb4c2a1
TYPE DHCP-SNOOPING
VERSION 1
BEGIN
192.1.168.1 3 0003.47d8.c91f 2BB6488E Gi1/0/4 21ae5fbb
192.1.168.3 3 0003.44d6.c52f 2BB648EB Gi1/0/4 1bd223f
192.1.168.2 3 0003.47d9.c8f1 2BB648AB Gi1/0/4 584a38f0
END
```

When the switch starts and the calculated checksum value equals the stored checksum value, the switch reads
entries from the binding file and adds the bindings to its DHCP snooping binding database. The switch ignores
an entry when one of these situations occurs:

- The switch reads the entry and the calculated checksum value does not equal the stored checksum value.
  The entry and the ones following it are ignored.

- An entry has an expired lease time (the switch might not remove a binding entry when the lease time
  expires).

- The interface in the entry no longer exists on the system.

- The interface is a routed interface or a DHCP snooping-trusted interface.

## DHCP Snooping and Switch Stacks

DHCP snooping is managed on the stack master. When a new switch joins the stack, the switch receives the
DHCP snooping configuration from the stack master. When a member leaves the stack, all DHCP snooping
address bindings associated with the switch age out.

All snooping statistics are generated on the stack master. If a new stack master is elected, the statistics counters
reset.

When a stack merge occurs, all DHCP snooping bindings in the stack master are lost if it is no longer the
stack master. With a stack partition, the existing stack master is unchanged, and the bindings belonging to the
partitioned switches age out. The new master of the partitioned stack begins processing the new incoming DHCP packets.

### How to Configure DHCP Features

#### Default DHCP Snooping Configuration

<table>
<thead>
<tr>

<tr>
<td></td>
<td>This feature is operational only when a destination is configured.</td>
</tr>
</tbody>
</table>

13 The switch responds to DHCP requests only if it is configured as a DHCP server.
14 The switch relays DHCP packets only if the IP address of the DHCP server is configured on the SVI of the DHCP client.
15 Use this feature when the switch is an aggregation switch that receives packets with option-82 information from an edge switch.

DHCP Snooping Configuration Guidelines

- If a switch port is connected to a DHCP server, configure a port as trusted by entering the `ip dhcp snooping trust interface` configuration command.
- If a switch port is connected to a DHCP client, configure a port as untrusted by entering the `no ip dhcp snooping trust` interface configuration command.
- You can display DHCP snooping statistics by entering the `show ip dhcp snooping statistics` user EXEC command, and you can clear the snooping statistics counters by entering the `clear ip dhcp snooping statistics` privileged EXEC command.

Configuring the DHCP Server

The switch can act as a DHCP server.

For procedures to configure the switch as a DHCP server, see the “Configuring DHCP” section of the “IP addressing and Services” section of the Cisco IOS IP Configuration Guide, Release 12.4.

DHCP Server and Switch Stacks

The DHCP binding database is managed on the stack master. When a new stack master is assigned, the new master downloads the saved binding database from the TFTP server. When a switchover happens, the new active stack master will use its database file that has been synced from the old active stack master using the SSO function. The IP addresses associated with the lost bindings are released. You should configure an automatic backup by using the `ip dhcp database url [timeout seconds] | write-delay seconds` global configuration command.

Configuring the DHCP Relay Agent

Follow these steps to enable the DHCP relay agent on the switch:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. service dhcp
4. end
5. show running-config
6. copy running-config startup-config

</tbody>
</table>

### What to do next

See the “Configuring DHCP” section of the “IP Addressing and Services” section of the *Cisco IOS IP Configuration Guide, Release 12.4* for these procedures:

- Checking (validating) the relay agent information
- Configuring the relay agent forwarding policy
Specifying the Packet Forwarding Address

If the DHCP server and the DHCP clients are on different networks or subnets, you must configure the switch with the `ip helper-address address` interface configuration command. The general rule is to configure the command on the Layer 3 interface closest to the client. The address used in the `ip helper-address` command can be a specific DHCP server IP address, or it can be the network address if other DHCP servers are on the destination network segment. Using the network address enables any DHCP server to respond to requests.

Beginning in privileged EXEC mode, follow these steps to specify the packet forwarding address:

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface vlan vlan-id`
4. `ip address ip-address subnet-mask`
5. `ip helper-address address`
6. `end`
7. Use one of the following:
   - `interface range port-range`
   - `interface interface-id`
8. `switchport mode access`
9. `switchport access vlan vlan-id`
10. `end`
11. `show running-config`
12. `copy running-config startup-config`

Prerequisites for Configuring DHCP Snooping and Option 82

The prerequisites for DHCP Snooping and Option 82 are as follows:

* You must globally enable DHCP snooping on the switch.
* Before globally enabling DHCP snooping on the switch, make sure that the devices acting as the DHCP server and the DHCP relay agent are configured and enabled.
* If you want the switch to respond to DHCP requests, it must be configured as a DHCP server.
* Before configuring the DHCP snooping information option on your switch, be sure to configure the device that is acting as the DHCP server. You must specify the IP addresses that the DHCP server can assign or exclude, or you must configure DHCP options for these devices.
* For DHCP snooping to function properly, all DHCP servers must be connected to the switch through trusted interfaces. In a service-provider network, a trusted interface is connected to a port on a device in the same network.
* You must configure the switch to use the Cisco IOS DHCP server binding database to use it for DHCP snooping.
* To use the DHCP snooping option of accepting packets on untrusted inputs, the switch must be an aggregation switch that receives packets with option-82 information from an edge switch.
* The following prerequisites apply to DHCP snooping binding database configuration:
  * You must configure a destination on the DHCP snooping binding database to use the switch for DHCP snooping.
  * Because both NVRAM and the flash memory have limited storage capacity, we recommend that you store the binding file on a TFTP server.
  * For network-based URLs (such as TFTP and FTP), you must create an empty file at the configured URL before the switch can write bindings to the binding file at that URL. See the documentation for your TFTP server to determine whether you must first create an empty file on the server; some TFTP servers cannot be configured this way.
  * To ensure that the lease time in the database is accurate, we recommend that you enable and configure Network Time Protocol (NTP).
  * If NTP is configured, the switch writes binding changes to the binding file only when the switch system clock is synchronized with NTP.
  * Before configuring the DHCP relay agent on your switch, make sure to configure the device that is acting as the DHCP server. You must specify the IP addresses that the DHCP server can assign or exclude, configure DHCP options for devices, or set up the DHCP database agent.

Device# copy running-config startup-config
• If you want the switch to relay DHCP packets, the IP address of the DHCP server must be configured on the switch virtual interface (SVI) of the DHCP client.

• If a switch port is connected to a DHCP server, configure a port as trusted by entering the `ip dhcp snooping trust interface` configuration command.

• If a switch port is connected to a DHCP client, configure a port as untrusted by entering the `no ip dhcp snooping trust` interface configuration command.

Enabling DHCP Snooping and Option 82

Follow these steps to enable DHCP snooping on the switch:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip dhcp snooping`
4. `ip dhcp snooping vlan vlan-range`
5. `ip dhcp snooping information-option`
6. `ip dhcp snooping information-option format remote-id [string ASCII-string | hostname]`
7. `ip dhcp snooping information-option allow-untrusted`
8. `ip dhcp snooping wireless bootp-broadcast enable (optional)`
9. `interface interface-id`
10. `ip dhcp snooping vlan vlan information-option format-type circuit-id [override] string ASCII-string`
11. `ip dhcp snooping trust`
12. `ip dhcp snooping limit rate rate`
13. `exit`
14. `ip dhcp snooping verify mac-address`
15. `end`
16. `show running-config`
17. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

<td></td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Step 3**

ip dhcp snooping  
**Example:**  
Device(config)# ip dhcp snooping  

Enables DHCP snooping globally.

**Step 4**

ip dhcp snooping vlan *vlan-range*  
**Example:**  
Device(config)# ip dhcp snooping vlan 10  

Enables DHCP snooping on a VLAN or range of VLANs. The range is 1 to 4094. You can enter a single VLAN ID identified by VLAN ID number, a series of VLAN IDs separated by commas, a range of VLAN IDs separated by hyphens, or a range of VLAN IDs separated by entering the starting and ending VLAN IDs separated by a space.

- You can enter a single VLAN ID identified by VLAN ID number, a series of VLAN IDs separated by commas, a range of VLAN IDs separated by hyphens, or a range of VLAN IDs separated by entering the starting and ending VLAN IDs separated by a space.

**Step 5**

ip dhcp snooping information option  
**Example:**  
Device(config)# ip dhcp snooping information option  

Enables the switch to insert and remove DHCP relay information (option-82 field) in forwarded DHCP request messages to the DHCP server. This is the default setting.

**Step 6**

ip dhcp snooping information option format remote-id [string *ASCII-string* | hostname]  
**Example:**  
Device(config)# ip dhcp snooping information option format remote-id string acsiistring2  

(Optional) Configures the remote-ID suboption.  
You can configure the remote ID as:

- String of up to 63 ASCII characters (no spaces)  
- Configured hostname for the switch  

**Note**  
If the hostname is longer than 63 characters, it is truncated to 63 characters in the remote-ID configuration.

The default remote ID is the switch MAC address.

**Step 7**

ip dhcp snooping information option allow-untrusted  
**Example:**  
Device(config)# ip dhcp snooping information option allow-untrusted  

(Optional) If the switch is an aggregation switch connected to an edge switch, this command enables the switch to accept incoming DHCP snooping packets with option-82 information from the edge switch.

The default setting is disabled.

**Note**  
Enter this command only on aggregation switches that are connected to trusted devices.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 8** ip dhcp snooping wireless bootp-broadcast enable (optional)  
Example:  
Device(config)# ip dhcp snooping wireless bootp-broadcast enable | Enables broadcast address sent by the server to be retained by the switch when it forwards DHCP packets to wireless clients. |
| **Step 9** interface interface-id  
Example:  
Device(config)# interface gigabitethernet2/0/1 | Specifies the interface to be configured, and enter interface configuration mode. |
| **Step 10** ip dhcp snooping vlan vlan information option format-type circuit-id [override] string ASCII-string  
Example:  
Device(config-if)# ip dhcp snooping vlan 1 information option format-type circuit-id override string override2 | (Optional) Configures the circuit-ID suboption for the specified interface.  
Specify the VLAN and port identifier, using a VLAN ID in the range of 1 to 4094. The default circuit ID is the port identifier, in the format `vlan-mod-port`.  
You can configure the circuit ID to be a string of 3 to 63 ASCII characters (no spaces).  
(Optional) Use the `override` keyword when you do not want the circuit-ID suboption inserted in TLV format to define subscriber information. |
| **Step 11** ip dhcp snooping trust  
Example:  
Device(config-if)# ip dhcp snooping trust | (Optional) Configures the interface as trusted or untrusted.  
Use the `no` keyword to configure an interface to receive messages from an untrusted client. The default setting is untrusted. |
| **Step 12** ip dhcp snooping limit rate rate  
Example:  
Device(config-if)# ip dhcp snooping limit rate 100 | (Optional) Configures the number of DHCP packets per second that an interface can receive. The range is 1 to 2048. By default, no rate limit is configured.  
**Note** We recommend an untrusted rate limit of not more than 100 packets per second. If you configure rate limiting for trusted interfaces, you might need to increase the rate limit if the port is a trunk port assigned to more than one VLAN with DHCP snooping. |
| **Step 13** exit  
Example:  
Device(config-if)# exit | Returns to global configuration mode. |
| **Step 14** ip dhcp snooping verify mac-address  
Example:  
Device(config-if)# | (Optional) Configures the switch to verify that the source MAC address in a DHCP packet received on untrusted ports matches the client hardware address in the packet. |
### Command or Action

<td>Display the dynamically and statically configured bindings.</td>
</tr>
</tbody>
</table>
If DHCP snooping is enabled and an interface changes to the down state, the switch does not delete the statically configured bindings.

Configuring DHCP Server Port-Based Address Allocation

Information About Configuring DHCP Server Port-Based Address Allocation

DHCP server port-based address allocation is a feature that enables DHCP to maintain the same IP address on an Ethernet switch port regardless of the attached device client identifier or client hardware address.

When Ethernet switches are deployed in the network, they offer connectivity to the directly connected devices. In some environments, such as on a factory floor, if a device fails, the replacement device must be working immediately in the existing network. With the current DHCP implementation, there is no guarantee that DHCP would offer the same IP address to the replacement device. Control, monitoring, and other software expect a stable IP address associated with each device. If a device is replaced, the address assignment should remain stable even though the DHCP client has changed.

When configured, the DHCP server port-based address allocation feature ensures that the same IP address is always offered to the same connected port even as the client identifier or client hardware address changes in the DHCP messages received on that port. The DHCP protocol recognizes DHCP clients by the client identifier option in the DHCP packet. Clients that do not include the client identifier option are identified by the client hardware address. When you configure this feature, the port name of the interface overrides the client identifier or hardware address and the actual point of connection, the switch port, becomes the client identifier.

In all cases, by connecting the Ethernet cable to the same port, the same IP address is allocated through DHCP to the attached device.

The DHCP server port-based address allocation feature is only supported on a Cisco IOS DHCP server and not a third-party server.

Default Port-Based Address Allocation Configuration

By default, DHCP server port-based address allocation is disabled.

Port-Based Address Allocation Configuration Guidelines

- By default, DHCP server port-based address allocation is disabled.
- To restrict assignments from the DHCP pool to preconfigured reservations (unreserved addresses are not offered to the client and other clients are not served by the pool), you can enter the reserved-only DHCP pool configuration command.

Enabling the DHCP Snooping Binding Database Agent

Beginning in privileged EXEC mode, follow these steps to enable and configure the DHCP snooping binding database agent on the switch:
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip dhcp snooping database {flash[number]::filename | ftp://user:password@host::filename | http://[[username:password@]]::hostname | host-ip}/[directory]::image-name.tar | rcp://user@host::filename] | tftp://host::filename`
4. `ip dhcp snooping database timeout seconds`
5. `ip dhcp snooping database write-delay seconds`
6. `end`
7. `ip dhcp snooping binding mac-address vlan vlan-id ip-address interface interface-id expiry seconds`
8. `show ip dhcp snooping database [detail]`
9. `show running-config`
10. `copy running-config startup-config`

### Enabling DHCP Server Port-Based Address Allocation

Follow these steps to globally enable port-based address allocation and to automatically generate a subscriber identifier on an interface.

#### SUMMARY STEPS

1. `enable`

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config)# ip dhcp snooping database timeout 300</code></td>
<td>The default is 300 seconds. The range is 0 to 86400. Use 0 to define an infinite duration, which means to continue trying the transfer indefinitely.</td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>ip dhcp snooping database write-delay seconds</code></td>
<td>Specifies the duration for which the transfer should be delayed after the binding database changes. The range is from 15 to 86400 seconds. The default is 300 seconds (5 minutes).</td>
</tr>
<tr>
<td><code>Device(config)# ip dhcp snooping database write-delay 15</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> <code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> <code>ip dhcp snooping binding mac-address vlan vlan-id ip-address interface interface-id expiry seconds</code></td>
<td>(Optional) Adds binding entries to the DHCP snooping binding database. The <code>vlan-id</code> range is from 1 to 4904. The <code>seconds</code> range is from 1 to 4294967295. Enter this command for each entry that you add. Use this command when you are testing or debugging the switch.</td>
</tr>
<tr>
<td><code>Device# ip dhcp snooping binding 0001.1234.1234 vlan 1 172.20.50.5 interface gi1/1 expiry 1000</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> <code>show ip dhcp snooping database [detail]</code></td>
<td>Displays the status and statistics of the DHCP snooping binding database agent.</td>
</tr>
<tr>
<td><code>Device# show ip dhcp snooping database detail</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> <code>show running-config</code></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><code>Device# show running-config</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> <code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>
2. configure terminal
3. ip dhcp use subscriber-id client-id
4. ip dhcp subscriber-id interface-name
5. interface interface-id
6. ip dhcp server use subscriber-id client-id
7. end
8. show running-config
9. copy running-config startup-config

**DETAILED STEPS**

<table>

<td>Specifies the interface to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>ip dhcp server use subscriber-id client-id&lt;br&gt;&lt;br&gt;Example: Device(config-if)# ip dhcp server use subscriber-id client-id</td>
<td>Configures the DHCP server to use the subscriber identifier as the client identifier on all incoming DHCP messages on the interface.</td>
</tr>
</tbody>
</table>
### Purpose

Command or Action | Purpose
--- | ---
**Step 7** end | Returns to privileged EXEC mode.
   **Example:**
   Device(config)# end

**Step 8** show running-config | Verifies your entries.
   **Example:**
   Device# show running-config

**Step 9** copy running-config startup-config | (Optional) Saves your entries in the configuration file.
   **Example:**
   Device# copy running-config startup-config

### What to do next

After enabling DHCP port-based address allocation on the switch, use the **ip dhcp pool** global configuration command to preassign IP addresses and to associate them to clients.

### Monitoring DHCP Server Port-Based Address Allocation

CHAPTER 86

Configuring IP Source Guard

IP Source Guard (IPSG) is a security feature that restricts IP traffic on nonrouted, Layer 2 interfaces by filtering traffic based on the DHCP snooping binding database and on manually configured IP source bindings.

This chapter contains the following topics:

- Finding Feature Information, on page 1699
- Information About IP Source Guard, on page 1699
- How to Configure IP Source Guard, on page 1701
- Monitoring IP Source Guard, on page 1705
- Additional References, on page 1705

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IP Source Guard

IP Source Guard

You can use IP source guard to prevent traffic attacks if a host tries to use the IP address of its neighbor and you can enable IP source guard when DHCP snooping is enabled on an untrusted interface.

After IPSG is enabled on an interface, the switch blocks all IP traffic received on the interface except for DHCP packets allowed by DHCP snooping.

The switch uses a source IP lookup table in hardware to bind IP addresses to ports. For IP and MAC filtering, a combination of source IP and source MAC lookups are used. IP traffic with a source IP address is the binding table is allowed, all other traffic is denied.
The IP source binding table has bindings that are learned by DHCP snooping or are manually configured (static IP source bindings). An entry in this table has an IP address, its associated MAC address, and its associated VLAN number. The switch uses the IP source binding table only when IP source guard is enabled.

IPSG is supported only on Layer 2 ports, including access and trunk ports. You can configure IPSG with source IP address filtering or with source IP and MAC address filtering.

**IP Source Guard for Static Hosts**

---

**Note**

Do not use IPSG (IP source guard) for static hosts on uplink ports or trunk ports.

IPSG for static hosts extends the IPSG capability to non-DHCP and static environments. The previous IPSG used the entries created by DHCP snooping to validate the hosts connected to a switch. Any traffic received from a host without a valid DHCP binding entry is dropped. This security feature restricts IP traffic on nonrouted Layer 2 interfaces. It filters traffic based on the DHCP snooping binding database and on manually configured IP source bindings. The previous version of IPSG required a DHCP environment for IPSG to work.

IPSG for static hosts allows IPSG to work without DHCP. IPSG for static hosts relies on IP device tracking-table entries to install port ACLs. The switch creates static entries based on ARP requests or other IP packets to maintain the list of valid hosts for a given port. You can also specify the number of hosts allowed to send traffic to a given port. This is equivalent to port security at Layer 3.

IPSG for static hosts also supports dynamic hosts. If a dynamic host receives a DHCP-assigned IP address that is available in the IP DHCP snooping table, the same entry is learned by the IP device tracking table. In a stacked environment, when the master failover occurs, the IP source guard entries for static hosts attached to member ports are retained. When you enter the `show ip device tracking all` EXEC command, the IP device tracking table displays the entries as ACTIVE.

---

**Note**

Some IP hosts with multiple network interfaces can inject some invalid packets into a network interface. The invalid packets contain the IP or MAC address for another network interface of the host as the source address. The invalid packets can cause IPSG for static hosts to connect to the host, to learn the invalid IP or MAC address bindings, and to reject the valid bindings. Consult the vendor of the corresponding operating system and the network interface to prevent the host from injecting invalid packets.

IPSG for static hosts initially learns IP or MAC bindings dynamically through an ACL-based snooping mechanism. IP or MAC bindings are learned from static hosts by ARP and IP packets. They are stored in the device tracking database. When the number of IP addresses that have been dynamically learned or statically configured on a given port reaches a maximum, the hardware drops any packet with a new IP address. To resolve hosts that have moved or gone away for any reason, IPSG for static hosts leverages IP device tracking to age out dynamically learned IP address bindings. This feature can be used with DHCP snooping. Multiple bindings are established on a port that is connected to both DHCP and static hosts. For example, bindings are stored in both the device tracking database as well as in the DHCP snooping binding database.
IP Source Guard Configuration Guidelines

- You can configure static IP bindings only on nonrouted ports. If you enter the `ip source binding mac-address vlan vlan-id ip-address interface interface-id` global configuration command on a routed interface, this error message appears:

  Static IP source binding can only be configured on switch port.

- When IP source guard with source IP filtering is enabled on an interface, DHCP snooping must be enabled on the access VLAN for that interface.

- If you are enabling IP source guard on a trunk interface with multiple VLANs and DHCP snooping is enabled on all the VLANs, the source IP address filter is applied on all the VLANs.

  **Note**
  If IP source guard is enabled and you enable or disable DHCP snooping on a VLAN on the trunk interface, the switch might not properly filter traffic.

- You can enable this feature when 802.1x port-based authentication is enabled.

- When you configure IP source guard smart logging, packets with a source address other than the specified address or an address learned by DHCP are denied, and the packet contents are sent to a NetFlow collector. If you configure this feature, make sure that smart logging is globally enabled.

- In a switch stack, if IP source guard is configured on a stack member interface and you remove the the configuration of that switch by entering the `no switch stack-member-number provision` global configuration command, the interface static bindings are removed from the binding table, but they are not removed from the running configuration. If you again provision the switch by entering the `switch stack-member-number provision` command, the binding is restored.

To remove the binding from the running configuration, you must disable IP source guard before entering the `no switch provision` command. The configuration is also removed if the switch reloads while the interface is removed from the binding table.

How to Configure IP Source Guard

Enabling IP Source Guard

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip verify source [mac-check ]
5. exit
6. ip source binding mac-address vlan vlan-id ip-address interface interface-id
7. end

### Configuring IP Source Guard for Static Hosts on a Layer 2 Access Port

You must configure the `ip device tracking maximum limit-number interface` configuration command globally for IPSG for static hosts to work. If you only configure this command on a port without enabling IP device tracking globally or by setting an IP device tracking maximum on that interface, IPSG with static hosts rejects all the IP traffic from that interface.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. ip device tracking
4. interface interface-id
5. switchport mode access
6. switchport access vlan vlan-id
7. ip verify source[tracking] [mac-check ]
8. ip device tracking maximum number
9. end

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Dynamic ARP Inspection

This section lists the restrictions and guidelines for configuring Dynamic ARP Inspection on the switch.

- Dynamic ARP inspection is an ingress security feature; it does not perform any egress checking.

- Dynamic ARP inspection is not effective for hosts connected to switches that do not support dynamic ARP inspection or that do not have this feature enabled. Because man-in-the-middle attacks are limited to a single Layer 2 broadcast domain, separate the domain with dynamic ARP inspection checks from the one with no checking. This action secures the ARP caches of hosts in the domain enabled for dynamic ARP inspection.
• Dynamic ARP inspection depends on the entries in the DHCP snooping binding database to verify IP-to-MAC address bindings in incoming ARP requests and ARP responses. Make sure to enable DHCP snooping to permit ARP packets that have dynamically assigned IP addresses.

When DHCP snooping is disabled or in non-DHCP environments, use ARP ACLs to permit or to deny packets.

• Dynamic ARP inspection is supported on access ports, trunk ports, and EtherChannel ports.

---

**Note**

Do not enable Dynamic ARP inspection on RSPAN VLANs. If Dynamic ARP inspection is enabled on RSPAN VLANs, Dynamic ARP inspection packets might not reach the RSPAN destination port.

---

• A physical port can join an EtherChannel port channel only when the trust state of the physical port and the channel port match. Otherwise, the physical port remains suspended in the port channel. A port channel inherits its trust state from the first physical port that joins the channel. Consequently, the trust state of the first physical port need not match the trust state of the channel.

Conversely, when you change the trust state on the port channel, the switch configures a new trust state on all the physical ports that comprise the channel.

• The rate limit is calculated separately on each switch in a switch stack. For a cross-stack EtherChannel, this means that the actual rate limit might be higher than the configured value. For example, if you set the rate limit to 30 pps on an EtherChannel that has one port on switch 1 and one port on switch 2, each port can receive packets at 29 pps without causing the EtherChannel to become error-disabled.

• The operating rate for the port channel is cumulative across all the physical ports within the channel. For example, if you configure the port channel with an ARP rate-limit of 400 pps, all the interfaces combined on the channel receive an aggregate 400 pps. The rate of incoming ARP packets on EtherChannel ports is equal to the sum of the incoming rate of packets from all the channel members. Configure the rate limit for EtherChannel ports only after examining the rate of incoming ARP packets on the channel-port members.

The rate of incoming packets on a physical port is checked against the port-channel configuration rather than the physical-ports configuration. The rate-limit configuration on a port channel is independent of the configuration on its physical ports.

If the EtherChannel receives more ARP packets than the configured rate, the channel (including all physical ports) is placed in the error-disabled state.

• Make sure to limit the rate of ARP packets on incoming trunk ports. Configure trunk ports with higher rates to reflect their aggregation and to handle packets across multiple dynamic ARP inspection-enabled VLANs. You also can use the `ip arp inspection limit none` interface configuration command to make the rate unlimited. A high rate-limit on one VLAN can cause a denial-of-service attack to other VLANs when the software places the port in the error-disabled state.

• When you enable dynamic ARP inspection on the switch, policers that were configured to police ARP traffic are no longer effective. The result is that all ARP traffic is sent to the CPU.
Understanding Dynamic ARP Inspection

ARP provides IP communication within a Layer 2 broadcast domain by mapping an IP address to a MAC address. For example, Host B wants to send information to Host A but does not have the MAC address of Host A in its ARP cache. Host B generates a broadcast message for all hosts within the broadcast domain to obtain the MAC address associated with the IP address of Host A. All hosts within the broadcast domain receive the ARP request, and Host A responds with its MAC address. However, because ARP allows a gratuitous reply from a host even if an ARP request was not received, an ARP spoofing attack and the poisoning of ARP caches can occur. After the attack, all traffic from the device under attack flows through the attacker’s computer and then to the router, switch, or host.

A malicious user can attack hosts, switches, and routers connected to your Layer 2 network by poisoning the ARP caches of systems connected to the subnet and by intercepting traffic intended for other hosts on the subnet. Figure 26-1 shows an example of ARP cache poisoning.

Figure 105: ARP Cache Poisoning

Hosts A, B, and C are connected to the switch on interfaces A, B and C, all of which are on the same subnet. Their IP and MAC addresses are shown in parentheses; for example, Host A uses IP address IA and MAC address MA. When Host A needs to communicate to Host B at the IP layer, it broadcasts an ARP request for the MAC address associated with IP address IB. When the switch and Host B receive the ARP request, they populate their ARP caches with an ARP binding for a host with the IP address IA and a MAC address MA; for example, IP address IA is bound to MAC address MA. When Host B responds, the switch and Host A populate their ARP caches with a binding for a host with the IP address IB and the MAC address MB.

Host C can poison the ARP caches of the switch, Host A, and Host B by broadcasting forged ARP responses with bindings for a host with an IP address of IA (or IB) and a MAC address of MC. Hosts with poisoned ARP caches use the MAC address MC as the destination MAC address for traffic intended for IA or IB. This means that Host C intercepts that traffic. Because Host C knows the true MAC addresses associated with IA and IB, it can forward the intercepted traffic to those hosts by using the correct MAC address as the destination. Host C has inserted itself into the traffic stream from Host A to Host B, the classic man-in-the-middle attack.

Dynamic ARP inspection is a security feature that validates ARP packets in a network. It intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. This capability protects the network from certain man-in-the-middle attacks.

Dynamic ARP inspection ensures that only valid ARP requests and responses are relayed. The switch performs these activities:

- Intercepts all ARP requests and responses on untrusted ports
- Verifies that each of these intercepted packets has a valid IP-to-MAC address binding before updating the local ARP cache or before forwarding the packet to the appropriate destination
- Drops invalid ARP packets
Dynamic ARP inspection determines the validity of an ARP packet based on valid IP-to-MAC address bindings stored in a trusted database, the DHCP snooping binding database. This database is built by DHCP snooping if DHCP snooping is enabled on the VLANs and on the switch. If the ARP packet is received on a trusted interface, the switch forwards the packet without any checks. On untrusted interfaces, the switch forwards the packet only if it is valid.

You enable dynamic ARP inspection on a per-VLAN basis by using the `ip arp inspection vlan vlan-range` global configuration command.

In non-DHCP environments, dynamic ARP inspection can validate ARP packets against user-configured ARP access control lists (ACLs) for hosts with statically configured IP addresses. You define an ARP ACL by using the `arp access-list acl-name` global configuration command.

You can configure dynamic ARP inspection to drop ARP packets when the IP addresses in the packets are invalid or when the MAC addresses in the body of the ARP packets do not match the addresses specified in the Ethernet header. Use the `ip arp inspection validate {src-mac | dst-mac | ip}` global configuration command.

### Interface Trust States and Network Security

Dynamic ARP inspection associates a trust state with each interface on the switch. Packets arriving on trusted interfaces bypass all dynamic ARP inspection validation checks, and those arriving on untrusted interfaces undergo the dynamic ARP inspection validation process.

In a typical network configuration, you configure all switch ports connected to host ports as untrusted and configure all switch ports connected to switches as trusted. With this configuration, all ARP packets entering the network from a given switch bypass the security check. No other validation is needed at any other place in the VLAN or in the network. You configure the trust setting by using the `ip arp inspection trust interface` configuration command.

**Caution**

Use the trust state configuration carefully. Configuring interfaces as untrusted when they should be trusted can result in a loss of connectivity.

In the following figure, assume that both Switch A and Switch B are running dynamic ARP inspection on the VLAN that includes Host 1 and Host 2. If Host 1 and Host 2 acquire their IP addresses from the DHCP server connected to Switch A, only Switch A binds the IP-to-MAC address of Host 1. Therefore, if the interface between Switch A and Switch B is untrusted, the ARP packets from Host 1 are dropped by Switch B. Connectivity between Host 1 and Host 2 is lost.
Configuring interfaces to be trusted when they are actually untrusted leaves a security hole in the network. If Switch A is not running dynamic ARP inspection, Host 1 can easily poison the ARP cache of Switch B (and Host 2, if the link between the switches is configured as trusted). This condition can occur even though Switch B is running dynamic ARP inspection.

Dynamic ARP inspection ensures that hosts (on untrusted interfaces) connected to a switch running dynamic ARP inspection do not poison the ARP caches of other hosts in the network. However, dynamic ARP inspection does not prevent hosts in other portions of the network from poisoning the caches of the hosts that are connected to a switch running dynamic ARP inspection.

In cases in which some switches in a VLAN run dynamic ARP inspection and other switches do not, configure the interfaces connecting such switches as untrusted. However, to validate the bindings of packets from nondynamic ARP inspection switches, configure the switch running dynamic ARP inspection with ARP ACLs. When you cannot determine such bindings, at Layer 3, isolate switches running dynamic ARP inspection from switches not running dynamic ARP inspection switches.

**Note**

Depending on the setup of the DHCP server and the network, it might not be possible to validate a given ARP packet on all switches in the VLAN.

## Rate Limiting of ARP Packets

The switch CPU performs dynamic ARP inspection validation checks; therefore, the number of incoming ARP packets is rate-limited to prevent a denial-of-service attack. By default, the rate for untrusted interfaces is 15 packets per second (pps). Trusted interfaces are not rate-limited. You can change this setting by using the `ip arp inspection limit` interface configuration command.

When the rate of incoming ARP packets exceeds the configured limit, the switch places the port in the error-disabled state. The port remains in that state until you intervene. You can use the `errdisable recovery` global configuration command to enable error disable recovery so that ports automatically emerge from this state after a specified timeout period.
Relative Priority of ARP ACLs and DHCP Snooping Entries

Dynamic ARP inspection uses the DHCP snooping binding database for the list of valid IP-to-MAC address bindings.

ARP ACLs take precedence over entries in the DHCP snooping binding database. The switch uses ACLs only if you configure them by using the `ip arp inspection filter vlan` global configuration command. The switch first compares ARP packets to user-configured ARP ACLs. If the ARP ACL denies the ARP packet, the switch also denies the packet even if a valid binding exists in the database populated by DHCP snooping.

Logging of Dropped Packets

When the switch drops a packet, it places an entry in the log buffer and then generates system messages on a rate-controlled basis. After the message is generated, the switch clears the entry from the log buffer. Each log entry contains flow information, such as the receiving VLAN, the port number, the source and destination IP addresses, and the source and destination MAC addresses.

You use the `ip arp inspection log-buffer` global configuration command to configure the number of entries in the buffer and the number of entries needed in the specified interval to generate system messages. You specify the type of packets that are logged by using the `ip arp inspection vlan logging` global configuration command.

Default Dynamic ARP Inspection Configuration

</tr>
<tr>
<td>ARP ACLs for non-DHCP environments</td>
<td>No ARP ACLs are defined.</td>
</tr>
<tr>
<td>Validation checks</td>
<td>No checks are performed.</td>
</tr>
</tbody>
</table>
Relative Priority of ARP ACLs and DHCP Snooping Entries

Dynamic ARP inspection uses the DHCP snooping binding database for the list of valid IP-to-MAC address bindings.

ARP ACLs take precedence over entries in the DHCP snooping binding database. The switch uses ACLs only if you configure them by using the ip arp inspection filter vlan global configuration command. The switch first compares ARP packets to user-configured ARP ACLs. If the ARP ACL denies the ARP packet, the switch also denies the packet even if a valid binding exists in the database populated by DHCP snooping.

Configuring ARP ACLs for Non-DHCP Environments

This procedure shows how to configure dynamic ARP inspection when Switch B shown in Figure 2 does not support dynamic ARP inspection or DHCP snooping.

If you configure port 1 on Switch A as trusted, a security hole is created because both Switch A and Host 1 could be attacked by either Switch B or Host 2. To prevent this possibility, you must configure port 1 on Switch A as untrusted. To permit ARP packets from Host 2, you must set up an ARP ACL and apply it to VLAN 1. If the IP address of Host 2 is not static (it is impossible to apply the ACL configuration on Switch A) you must separate Switch A from Switch B at Layer 3 and use a router to route packets between them.

Follow these steps to configure an ARP ACL on Switch A. This procedure is required in non-DHCP environments.

SUMMARY STEPS

1. enable
2. configure terminal
3. arp access-list acl-name
4. permit ip host sender-ip mac host sender-mac
5. exit
6. ip arp inspection filter arp-acl-name vlan vlan-range [static]
7. interface interface-id
8. no ip arp inspection trust
9. end
10. Use the following show commands:

Configuring Dynamic ARP Inspection in DHCP Environments

Before you begin

This procedure shows how to configure dynamic ARP inspection when two switches support this feature. Host 1 is connected to Switch A, and Host 2 is connected to Switch B. Both switches are running dynamic ARP inspection on VLAN 1 where the hosts are located. A DHCP server is connected to Switch A. Both hosts acquire their IP addresses from the same DHCP server. Therefore, Switch A has the bindings for Host 1 and Host 2, and Switch B has the binding for Host 2.

Note

Dynamic ARP inspection depends on the entries in the DHCP snooping binding database to verify IP-to-MAC address bindings in incoming ARP requests and ARP responses. Make sure to enable DHCP snooping to permit ARP packets that have dynamically assigned IP addresses.

Follow these steps to configure dynamic ARP inspection. You must perform this procedure on both switches. This procedure is required.

SUMMARY STEPS

1. enable
2. show cdp neighbors
3. configure terminal
4. ip arp inspection vlan vlan-range
5. Interface interface-id
6. ip arp inspection trust
7. end
8. show ip arp inspection interfaces
9. show ip arp inspection vlan vlan-range
10. show ip dhcp snooping binding
11. show ip arp inspection statistics vlan vlan-range
12. configure terminal
13. configure terminal

Limiting the Rate of Incoming ARP Packets

The switch CPU performs dynamic ARP inspection validation checks; therefore, the number of incoming ARP packets is rate-limited to prevent a denial-of-service attack.

When the rate of incoming ARP packets exceeds the configured limit, the switch places the port in the error-disabled state. The port remains in that state until you enable error-disabled recovery so that ports automatically emerge from this state after a specified timeout period.

Note

Unless you configure a rate limit on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state. After you configure the rate limit, the interface retains the rate limit even when its trust state is changed. If you enter the no ip arp inspection limit interface configuration command, the interface reverts to its default rate limit.

Follow these steps to limit the rate of incoming ARP packets. This procedure is optional.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. ip arp inspection limit {rate pps [burst interval seconds] | none}
5. exit
6. Use the following commands:
   - errdisable detect cause arp-inspection
Limiting the Rate of Incoming ARP Packets

- errdisable recovery cause arp-inspection
- errdisable recovery interval *interval*

7. exit
8. Use the following show commands:
   - show ip arp inspection interfaces
   - show errdisable recovery
9. show running-config
10. copy running-config startup-config

**DETAILED STEPS**

<table>

### Performing Dynamic ARP Inspection Validation Checks

Dynamic ARP inspection intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. You can configure the switch to perform additional checks on the destination MAC address, the sender and target IP addresses, and the source MAC address.

Follow these steps to perform specific checks on incoming ARP packets. This procedure is optional.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ip arp inspection validate \{[src-mac] [dst-mac] [ip]\}
4. exit
5. show ip arp inspection vlan vlan-range
6. show running-config
7. copy running-config startup-config
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 3** ip arp inspection validate {[src-mac] [dst-mac] [ip]} | Performs a specific check on incoming ARP packets. By default, no checks are performed. The keywords have these meanings:  
  • For **src-mac**, check the source MAC address in the Ethernet header against the sender MAC address in the ARP body. This check is performed on both ARP requests and responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped.  
  • For **dst-mac**, check the destination MAC address in the Ethernet header against the target MAC address in ARP body. This check is performed for ARP responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped.  
  • For **ip**, check the ARP body for invalid and unexpected IP addresses. Addresses include 0.0.0.0, 255.255.255.255, and all IP multicast addresses. Sender IP addresses are checked in all ARP requests and responses, and target IP addresses are checked only in ARP responses.  
  You must specify at least one of the keywords. Each command overrides the configuration of the previous command; that is, if a command enables src and dst mac validations, and a second command enables IP validation only, the src and dst mac validations are disabled as a result of the second command. |
| **Step 4** exit            | Returns to privileged EXEC mode.                                        |
| **Step 5** show ip arp inspection vlan vlan-range | Verifies your settings.                                                  |
| **Step 6** show running-config | Verifies your entries.                                                  |
| **Example:**               |                                                                         |
### Monitoring DAI

To monitor DAI, use the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ip arp inspection statistics</td>
<td>Clears dynamic ARP inspection statistics.</td>
</tr>
<tr>
<td>show ip arp inspection statistics [vlan vlan-range]</td>
<td>Displays statistics for forwarded, dropped, MAC validation failure, IP validation failure, ACL permitted and denied, and DHCP permitted and denied packets for the specified VLAN. If no VLANs are specified or if a range is specified, displays information only for VLANs with dynamic ARP inspection enabled (active).</td>
</tr>
<tr>
<td>clear ip arp inspection log</td>
<td>Clears the dynamic ARP inspection log buffer.</td>
</tr>
<tr>
<td>show ip arp inspection log</td>
<td>Displays the configuration and contents of the dynamic ARP inspection log buffer.</td>
</tr>
</tbody>
</table>

For the `show ip arp inspection statistics` command, the switch increments the number of forwarded packets for each ARP request and response packet on a trusted dynamic ARP inspection port. The switch increments the number of ACL or DHCP permitted packets for each packet that is denied by source MAC, destination MAC, or IP validation checks, and the switch increments the appropriate.

### Verifying the DAI Configuration

To display and verify the DAI configuration, use the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show arp access-list [acl-name]</td>
<td>Displays detailed information about ARP ACLs.</td>
</tr>
<tr>
<td>show ip arp inspection interfaces [interface-id]</td>
<td>Displays the trust state and the rate limit of ARP packets for the specified interface or all interfaces.</td>
</tr>
</tbody>
</table>
### Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip arp inspection vlan vlan-range</code></td>
<td>Displays the configuration and the operating state of dynamic ARP inspection for the specified VLAN. If no VLANs are specified or if a range is specified, displays information only for VLANs with dynamic ARP inspection enabled (active).</td>
</tr>
</tbody>
</table>

CHAPTER 88

Configuring IEEE 802.1x Port-Based Authentication

This chapter describes how to configure IEEE 802.1x port-based authentication. IEEE 802.1x authentication prevents unauthorized devices (clients) from gaining access to the network. Unless otherwise noted, the term switch refers to a standalone switch or a switch stack.

• Finding Feature Information, on page 1725
• Information About 802.1x Port-Based Authentication, on page 1725
• How to Configure 802.1x Port-Based Authentication, on page 1756
• Monitoring 802.1x Statistics and Status, on page 1805
• Additional References, on page 1806

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About 802.1x Port-Based Authentication

The 802.1x standard defines a client-server-based access control and authentication protocol that prevents unauthorized clients from connecting to a LAN through publicly accessible ports unless they are properly authenticated. The authentication server authenticates each client connected to a switch port before making available any services offered by the switch or the LAN.

Note

TACACS is not supported with 802.1x authentication.
Until the client is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL), Cisco Discovery Protocol (CDP), and Spanning Tree Protocol (STP) traffic through the port to which the client is connected. After authentication is successful, normal traffic can pass through the port.

To view debug logs for RADIUS and AAA, use the `show platform software trace message smd` command. For more information, see the Trace Commands section in Command Reference Guide, Cisco IOS XE Denali 16.1.1

### Port-Based Authentication Process

To configure IEEE 802.1X port-based authentication, you must enable authentication, authorization, and accounting (AAA) and specify the authentication method list. A method list describes the sequence and authentication method to be queried to authenticate a user.

The AAA process begins with authentication. When 802.1x port-based authentication is enabled and the client supports 802.1x-compliant client software, these events occur:

- If the client identity is valid and the 802.1x authentication succeeds, the switch grants the client access to the network.

- If 802.1x authentication times out while waiting for an EAPOL message exchange and MAC authentication bypass is enabled, the switch can use the client MAC address for authorization. If the client MAC address is valid and the authorization succeeds, the switch grants the client access to the network. If the client MAC address is invalid and the authorization fails, the switch assigns the client to a guest VLAN that provides limited services if a guest VLAN is configured.

- If the switch gets an invalid identity from an 802.1x-capable client and a restricted VLAN is specified, the switch can assign the client to a restricted VLAN that provides limited services.

- If the RADIUS authentication server is unavailable (down) and inaccessible authentication bypass is enabled, the switch grants the client access to the network by putting the port in the critical-authentication state in the RADIUS-configured or the user-specified access VLAN.

Inaccessible authentication bypass is also referred to as critical authentication or the AAA fail policy.

If Multi Domain Authentication (MDA) is enabled on a port, this flow can be used with some exceptions that are applicable to voice authorization.
The switch re-authenticates a client when one of these situations occurs:

- Periodic re-authentication is enabled, and the re-authentication timer expires.

You can configure the re-authentication timer to use a switch-specific value or to be based on values from the RADIUS server.

After 802.1x authentication using a RADIUS server is configured, the switch uses timers based on the Session-Timeout RADIUS attribute (Attribute[27]) and the Termination-Action RADIUS attribute (Attribute [29]).

The Session-Timeout RADIUS attribute (Attribute[27]) specifies the time after which re-authentication occurs.

The Termination-Action RADIUS attribute (Attribute [29]) specifies the action to take during re-authentication. The actions are Initialize and ReAuthenticate. When the Initialize action is set (the attribute value is DEFAULT), the 802.1x session ends, and connectivity is lost during re-authentication. When the ReAuthenticate action is set (the attribute value is RADIUS-Request), the session is not affected during re-authentication.

- You manually re-authenticate the client by entering the **dot1x re-authenticate interface interface-id** privileged EXEC command.
Port-Based Authentication Initiation and Message Exchange

During 802.1x authentication, the switch or the client can initiate authentication. If you enable authentication on a port by using the `authentication port-control auto` interface configuration command, the switch initiates authentication when the link state changes from down to up or periodically as long as the port remains up and unauthenticated. The switch sends an EAP-request/identity frame to the client to request its identity. Upon receipt of the frame, the client responds with an EAP-response/identity frame.

However, if during bootup, the client does not receive an EAP-request/identity frame from the switch, the client can initiate authentication by sending an EAPOL-start frame, which prompts the switch to request the client's identity.

Note

If 802.1x authentication is not enabled or supported on the network access device, any EAPOL frames from the client are dropped. If the client does not receive an EAP-request/identity frame after three attempts to start authentication, the client sends frames as if the port is in the authorized state. A port in the authorized state effectively means that the client has been successfully authenticated.

When the client supplies its identity, the switch begins its role as the intermediary, passing EAP frames between the client and the authentication server until authentication succeeds or fails. If the authentication succeeds, the switch port becomes authorized. If the authentication fails, authentication can be retried, the port might be assigned to a VLAN that provides limited services, or network access is not granted.

The specific exchange of EAP frames depends on the authentication method being used.

Figure 108: Message Exchange

This figure shows a message exchange initiated by the client when the client uses the One-Time-Password (OTP) authentication method with a RADIUS server.

If 802.1x authentication times out while waiting for an EAPOL message exchange and MAC authentication bypass is enabled, the switch can authorize the client when the switch detects an Ethernet packet from the...
The switch uses the MAC address of the client as its identity and includes this information in the RADIUS-access/request frame that is sent to the RADIUS server. After the server sends the switch the RADIUS-access/accept frame (authorization is successful), the port becomes authorized. If authorization fails and a guest VLAN is specified, the switch assigns the port to the guest VLAN. If the switch detects an EAPOL packet while waiting for an Ethernet packet, the switch stops the MAC authentication bypass process and starts 802.1x authentication.

**Figure 109: Message Exchange During MAC Authentication Bypass**

This figure shows the message exchange during MAC authentication.

16 Supported in Cisco IOS Release 12.2(50)SE and later.
17 For clients that do not support 802.1x authentication.

---

**Per-User ACLs and Filter-Ids**

**Note**

You can only set `any` as the source in the ACL.

---

**Note**

For any ACL configured for multiple-host mode, the source portion of statement must be `any`. (For example, `permit icmp any host 10.10.1.1`.)

You must specify `any` in the source ports of any defined ACL. Otherwise, the ACL cannot be applied and authorization fails. Single host is the only exception to support backward compatibility.

More than one host can be authenticated on MDA-enabled and multi-auth ports. The ACL policy applied for one host does not effect the traffic of another host. If only one host is authenticated on a multi-host port, and the other hosts gain network access without authentication, the ACL policy for the first host can be applied to the other connected hosts by specifying any in the source address.
Port-Based Authentication Manager CLI Commands

The authentication-manager interface-configuration commands control all the authentication methods, such as 802.1x, MAC authentication bypass, and web authentication. The authentication manager commands determine the priority and order of authentication methods applied to a connected host.

The authentication manager commands control generic authentication features, such as host-mode, violation mode, and the authentication timer. Generic authentication commands include the authentication host-mode, authentication violation, and authentication timer interface configuration commands.

802.1x-specific commands begin with the dot1x keyword. For example, the authentication port-control auto interface configuration command enables authentication on an interface. However, the dot1x system-authentication control global configuration command only globally enables or disables 802.1x authentication.

Note

If 802.1x authentication is globally disabled, other authentication methods are still enabled on that port, such as web authentication.

The authentication manager commands provide the same functionality as earlier 802.1x commands.

When filtering out verbose system messages generated by the authentication manager, the filtered content typically relates to authentication success. You can also filter verbose messages for 802.1x authentication and MAB authentication. There is a separate command for each authentication method:

- The no authentication logging verbose global configuration command filters verbose messages from the authentication manager.
- The no dot1x logging verbose global configuration command filters 802.1x authentication verbose messages.
- The no mab logging verbose global configuration command filters MAC authentication bypass (MAB) verbose messages

Table 141: Authentication Manager Commands and Earlier 802.1x Commands

Specify an active VLAN as an 802.1x guest VLAN. |
The authentication manager commands in Cisco IOS Release 12.2(50)SE or later | The equivalent 802.1x commands in Cisco IOS Release 12.2(46)SE and earlier | Description
---|---|---
authentication fallback fallback-profile | dot1x fallback fallback-profile | Configure a port to use web authentication as a fallback method for clients that do not support 802.1x authentication.
authentication host-mode [multi-auth | multi-domain | multi-host | single-host] | dot1x host-mode [single-host | multi-host | multi-domain] | Allow a single host (client) or multiple hosts on an 802.1x-authorized port.
authentication order mab | mab | Provides the flexibility to define the order of authentication methods to be used.
authentication periodic dot1x reauthentication | dot1x reauthentication | Enable periodic re-authentication of the client.
authentication timer dot1x timeout | dot1x timeout | Set the 802.1x timers.
authentication violation [protect | restrict | shutdown] | dot1x violation-mode [shutdown | restrict | protect] | Configure the violation modes that occur when a new device connects to a port or when a new device connects to a port after the maximum number of devices are connected to that port.

### Ports in Authorized and Unauthorized States

During 802.1x authentication, depending on the switch port state, the switch can grant a client access to the network. The port starts in the unauthorized state. While in this state, the port that is not configured as a voice VLAN port disallows all ingress and egress traffic except for 802.1x authentication, CDP, and STP packets. When a client is successfully authenticated, the port changes to the authorized state, allowing all traffic for the client to flow normally. If the port is configured as a voice VLAN port, the port allows VoIP traffic and 802.1x protocol packets before the client is successfully authenticated.

**Note**

CDP bypass is not supported and may cause a port to go into err-disabled state.

If a client that does not support 802.1x authentication connects to an unauthorized 802.1x port, the switch requests the client’s identity. In this situation, the client does not respond to the request, the port remains in the unauthorized state, and the client is not granted access to the network.

In contrast, when an 802.1x-enabled client connects to a port that is not running the 802.1x standard, the client initiates the authentication process by sending the EAPOL-start frame. When no response is received, the
clientsendstherequestforafixednumberoftimes. Because no response is received, the client begins sending frames as if the port is in the authorized state.

You control the port authorization state by using the `authentication port-control` interface configuration command and these keywords:

- **force-authorized**—disables 802.1x authentication and causes the port to change to the authorized state without any authentication exchange required. The port sends and receives normal traffic without 802.1x-based authentication of the client. This is the default setting.

- **force-unauthorized**—causes the port to remain in the unauthorized state, ignoring all attempts by the client to authenticate. The switch cannot provide authentication services to the client through the port.

- **auto**—enables 802.1x authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the port. The authentication process begins when the link state of the port changes from down to up or when an EAPOL-start frame is received. The switch requests the identity of the client and begins relaying authentication messages between the client and the authentication server. Each client attempting to access the network is uniquely identified by the switch by using the client MAC address.

If the client is successfully authenticated (receives an Accept frame from the authentication server), the port state changes to authorized, and all frames from the authenticated client are allowed through the port. If the authentication fails, the port remains in the unauthorized state, but authentication can be retried. If the authentication server cannot be reached, the switch can resend the request. If no response is received from the server after the specified number of attempts, authentication fails, and network access is not granted.

When a client logs off, it sends an EAPOL-logoff message, causing the switch port to change to the unauthorized state.

If the link state of a port changes from up to down, or if an EAPOL-logoff frame is received, the port returns to the unauthorized state.

### Port-Based Authentication and Switch Stacks

If a switch is added to or removed from a switch stack, 802.1x authentication is not affected as long as the IP connectivity between the RADIUS server and the stack remains intact. This statement also applies if the stack master is removed from the switch stack. Note that if the stack master fails, a stack member becomes the new stack master by using the election process, and the 802.1x authentication process continues as usual.

If IP connectivity to the RADIUS server is interrupted because the switch that was connected to the server is removed or fails, these events occur:

- Ports that are already authenticated and that do not have periodic re-authentication enabled remain in the authenticated state. Communication with the RADIUS server is not required.

- Ports that are already authenticated and that have periodic re-authentication enabled (with the `dot1x re-authentication` global configuration command) fail the authentication process when the re-authentication occurs. Ports return to the unauthenticated state during the re-authentication process. Communication with the RADIUS server is required.

  For an ongoing authentication, the authentication fails immediately because there is no server connectivity.

If the switch that failed comes up and rejoins the switch stack, the authentications might or might not fail depending on the boot-up time and whether the connectivity to the RADIUS server is re-established by the time the authentication is attempted.
To avoid loss of connectivity to the RADIUS server, you should ensure that there is a redundant connection to it. For example, you can have a redundant connection to the stack master and another to a stack member, and if the stack master fails, the switch stack still has connectivity to the RADIUS server.

### 802.1x Host Mode

You can configure an 802.1x port for single-host or for multiple-hosts mode. In single-host mode, only one client can be connected to the 802.1x-enabled switch port. The switch detects the client by sending an EAPOL frame when the port link state changes to the up state. If a client leaves or is replaced with another client, the switch changes the port link state to down, and the port returns to the unauthorized state.

In multiple-hosts mode, you can attach multiple hosts to a single 802.1x-enabled port. In this mode, only one of the attached clients must be authorized for all clients to be granted network access. If the port becomes unauthorized (re-authentication fails or an EAPOL-logoff message is received), the switch denies network access to all of the attached clients. In this topology, the wireless access point is responsible for authenticating the clients attached to it, and it also acts as a client to the switch.

![Figure 110: Multiple Host Mode Example](image)

---

**Note**

For all host modes, the line protocol stays up before authorization when port-based authentication is configured.

The switch supports multidomain authentication (MDA), which allows both a data device and a voice device, such as an IP Phone (Cisco or non-Cisco), to connect to the same switch port.

### 802.1x Multiple Authentication Mode

Multiple-authentication (multiauth) mode allows multiple authenticated clients on the data VLAN and voice VLAN. Each host is individually authenticated. There is no limit to the number of data or voice device that can be authenticated on a multiauth port.

If a hub or access point is connected to an 802.1x-enabled port, each connected client must be authenticated. For non-802.1x devices, you can use MAC authentication bypass or web authentication as the per-host authentication fallback method to authenticate different hosts with different methods on a single port.

---

**Note**

When a port is in multiple-authentication mode, the authentication-failed VLAN features do not activate.

You can assign a RADIUS-server-supplied VLAN in multi-auth mode, under the following conditions:

- The host is the first host authorized on the port, and the RADIUS server supplies VLAN information
- Subsequent hosts are authorized with a VLAN that matches the operational VLAN.
• A host is authorized on the port with no VLAN assignment, and subsequent hosts either have no VLAN assignment, or their VLAN information matches the operational VLAN.

• The first host authorized on the port has a group VLAN assignment, and subsequent hosts either have no VLAN assignment, or their group VLAN matches the group VLAN on the port. Subsequent hosts must use the same VLAN from the VLAN group as the first host. If a VLAN list is used, all hosts are subject to the conditions specified in the VLAN list.

• After a VLAN is assigned to a host on the port, subsequent hosts must have matching VLAN information or be denied access to the port.

• You cannot configure a guest VLAN or an auth-fail VLAN in multi-auth mode.

• The behavior of the critical-auth VLAN is not changed for multi-auth mode. When a host tries to authenticate and the server is not reachable, all authorized hosts are reinitialized in the configured VLAN.

Multi-auth Per User VLAN assignment

The Multi-auth Per User VLAN assignment feature allows you to create multiple operational access VLANs based on VLANs assigned to the clients on the port that has a single configured access VLAN. The port configured as an access port where the traffic for all the VLANs associated with data domain is not dot1q tagged, and these VLANs are treated as native VLANs.

The number of hosts per multi-auth port is 8, however there can be more hosts.

The following scenarios are associated with the multi-auth Per User VLAN assignments:

Scenario one

When a hub is connected to an access port, and the port is configured with an access VLAN (V0).

The host (H1) is assigned to VLAN (V1) through the hub. The operational VLAN of the port is changed to V1. This behaviour is similar on a single-host or multi-domain-auth port.

When a second host (H2) is connected and gets assigned to VLAN (V2), the port will have two operational VLANs (V1 and V2). If H1 and H2 sends untagged ingress traffic, H1 traffic is mapped to VLAN (V1) and H2 traffic to VLAN (V2), all egress traffic going out of the port on VLAN (V1) and VLAN (V2) are untagged.

If both the hosts, H1 and H2 are logged out or the sessions are removed due to some reason then VLAN (V1) and VLAN (V2) are removed from the port, and the configured VLAN (V0) is restored on the port.

Scenario two

When a hub is connected to an access port, and the port is configured with an access VLAN (V0). The host (H1) is assigned to VLAN (V1) through the hub. The operational VLAN of the port is changed to V1.

When a second host (H2) is connected and gets authorized without explicit vlan policy, H2 is expected to use the configured VLAN (V0) that is restored on the port. All egress traffic going out of two operational VLANs, VLAN (V0) and VLAN (V1) are untagged.

If host (H2) is logged out or the session is removed due to some reason then the configured VLAN (V0) is removed from the port, and VLAN (V1) becomes the only operational VLAN on the port.

Scenario three

When a hub is connected to an access port in open mode, and the port is configured with an access VLAN (V0).
The host (H1) is assigned to VLAN (V1) through the hub. The operational VLAN of the port is changed to V1. When a second host (H2) is connected and remains unauthorized, it still has access to operational VLAN (V1) due to open mode.

If host H1 is logged out or the session is removed due to some reason, VLAN (V1) is removed from the port and host (H2) gets assigned to VLAN (V0).

**Note**
The combination of Open mode and VLAN assignment has an adverse affect on host (H2) because it has an IP address in the subnet that corresponds to VLAN (V1).

**Limitation in Multi-auth Per User VLAN assignment**

In the Multi-auth Per User VLAN assignment feature, egress traffic from multiple vlans are untagged on a port where the hosts receive traffic that is not meant for them. This can be a problem with broadcast and multicast traffic.

- **IPv4 ARPs**: Hosts receive ARP packets from other subnets. This is a problem if two subnets in different Virtual Routing and Forwarding (VRF) tables with overlapping IP address range are active on the port. The host ARP cache may get invalid entries.

- **IPv6 control packets**: In IPv6 deployments, Router Advertisements (RA) are processed by hosts that are not supposed to receive them. When a host from one VLAN receives RA from a different VLAN, the host assign incorrect IPv6 address to itself. Such a host is unable to get access to the network.

  The workaround is to enable the IPv6 first hop security so that the broadcast ICMPv6 packets are converted to unicast and sent out from multi-auth enabled ports. The packet is replicated for each client in multi-auth port belonging to the VLAN and the destination MAC is set to an individual client. Ports having one VLAN, ICMPv6 packets broadcast normally.

- **IP multicast**: Multicast traffic destined to a multicast group gets replicated for different VLANs if the hosts on those VLANs join the multicast group. When two hosts in different VLANs join a multicast group (on the same multi-auth port), two copies of each multicast packet are sent out from that port.

**MAC Move**

When a MAC address is authenticated on one switch port, that address is not allowed on another authentication manager-enabled port of the switch. If the switch detects that same MAC address on another authentication manager-enabled port, the address is not allowed.

There are situations where a MAC address might need to move from one port to another on the same switch. For example, when there is another device (for example a hub or an IP phone) between an authenticated host and a switch port, you might want to disconnect the host from the device and connect it directly to another port on the same switch.

You can globally enable MAC move so the device is reauthenticated on the new port. When a host moves to a second port, the session on the first port is deleted, and the host is reauthenticated on the new port. MAC move is supported on all host modes. (The authenticated host can move to any port on the switch, no matter which host mode is enabled on the that port.) When a MAC address moves from one port to another, the switch terminates the authenticated session on the original port and initiates a new authentication sequence on the new port. The MAC move feature applies to both voice and data hosts.
In open authentication mode, a MAC address is immediately moved from the original port to the new port, with no requirement for authorization on the new port.

**MAC Replace**

The MAC replace feature can be configured to address the violation that occurs when a host attempts to connect to a port where another host was previously authenticated.

This feature does not apply to ports in multi-auth mode, because violations are not triggered in that mode. It does not apply to ports in multiple host mode, because in that mode, only the first host requires authentication.

If you configure the `authentication violation` interface configuration command with the `replace` keyword, the authentication process on a port in multi-domain mode is:

- A new MAC address is received on a port with an existing authenticated MAC address.
- The authentication manager replaces the MAC address of the current data host on the port with the new MAC address.
- The authentication manager initiates the authentication process for the new MAC address.
- If the authentication manager determines that the new host is a voice host, the original voice host is removed.

If a port is in open authentication mode, any new MAC address is immediately added to the MAC address table.

**802.1x Accounting**

The 802.1x standard defines how users are authorized and authenticated for network access but does not keep track of network usage. 802.1x accounting is disabled by default. You can enable 802.1x accounting to monitor this activity on 802.1x-enabled ports:

- User successfully authenticates.
- User logs off.
- Link-down occurs.
- Re-authentication successfully occurs.
- Re-authentication fails.

The switch does not log 802.1x accounting information. Instead, it sends this information to the RADIUS server, which must be configured to log accounting messages.
802.1x Accounting Attribute-Value Pairs

The information sent to the RADIUS server is represented in the form of Attribute-Value (AV) pairs. These AV pairs provide data for different applications. (For example, a billing application might require information that is in the Acct-Input-Octets or the Acct-Output-Octets attributes of a RADIUS packet.)

AV pairs are automatically sent by a switch that is configured for 802.1x accounting. Three types of RADIUS accounting packets are sent by a switch:

- **START**—sent when a new user session starts
- **INTERIM**—sent during an existing session for updates
- **STOP**—sent when a session terminates

Note

To view debug logs for RADIUS and AAA, use the `show platform software trace message smd` command. For more information, see the Tracing Commands section in Command Reference Guide, Cisco IOS XE Denali 16.1.1.

This table lists the AV pairs and when they are sent are sent by the switch.

**Table 142: Accounting AV Pairs**

<table>

</tbody>
</table>
The Framed-IP-Address AV pair is sent when a valid static IP address is configured or when a Dynamic Host Control Protocol (DHCP) binding exists for the host in the DHCP snooping bindings table.

### 802.1x Readiness Check

The 802.1x readiness check monitors 802.1x activity on all the switch ports and displays information about the devices connected to the ports that support 802.1x. You can use this feature to determine if the devices connected to the switch ports are 802.1x-capable. You use an alternate authentication such as MAC authentication bypass or web authentication for the devices that do not support 802.1x functionality.

This feature only works if the supplicant on the client supports a query with the NOTIFY EAP notification packet. The client must respond within the 802.1x timeout value.

### Switch-to-RADIUS-Server Communication

RADIUS security servers are identified by their hostname or IP address, hostname and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, which enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authentication—the second host entry configured acts as the fail-over backup to the first one. The RADIUS host entries are tried in the order that they were configured.

### 802.1x Authentication with VLAN Assignment

The switch supports 802.1x authentication with VLAN assignment. After successful 802.1x authentication of a port, the RADIUS server sends the VLAN assignment to configure the switch port. The RADIUS server database maintains the username-to-VLAN mappings, assigning the VLAN based on the username of the client connected to the switch port. You can use this feature to limit network access for certain users.

Voice device authentication is supported with multidomain host mode in Cisco IOS Release 12.2(37)SE. In Cisco IOS Release 12.2(40)SE and later, when a voice device is authorized and the RADIUS server returned an authorized VLAN, the voice VLAN on the port is configured to send and receive packets on the assigned voice VLAN. Voice VLAN assignment behaves the same as data VLAN assignment on multidomain authentication (MDA)-enabled ports.

When configured on the switch and the RADIUS server, 802.1x authentication with VLAN assignment has these characteristics:
• If no VLAN is supplied by the RADIUS server or if 802.1x authentication is disabled, the port is configured in its access VLAN after successful authentication. Recall that an access VLAN is a VLAN assigned to an access port. All packets sent from or received on this port belong to this VLAN.

• If 802.1x authentication is enabled but the VLAN information from the RADIUS server is not valid, authorization fails and configured VLAN remains in use. This prevents ports from appearing unexpectedly in an inappropriate VLAN because of a configuration error.

Configuration errors could include specifying a VLAN for a routed port, a malformed VLAN ID, a nonexistent or internal (routed port) VLAN ID, an RSPAN VLAN, a shut down or suspended VLAN. In the case of a multidomain host port, configuration errors can also be due to an attempted assignment of a data VLAN that matches the configured or assigned voice VLAN ID (or the reverse).

• If 802.1x authentication is enabled and all information from the RADIUS server is valid, the authorized device is placed in the specified VLAN after authentication.

• If the multiple-hosts mode is enabled on an 802.1x port, all hosts are placed in the same VLAN (specified by the RADIUS server) as the first authenticated host.

• Enabling port security does not impact the RADIUS server-assigned VLAN behavior.

• If 802.1x authentication is disabled on the port, it is returned to the configured access VLAN and configured voice VLAN.

• If an 802.1x port is authenticated and put in the RADIUS server-assigned VLAN, any change to the port access VLAN configuration does not take effect. In the case of a multidomain host, the same applies to voice devices when the port is fully authorized with these exceptions:
  • If the VLAN configuration change of one device results in matching the other device configured or assigned VLAN, then authorization of all devices on the port is terminated and multidomain host mode is disabled until a valid configuration is restored where data and voice device configured VLANs no longer match.
  • If a voice device is authorized and is using a downloaded voice VLAN, the removal of the voice VLAN configuration, or modifying the configuration value to dot1p or untagged results in voice device un-authorization and the disablement of multi-domain host mode.

When the port is in the force authorized, force unauthorized, unauthorized, or shutdown state, it is put into the configured access VLAN.

If an 802.1x port is authenticated and put in the RADIUS server-assigned VLAN, any change to the port access VLAN configuration does not take effect. In the case of a multidomain host, the same applies to voice devices when the port is fully authorized with these exceptions:

• If the VLAN configuration change of one device results in matching the other device configured or assigned VLAN, authorization of all devices on the port is terminated and multidomain host mode is disabled until a valid configuration is restored where data and voice device configured VLANs no longer match.

• If a voice device is authorized and is using a downloaded voice VLAN, the removal of the voice VLAN configuration, or modifying the configuration value to dot1p or untagged results in voice device un-authorization and the disablement of multi-domain host mode.

When the port is in the force authorized, force unauthorized, unauthorized, or shutdown state, it is put into the configured access VLAN.
To configure VLAN assignment you need to perform these tasks:

- Enable AAA authorization by using the **network** keyword to allow interface configuration from the RADIUS server.
- Enable 802.1x authentication. (The VLAN assignment feature is automatically enabled when you configure 802.1x authentication on an access port).
- Assign vendor-specific tunnel attributes in the RADIUS server. The RADIUS server must return these attributes to the switch:
  - [64] Tunnel-Type = VLAN
  - [65] Tunnel-Medium-Type = 802
  - [81] Tunnel-Private-Group-ID = VLAN name or VLAN ID
  - [83] Tunnel-Preference

Attribute [64] must contain the value **VLAN** (type 13). Attribute [65] must contain the value **802** (type 6). Attribute [81] specifies the **VLAN name or VLAN ID** assigned to the IEEE 802.1x-authenticated user.

### 802.1x Authentication with Per-User ACLs

You can enable per-user access control lists (ACLs) to provide different levels of network access and service to an 802.1x-authenticated user. When the RADIUS server authenticates a user connected to an 802.1x port, it retrieves the ACL attributes based on the user identity and sends them to the switch. The switch applies the attributes to the 802.1x port for the duration of the user session. The switch removes the per-user ACL configuration when the session is over, if authentication fails, or if a link-down condition occurs. The switch does not save RADIUS-specified ACLs in the running configuration. When the port is unauthorized, the switch removes the ACL from the port.

You can configure router ACLs and input port ACLs on the same switch. However, a port ACL takes precedence over a router ACL. If you apply input port ACL to an interface that belongs to a VLAN, the port ACL takes precedence over an input router ACL applied to the VLAN interface. Incoming packets received on the port to which a port ACL is applied are filtered by the port ACL. Incoming routed packets received on other ports are filtered by the router ACL. Outgoing routed packets are filtered by the router ACL. To avoid configuration conflicts, you should carefully plan the user profiles stored on the RADIUS server.

RADIUS supports per-user attributes, including vendor-specific attributes. These vendor-specific attributes (VSAs) are in octet-string format and are passed to the switch during the authentication process. The VSAs used for per-user ACLs are inacls#<n> for the ingress direction and outacls#<n> for the egress direction. MAC ACLs are supported only in the ingress direction. The switch supports VSAs only in the ingress direction. It does not support port ACLs in the egress direction on Layer 2 ports.

Use only the extended ACL syntax style to define the per-user configuration stored on the RADIUS server. When the definitions are passed from the RADIUS server, they are created by using the extended naming convention. However, if you use the Filter-Id attribute, it can point to a standard ACL.

You can use the Filter-Id attribute to specify an inbound or outbound ACL that is already configured on the switch. The attribute contains the ACL number followed by .in for ingress filtering or .out for egress filtering. If the RADIUS server does not allow the .in or .out syntax, the access list is applied to the outbound ACL by default. Because of limited support of Cisco IOS access lists on the switch, the Filter-Id attribute is supported only for IP ACLs numbered 1 to 199 and 1300 to 2699 (IP standard and IP extended ACLs).
The maximum size of the per-user ACL is 4000 ASCII characters but is limited by the maximum size of RADIUS-server per-user ACLs.

To configure per-user ACLs:

- Enable AAA authentication.
- Enable AAA authorization by using the network keyword to allow interface configuration from the RADIUS server.
- Enable 802.1x authentication.
- Configure the user profile and VSAs on the RADIUS server.
- Configure the 802.1x port for single-host mode.

**Note** Per-user ACLs are supported only in single-host mode.

### 802.1x Authentication with Downloadable ACLs and Redirect URLs

You can download ACLs and redirect URLs from a RADIUS server to the switch during 802.1x authentication or MAC authentication bypass of the host. You can also download ACLs during web authentication.

**Note** A downloadable ACL is also referred to as a dACL.

If more than one host is authenticated and the host is in single-host, MDA, or multiple-authentication mode, the switch changes the source address of the ACL to the host IP address.

You can apply the ACLs and redirect URLs to all the devices connected to the 802.1x-enabled port.

If no ACLs are downloaded during 802.1x authentication, the switch applies the static default ACL on the port to the host. On a voice VLAN port configured in multi-auth or MDA mode, the switch applies the ACL only to the phone as part of the authorization policies.

**Note** The limit for dACL with stacking is 64 ACEs per dACL per port. The limit without stacking is the number of available TCAM entries which varies based on the other ACL features that are active.

Beginning with Cisco IOS Release 12.2(55)SE, if there is no static ACL on a port, a dynamic auth-default ACL is created, and policies are enforced before dACLs are downloaded and applied.

**Note** The auth-default-ACL does not appear in the running configuration.

The auth-default ACL is created when at least one host with an authorization policy is detected on the port. The auth-default ACL is removed from the port when the last authenticated session ends. You can configure the auth-default ACL by using the `ip access-list extended auth-default-acl` global configuration command.
The auth-default-ACL does not support Cisco Discovery Protocol (CDP) bypass in the single host mode. You must configure a static ACL on the interface to support CDP bypass.

The 802.1x and MAB authentication methods support two authentication modes, open and closed. If there is no static ACL on a port in closed authentication mode:

- An auth-default-ACL is created.
- The auth-default-ACL allows only DHCP traffic until policies are enforced.
- When the first host authenticates, the authorization policy is applied without IP address insertion.
- When a second host is detected, the policies for the first host are refreshed, and policies for the first and subsequent sessions are enforced with IP address insertion.

If there is no static ACL on a port in open authentication mode:

- An auth-default-ACL-OPEN is created and allows all traffic.
- Policies are enforced with IP address insertion to prevent security breaches.
- Web authentication is subject to the auth-default-ACL-OPEN.

To control access for hosts with no authorization policy, you can configure a directive. The supported values for the directive are open and default. When you configure the open directive, all traffic is allowed. The default directive subjects traffic to the access provided by the port. You can configure the directive either in the user profile on the AAA server or on the switch. To configure the directive on the AAA server, use the authz-directive =<open/default> global command. To configure the directive on the switch, use the epm access-control open global configuration command.

The default value of the directive is default.

If a host falls back to web authentication on a port without a configured ACL:

- If the port is in open authentication mode, the auth-default-ACL-OPEN is created.
- If the port is in closed authentication mode, the auth-default-ACL is created.

The access control entries (ACEs) in the fallback ACL are converted to per-user entries. If the configured fallback profile does not include a fallback ACL, the host is subject to the auth-default-ACL associated with the port.

If you use a custom logo with web authentication and it is stored on an external server, the port ACL must allow access to the external server before authentication. You must either configure a static port ACL or change the auth-default-ACL to provide appropriate access to the external server.

Cisco Secure ACS and Attribute-Value Pairs for the Redirect URL

The switch uses these cisco-av-pair VSAs:
• url-redirect is the HTTP or HTTPS URL.
• url-redirect-acl is the switch ACL name or number.

The switch uses the CiscoSecure-defined-ACL attribute value pair to intercept an HTTP or HTTPS request from the endpoint. The switch then forwards the client web browser to the specified redirect address. The url-redirect AV pair on the Cisco Secure ACS contains the URL to which the web browser is redirected. The url-redirect-acl attribute value pair contains the name or number of an ACL that specifies the HTTP or HTTPS traffic to redirect.

**Note**
- Traffic that matches a permit ACE in the ACL is redirected.
- An ACE that matches permit rule of the url-redirect-acl gets the client redirected to url-redirect page. The client traffic is allowed when a deny rule is matched.
- Define the URL redirect ACL and the default port ACL on the switch.

If a redirect URL is configured for a client on the authentication server, a default port ACL on the connected client switch port must also be configured.

When security ACL/dACL and punt/redirect ACLs are applied together to the session, the url-redirect-acl has the higher priority.

For more information about using redirect ACLs, refer the document [here](#).

### Cisco Secure ACS and Attribute-Value Pairs for Downloadable ACLs

You can set the CiscoSecure-Defined-ACL Attribute-Value (AV) pair on the Cisco Secure ACS with the RADIUS cisco-av-pair vendor-specific attributes (VSAs). This pair specifies the names of the downloadable ACLs on the Cisco Secure ACS with the #ACL##-IP-name-number attribute.

- The *name* is the ACL name.
- The *number* is the version number (for example, 3f783768).

If a downloadable ACL is configured for a client on the authentication server, a default port ACL on the connected client switch port must also be configured.

If the default ACL is configured on the switch and the Cisco Secure ACS sends a host-access-policy to the switch, it applies the policy to traffic from the host connected to a switch port. If the policy does not apply, the switch applies the default ACL. If the Cisco Secure ACS sends the switch a downloadable ACL, this ACL takes precedence over the default ACL that is configured on the switch port. However, if the switch receives an host access policy from the Cisco Secure ACS but the default ACL is not configured, the authorization failure is declared.

### VLAN ID-based MAC Authentication

You can use VLAN ID-based MAC authentication if you wish to authenticate hosts based on a static VLAN ID instead of a downloadable VLAN. When you have a static VLAN policy configured on your switch, VLAN information is sent to an IAS (Microsoft) RADIUS server along with the MAC address of each host for authentication. The VLAN ID configured on the connected port is used for MAC authentication. By using
VLAN ID-based MAC authentication with an IAS server, you can have a fixed number of VLANs in the network.

The feature also limits the number of VLANs monitored and handled by STP. The network can be managed as a fixed VLAN.

---

**Note**

This feature is not supported on Cisco ACS Server. (The ACS server ignores the sent VLAN-IDs for new hosts and only authenticates based on the MAC address.)

---

### 802.1x Authentication with Guest VLAN

You can configure a guest VLAN for each 802.1x port on the switch to provide limited services to clients, such as downloading the 802.1x client. These clients might be upgrading their system for 802.1x authentication, and some hosts, such as Windows 98 systems, might not be IEEE 802.1x-capable.

When you enable a guest VLAN on an 802.1x port, the switch assigns clients to a guest VLAN when the switch does not receive a response to its EAP request/identity frame or when EAPOL packets are not sent by the client.

The switch maintains the EAPOL packet history. If an EAPOL packet is detected on the interface during the lifetime of the link, the switch determines that the device connected to that interface is an IEEE 802.1x-capable supplicant, and the interface does not change to the guest VLAN state. EAPOL history is cleared if the interface link status goes down. If no EAPOL packet is detected on the interface, the interface changes to the guest VLAN state.

If the switch is trying to authorize an 802.1x-capable voice device and the AAA server is unavailable, the authorization attempt fails, but the detection of the EAPOL packet is saved in the EAPOL history. When the AAA server becomes available, the switch authorizes the voice device. However, the switch no longer allows other devices access to the guest VLAN. To prevent this situation, use one of these command sequences:

- Enter the `authentication event no-response action authorize vlan vlan-id` interface configuration command to allow access to the guest VLAN.

- Enter the `shutdown` interface configuration command followed by the `no shutdown` interface configuration command to restart the port.

If devices send EAPOL packets to the switch during the lifetime of the link, the switch no longer allows clients that fail authentication access to the guest VLAN.

---

**Note**

If an EAPOL packet is detected after the interface has changed to the guest VLAN, the interface reverts to an unauthorized state, and 802.1x authentication restarts.

Any number of 802.1x-incapable clients are allowed access when the switch port is moved to the guest VLAN. If an 802.1x-capable client joins the same port on which the guest VLAN is configured, the port is put into the unauthorized state in the user-configured access VLAN, and authentication is restarted.

Guest VLANs are supported on 802.1x ports in single host, multiple host, multi-auth and multi-domain modes.
You can configure any active VLAN except an RSPAN VLAN, a private VLAN, or a voice VLAN as an 802.1x guest VLAN. The guest VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

The switch supports MAC authentication bypass. When MAC authentication bypass is enabled on an 802.1x port, the switch can authorize clients based on the client MAC address when IEEE 802.1x authentication times out while waiting for an EAPOL message exchange. After detecting a client on an 802.1x port, the switch waits for an Ethernet packet from the client. The switch sends the authentication server a RADIUS-access/request frame with a username and password based on the MAC address. If authorization succeeds, the switch grants the client access to the network. If authorization fails, the switch assigns the port to the guest VLAN if one is specified.

### 802.1x Authentication with Restricted VLAN

You can configure a restricted VLAN (also referred to as an authentication failed VLAN) for each IEEE 802.1x port on a switch stack or a switch to provide limited services to clients that cannot access the guest VLAN. These clients are 802.1x-compliant and cannot access another VLAN because they fail the authentication process. A restricted VLAN allows users without valid credentials in an authentication server (typically, visitors to an enterprise) to access a limited set of services. The administrator can control the services available to the restricted VLAN.

**Note**

You can configure a VLAN to be both the guest VLAN and the restricted VLAN if you want to provide the same services to both types of users.

Without this feature, the client attempts and fails authentication indefinitely, and the switch port remains in the spanning-tree blocking state. With this feature, you can configure the switch port to be in the restricted VLAN after a specified number of authentication attempts (the default value is 3 attempts).

The authenticator counts the failed authentication attempts for the client. When this count exceeds the configured maximum number of authentication attempts, the port moves to the restricted VLAN. The failed attempt count increments when the RADIUS server replies with either an EAP failure or an empty response without an EAP packet. When the port moves into the restricted VLAN, the failed attempt counter resets.

Users who fail authentication remain in the restricted VLAN until the next re-authentication attempt. A port in the restricted VLAN tries to re-authenticate at configured intervals (the default is 60 seconds). If re-authentication fails, the port remains in the restricted VLAN. If re-authentication is successful, the port moves either to the configured VLAN or to a VLAN sent by the RADIUS server. You can disable re-authentication. If you do this, the only way to restart the authentication process is for the port to receive a link down or EAP logoff event. We recommend that you keep re-authentication enabled if a client might connect through a hub. When a client disconnects from the hub, the port might not receive the link down or EAP logoff event.

After a port moves to the restricted VLAN, a simulated EAP success message is sent to the client. This prevents clients from indefinitely attempting authentication. Some clients (for example, devices running Windows XP) cannot implement DHCP without EAP success.

Restricted VLANs are supported on 802.1x ports in all host modes and on Layer 2 ports.

You can configure any active VLAN except an RSPAN VLAN, a primary private VLAN, or a voice VLAN as an 802.1x restricted VLAN. The restricted VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.
Other security port features such as dynamic ARP Inspection, DHCP snooping, and IP source guard can be configured independently on a restricted VLAN.

802.1x Authentication with Inaccessible Authentication Bypass

Use the inaccessible authentication bypass feature, also referred to as critical authentication or the AAA fail policy, when the switch cannot reach the configured RADIUS servers and new hosts cannot be authenticated. You can configure the switch to connect those hosts to critical ports.

When a new host tries to connect to the critical port, that host is moved to a user-specified access VLAN, the critical VLAN. The administrator gives limited authentication to the hosts.

When the switch tries to authenticate a host connected to a critical port, the switch checks the status of the configured RADIUS server. If a server is available, the switch can authenticate the host. However, if all the RADIUS servers are unavailable, the switch grants network access to the host and puts the port in the critical-authentication state, which is a special case of the authentication state.

Inaccessible Authentication Bypass Support on Multiple-Authentication Ports

When a port is configured on any host mode and the AAA server is unavailable, the port is then configured to multi-host mode and moved to the critical VLAN. To support this inaccessible bypass on multiple-authentication (multi-auth) ports, use the authentication event server dead action reinitialize vlan vlan-id command. When a new host tries to connect to the critical port, that port is reinitialized and all the connected hosts are moved to the user-specified access VLAN.

This command is supported on all host modes.

Inaccessible Authentication Bypass Authentication Results

The behavior of the inaccessible authentication bypass feature depends on the authorization state of the port:

- If the port is unauthorized when a host connected to a critical port tries to authenticate and all servers are unavailable, the switch puts the port in the critical-authentication state in the RADIUS-configured or user-specified access VLAN.

- If the port is already authorized and reauthentication occurs, the switch puts the critical port in the critical-authentication state in the current VLAN, which might be the one previously assigned by the RADIUS server.

- If the RADIUS server becomes unavailable during an authentication exchange, the current exchange times out, and the switch puts the critical port in the critical-authentication state during the next authentication attempt.

You can configure the critical port to reinitialize hosts and move them out of the critical VLAN when the RADIUS server is again available. When this is configured, all critical ports in the critical-authentication state are automatically re-authenticated.

Inaccessible Authentication Bypass Feature Interactions

Inaccessible authentication bypass interacts with these features:

- Guest VLAN—Inaccessible authentication bypass is compatible with guest VLAN. When a guest VLAN is enabled on 8021.x port, the features interact as follows:
If at least one RADIUS server is available, the switch assigns a client to a guest VLAN when the switch does not receive a response to its EAP request/identity frame or when EAPOL packets are not sent by the client.

If all the RADIUS servers are not available and the client is connected to a critical port, the switch authenticates the client and puts the critical port in the critical-authentication state in the RADIUS-configured or user-specified access VLAN.

If all the RADIUS servers are not available and the client is not connected to a critical port, the switch might not assign clients to the guest VLAN if one is configured.

If all the RADIUS servers are not available and if a client is connected to a critical port and was previously assigned to a guest VLAN, the switch keeps the port in the guest VLAN.

Restricted VLAN—If the port is already authorized in a restricted VLAN and the RADIUS servers are unavailable, the switch puts the critical port in the critical-authentication state in the restricted VLAN.

802.1x accounting—Accounting is not affected if the RADIUS servers are unavailable.

Private VLAN—You can configure inaccessible authentication bypass on a private VLAN host port. The access VLAN must be a secondary private VLAN.

Voice VLAN—Inaccessible authentication bypass is compatible with voice VLAN, but the RADIUS-configured or user-specified access VLAN and the voice VLAN must be different.

Remote Switched Port Analyzer (RSPAN)—Do not configure an RSPAN VLAN as the RADIUS-configured or user-specified access VLAN for inaccessible authentication bypass.

In a switch stack:

The stack master checks the status of the RADIUS servers by sending keepalive packets. When the status of a RADIUS server changes, the stack master sends the information to the stack members. The stack members can then check the status of RADIUS servers when re-authenticating critical ports.

If the new stack master is elected, the link between the switch stack and RADIUS server might change, and the new stack immediately sends keepalive packets to update the status of the RADIUS servers. If the server status changes from dead to alive, the switch re-authenticates all switch ports in the critical-authentication state.

When a member is added to the stack, the stack master sends the member the server status.

Note
Switch stacks are supported only on Catalyst 2960-S switches running the LAN base image.

802.1x Critical Voice VLAN

When an IP phone connected to a port is authenticated by the access control server (ACS), the phone is put into the voice domain. If the ACS is not reachable, the switch cannot determine if the device is a voice device. If the server is unavailable, the phone cannot access the voice network and therefore cannot operate.

For data traffic, you can configure inaccessible authentication bypass, or critical authentication, to allow traffic to pass through on the native VLAN when the server is not available. If the RADIUS authentication server is unavailable (down) and inaccessible authentication bypass is enabled, the switch grants the client access...
to the network and puts the port in the critical-authentication state in the RADIUS-configured or the user-specified access VLAN. When the switch cannot reach the configured RADIUS servers and new hosts cannot be authenticated, the switch connects those hosts to critical ports. A new host trying to connect to the critical port is moved to a user-specified access VLAN, the critical VLAN, and granted limited authentication.

You can enter the `authentication event server dead action authorize voice` interface configuration command to configure the critical voice VLAN feature. When the ACS does not respond, the port goes into critical authentication mode. When traffic coming from the host is tagged with the voice VLAN, the connected device (the phone) is put in the configured voice VLAN for the port. The IP phones learn the voice VLAN identification through CDP (Cisco devices) or through LLDP or DHCP.

You can configure the voice VLAN for a port by entering the `switchport voice vlan vlan-id` interface configuration command.

This feature is supported in multidomain and multi-auth host modes. Although you can enter the command when the switch in single-host or multi-host mode, the command has no effect unless the device changes to multidomain or multi-auth host mode.

### 802.1x User Distribution

You can configure 802.1x user distribution to load-balance users with the same group name across multiple different VLANs.

The VLANs are either supplied by the RADIUS server or configured through the switch CLI under a VLAN group name.

- Configure the RADIUS server to send more than one VLAN name for a user. The multiple VLAN names can be sent as part of the response to the user. The 802.1x user distribution tracks all the users in a particular VLAN and achieves load balancing by moving the authorized user to the least populated VLAN.

- Configure the RADIUS server to send a VLAN group name for a user. The VLAN group name can be sent as part of the response to the user. You can search for the selected VLAN group name among the VLAN group names that you configured by using the switch CLI. If the VLAN group name is found, the corresponding VLANs under this VLAN group name are searched to find the least populated VLAN. Load balancing is achieved by moving the corresponding authorized user to that VLAN.

  **Note** The RADIUS server can send the VLAN information in any combination of VLAN-IDs, VLAN names, or VLAN groups.

### 802.1x User Distribution Configuration Guidelines

- Confirm that at least one VLAN is mapped to the VLAN group.

- You can map more than one VLAN to a VLAN group.

- You can modify the VLAN group by adding or deleting a VLAN.

- When you clear an existing VLAN from the VLAN group name, none of the authenticated ports in the VLAN are cleared, but the mappings are removed from the existing VLAN group.

- If you clear the last VLAN from the VLAN group name, the VLAN group is cleared.
• You can clear a VLAN group even when the active VLANs are mapped to the group. When you clear a VLAN group, none of the ports or users that are in the authenticated state in any VLAN within the group are cleared, but the VLAN mappings to the VLAN group are cleared.

IEEE 802.1x Authentication with Voice VLAN Ports

A voice VLAN port is a special access port associated with two VLAN identifiers:

• VVID to carry voice traffic to and from the IP phone. The VVID is used to configure the IP phone connected to the port.

• PVID to carry the data traffic to and from the workstation connected to the switch through the IP phone. The PVID is the native VLAN of the port.

The IP phone uses the VVID for its voice traffic, regardless of the authorization state of the port. This allows the phone to work independently of IEEE 802.1x authentication.

In single-host mode, only the IP phone is allowed on the voice VLAN. In multiple-hosts mode, additional clients can send traffic on the voice VLAN after a supplicant is authenticated on the PVID. When multiple-hosts mode is enabled, the supplicant authentication affects both the PVID and the VVID.

A voice VLAN port becomes active when there is a link, and the device MAC address appears after the first CDP message from the IP phone. Cisco IP phones do not relay CDP messages from other devices. As a result, if several IP phones are connected in series, the switch recognizes only the one directly connected to it. When IEEE 802.1x authentication is enabled on a voice VLAN port, the switch drops packets from unrecognized IP phones more than one hop away.

When IEEE 802.1x authentication is enabled on a switch port, you can configure an access port VLAN that is also a voice VLAN.

When IP phones are connected to an 802.1x-enabled switch port that is in single host mode, the switch grants the phones network access without authenticating them. We recommend that you use multidomain authentication (MDA) on the port to authenticate both a data device and a voice device, such as an IP phone.

Note

If you enable IEEE 802.1x authentication on an access port on which a voice VLAN is configured and to which a Cisco IP Phone is connected, the Cisco IP phone loses connectivity to the switch for up to 30 seconds.

IEEE 802.1x Authentication with Port Security

In general, Cisco does not recommend enabling port security when IEEE 802.1x is enabled. Since IEEE 802.1x enforces a single MAC address per port (or per VLAN when MDA is configured for IP telephony), port security is redundant and in some cases may interfere with expected IEEE 802.1x operations.

IEEE 802.1x Authentication with Wake-on-LAN

The IEEE 802.1x authentication with wake-on-LAN (WoL) feature allows dormant PCs to be powered when the switch receives a specific Ethernet frame, known as the magic packet. You can use this feature in environments where administrators need to connect to systems that have been powered down.
When a host that uses WoL is attached through an IEEE 802.1x port and the host powers off, the IEEE 802.1x port becomes unauthorized. The port can only receive and send EAPOL packets, and WoL magic packets cannot reach the host. When the PC is powered off, it is not authorized, and the switch port is not opened.

When the switch uses IEEE 802.1x authentication with WoL, the switch forwards traffic to unauthorized IEEE 802.1x ports, including magic packets. While the port is unauthorized, the switch continues to block ingress traffic other than EAPOL packets. The host can receive packets but cannot send packets to other devices in the network.

**Note**

If PortFast is not enabled on the port, the port is forced to the bidirectional state.

When you configure a port as unidirectional by using the `authentication control-direction in` interface configuration command, the port changes to the spanning-tree forwarding state. The port can send packets to the host but cannot receive packets from the host.

When you configure a port as bidirectional by using the `authentication control-direction both` interface configuration command, the port is access-controlled in both directions. The port does not receive packets from or send packets to the host.

### IEEE 802.1x Authentication with MAC Authentication Bypass

You can configure the switch to authorize clients based on the client MAC address by using the MAC authentication bypass feature. For example, you can enable this feature on IEEE 802.1x ports connected to devices such as printers.

If IEEE 802.1x authentication times out while waiting for an EAPOL response from the client, the switch tries to authorize the client by using MAC authentication bypass.

When the MAC authentication bypass feature is enabled on an IEEE 802.1x port, the switch uses the MAC address as the client identity. The authentication server has a database of client MAC addresses that are allowed network access. After detecting a client on an IEEE 802.1x port, the switch waits for an Ethernet packet from the client. The switch sends the authentication server a RADIUS-access/request frame with a username and password based on the MAC address. If authorization succeeds, the switch grants the client access to the network. If authorization fails, the switch assigns the port to the guest VLAN if one is configured. This process works for most client devices; however, it does not work for clients that use an alternate MAC address format.

You can configure how MAB authentication is performed for clients with MAC addresses that deviate from the standard format or where the RADIUS configuration requires the user name and password to differ.

If an EAPOL packet is detected on the interface during the lifetime of the link, the switch determines that the device connected to that interface is an 802.1x-capable supplicant and uses 802.1x authentication (not MAC authentication bypass) to authorize the interface. EAPOL history is cleared if the interface link status goes down.

If the switch already authorized a port by using MAC authentication bypass and detects an IEEE 802.1x supplicant, the switch does not unauthorize the client connected to the port. When re-authentication occurs, the switch uses the authentication or re-authentication methods configured on the port, if the previous session ended because the Termination-Action RADIUS attribute value is DEFAULT.

Clients that were authorized with MAC authentication bypass can be re-authenticated. The re-authentication process is the same as that for clients that were authenticated with IEEE 802.1x. During re-authentication, the port remains in the previously assigned VLAN. If re-authentication is successful, the switch keeps the port in the same VLAN. If re-authentication fails, the switch assigns the port to the guest VLAN, if one is configured.
If re-authentication is based on the Session-Timeout RADIUS attribute (Attribute[27]) and the Termination-Action RADIUS attribute (Attribute[29]) and if the Termination-Action RADIUS attribute (Attribute[29]) action is Initialize (the attribute value is DEFAULT), the MAC authentication bypass session ends, and connectivity is lost during re-authentication. If MAC authentication bypass is enabled and the IEEE 802.1x authentication times out, the switch uses the MAC authentication bypass feature to initiate re-authorization. For more information about these AV pairs, see RFC 3580, “IEEE 802.1X Remote Authentication Dial In User Service (RADIUS) Usage Guidelines.”

MAC authentication bypass interacts with the features:

- IEEE 802.1x authentication—You can enable MAC authentication bypass only if 802.1x authentication is enabled on the port.
- Guest VLAN—If a client has an invalid MAC address identity, the switch assigns the client to a guest VLAN if one is configured.
- Restricted VLAN—This feature is not supported when the client connected to an IEEE 802.1x port is authenticated with MAC authentication bypass.
- Port security
- Voice VLAN
- VLAN Membership Policy Server (VMPS)—IEEE 802.1x and VMPS are mutually exclusive.
- Private VLAN—You can assign a client to a private VLAN.

Cisco IOS Release 12.2(55)SE and later supports filtering of verbose MAB system messages.

**Network Admission Control Layer 2 IEEE 802.1x Validation**

The switch supports the Network Admission Control (NAC) Layer 2 IEEE 802.1x validation, which checks the antivirus condition or posture of endpoint systems or clients before granting the devices network access. With NAC Layer 2 IEEE 802.1x validation, you can do these tasks:

- Download the Session-Timeout RADIUS attribute (Attribute[27]) and the Termination-Action RADIUS attribute (Attribute[29]) from the authentication server.
- Set the number of seconds between re-authentication attempts as the value of the Session-Timeout RADIUS attribute (Attribute[27]) and get an access policy against the client from the RADIUS server.
- Set the action to be taken when the switch tries to re-authenticate the client by using the Termination-Action RADIUS attribute (Attribute[29]). If the value is the DEFAULT or is not set, the session ends. If the value is RADIUS-Request, the re-authentication process starts.
- Set the list of VLAN number or name or VLAN group name as the value of the Tunnel Group Private ID (Attribute[81]) and the preference for the VLAN number or name or VLAN group name as the value of the Tunnel Preference (Attribute[83]). If you do not configure the Tunnel Preference, the first Tunnel Group Private ID (Attribute[81]) attribute is picked up from the list.
- View the NAC posture token, which shows the posture of the client, by using the **show authentication** privileged EXEC command.
- Configure secondary private VLANs as guest VLANs.
Configuring NAC Layer 2 IEEE 802.1x validation is similar to configuring IEEE 802.1x port-based authentication except that you must configure a posture token on the RADIUS server.

**Flexible Authentication Ordering**

You can use flexible authentication ordering to configure the order of methods that a port uses to authenticate a new host. The IEEE 802.1X Flexible Authentication feature supports three authentication methods:

- **dot1X**—IEEE 802.1X authentication is a Layer 2 authentication method.
- **mab**—MAC-Authentication Bypass is a Layer 2 authentication method.
- **webauth**—Web authentication is a Layer 3 authentication method.

Using this feature, you can control which ports use which authentication methods, and you can control the failover sequencing of methods on those ports. For example, MAC authentication bypass and 802.1x can be the primary or secondary authentication methods, and web authentication can be the fallback method if either or both of those authentication attempts fail.

The IEEE 802.1X Flexible Authentication feature supports the following host modes:

- **multi-auth**—Multiauthentication allows one authentication on a voice VLAN and multiple authentications on the data VLAN.
- **multi-domain**—Multidomain authentication allows two authentications: one on the voice VLAN and one on the data VLAN.

**Related Topics**

 Configuring Flexible Authentication Ordering, on page 1800

**Open1x Authentication**

Open1x authentication allows a device access to a port before that device is authenticated. When open authentication is configured, a new host can pass traffic according to the access control list (ACL) defined on the port. After the host is authenticated, the policies configured on the RADIUS server are applied to that host.

You can configure open authentication with these scenarios:

- **Single-host mode with open authentication**—Only one user is allowed network access before and after authentication.
- **MDA mode with open authentication**—Only one user in the voice domain and one user in the data domain are allowed.
- **Multiple-hosts mode with open authentication**—Any host can access the network.
- **Multiple-authentication mode with open authentication**—Similar to MDA, except multiple hosts can be authenticated.
If open authentication is configured, it takes precedence over other authentication controls. This means that if you use the `authentication open` interface configuration command, the port will grant access to the host irrespective of the `authentication port-control` interface configuration command.

Configuring Open1x, on page 1801

### Multidomain Authentication

The switch supports multidomain authentication (MDA), which allows both a data device and voice device, such as an IP phone (Cisco or non-Cisco), to authenticate on the same switch port. The port is divided into a data domain and a voice domain.

**Note**

For all host modes, the line protocol stays up before authorization when port-based authentication is configured.

MDA does not enforce the order of device authentication. However, for best results, we recommend that a voice device is authenticated before a data device on an MDA-enabled port.

Follow these guidelines for configuring MDA:

- You must configure a switch port for MDA.
- You must configure the voice VLAN for the IP phone when the host mode is set to multidomain.
- Voice VLAN assignment on an MDA-enabled port is supported Cisco IOS Release 12.2(40)SE and later.

**Note**

You can assign a dynamic VLAN to a voice device on an MDA-enabled switch port, but the voice device fails authorization if a static voice VLAN configured on the switchport is the same as the dynamic VLAN assigned for the voice device in the RADIUS server.

- To authorize a voice device, the AAA server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of `device-traffic-class=voice`. Without this value, the switch treats the voice device as a data device.
- The guest VLAN and restricted VLAN features only apply to the data devices on an MDA-enabled port. The switch treats a voice device that fails authorization as a data device.
- If more than one device attempts authorization on either the voice or the data domain of a port, it is error disabled.
- Until a device is authorized, the port drops its traffic. Non-Cisco IP phones or voice devices are allowed into both the data and voice VLANs. The data VLAN allows the voice device to contact a DHCP server to obtain an IP address and acquire the voice VLAN information. After the voice device starts sending on the voice VLAN, its access to the data VLAN is blocked.
• A voice device MAC address that is binding on the data VLAN is not counted towards the port security MAC address limit.

• You can use dynamic VLAN assignment from a RADIUS server only for data devices.

• MDA can use MAC authentication bypass as a fallback mechanism to allow the switch port to connect to devices that do not support IEEE 802.1x authentication.

• When a data or a voice device is detected on a port, its MAC address is blocked until authorization succeeds. If the authorization fails, the MAC address remains blocked for 5 minutes.

• If more than five devices are detected on the data VLAN or more than one voice device is detected on the voice VLAN while a port is unauthorized, the port is error disabled.

• When a port host mode is changed from single- or multihost to multidomain mode, an authorized data device remains authorized on the port. However, a Cisco IP phone that has been allowed on the port voice VLAN is automatically removed and must be reauthenticated on that port.

• Active fallback mechanisms such as guest VLAN and restricted VLAN remain configured after a port changes from single-host or multihost mode to multidomain mode.

• Switching a port host mode from multidomain to single- or multihost mode removes all authorized devices from the port.

• If a data domain is authorized first and placed in the guest VLAN, non-IEEE 802.1x-capable voice devices need to tag their packets on the voice VLAN to trigger authentication.

• We do not recommend per-user ACLs with an MDA-enabled port. An authorized device with a per-user ACL policy might impact traffic on both the voice and data VLANs of the port. If used, only one device on the port should enforce per-user ACLs.

**Voice Aware 802.1x Security**

---

**Note**

To use voice aware IEEE 802.1x authentication, the switch must be running the LAN base image.

You use the voice aware 802.1x security feature to configure the switch to disable only the VLAN on which a security violation occurs, whether it is a data or voice VLAN. In previous releases, when an attempt to authenticate the data client caused a security violation, the entire port shut down, resulting in a complete loss of connectivity.

You can use this feature in IP phone deployments where a PC is connected to the IP phone. A security violation found on the data VLAN results in the shutdown of only the data VLAN. The traffic on the voice VLAN flows through the switch without interruption.

Common Session ID

Authentication manager uses a single session ID (referred to as a common session ID) for a client no matter which authentication method is used. This ID is used for all reporting purposes, such as the show commands and MIBs. The session ID appears with all per-session syslog messages.

The session ID includes:

- The IP address of the Network Access Device (NAD)
- A monotonically increasing unique 32 bit integer
- The session start time stamp (a 32 bit integer)

This example shows how the session ID appears in the output of the show authentication command. The session ID in this example is 160000050000000B288508E5:

```
Device# show authentication sessions
Interface MAC Address Method Domain Status Session ID
Fa4/0/4 0000.0000.0203 mab DATA Authz Success 160000050000000B288508E5
```

This is an example of how the session ID appears in the syslog output. The session ID in this example is also 160000050000000B288508E5:

```
1w0d: %AUTHMGR-5-START: Starting 'mab' for client (0000.0000.0203) on Interface Fa4/0/4
AuditSessionID 160000050000000B288508E5
1w0d: %MAB-5-SUCCESS: Authentication successful for client (0000.0000.0203) on Interface Fa4/0/4 AuditSessionID 160000050000000B288508E5
1w0d: %AUTHMGR-7-RESULT: Authentication result 'success' from 'mab' for client (0000.0000.0203) on Interface Fa4/0/4 AuditSessionID 160000050000000B288508E5
```

The session ID is used by the NAD, the AAA server, and other report-analyzing applications to identify the client. The ID appears automatically. No configuration is required.

How to Configure 802.1x Port-Based Authentication

Default 802.1x Authentication Configuration

802.1x Authentication Configuration Guidelines

802.1x Authentication

These are the 802.1x authentication configuration guidelines:

- When 802.1x authentication is enabled, ports are authenticated before any other Layer 2 or Layer 3 features are enabled.

- If the VLAN to which an 802.1x-enabled port is assigned changes, this change is transparent and does not affect the switch. For example, this change occurs if a port is assigned to a RADIUS server-assigned VLAN and is then assigned to a different VLAN after re-authentication.

If the VLAN to which an 802.1x port is assigned to shut down, disabled, or removed, the port becomes unauthorized. For example, the port is unauthorized after the access VLAN to which a port is assigned shuts down or is removed.

- The 802.1x protocol is supported on Layer 2 static-access ports, voice VLAN ports, and Layer 3 routed ports, but it is not supported on these port types:
  - Dynamic ports—A port in dynamic mode can negotiate with its neighbor to become a trunk port. If you try to enable 802.1x authentication on a dynamic port, an error message appears, and 802.1x authentication is not enabled. If you try to change the mode of an 802.1x-enabled port to dynamic, an error message appears, and the port mode is not changed.
  - Dynamic-access ports—If you try to enable 802.1x authentication on a dynamic-access (VLAN Query Protocol [VQP]) port, an error message appears, and 802.1x authentication is not enabled. If you try to change an 802.1x-enabled port to dynamic VLAN assignment, an error message appears, and the VLAN configuration is not changed.
  - EtherChannel port—Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an 802.1x port. If you try to enable 802.1x authentication on an EtherChannel port, an error message appears, and 802.1x authentication is not enabled.
  - Switched Port Analyzer (SPAN) and Remote SPAN (RSPAN) destination ports—You can enable 802.1x authentication on a port that is a SPAN or RSPAN destination port. However, 802.1x authentication is disabled until the port is removed as a SPAN or RSPAN destination port. You can enable 802.1x authentication on a SPAN or RSPAN source port.

- Before globally enabling 802.1x authentication on a switch by entering the `dot1x system-auth-control` global configuration command, remove the EtherChannel configuration from the interfaces on which 802.1x authentication and EtherChannel are configured.
VLAN Assignment, Guest VLAN, Restricted VLAN, and Inaccessible Authentication Bypass

These are the configuration guidelines for VLAN assignment, guest VLAN, restricted VLAN, and inaccessible authentication bypass:

- When 802.1x authentication is enabled on a port, you cannot configure a port VLAN that is equal to a voice VLAN.

- You can configure any VLAN except an RSPAN VLAN or a voice VLAN as an 802.1x guest VLAN. The guest VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

- After you configure a guest VLAN for an 802.1x port to which a DHCP client is connected, you might need to get a host IP address from a DHCP server. You can change the settings for restarting the 802.1x authentication process on the switch before the DHCP process on the client times out and tries to get a host IP address from the DHCP server. Decrease the settings for the 802.1x authentication process (authentication timer inactivity and authentication timer reauthentication interface configuration commands). The amount to decrease the settings depends on the connected 802.1x client type.

- When configuring the inaccessible authentication bypass feature, follow these guidelines:
  - The feature is supported on 802.1x port in single-host mode and multihosts mode.
  - If the client is running Windows XP and the port to which the client is connected is in the critical-authentication state, Windows XP might report that the interface is not authenticated.
  - If the Windows XP client is configured for DHCP and has an IP address from the DHCP server, receiving an EAP-Success message on a critical port might not re-initiate the DHCP configuration process.
  - You can configure the inaccessible authentication bypass feature and the restricted VLAN on an 802.1x port. If the switch tries to re-authenticate a critical port in a restricted VLAN and all the RADIUS servers are unavailable, switch changes the port state to the critical authentication state and remains in the restricted VLAN.
  - If the CTS links are in Critical Authentication mode and the master reloads, the policy where SGT was configured on a device will not be available on the new master. This is because the internal bindings will not be synced to the standby switch in a 3750-X switch stack.

- You can configure any VLAN except an RSPAN VLAN or a voice VLAN as an 802.1x restricted VLAN. The restricted VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

- When wireless guest clients obtains IP from foreign client VLAN instead of anchor client VLAN, you should use the ip dhcp required command under the WLAN configuration to force clients to issue a new DHCP request. This prevents the clients from getting an incorrect IP at anchor.

- If the wired guest clients fail to get IP address after a Cisco WLC (foreign) reload, perform a shut/no shut on the ports used by the clients to reconnect them.
MAC Authentication Bypass

These are the MAC authentication bypass configuration guidelines:

- Unless otherwise stated, the MAC authentication bypass guidelines are the same as the 802.1x authentication guidelines.
- If you disable MAC authentication bypass from a port after the port has been authorized with its MAC address, the port state is not affected.
- If the port is in the unauthorized state and the client MAC address is not the authentication-server database, the port remains in the unauthorized state. However, if the client MAC address is added to the database, the switch can use MAC authentication bypass to re-authorize the port.
- If the port is in the authorized state, the port remains in this state until re-authorization occurs.
- You can configure a timeout period for hosts that are connected by MAC authentication bypass but are inactive. The range is 1 to 65535 seconds.

Maximum Number of Allowed Devices Per Port

This is the maximum number of devices allowed on an 802.1x-enabled port:

- In single-host mode, only one device is allowed on the access VLAN. If the port is also configured with a voice VLAN, an unlimited number of Cisco IP phones can send and receive traffic through the voice VLAN.
- In multidomain authentication (MDA) mode, one device is allowed for the access VLAN, and one IP phone is allowed for the voice VLAN.
- In multihost mode, only one 802.1x supplicant is allowed on the port, but an unlimited number of non-802.1x hosts are allowed on the access VLAN. An unlimited number of devices are allowed on the voice VLAN.

Configuring 802.1x Readiness Check

The 802.1x readiness check monitors 802.1x activity on all the switch ports and displays information about the devices connected to the ports that support 802.1x. You can use this feature to determine if the devices connected to the switch ports are 802.1x-capable.

The 802.1x readiness check is allowed on all ports that can be configured for 802.1x. The readiness check is not available on a port that is configured as dot1x force-unauthorized.

Follow these steps to enable the 802.1x readiness check on the switch:

**Before you begin**

Follow these guidelines to enable the readiness check on the switch:

- The readiness check is typically used before 802.1x is enabled on the switch.
- If you use the dot1x test capol-capable privileged EXEC command without specifying an interface, all the ports on the switch stack are tested.
- When you configure the dot1x test capol-capable command on an 802.1x-enabled port, and the link comes up, the port queries the connected client about its 802.1x capability. When the client responds with a notification packet, it is 802.1x-capable. A syslog message is generated if the client responds.
within the timeout period. If the client does not respond to the query, the client is not 802.1x-capable. No syslog message is generated

- When you configure the `dot1x test eapol-capable` command on an 802.1x-enabled port, and the link comes up, the port queries the connected client about its 802.1x capability. When the client responds with a notification packet, it is 802.1x-capable. A syslog message is generated if the client responds within the timeout period. If the client does not respond to the query, the client is not 802.1x-capable. No syslog message is generated

- The readiness check can be sent on a port that handles multiple hosts (for example, a PC that is connected to an IP phone). A syslog message is generated for each of the clients that respond to the readiness check within the timer period.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `dot1x test eapol-capable [interface interface-id]`
4. `dot1x test timeout timeout`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

## Configuring Voice Aware 802.1x Security

To use voice aware IEEE 802.1x authentication, the switch must be running the LAN base image.

You use the voice aware 802.1x security feature on the switch to disable only the VLAN on which a security violation occurs, whether it is a data or voice VLAN. You can use this feature in IP phone deployments where a PC is connected to the IP phone. A security violation found on the data VLAN results in the shutdown of only the data VLAN. The traffic on the voice VLAN flows through the switch without interruption.

Follow these guidelines to configure voice aware 802.1x voice security on the switch:

- You enable voice aware 802.1x security by entering the `errdisable detect cause security-violation shutdown vlan` global configuration command. You disable voice aware 802.1x security by entering the `no` version of this command. This command applies to all 802.1x-configured ports in the switch.

  **Note**
  If you do not include the `shutdown vlan` keywords, the entire port is shut down when it enters the error-disabled state.

- If you use the `errdisable recovery cause security-violation` global configuration command to configure error-disabled recovery, the port is automatically re-enabled. If error-disabled recovery is not configured for the port, you re-enable it by using the `shutdown` and `no shutdown` interface configuration commands.

- You can re-enable individual VLANs by using the `clear errdisable interface interface-id vlan [vlan-list]` privileged EXEC command. If you do not specify a range, all VLANs on the port are enabled.
Beginning in privileged EXEC mode, follow these steps to enable voice aware 802.1x security:

**SUMMARY STEPS**

1. configure terminal
2. errdisable detect cause security-violation shutdown vlan
3. errdisable recovery cause security-violation
4. clear errdisable interface interface-id vlan [vlan-list]
5. Enter the following:
   - shutdown
   - no shutdown
6. end
7. show errdisable detect

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>errdisable detect cause security-violation shutdown vlan</td>
<td>Shut down any VLAN on which a security violation error occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> If the <strong>shutdown vlan</strong> keywords are not included, the entire port enters the error-disabled state and shuts down.</td>
</tr>
<tr>
<td>Step 3</td>
<td>errdisable recovery cause security-violation</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>clear errdisable interface interface-id vlan [vlan-list]</td>
<td>(Optional) Reenable individual VLANs that have been error disabled.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For interface-id specify the port on which to reenable individual VLANs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• (Optional) For vlan-list specify a list of VLANs to be re-enabled. If vlan-list is not specified, all VLANs are re-enabled.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Enter the following:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• shutdown</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• no shutdown</td>
<td>(Optional) Re-enable an error-disabled VLAN, and clear all error-disable indications.</td>
</tr>
<tr>
<td>Step 6</td>
<td>end</td>
<td>Return to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 7</td>
<td>show errdisable detect</td>
<td>Verify your entries.</td>
</tr>
</tbody>
</table>

**Example**

This example shows how to configure the switch to shut down any VLAN on which a security violation error occurs:
Switch(config)# errdisable detect cause security-violation shutdown vlan

This example shows how to re-enable all VLANs that were error disabled on port Gigabit Ethernet 40/2.

Switch# clear errdisable interface gigabitethernet4/0/2 vlan

You can verify your settings by entering the show errdisable detect privileged EXEC command.

Configuring 802.1x Violation Modes

You can configure an 802.1x port so that it shuts down, generates a syslog error, or discards packets from a new device when:

- a device connects to an 802.1x-enabled port
- the maximum number of allowed about devices have been authenticated on the port

Beginning in privileged EXEC mode, follow these steps to configure the security violation actions on the switch:

SUMMARY STEPS

1. configure terminal
2. aaa new-model
3. aaa authentication dot1x {default} method1
4. interface interface-id
5. switchport mode access
6. authentication violation {shutdown | restrict | protect | replace}
7. end

DETAILED STEPS

### Configuring 802.1x Authentication

To allow per-user ACLs or VLAN assignment, you must enable AAA authorization to configure the switch for all network-related service requests.

This is the 802.1x AAA process:
Before you begin

To configure 802.1x port-based authentication, you must enable authentication, authorization, and accounting (AAA) and specify the authentication method list. A method list describes the sequence and authentication method to be queried to authenticate a user.

SUMMARY STEPS

1. A user connects to a port on the switch.
2. Authentication is performed.
3. VLAN assignment is enabled, as appropriate, based on the RADIUS server configuration.
4. The switch sends a start message to an accounting server.
5. Re-authentication is performed, as necessary.
6. The switch sends an interim accounting update to the accounting server that is based on the result of re-authentication.
7. The user disconnects from the port.
8. The switch sends a stop message to the accounting server.

Configuring the Switch-to-RADIUS-Server Communication

You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers by using the `radius server` global configuration command. If you want to configure these options on a per-server basis, use the `radius-server timeout`, the `radius-server retransmit`, and the `key string` global configuration commands.

You also need to configure some settings on the RADIUS server. These settings include the IP address of the switch and the key string to be shared by both the server and the switch. For more information, see the RADIUS server documentation.

Follow these steps to configure the RADIUS server parameters on the switch. This procedure is required.

**Before you begin**

You must enable authentication, authorization, and accounting (AAA) and specify the authentication method list. A method list describes the sequence and authentication method to be queried to authenticate a user.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `radius server`  `server name`
4. `address {ipv4 | ipv6} ip address auth-port port number acct-port port number`
5. `key string`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>

### Configuring the Host Mode

Beginning in privileged EXEC mode, follow these steps to allow multiple hosts (clients) on an IEEE 802.1x-authorized port that has the `authentication port-control` interface configuration command set to `auto`. Use the `multi-domain` keyword to configure and enable multidomain authentication (MDA), which allows both a host and a voice device, such as an IP phone (Cisco or non-Cisco), on the same switch port. This procedure is optional.

#### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`

---

</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>authentication timer</code> `{{[inactivity</td>
</tr>
</tbody>
</table>

**Note**: The default value is 3600 seconds. To change the value of the reauthentication timer or to have the switch use a RADIUS-provided session timeout, enter the `authentication timer reauthenticate` command.

Sets the number of seconds between re-authentication attempts.

The **authentication timer** keywords have these meanings:

- **inactivity**—Interval in seconds after which if there is no activity from the client then it is unauthorized
- **reauthenticate**—Time in seconds after which an automatic re-authentication attempt is initiated
Changing the Quiet Period

When the switch cannot authenticate the client, the switch remains idle for a set period of time and then tries again. The **authentication timer restart** interface configuration command controls the idle period. A failed authentication of the client might occur because the client provided an invalid password. You can provide a faster response time to the user by entering a number smaller than the default.

Beginning in privileged EXEC mode, follow these steps to change the quiet period. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. authentication timer restart seconds
4. end
5. show authentication sessions interface interface-id
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>

</tr>
</tbody>
</table>
Changing the Switch-to-Client Retransmission Time

The client responds to the EAP-request/identity frame from the switch with an EAP-response/identity frame. If the switch does not receive this response, it waits a set period of time (known as the retransmission time) and then resends the frame.

**Note**
You should change the default value of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Beginning in privileged EXEC mode, follow these steps to change the amount of time that the switch waits for client notification. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `authentication timer reauthenticate seconds`
4. `end`
5. `show authentication sessions interface interface-id`
6. `copy running-config startup-config`
### Setting the Switch-to-Client Frame-Retransmission Number

In addition to changing the switch-to-client retransmission time, you can change the number of times that the switch sends an EAP-request/identity frame (assuming no response is received) to the client before restarting the authentication process.

### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | configure terminal  
Example: Device# configure terminal | Enters the global configuration mode. |
| **Step 2** | interface interface-id  
Example: Device(config)# interface gigabitethernet2/0/1 | Specifies the port to be configured, and enter interface configuration mode. |
| **Step 3** | authentication timer reauthenticate seconds  
Example: Device(config-if)# authentication timer reauthenticate 60 | Sets the number of seconds that the switch waits for a response to an EAP-request/identity frame from the client before resending the request.  
The range is 1 to 65535 seconds; the default is 5. |
| **Step 4** | end  
Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| **Step 5** | show authentication sessions interface interface-id  
Example: Device# show authentication sessions interface gigabitethernet2/0/1 | Verifies your entries. |
| **Step 6** | copy running-config startup-config  
Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
You should change the default value of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Beginning in privileged EXEC mode, follow these steps to set the switch-to-client frame-retransmission number. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. dot1x max-reauth-req count
4. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td>Specifies the port to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet2/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> dot1x max-reauth-req count</td>
<td>Sets the number of times that the switch sends an EAP-request/identity frame to the client before restarting the authentication process. The range is 1 to 10; the default is 2.</td>
</tr>
<tr>
<td>Example: Device(config-if)# dot1x max-reauth-req 5</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Setting the Re-Authentication Number**

You can also change the number of times that the switch restarts the authentication process before the port changes to the unauthorized state.
You should change the default value of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Beginning in privileged EXEC mode, follow these steps to set the re-authentication number. This procedure is optional.

### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `switchport mode access`
4. `dot1x max-req count`
5. `end`

<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>
Configuring 802.1x Accounting

Enabling AAA system accounting with 802.1x accounting allows system reload events to be sent to the accounting RADIUS server for logging. The server can then infer that all active 802.1x sessions are closed. Because RADIUS uses the unreliable UDP transport protocol, accounting messages might be lost due to poor network conditions. If the switch does not receive the accounting response message from the RADIUS server after a configurable number of retransmissions of an accounting request, this system message appears:

```
Accounting message %s for session %s failed to receive Accounting Response.
```

When the stop message is not sent successfully, this message appears:

```
00:09:55: %RADIUS-4-RADIUS_DEAD: RADIUS server 172.20.246.201:1645,1646 is not responding.
```

**Summary Steps**

1. configure terminal
2. interface interface-id
3. aaa accounting dot1x default start-stop group radius
4. aaa accounting system default start-stop group radius
5. end
6. show running-config
7. copy running-config startup-config

**Note**

You must configure the RADIUS server to perform accounting tasks, such as logging start, stop, and interim-update messages and time stamps. To turn on these functions, enable logging of “Update/Watchdog packets from this AAA client” in your RADIUS server Network Configuration tab. Next, enable “CVS RADIUS Accounting” in your RADIUS server System Configuration tab.

Beginning in privileged EXEC mode, follow these steps to configure 802.1x accounting after AAA is enabled on your switch. This procedure is optional.
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  configure terminal  
  **Example:**
  Device# configure terminal | Enters global configuration mode. |
| **Step 2**
  interface interface-id  
  **Example:**
  Device(config)# interface gigabitethernet1/0/3 | Specifies the port to be configured, and enter interface configuration mode. |
| **Step 3**
  aaa accounting dot1x default start-stop group radius  
  **Example:**
  Device(config-if)# aaa accounting dot1x default start-stop group radius | Enables 802.1x accounting using the list of all RADIUS servers. |
| **Step 4**
  aaa accounting system default start-stop group radius  
  **Example:**
  Device(config-if)# aaa accounting system default start-stop group radius | (Optional) Enables system accounting (using the list of all RADIUS servers) and generates system accounting reload event messages when the switch reloads. |
| **Step 5**
  end  
  **Example:**
  Device(config-if)# end | Returns to privileged EXEc mode. |
| **Step 6**
  show running-config  
  **Example:**
  Device# show running-config | Verifies your entries. |
| **Step 7**
  copy running-config startup-config  
  **Example:**
  Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
Configuring a Guest VLAN

When you configure a guest VLAN, clients that are not 802.1x-capable are put into the guest VLAN when the server does not receive a response to its EAP request/identity frame. Clients that are 802.1x-capable but that fail authentication are not granted network access. The switch supports guest VLANs in single-host or multiple-hosts mode.

Beginning in privileged EXEC mode, follow these steps to configure a guest VLAN. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. Use one of the following:
   - switchport mode access
   - switchport mode private-vlan host
4. authentication event no-response action authorize vlan vlan-id
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>• Enters the global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>• Specifies the port to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td>interface interface-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet2/0/2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>• Sets the port to access mode.</td>
</tr>
<tr>
<td>Use one of the following:</td>
<td></td>
</tr>
<tr>
<td>• switchport mode access</td>
<td></td>

<tr>
<td>Example:</td>
<td>• Configures the Layer 2 port as a private-VLAN host port.</td>
</tr>
<tr>
<td>Device(config-if)# switchport mode private-vlan host</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>• Specifies an active VLAN as an 802.1x guest VLAN. The range is 1 to 4094.</td>
</tr>
<tr>
<td>authentication event no-response action authorize vlan vlan-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>You can configure any active VLAN except an internal VLAN (routed port), an RSPAN VLAN or a voice VLAN as an 802.1x guest VLAN.</td>
</tr>
<tr>
<td>Device(config-if)# authentication event no-response</td>
<td></td>
</tr>
</tbody>
</table>
Configuring a Restricted VLAN

When you configure a restricted VLAN on a switch stack or a switch, clients that are IEEE 802.1x-compliant are moved into the restricted VLAN when the authentication server does not receive a valid username and password. The switch supports restricted VLANs only in single-host mode.

Beginning in privileged EXEC mode, follow these steps to configure a restricted VLAN. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. Use one of the following:
   - `switchport mode access`
   - `switchport mode private-vlan host`
4. `authentication port-control auto`
5. `authentication event fail action authorize vlan vlan-id`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>

<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• switchport mode private-vlan host</td>
<td>• Configures the Layer 2 port as a private-VLAN host port.</td>
</tr>
</tbody>
</table>

### Example:

```
Device(config-if)# switchport mode access
```

#### Step 4

**authentication port-control auto**

### Example:

```
Device(config-if)# authentication port-control auto
```

#### Step 5

**authentication event fail action authorize vlan vlan-id**

### Example:

```
Device(config-if)# authentication event fail action authorize vlan 2
```

#### Step 6

**end**

### Example:

```
Device(config-if)# end
```

### Configuring Number of Authentication Attempts on a Restricted VLAN

You can configure the maximum number of authentication attempts allowed before a user is assigned to the restricted VLAN by using the `authentication event retry retry count` interface configuration command. The range of allowable authentication attempts is 1 to 3. The default is 3 attempts.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of allowed authentication attempts. This procedure is optional.

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. Use one of the following:
   - `switchport mode access`
   - `switchport mode private-vlan host`
4. `authentication port-control auto`
5. `authentication event fail action authorize vlan vlan-id`
6. `authentication event retry retry count`
7. `end`

</table>
Configuring 802.1x Inaccessible Authentication Bypass with Critical Voice VLAN

Beginning in privileged EXEC mode, follow these steps to configure critical voice VLAN on a port and enable the inaccessible authentication bypass feature.

SUMMARY STEPS

1. configure terminal
2. aaa new-model
3. radius-server dead-criteria {time seconds } [tries number]
4. radius-serverdeadtimeminutes
5. radius server  server name
6. address {ipv4 | ipv6} ip address auth-port port_number acct-port port_number
7. key  string
8. exit
9. dot1x critical {eapol | recovery delay milliseconds}
10. interface interface-id
11. authentication event server dead action {authorize | reinitialize} vlan vlan-id
12. switchport voice vlan vlan-id
13. authentication event server dead action authorize voice
14. show authentication interface interface-id
15. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
</tbody>
</table>

  

Example:

Device# configure terminal

<table>
<thead>
<tr>
<th><strong>Step 2</strong></th>
<th>aaa new-model</th>
</tr>
</thead>
</table>

  

Example:

Device(config)# aaa new-model

<table>
<thead>
<tr>
<th><strong>Step 3</strong></th>
<th>radius-server dead-criteria {time seconds } [tries number]</th>
</tr>
</thead>
</table>

  

Example:

Device(config)# radius-server dead-criteria time 20 tries 10

Sets the conditions that determine when a RADIUS server is considered unavailable or down (dead).

- **time**—1 to 120 seconds. The switch dynamically determines a default seconds value between 10 and 60.
- **number**—1 to 100 tries. The switch dynamically determines a default triesnumber between 10 and 100.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong> radius-server deadtime &lt;minutes&gt; Example: Device(config)# radius-server deadtime 60</td>
<td>(Optional) Sets the number of minutes during which a RADIUS server is not sent requests. The range is from 0 to 1440 minutes (24 hours). The default is 0 minutes.</td>
</tr>
<tr>
<td><strong>Step 5</strong> radius server &lt;server name&gt; Example: Device(config)# radius server rsim address ipv4 124.2.2.12</td>
<td>(Optional) Specifies the IP address of the RADIUS server.</td>
</tr>
<tr>
<td><strong>Step 6</strong> address {ipv4</td>
<td>ipv6} ip address auth-port &lt;port_number&gt; acct-port &lt;port_number&gt; Example: Device(config-radius-server)# address ipv4 10.0.1.2 auth-port 1550 acct-port 1560</td>
</tr>
<tr>
<td><strong>Step 7</strong> key &lt;string&gt; Example: Device(config-radius-server)# key rad123</td>
<td>(Optional) Specifies the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server.</td>
</tr>
<tr>
<td><strong>Step 8</strong> exit Example: Device(config-radius-server)# exit</td>
<td>Exits the RADIUS server mode and enters the global configuration mode.</td>
</tr>
</tbody>
</table>
| **Step 9** dot1x critical {eapol | recovery delay milliseconds} Example: Device(config)# dot1x critical eapol (config)# dot1x critical recovery delay 2000 | (Optional) Configure the parameters for inaccessible authentication bypass:  
  • eapol—Specify that the switch sends an EAPOL-Success message when the switch successfully authenticates the critical port.  
  • recovery delay milliseconds—Set the recovery delay period during which the switch waits to re-initialize a critical port when a RADIUS server that was unavailable becomes available. The range is from 1 to 10000 milliseconds. The default is 1000 milliseconds (a port can be re-initialized every second). |
| **Step 10** interface <interface-id> Example: | Specify the port to be configured, and enter interface configuration mode. |
### Configuring 802.1x Inaccessible Authentication Bypass with Critical Voice VLAN

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `interface gigabitethernet 1/0/1` | **Use these keywords to move hosts on the port if the RADIUS server is unreachable:**
| `authentication event server dead action {authorize | reinitialize} vlan vlan-id` | • **authorize**—Move any new hosts trying to authenticate to the user-specified critical VLAN.
| | • **reinitialize**—Move all authorized hosts on the port to the user-specified critical VLAN. |
| **Step 11** | |
| `switchport voice vlan vlan-id` | **Specifies the voice VLAN for the port. The voice VLAN cannot be the same as the critical data VLAN configured in Step 6.** |
| **Step 12** | |
| `authentication event server dead action authorize voice` | **Configures critical voice VLAN to move data traffic on the port to the voice VLAN if the RADIUS server is unreachable.** |
| **Step 13** | |
| `show authentication interface interface-id` | (Optional) Verify your entries. |
| **Step 14** | |
| `copy running-config startup-config` | (Optional) Verify your entries. |
| **Step 15** | |

**Example**

To return to the RADIUS server default settings, use the **no radius-server dead-criteria**, the **no radius-server deadtime**, and the **no radius server** global configuration commands. To disable inaccessible authentication bypass, use the **no authentication event server dead action** interface configuration command. To disable critical voice VLAN, use the **no authentication event server dead action authorize voice** interface configuration command.
Example of Configuring Inaccessible Authentication Bypass

This example shows how to configure the inaccessible authentication bypass feature:

Device(config)# radius-server dead-criteria time 30 tries 20
Device(config)# radius-server deadtime 60
Device(config)# radius-server server1
Device(config-radius-server)# address ipv4 172.29.36.49 acct-port 1618 auth-port 1612
Device(config-radius-server)# key abc1234
Device(config-radius-server)# exit
Device(config)# dot1x critical eapol
Device(config)# dot1x critical recovery delay 2000
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# dot1x critical
Device(config-if)# dot1x critical recovery action reinitialize
Device(config-if)# dot1x critical vlan 20
Device(config-if)# end

Configuring 802.1x Authentication with WoL

Beginning in privileged EXEC mode, follow these steps to enable 802.1x authentication with WoL. This procedure is optional.

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. authentication control-direction {both | in}
4. end
5. show authentication sessions interface interface-id
6. copy running-config startup-config

DETAILED STEPS

<table>

## Configuring MAC Authentication Bypass

Beginning in privileged EXEC mode, follow these steps to enable MAC authentication bypass. This procedure is optional.

### SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. authentication port-control auto
4. mab [eap]
5. end
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** interface interface-id | Specifies the port to be configured, and enter interface configuration mode. |
| Example:                          |                                                  |
| Device(config)# interface gigabitethernet2/0/1 |                                                  |

| **Step 3** authentication port-control auto | Enables 802.1x authentication on the port. |
| Example:                                    |                                                  |
| Device(config-if)# authentication port-control auto |                                                  |

| **Step 4** mab [eap]                     | Enables MAC authentication bypass.              |
| Example:                                 | (Optional) Use the `eap` keyword to configure the switch to use EAP for authorization. |
| Device(config-if)# mab                  |                                                  |

| **Step 5** end                          | Returns to privileged EXEC mode.                |
| Example:                                |                                                  |
| Device(config-if)# end                  |                                                  |

### Configuring 802.1x User Distribution

Beginning in privileged EXEC mode, follow these steps to configure a VLAN group and to map a VLAN to it:

### SUMMARY STEPS

1. `configure terminal`
2. `vlan group vlan-group-name vlan-list vlan-list`
3. `end`
4. `no vlan group vlan-group-name vlan-list vlan-list`
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> vlan group vlan-group-name vlan-list</td>
<td>Configures a VLAN group, and maps a single VLAN or a range of VLANs to it.</td>
</tr>
<tr>
<td>Example: Device(config)# vlan group eng-dept vlan-list 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> no vlan group vlan-group-name vlan-list</td>
<td>Clears the VLAN group configuration or elements of the VLAN group configuration.</td>
</tr>
<tr>
<td>Example: Device(config)# no vlan group eng-dept vlan-list 10</td>
<td></td>
</tr>
</tbody>
</table>

**Example of Configuring VLAN Groups**

This example shows how to configure the VLAN groups, to map the VLANs to the groups, to and verify the VLAN group configurations and mapping to the specified VLANs:

```
Device(config)# vlan group eng-dept vlan-list 10
Device(config)# show vlan group group-name eng-dept
  Group Name          Vlans Mapped
    ---------          ------------
    eng-dept          10

Device(config)# show dot1x vlan-group all
  Group Name          Vlans Mapped
    ---------          ------------
    eng-dept          10
    hr-dept           20
```

This example shows how to add a VLAN to an existing VLAN group and to verify that the VLAN was added:

```
Device(config)# vlan group eng-dept vlan-list 30
Device(config)# show vlan group eng-dept
  Group Name          Vlans Mapped
    ---------          ------------
    eng-dept          30
```
This example shows how to remove a VLAN from a VLAN group:

```
Device# no vlan group eng-dept vlan-list 10
```

This example shows that when all the VLANs are cleared from a VLAN group, the VLAN group is cleared:

```
Device(config)# no vlan group eng-dept_vlan-list 30
Vlan 30 is successfully cleared from vlan group eng-dept.
```

```
Device(config)# show vlan group group-name eng-dept
Device(config)#
```

This example shows how to clear all the VLAN groups:

```
Device(config)# no vlan group end-dept_vlan-list all
Device(config)# show vlan-group all
```

For more information about these commands, see the Cisco IOS Security Command Reference.

### Configuring NAC Layer 2 802.1x Validation

You can configure NAC Layer 2 802.1x validation, which is also referred to as 802.1x authentication with a RADIUS server.

Beginning in privileged EXEC mode, follow these steps to configure NAC Layer 2 802.1x validation. The procedure is optional.

#### SUMMARY STEPS

1. `configure terminal`
2. `interface interface-id`
3. `switchport mode access`
4. `authentication event no-response action authorize vlan vlan-id`
5. `authentication periodic`
6. `authentication timer reauthenticate`
7. `end`
8. `show authentication sessions interface interface-id`
9. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>----------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td>Specifies the port to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet2/0/3</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> switchport mode access</td>
<td>Sets the port to access mode only if you configured the RADIUS server.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# switchport mode access</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> authentication event no-response action authorize vlan vlan-id</td>
<td>Specifies an active VLAN as an 802.1x guest VLAN. The range is 1 to 4094.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>You can configure any active VLAN except an internal VLAN (routed port), an RSPAN VLAN, or a voice VLAN as an 802.1x guest VLAN.</td>
</tr>
<tr>
<td>Device(config-if)# authentication event no-response action authorize vlan 8</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> authentication periodic</td>
<td>Enables periodic re-authentication of the client, which is disabled by default.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# authentication periodic</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> authentication timer reauthenticate</td>
<td>Sets re-authentication attempt for the client (set to one hour). This command affects the behavior of the switch only if periodic re-authentication is enabled.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# authentication timer reauthenticate</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> show authentication sessions interface interface-id</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# show authentication sessions interface gigabitethernet2/0/3</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
Configuring 802.1x Authentication with Downloadable ACLs and Redirect URLs

In addition to configuring 802.1x authentication on the switch, you need to configure the ACS. For more information, see the Configuration Guide for Cisco Secure ACS 4.2:

You must configure a downloadable ACL on the ACS before downloading it to the switch.

After authentication on the port, you can use the `show ip access-list` privileged EXEC command to display the downloaded ACLs on the port.

Configuring Downloadable ACLs

The policies take effect after client authentication and the client IP address addition to the IP device tracking table. The switch then applies the downloadable ACL to the port.

Beginning in privileged EXEC mode:

**SUMMARY STEPS**

1. configure terminal
2. ip device tracking
3. aaa new-model
4. aaa authorization network default local group radius
5. radius-server vsa send authentication
6. interface interface-id
7. ip access-group acl-id in
8. show running-config interface interface-id
9. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** configure terminal
  Example:
  Device# configure terminal | Enters global configuration mode.            |
| **Step 2** ip device tracking
  Example:                  | Sets the ip device tracking table.           |
### Configuring Downloadable ACLs

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config)# ip device tracking</code></td>
<td></td>
</tr>
</tbody>
</table>
| **Step 3** aaa new-model  
**Example:**  
`Device(config)# aaa new-model` | Enables AAA. |
| **Step 4** aaa authorization network default local group radius  
**Example:**  
`Device(config)# aaa authorization network default local group radius` | Sets the authorization method to local. To remove the authorization method, use the `no aaa authorization network default local group radius` command. |
| **Step 5** radius-server vsa send authentication  
**Example:**  
`Device(config)# radius-server vsa send authentication` | Configures the radius vsa send authentication. |
| **Step 6** interface `interface-id`  
**Example:**  
`Device(config)# interface gigabitethernet2/0/4` | Specifies the port to be configured, and enter interface configuration mode. |
| **Step 7** ip access-group `acl-id` in  
**Example:**  
`Device(config-if)# ip access-group default_acl in` | Configures the default ACL on the port in the input direction.  
**Note** The `acl-id` is an access list name or number. |
| **Step 8** show running-config interface `interface-id`  
**Example:**  
`Device(config-if)# show running-config interface gigabitethernet2/0/4` | Verifies your configuration. |
| **Step 9** copy running-config startup-config  
**Example:**  
`Device# copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
# Configuring a Downloadable Policy

Beginning in privileged EXEC mode:

## SUMMARY STEPS

1. `configure terminal`
2. `access-list access-list-number { deny | permit } { hostname | any | host } log`
3. `interface interface-id`
4. `ip access-group acl-id in`
5. `exit`
6. `aaa new-model`
7. `aaa authorization network default group radius`
8. `ip device tracking`
9. `ip device tracking probe [count | interval | use-svi]`
10. `radius-server vsa send authentication`
11. `end`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Defines the default port ACL.</td>
</tr>
<tr>
<td>`access-list access-list-number { deny</td>
<td>permit } { hostname</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# access-list 1 deny any log</code></td>
<td></td>
</tr>
</tbody>
</table>

- **hostname**: The 32-bit quantity in dotted-decimal format.
- **any**: The keyword any as an abbreviation for source and source-wildcard value of 0.0.0.0 255.255.255.255. You do not need to enter a source-wildcard value.
- **host**: The keyword host as an abbreviation for source and source-wildcard of source 0.0.0.0. (Optional) Applies the source-wildcard wildcard bits to the source.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3** `interface interface-id`  
**Example:**  
Device(config)# interface gigabitethernet2/0/2 | (Optional) Enters log to cause an informational logging message about the packet that matches the entry to be sent to the console. |
| **Step 4** `ip access-group acl-id in`  
**Example:**  
Device(config-if)# ip access-group default_acl in | Enters interface configuration mode. |
| **Step 5** `exit`  
**Example:**  
Device(config-if)# exit | Configures the ACL on the port in the input direction.  
**Note** The acl-id is an access list name or number. |
| **Step 6** `aaa new-model`  
**Example:**  
Device(config)# aaa new-model | Returns to global configuration mode. |
| **Step 7** `aaa authorization network default group radius`  
**Example:**  
Device(config)# aaa authorization network default group radius | Enables AAA. |
| **Step 8** `ip device tracking`  
**Example:**  
Device(config)# ip device tracking | Sets the authorization method to local. To remove the authorization method, use the `no aaa authorization network default group radius` command. |
| **Step 9** `ip device tracking probe [count | interval | use-svi]`  
**Example:**  
Device(config)# ip device tracking probe count | Enables the IP device tracking table.  
To disable the IP device tracking table, use the `no ip device tracking` global configuration commands. |
| (Optional) Configures the IP device tracking table:  
  • `count count`—Sets the number of times that the switch sends the ARP probe. The range is from 1 to 5. The default is 3.  
  • `interval interval`—Sets the number of seconds that the switch waits for a response before resending the ARP probe. The range is from 30 to 300 seconds. The default is 30 seconds. |
## Configuring VLAN ID-based MAC Authentication

Beginning in privileged EXEC mode, follow these steps:

**SUMMARY STEPS**

1. configure terminal
2. mab request format attribute 32 vlan access-vlan
3. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> mab request format attribute 32 vlan access-vlan</td>
<td>Enables VLAN ID-based MAC authentication.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# mab request format attribute 32</td>
<td></td>
</tr>
<tr>
<td>vlan access-vlan</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

### Purpose

- **use-svi**—Uses the switch virtual interface (SVI) IP address as source of ARP probes.

### Step 10

**radius-server vsa send authentication**

*Example:*

```
Device(config)# radius-server vsa send authentication
```

**Purpose**

Configures the network access server to recognize and use vendor-specific attributes.

**Note**

The downloadable ACL must be operational.

### Step 11

**end**

*Example:*

```
Device(config)# end
```

**Returnsto privileged EXEC mode.**
Configuring Flexible Authentication Ordering

The examples used in the instructions below change the order of Flexible Authentication Ordering so that MAB is attempted before IEEE 802.1X authentication (dot1x). MAB is configured as the first authentication method, so MAB will have priority over all other authentication methods.

Beginning in privileged EXEC mode, follow these steps:

SUMMARY STEPS

1. configure terminal
2. interface interface-id
3. switchport mode access
4. authentication order [ dot1x | mab ] | {webauth}
5. authentication priority [ dot1x | mab ] | {webauth}
6. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> interface interface-id</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# interface gigabitethernet 1/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> switchport mode access</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# switchport mode access</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> authentication order [ dot1x</td>
<td>mab ]</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
| Device(config-if)# authentication order mab dot1x | (Optional) Sets the order of the authentication methods used on a port.
### Configuring Open1x

Beginning in privileged EXEC mode, follow these steps to enable manual control of the port authorization state:

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. switchport mode access
4. authentication control-direction {both | in}
5. authentication fallback name
6. authentication host-mode [multi-auth | multi-domain | multi-host | single-host]
7. authentication open
8. authentication order [ dot1x | mab ] | {webauth}
9. authentication periodic
10. authentication port-control {auto | force-authorized | force-unauthorized}
11. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>

<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config-if)# authentication order dot1x webauth</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>authentication periodic</td>
<td>(Optional) Enables or disable reauthentication on a port.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config-if)# authentication periodic</code></td>
<td></td>
</tr>
</tbody>
</table>
Disabling 802.1x Authentication on the Port

You can disable 802.1x authentication on the port by using the no dot1x pae interface configuration command.

Beginning in privileged EXEC mode, follow these steps to disable 802.1x authentication on the port. This procedure is optional.

**SUMMARY STEPS**

1. configure terminal
2. interface interface-id
3. switchport mode access
4. no dot1x pae authenticator
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
configure terminal  |
Example:

CHAPTER 89

Configuring Device Sensor

- About Device Sensor, on page 1809
- MSP-IOS Sensor Device Classifier Interaction, on page 1810
- Configuring Device Sensor, on page 1811
- Configuration Examples for the Device Sensor Feature, on page 1816
- Feature Information for Device Sensor, on page 1817

About Device Sensor

Device Sensor uses protocols such as Cisco Discovery Protocol (CDP), Link Layer Discovery Protocol (LLDP), and DHCP to obtain endpoint information from network devices and make this information available to its clients. Device Sensor has internal clients, such as the embedded Device Classifier (local analyzer), Auto Smartports (ASP), MediaNet Service Interface Media Services Proxy, and EnergyWise. Device Sensor also has an external client, Identity Services Engine (ISE), which uses RADIUS accounting to receive and analyze endpoint data. When integrated with ISE, Device Sensor provides central policy management and device-profiling capabilities.

Note

Cisco Identity Services Engine (ISE) based profiling is not supported on the LAN Base image.

Device profiling capability consists of two parts:
- Collector--Gathers endpoint data from network devices.
- Analyzer--Processes the data and determines the type of device.

Device Sensor represents the embedded collector functionality. The following illustration shows a Device Sensor in the context of its internal clients and the ISE.
Client notifications and accounting messages that contain profiling data and other session-related data are generated and sent to the internal clients and the ISE. By default, client notifications and accounting events are generated only when an incoming packet includes a Type-Length-Value (TLV) that has not previously been received within a given access session. You can enable client notifications and accounting events for TLV changes; that is, when a previously received TLV is received with a different value.

Device Sensor port security protects a switch from consuming memory and crashing during deliberate or unintentional denial-of-service (DoS)-type attacks. Device Sensor limits the maximum number of device monitoring sessions to 32 per port. While hosts are inactive, the age session limit is 12 hours.

### MSP-IOS Sensor Device Classifier Interaction

To enable MSP, you must configure the profile flow command. Once done, when SIP, H323, or mDNS traffic are present, appropriate (SIP, H323, or mDNS) TLV notifications are sent to the IOS sensor.

MSP (Media Service Proxy) offers bandwidth reservation for audio or video flows and Metadata services to 3rd-party endpoints. To offer and install Media services, MSP must identify flow attributes and device details. MSP device identification requires automatic identification of various media endpoints in the network, thereby avoiding any change to the installed endpoint base. To offer MSP device discovery services, MSP leverages current IOS sensor capability for device classification. (Starting with Release IOS XE 3.3.0SG and IOS 15.1(1)SG, IOS sensor can be used to perform device identification. MSP uses the same functionality with the addition of SIP, H323, and Multicast DNS (mDNS) protocols.) Starting with Release IOS XE 3.4.0SG...
and IOS 15.1(2)SG, MSP offers Media services to two kinds of media endpoints: IP Surveillance Cameras and Video-Conferencing Endpoints. Surveillance cameras are identified using mDNS protocol whereas Video-conference-Endpoints are identified using SIP and H.323 protocols.

mDNS compatible devices (Axis, Pelco cameras etc) send mDNS messages for DNS service discovery to a multicast IP address (224.0.0.251) on a standard mDNS port 5353. The mDNS client module listens to this UDP port, receives the mDNS message, and sends it in TLV format to the mDNS IOS sensor shim for further device classification. The module parses the mDNS query and Answer messages fields to create these TLVs.

A Session Initiation Protocol (SIP) registration message is used for SIP based device-discovery and is sent to Cisco Call manager by the SIP Client. A H.225 RAS client registration message is used for H323-based device discovery.

If no Cisco Unified Communicator Manager or GateKeeper exists in the topology, the Endpoint will not generate device Register messages. To handle device discovery in these scenarios, MSP expects the endpoint to make a SIP or H323 call so that MSP snoops the SIP invite or the H323 setup message to identify endpoint details and notify the IOS sensor.

After the IOS sensor receives these protocol details from MSP, the IOS sensor prepares Normalized TLVs, with the new protocols. These protocol details are sent to session manager for further classification.

**Configuring Device Sensor**

Device Sensor is enabled by default. Complete the following tasks when you want Device Sensor to include or exclude a list of TLVs (termed filter lists) for a particular protocol.

*Note*

If you do not perform any Device Sensor configuration tasks, the following TLVs are included by default:

- CDP filter--secondport-status-type and powernet-event-type (types 28 and 29)
- LLDP filter--organizationally-specific (type 127)
- DHCP filter--message-type (type 53)

**Enabling MSP**

You must configure the MSP profile flow command to activate the MSP platform Packet parser. This is because the MSP device handler is tightly coupled with MSP flow parser. Not enabling this command means that MSP will not send SIP, H323 notifications to the IOS sensor.

To enable MSP, follow these steps, beginning in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command or Action</strong></td>
</tr>
<tr>
<td><strong>Step 1</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Enabling Accounting Augmentation

For the Device Sensor protocol data to be added to accounting messages, you must first enable session accounting by using the following standard Authentication, Authorization, and Accounting (AAA) and RADIUS configuration commands:

Switch(config)# aaa new-model
Switch(config)# aaa accounting dot1x default start-stop group radius
Switch(config)# radius-server host {hostname|ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string]
Switch(config)# radius-server vsa send accounting

To add Device Sensor protocol data to accounting records, follow these steps, beginning in privileged EXEC mode:

### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Enables the addition of sensor protocol data to accounting records and also enables the generation of additional accounting events when new sensor data is detected.</td>
</tr>
<tr>
<td>device-sensor accounting</td>
<td></td>

<td></td>
</tr>
</tbody>
</table>

Creating a Cisco Discovery Protocol Filter

To create a CDP filter containing a list of TLVs that can be included or excluded in the Device Sensor output, follow these steps, beginning in privileged EXEC mode:

configure terminal
### Creating an LLDP Filter

To create an LLDP filter containing a list of TLVs that can be included or excluded in the Device Sensor output, follow these steps, beginning in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>device-sensor filter-list cdp list tlv-list-name</td>
<td></td>
</tr>
</tbody>
</table>

#### Creating a DHCP Filter

To create a DHCP filter containing a list of DHCP options that can be included or excluded in the Device Sensor output, follow these steps, beginning in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

### Creating an LLDP Filter

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>device-sensor filter-list lldp list tlv-list-name</td>
<td>Creates a TLV list and enters LLDP sensor configuration mode, where you can configure individual TLVs.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config)# device-sensor filter-list lldp list lldp-list</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>tlv { name tlv-name</td>
<td>number tlv-number }</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config-sensor-cdplist)# tlv number 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Switch(config-sensor-lldplist)# end</td>
<td></td>
</tr>
</tbody>
</table>
### Applying a Protocol Filter to the Device Sensor Output

Beginning in privileged EXEC mode, follow these steps to apply a CDP, LLDP, or DHCP filter to the sensor output. The output is session notifications to internal sensor clients and accounting requests to the RADIUS server.

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
configure terminal  
Example: Switch# configure terminal | Enters global configuration mode. |
| **Step 2**  
device-sensor filter-spec { cdp | dhcp | ldp } { exclude { all | list list-name } | include list list-name }  
Example: Switch(config)# device-sensor filter-spec cdp include list list1 | Applies a specific protocol filter containing a list of protocol TLV fields or DHCP options to the Device Sensor output.  
- **cdp** – Applies a CDP TLV filter list to the device sensor output  
- **ldp** – Applies an LLDP TLV filter list to the device sensor output  
- **dhcp** – Applies a DHCP option filter list to the device sensor output  
- **exclude** – Specifies the TLVs that must be excluded from the device sensor output  
- **include** – Specifies the TLVs that must be included from the device sensor output |
### Tracking TLV Changes

By default, client notifications and accounting events are generated only when an incoming packet includes a TLV that has not previously been received within a given session.

To enable client notifications and accounting events for TLV changes, follow these steps, beginning in privileged EXEC mode:

#### Procedure

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> device-sensor notify all-changes</td>
<td>Enables client notifications and accounting events for all TLV changes, that is, where either a new TLV is received or a previously received TLV is received with a new value in the context of a given session.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# device-sensor notify all-changes</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

### Verifying the Device Sensor Configuration

To verify the sensor cache entries for all devices, follow these steps, beginning in privileged EXEC mode:
Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>show device-sensor cache mac mac-address</td>
<td>Displays sensor cache entries (the list of protocol TLVs or options received from a device) for a specific device.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• mac-address is the MAC address of the endpoint</td>
</tr>
<tr>
<td>Step 2</td>
<td>show device-sensor cache all</td>
<td>Displays sensor cache entries for all devices.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>Switch(config)# device-sensor notify all-changes</td>
</tr>
</tbody>
</table>

Troubleshooting Commands

The following commands can help troubleshoot Device Sensor.

- `debug device-sensor { errors | events }`
- `debug authentication all`

Restrictions for Device Sensor

- Only CDP, LLDP, and DHCP protocols are supported.
- The session limit for profiling ports is 32.
- The length of one TLV must not be more than 1024 and the total length of TLVs (combined length of TLVs) of all protocols must not be more than 4096.
- Device Sensor profiles devices that are only one hop away.

Configuration Examples for the Device Sensor Feature

The following example shows how to create a CDP filter containing a list of TLVs:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-list cdp list cdp-list
Switch(config-sensor-cdplist)# tlv name address-type
Switch(config-sensor-cdplist)# tlv name device-name
Switch(config-sensor-cdplist)# tlv number 34
Switch(config-sensor-cdplist)# end
```

The following example shows how to create an LLDP filter containing a list of TLVs:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-list lldp list lldp-list
```
The following example shows how to create a DHCP filter containing a list of options:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-list dhcp list dhcp-list
Switch(config)# device-sensor filter-list dhcp list dhcp-list
Switch(config-sensor-dhcplist)# option name domain-name
Switch(config-sensor-dhcplist)# option name host-name
Switch(config-sensor-dhcplist)# option number 50
Switch(config-sensor-dhcplist)# end
```

The following example shows how to apply a CDP TLV filter list to the Device Sensor output:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor filter-spec cdp include cdp-list1
```

The following example shows how to enable client notifications and accounting events for all TLV changes:

```
Switch> enable
Switch# configure terminal
Switch(config)# device-sensor notify all-changes
```

## Feature Information for Device Sensor

**Table 146: Feature Information for Device Sensor**

<table>
<thead>
<tr>

CHAPTER 90

Configuring Web-Based Authentication

This chapter describes how to configure web-based authentication on the switch. It contains these sections:

- Finding Feature Information, on page 1819
- Web-Based Authentication Overview, on page 1819
- How to Configure Web-Based Authentication, on page 1828
- Monitoring Web-Based Authentication Status, on page 1843

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Web-Based Authentication Overview

Use the web-based authentication feature, known as web authentication proxy, to authenticate end users on host systems that do not run the IEEE 802.1x supplicant.

Note

You can configure web-based authentication on Layer 2 and Layer 3 interfaces.

When you initiate an HTTP session, web-based authentication intercepts ingress HTTP packets from the host and sends an HTML login page to the users. The users enter their credentials, which the web-based authentication feature sends to the authentication, authorization, and accounting (AAA) server for authentication.

If authentication succeeds, web-based authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.

If authentication fails, web-based authentication forwards a Login-Fail HTML page to the user, prompting the user to retry the login. If the user exceeds the maximum number of attempts, web-based authentication forwards a Login-Expired HTML page to the host, and the user is placed on a watch list for a waiting period.
HTTPS traffic interception for central web authentication redirect is not supported.

**Note**

You should use global parameter-map (for method-type, custom, and redirect) only for using the same web authentication methods like consent, web consent, and webauth, for all the clients and SSIDs. This ensures that all the clients have the same web-authentication method.

If the requirement is to use Consent for one SSID and Web-authentication for another SSID, then you should use two named parameter-maps. You should configure Consent in first parameter-map and configure webauth in second parameter-map.

### Device Roles

With web-based authentication, the devices in the network have these specific roles:

- **Client**—The device (workstation) that requests access to the LAN and the services and responds to requests from the switch. The workstation must be running an HTML browser with JavaScript enabled.

- **Authentication server**—Authenticates the client. The authentication server validates the identity of the client and notifies the switch that the client is authorized to access the LAN and the switch services or that the client is denied.

- **Switch**—Controls the physical access to the network based on the authentication status of the client. The switch acts as an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client.

**Figure 112: Web-Based Authentication Device Roles**

This figure shows the roles of these devices in a network.

### Host Detection

The switch maintains an IP device tracking table to store information about detected hosts.
By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.

For Layer 2 interfaces, web-based authentication detects IP hosts by using these mechanisms:

- ARP based trigger—ARP redirect ACL allows web-based authentication to detect hosts with a static IP address or a dynamic IP address.
- Dynamic ARP inspection
- DHCP snooping—Web-based authentication is notified when the switch creates a DHCP-binding entry for the host.

Session Creation

When web-based authentication detects a new host, it creates a session as follows:

- Reviews the exception list.
  
  If the host IP is included in the exception list, the policy from the exception list entry is applied, and the session is established.

- Reviews for authorization bypass
  
  If the host IP is not on the exception list, web-based authentication sends a nonresponsive-host (NRH) request to the server.
  
  If the server response is access accepted, authorization is bypassed for this host. The session is established.

- Sets up the HTTP intercept ACL
  
  If the server response to the NRH request is access rejected, the HTTP intercept ACL is activated, and the session waits for HTTP traffic from the host.

Authentication Process

When you enable web-based authentication, these events occur:

- The user initiates an HTTP session.

- The HTTP traffic is intercepted, and authorization is initiated. The switch sends the login page to the user. The user enters a username and password, and the switch sends the entries to the authentication server.

- If the authentication succeeds, the switch downloads and activates the user’s access policy from the authentication server. The login success page is sent to the user.

- If the authentication fails, the switch sends the login fail page. The user retries the login. If the maximum number of attempts fails, the switch sends the login expired page, and the host is placed in a watch list. After the watch list times out, the user can retry the authentication process.

- If the authentication server does not respond to the switch, and if an AAA fail policy is configured, the switch applies the failure access policy to the host. The login success page is sent to the user.
• The switch reauthorizes a client when the host does not respond to an ARP probe on a Layer 2 interface, or when the host does not send any traffic within the idle timeout on a Layer 3 interface.

• The feature applies the downloaded timeout or the locally configured session timeout.

---

**Note**

Beginning with Cisco IOS XE Denali 16.1.1 and later, the default session timeout value for web-based authentication on WLC is 1800 seconds. The default session timeout value was infinite seconds, prior to Cisco IOS XE Denali 16.1.1.

• If the terminate action is RADIUS, the feature sends a nonresponsive host (NRH) request to the server. The terminate action is included in the response from the server.

• If the terminate action is default, the session is dismantled, and the applied policy is removed.

### Local Web Authentication Banner

With Web Authentication, you can create a default and customized web-browser banners that appear when you log in to a switch.

The banner appears on both the login page and the authentication-result pop-up pages. The default banner messages are as follows:

- **Authentication Successful**
- **Authentication Failed**
- **Authentication Expired**

The Local Web Authentication Banner can be configured in legacy and new-style (Session-aware) CLIs as follows:

- **Legacy mode**—Use the `ip admission auth-proxy-banner http` global configuration command.
- **New-style mode**—Use the `parameter-map type webauth global banner` global configuration command.

The default banner *Cisco Systems* and *Switch host-name Authentication* appear on the Login Page. *Cisco Systems* appears on the authentication result pop-up page.
The banner can be customized as follows:

- Add a message, such as switch, router, or company name to the banner:
  - Legacy mode—Use the `ip admission auth-proxy-banner http banner-text` global configuration command.
  - New-style mode—Use the `parameter-map type webauth global banner` global configuration command

- Add a logo or text file to the banner:
  - Legacy mode—Use the `ip admission auth-proxy-banner http file-path` global configuration command.
  - New-style mode—Use the `parameter-map type webauth global banner` global configuration command
If you do not enable a banner, only the username and password dialog boxes appear in the web authentication login screen, and no banner appears when you log into the switch.

For more information, see the Session Aware Networking Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3850 Switches) Session Aware Networking Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3850 Switches) and the Web Authentication Enhancements - Customizing Authentication Proxy Web Pages.
Web Authentication Customizable Web Pages

During the web-based authentication process, the switch internal HTTP server hosts four HTML pages to deliver to an authenticating client. The server uses these pages to notify you of these four-authentication process states:

- Login—Your credentials are requested.
- Success—The login was successful.
- Fail—The login failed.
- Expire—The login session has expired because of excessive login failures.

Guidelines

- You can substitute your own HTML pages for the default internal HTML pages.
- You can use a logo or specify text in the login, success, failure, and expire web pages.
- On the banner page, you can specify text in the login page.
- The pages are in HTML.
- You must include an HTML redirect command in the success page to access a specific URL.
- The URL string must be a valid URL (for example, http://www.cisco.com). An incomplete URL might cause page not found or similar errors on a web browser.
- If you configure web pages for HTTP authentication, they must include the appropriate HTML commands (for example, to set the page time out, to set a hidden password, or to confirm that the same page is not submitted twice).
- The CLI command to redirect users to a specific URL is not available when the configured login form is enabled. The administrator should ensure that the redirection is configured in the web page.
- If the CLI command redirecting users to specific URL after authentication occurs is entered and then the command configuring web pages is entered, the CLI command redirecting users to a specific URL does not take effect.
- Configured web pages can be copied to the switch boot flash or flash.
- On stackable switches, configured pages can be accessed from the flash on the stack master or members.
- The login page can be on one flash, and the success and failure pages can be another flash (for example, the flash on the stack master or a member).
- You must configure all four pages.
- The banner page has no effect if it is configured with the web page.
- All of the logo files (image, flash, audio, video, and so on) that are stored in the system directory (for example, flash, disk0, or disk) and that must be displayed on the login page must use web_auth_<filename> as the file name.
- The configured authentication proxy feature supports both HTTP and SSL.
You can substitute your HTML pages for the default internal HTML pages. You can also specify a URL to which users are redirected after authentication occurs, which replaces the internal Success page.

Figure 116: Customizable Authentication Page

Authentication Proxy Web Page Guidelines

When configuring customized authentication proxy web pages, follow these guidelines:

- To enable the custom web pages feature, specify all four custom HTML files. If you specify fewer than four files, the internal default HTML pages are used.

- The four custom HTML files must be present on the flash memory of the switch. The maximum size of each HTML file is 8 KB.

- Any images on the custom pages must be on an accessible HTTP server. Configure an intercept ACL within the admission rule.

- Any external link from a custom page requires configuration of an intercept ACL within the admission rule.

- To access a valid DNS server, any name resolution required for external links or images requires configuration of an intercept ACL within the admission rule.

- If the custom web pages feature is enabled, a configured auth-proxy-banner is not used.

- If the custom web pages feature is enabled, the redirection URL for successful login feature is not available.

- To remove the specification of a custom file, use the `no` form of the command.

Because the custom login page is a public web form, consider these guidelines for the page:

- The login form must accept user entries for the username and password and must show them as `uname` and `pwd`.
The custom login page should follow best practices for a web form, such as page timeout, hidden password, and prevention of redundant submissions.

Related Topics

Customizing the Authentication Proxy Web Pages, on page 1837

Redirection URL for Successful Login Guidelines

When configuring a redirection URL for successful login, consider these guidelines:

- If the custom authentication proxy web pages feature is enabled, the redirection URL feature is disabled and is not available in the CLI. You can perform redirection in the custom-login-success page.
- If the redirection URL feature is enabled, a configured auth-proxy-banner is not used.
- To remove the specification of a redirection URL, use the `no` form of the command.
- If the redirection URL is required after the web-based authentication client is successfully authenticated, then the URL string must start with a valid URL (for example, http://) followed by the URL information. If only the URL is given without http://, then the redirection URL on successful authentication might cause page not found or similar errors on a web browser.

Specifying a Redirection URL for Successful Login, on page 1839

Web-based Authentication Interactions with Other Features

Port Security

You can configure web-based authentication and port security on the same port. Web-based authentication authenticates the port, and port security manages network access for all MAC addresses, including that of the client. You can then limit the number or group of clients that can access the network through the port.

Related Topics

Enabling and Configuring Port Security, on page 1861

LAN Port IP

You can configure LAN port IP (LPIP) and Layer 2 web-based authentication on the same port. The host is authenticated by using web-based authentication first, followed by LPIP posture validation. The LPIP host policy overrides the web-based authentication host policy.

If the web-based authentication idle timer expires, the NAC policy is removed. The host is authenticated, and posture is validated again.

Gateway IP

You cannot configure Gateway IP (GWIP) on a Layer 3 VLAN interface if web-based authentication is configured on any of the switch ports in the VLAN.

You can configure web-based authentication on the same Layer 3 interface as Gateway IP. The host policies for both features are applied in software. The GWIP policy overrides the web-based authentication host policy.
ACLs

If you configure a VLAN ACL or a Cisco IOS ACL on an interface, the ACL is applied to the host traffic only after the web-based authentication host policy is applied.

For Layer 2 web-based authentication, it is more secure, though not required, to configure a port ACL (PACL) as the default access policy for ingress traffic from hosts connected to the port. After authentication, the web-based authentication host policy overrides the PACL. The Policy ACL is applied to the session even if there is no ACL configured on the port.

You cannot configure a MAC ACL and web-based authentication on the same interface.

You cannot configure web-based authentication on a port whose access VLAN is configured for VACL capture.

Context-Based Access Control

Web-based authentication cannot be configured on a Layer 2 port if context-based access control (CBAC) is configured on the Layer 3 VLAN interface of the port VLAN.

EtherChannel

You can configure web-based authentication on a Layer 2 EtherChannel interface. The web-based authentication configuration applies to all member channels.

How to Configure Web-Based Authentication

Default Web-Based Authentication Configuration

The following table shows the default web-based authentication configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAA</td>
<td>Disabled</td>
</tr>
<tr>
<td>RADIUS server</td>
<td></td>
</tr>
<tr>

<td>• None specified</td>
</tr>
<tr>
<td>• UDP authentication port</td>
<td>• 1645</td>
</tr>
<tr>
<td>• Key</td>
<td>• None specified</td>
</tr>
<tr>
<td>Default value of inactivity timeout</td>
<td>3600 seconds</td>
</tr>
<tr>
<td>Inactivity timeout</td>
<td>Enabled</td>
</tr>
</tbody>
</table>
Web-Based Authentication Configuration Guidelines and Restrictions

- Web-based authentication is an ingress-only feature.
- You can configure web-based authentication only on access ports. Web-based authentication is not supported on trunk ports, EtherChannel member ports, or dynamic trunk ports.
- You cannot authenticate hosts on Layer 2 interfaces with static ARP cache assignment. These hosts are not detected by the web-based authentication feature because they do not send ARP messages.
- By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.
- You must configure at least one IP address to run the switch HTTP server. You must also configure routes to reach each host IP address. The HTTP server sends the HTTP login page to the host.
- Hosts that are more than one hop away might experience traffic disruption if an STP topology change results in the host traffic arriving on a different port. This occurs because the ARP and DHCP updates might not be sent after a Layer 2 (STP) topology change.
- Web-based authentication does not support VLAN assignment as a downloadable-host policy.
- Web-based authentication supports IPv6 in Session-aware policy mode. IPv6 Web-authentication requires at least one IPv6 address configured on the switch and IPv6 Snooping configured on the switchport.
- Web-based authentication and Network Edge Access Topology (NEAT) are mutually exclusive. You cannot use web-based authentication when NEAT is enabled on an interface, and you cannot use NEAT when web-based authentication is running on an interface.
- Web-based authentication NRH (Non-Responsive Host) is not supported for voice devices.
- Only the Password Authentication Protocol (PAP) is supported for web-based RADIUS authentication on controllers. The Challenge Handshake Authentication Protocol (CHAP) is not supported for web-based RADIUS authentication on controllers.
- Identify the following RADIUS security server settings that will be used while configuring switch-to-RADIUS-server communication:
  • Host name
  • Host IP address
  • Host name and specific UDP port numbers
  • IP address and specific UDP port numbers

The combination of the IP address and UDP port number creates a unique identifier, that enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service (for example, authentication) the second host entry that is configured functions as the failover backup to the first one. The RADIUS host entries are chosen in the order that they were configured.
- When you configure the RADIUS server parameters:
  • Specify the key string on a separate command line.
For **key string**, specify the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. The key is a text string that must match the encryption key used on the RADIUS server.

When you specify the **key string**, use spaces within and at the end of the key. If you use spaces in the key, do not enclose the key in quotation marks unless the quotation marks are part of the key. This key must match the encryption used on the RADIUS daemon.

You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers by using with the **radius-server host** global configuration command. If you want to configure these options on a per-server basis, use the **radius-server timeout**, radius-server transmit, and the radius-server key global configuration commands. For more information, see the *Cisco IOS Security Configuration Guide*, Release 12.4 and the *Cisco IOS Security Command Reference*, Release 12.4.

---

**Note**

You need to configure some settings on the RADIUS server, including: the switch IP address, the key string to be shared by both the server and the switch, and the downloadable ACL (DACL). For more information, see the RADIUS server documentation.

---

## Configuring the Authentication Rule and Interfaces

Examples in this section are legacy-style configurations. For new-style configurations, see the *Session Aware Networking Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*.

Follow these steps to configure the authentication rule and interfaces:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip admission name name proxy http`
4. `interface type slot/port`
5. `ip access-group name`
6. `ip admission name`
7. `exit`
8. `ip devicetracking`
9. `end`
10. `show ip admission status`
11. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip admission name <em>name</em> proxy http</td>
<td>Configures an authentication rule for web-based authorization.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ip admission name webauth1 proxy http</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface <em>type</em> slot/port</td>
<td>Enters interface configuration mode and specifies the ingress Layer 2 or Layer 3 interface to be enabled for web-based authentication.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# interface gigabitEthernet1/0/1</td>
<td><em>type</em> can be fastethernet, gigabit ethernet, or tengigabitethernet.</td>
</tr>
<tr>
<td><strong>Step 5</strong> ip access-group <em>name</em></td>
<td>Applies the default ACL.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ip access-group webauthag</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ip admission <em>name</em></td>
<td>Configures web-based authentication on the specified interface.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# ip admission webauth1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> exit</td>
<td>Returns to configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> ip device tracking</td>
<td>Enables the IP device tracking table.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# ip device tracking</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>----------------------------------------------</td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Step 10**

show ip admission status

Example:

Device# show ip admission status

**Step 11**

copy running-config startup-config

Example:

Device# copy running-config startup-config

---

**Configuring AAA Authentication**

If a method-list is configured under VTY lines, the corresponding method list must be added to the AAA configuration:

```plaintext
line vty 0 4
  authorization commands 15 abc
  aaa authorization commands 15 abc group tacacs+
```

If a method-list is not configured under VTY lines, you must add the default method list to the AAA configuration:

```plaintext
line vty 0 4
  aaa authorization commands 15 default group tacacs+
```

Follow these steps to configure AAA authentication:

---

**Note**

Use default list for AAA authorization, if you are planning to use features such as dACL.

---

**SUMMARY STEPS**

1. enable
2. configure terminal
3. aaa new-model
4. aaa authentication login default group {tacacs+ | radius}
5. aaa authorization auth-proxy default group {tacacs+ | radius}
6. tacacs server server-name
7. address {ipv4 | ipv6} ip address
8. key string
9. exit
10. end
11. show running-config
12. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>aaa new-model</td>
<td>Enables AAA functionality.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# aaa new-model</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>aaa authentication login default group {tacacs+ radius}</td>
<td>Defines the list of authentication methods at login.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# aaa authentication login default group tacacs+</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>aaa authorization auth-proxy default group {tacacs+ radius}</td>
<td>Creates an authorization method list for web-based authorization.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# aaa authorization auth-proxy default group tacacs+</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>tacacs server server-name</td>
<td>Specifies an AAA server.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# tacacs server yourserver</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>address {ipv4</td>
<td>ipv6} ip address</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config-server-tacacs)# address ipv4 10.0.1.12</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring Switch-to-RADIUS-Server Communication

Follow these steps to configure the RADIUS server parameters:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip radius source-interface vlan *vlan interface number*
4. radius server *server name*
5. address {ipv4 | ipv6} *ip address*
6. key *string*
7. exit
8. radius-server dead-criteria tries *num-tries*
9. end

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td><strong>key string</strong></td>
<td>Configures the authorization and encryption key used between the switch and the TACACS server.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-server-tacacs)# key cisco123</code></td>
<td></td>
</tr>
<tr>
<td>9</td>
<td><strong>exit</strong></td>
<td>Exits the TACACS server mode and enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config-server-tacacs)# exit</code></td>
<td></td>
</tr>
<tr>
<td>10</td>
<td><strong>end</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
<tr>
<td>11</td>
<td><strong>show running-config</strong></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# show running-config</code></td>
<td></td>
</tr>
<tr>
<td>12</td>
<td><strong>copy running-config startup-config</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable  
**Example:**  
Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| **Step 2** configure terminal  
**Example:**  
Device# configure terminal | Enters the global configuration mode. |
| **Step 3** ip radius source-interface vlan **vlan interface number**  
**Example:**  
Device(config)# ip radius source-interface vlan 80 | Specifies that the RADIUS packets have the IP address of the indicated interface. |
| **Step 4** radius server **servername**  
**Example:**  
Device(config)# radius server rsim address ipv4 124.2.2.12 | (Optional) Specifies the IP address of the RADIUS server. |
| **Step 5** address {ipv4 | ipv6} **ip address**  
**Example:**  
Device(config-radius-server)# address ipv4 10.0.1.2 auth-port 1550 acct-port 1560 | Configures the IP address for the RADIUS server. |
| **Step 6** key **string**  
**Example:**  
Device(config-radius-server)# key rad123 | (Optional) Specifies the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. |
| **Step 7** exit  
**Example:**  
Device(config-radius-server)# exit | Exits the RADIUS server mode and enters the global configuration mode. |
<table>
<thead>
<tr>
<th>Step 8</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

## Configuring the HTTP Server

To use web-based authentication, you must enable the HTTP server within the Device. You can enable the server for either HTTP or HTTPS.

⚠️ **Note**

The Apple pseudo-browser will not open if you configure only the `ip http secure-server` command. You should also configure the `ip http server` command.

Follow these steps to enable the server for either HTTP or HTTPS:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip http server`
4. `ip http secure-server`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device&gt; enable</td>
</tr>
</tbody>
</table>

| Step 2 | command terminal | Enters the global configuration mode. |
| Example: | | |
|        | Device# configure terminal | | |
### Customizing the Authentication Proxy Web Pages

You can configure web authentication to display four substitute HTML pages to the user in place of the Device default HTML pages during web-based authentication.

For the equivalent Session Aware Networking configuration example for this feature, see the section "Configuring a Parameter Map for Web-Based Authentication" in the chapter, "Configuring Identity Control Policies." of the book, "Session Aware Networking Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)."

Follow these steps to specify the use of your custom authentication proxy web pages:

**Before you begin**

Store your custom HTML files on the Device flash memory.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip admission proxy http login page file device:login-filename
4. ip admission proxy http success page file device:success-filename
5. ip admission proxy http failure page file device:fail-filename
6. ip admission proxy http login expired page file device:expired-filename
7. end
# Customizing the Authentication Proxy Web Pages

## Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ip admission proxy http login page file&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ip admission proxy http login page file disk1:login.htm</td>
<td>Specifies the location in the Device memory file system of the custom HTML file to use in place of the default login page. The <em>device:</em> is flash memory.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>ip admission proxy http success page file&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ip admission proxy http success page file disk1:success.htm</td>
<td>Specifies the location of the custom HTML file to use in place of the default login success page.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>ip admission proxy http failure page file&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ip admission proxy http fail page file disk1:fail.htm</td>
<td>Specifies the location of the custom HTML file to use in place of the default login failure page.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>ip admission proxy http login expired page file&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# ip admission proxy http login expired page file disk1:expired.htm</td>
<td>Specifies the location of the custom HTML file to use in place of the default login expired page.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>end&lt;br&gt;<strong>Example:</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>
**Specifying a Redirection URL for Successful Login**

Follow these steps to specify a URL to which the user is redirected after authentication, effectively replacing the internal Success HTML page:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip admission proxy http success redirect url-string`
4. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Example: <code>Device&gt; enable</code></td>
</tr>
</tbody>
</table>

| Step 2 | Enters the global configuration mode. |
| `configure terminal` | Example: `Device# configure terminal` |

| Step 3 | Specifies a URL for redirection of the user in place of the default login success page. |
| `ip admission proxy http success redirect url-string` | Example: `Device(config)# ip admission proxy http success redirect www.example.com` |

| Step 4 | Returns to privileged EXEC mode. |
| `end` | Example: `Device(config)# end` |
Configuring the Web-Based Authentication Parameters

Follow these steps to configure the maximum number of failed login attempts before the client is placed in a watch list for a waiting period:

SUMMARY STEPS

1. enable
2. configure terminal
3. ip admission max-login-attempts number
4. end
5. show running-config
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip admission max-login-attempts number</td>
<td>Sets the maximum number of failed login attempts. The range is 1 to 2147483647 attempts. The default is 5.</td>
</tr>
<tr>
<td>Example: Device(config)# ip admission max-login-attempts 10</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

### Configuring a Web-Based Authentication Local Banner

Follow these steps to configure a local banner on a switch that has web authentication configured.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip admission auth-proxy-banner http [banner-text | file-path]
4. end
5. show running-config
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1  
enable  
Example:  
Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2  
configure terminal  
Example:  
Device# configure terminal | Enters the global configuration mode. |
| Step 3  
ip admission auth-proxy-banner http [banner-text | file-path]  
Example:  
Device(config)# ip admission auth-proxy-banner http C My Switch C | Enables the local banner.  
(Optional) Create a custom banner by entering C banner-text C (where C is a delimiting character), or file-path that indicates a file (for example, a logo or text file) that appears in the banner. |
## Purpose

### Command or Action

**Step 4**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Example:**

```bash
Device(config)# end
```

**Step 5**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
</tbody>
</table>

**Example:**

```bash
Device# show running-config
```

**Step 6**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

**Example:**

```bash
Device# copy running-config startup-config
```

## Removing Web-Based Authentication Cache Entries

Follow these steps to remove web-based authentication cache entries:

### SUMMARY STEPS

1. enable
2. clear ip auth-proxy cache {* | host ip address}
3. clear ip admission cache {* | host ip address}

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**              |                                             |
| clear ip auth-proxy cache {* | host ip address} | Delete authentication proxy entries. Use an asterisk to delete all cache entries. Enter a specific IP address to delete the entry for a single host. |
| Example:                |                                             |
| Device# clear ip auth-proxy cache 192.168.4.5 |                                             |
**Monitoring Web-Based Authentication Status**

Use the commands in this topic to display the web-based authentication settings for all interfaces or for specific ports.

*Table 148: Privileged EXEC show Commands*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>

**Step 3**

`clear ip admission cache {* | host ip address}`

Example:

```
Device# clear ip admission cache 192.168.4.5
```
Monitoring Web-Based Authentication Status
Overview of Port-Based Traffic Control

Port-based traffic control is a set of Layer 2 features on the Cisco Catalyst switches used to filter or block packets at the port level in response to specific traffic conditions. The following port-based traffic control features are supported in the Cisco IOS Release for which this guide is written:

- Storm Control
- Protected Ports
- Port Blocking
- Port Security
- Protocol Storm Protection
Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Storm Control

Storm Control

Storm control prevents traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on one of the physical interfaces. A LAN storm occurs when packets flood the LAN, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation, mistakes in network configurations, or users issuing a denial-of-service attack can cause a storm.

Storm control (or traffic suppression) monitors packets passing from an interface to the switching bus and determines if the packet is unicast, multicast, or broadcast. The switch counts the number of packets of a specified type received within the 1-second time interval and compares the measurement with a predefined suppression-level threshold.

How Traffic Activity is Measured

Storm control uses one of these methods to measure traffic activity:

- Bandwidth as a percentage of the total available bandwidth of the port that can be used by the broadcast, multicast, or unicast traffic
- Traffic rate in packets per second at which broadcast, multicast, or unicast packets are received
- Traffic rate in bits per second at which broadcast, multicast, or unicast packets are received
- Traffic rate in packets per second and for small frames. This feature is enabled globally. The threshold for small frames is configured for each interface.

With each method, the port blocks traffic when the rising threshold is reached. The port remains blocked until the traffic rate drops below the falling threshold (if one is specified) and then resumes normal forwarding. If the falling suppression level is not specified, the switch blocks all traffic until the traffic rate drops below the rising suppression level. In general, the higher the level, the less effective the protection against broadcast storms.
When the storm control threshold for multicast traffic is reached, all multicast traffic except control traffic, such as bridge protocol data unit (BDPU) and Cisco Discovery Protocol (CDP) frames, are blocked. However, the switch does not differentiate between routing updates, such as OSPF, and regular multicast data traffic, so both types of traffic are blocked.

**Traffic Patterns**

*Figure 117: Broadcast Storm Control Example*

This example shows broadcast traffic patterns on an interface over a given period of time.

![Graph](image)

Broadcast traffic being forwarded exceeded the configured threshold between time intervals T1 and T2 and between T4 and T5. When the amount of specified traffic exceeds the threshold, all traffic of that kind is dropped for the next time period. Therefore, broadcast traffic is blocked during the intervals following T2 and T5. At the next time interval (for example, T3), if broadcast traffic does not exceed the threshold, it is again forwarded.

The combination of the storm-control suppression level and the 1-second time interval controls the way the storm control algorithm works. A higher threshold allows more packets to pass through. A threshold value of 100 percent means that no limit is placed on the traffic. A value of 0.0 means that all broadcast, multicast, or unicast traffic on that port is blocked.

**Note**

Because packets do not arrive at uniform intervals, the 1-second time interval during which traffic activity is measured can affect the behavior of storm control.

You use the `storm-control` interface configuration commands to set the threshold value for each traffic type.
How to Configure Storm Control

Configuring Storm Control and Threshold Levels

You configure storm control on a port and enter the threshold level that you want to be used for a particular type of traffic.

However, because of hardware limitations and the way in which packets of different sizes are counted, threshold percentages are approximations. Depending on the sizes of the packets making up the incoming traffic, the actual enforced threshold might differ from the configured level by several percentage points.

Note
Storm control is supported on physical interfaces. You can also configure storm control on an EtherChannel. When storm control is configured on an EtherChannel, the storm control settings propagate to the EtherChannel physical interfaces.

Follow these steps to storm control and threshold levels:

Before you begin
Storm control is supported on physical interfaces. You can also configure storm control on an EtherChannel. When storm control is configured on an EtherChannel, the storm control settings propagate to the EtherChannel physical interfaces.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. storm-control {broadcast | multicast | unicast} level {level [level-low] | bps bps [bps-low] | pps pps [pps-low]}
5. storm-control action {shutdown | trap}
6. end
7. show storm-control [interface-id] [broadcast | multicast | unicast]
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>

<tr>
<td><strong>Step 4</strong></td>
<td>**storm-control {broadcast</td>
<td>multicast</td>
</tr>
</tbody>
</table>
| **Purpose** | Configures broadcast, multicast, or unicast storm control. By default, storm control is disabled. The keywords have these meanings:<br><ul><li>• For **level**, specifies the rising threshold level for broadcast, multicast, or unicast traffic as a percentage (up to two decimal places) of the bandwidth. The port blocks traffic when the rising threshold is reached. The range is 0.00 to 100.00.</li><li>• (Optional) For **level-low**, specifies the falling threshold level as a percentage (up to two decimal places) of the bandwidth. This value must be less than or equal to the rising suppression value. The port forwards traffic when traffic drops below this level. If you do not configure a falling suppression level, it is set to the rising suppression level. The range is 0.00 to 100.00. If you set the threshold to the maximum value (100 percent), no limit is placed on the traffic. If you set the threshold to 0.0, all broadcast, multicast, and unicast traffic on that port is blocked.</li><li>• For **bps bps**, specifies the rising threshold level for broadcast, multicast, or unicast traffic in bits per second (up to one decimal place). The port blocks traffic when the rising threshold is reached. The range is 0.0 to 10000000000.0.</li><li>• (Optional) For **bps-low**, specifies the falling threshold level in bits per second (up to one decimal place). It can be less than or equal to the rising threshold level. The port forwards traffic when traffic drops below this level. The range is 0.0 to 10000000000.0.</li><li>• For **pps pps**, specifies the rising threshold level for broadcast, multicast, or unicast traffic in packets per second (up to one decimal place). The port blocks traffic when the rising threshold is reached. The range is 0.0 to 10000000000.0.</li></ul>
Information About Protected Ports

Protected Ports

Some applications require that no traffic be forwarded at Layer 2 between ports on the same switch so that one neighbor does not see the traffic generated by another neighbor. In such an environment, the use of protected ports ensures that there is no exchange of unicast, broadcast, or multicast traffic between these ports on the switch.

Protected ports have these features:

- A protected port does not forward any traffic (unicast, multicast, or broadcast) to any other port that is also a protected port. Data traffic cannot be forwarded between protected ports at Layer 2; only control
traffic, such as PIM packets, is forwarded because these packets are processed by the CPU and forwarded in software. All data traffic passing between protected ports must be forwarded through a Layer 3 device.

- Forwarding behavior between a protected port and a nonprotected port proceeds as usual.

Because a switch stack represents a single logical switch, Layer 2 traffic is not forwarded between any protected ports in the switch stack, whether they are on the same or different switches in the stack.

**Default Protected Port Configuration**

The default is to have no protected ports defined.

**Protected Ports Guidelines**

You can configure protected ports on a physical interface (for example, Gigabit Ethernet port 1) or an EtherChannel group (for example, port-channel 5). When you enable protected ports for a port channel, it is enabled for all ports in the port-channel group.

**How to Configure Protected Ports**

**Configuring a Protected Port**

**Before you begin**

Protected ports are not pre-defined. This is the task to configure one.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport protected`
5. `end`
6. `show interfaces interface-id switchport`
7. `show running-config`
8. `copy running-config startup-config`

Information About Port Blocking

Port Blocking

By default, the switch floods packets with unknown destination MAC addresses out of all ports. If unknown unicast and multicast traffic is forwarded to a protected port, there could be security issues. To prevent unknown unicast or multicast traffic from being forwarded from one port to another, you can block a port (protected or nonprotected) from flooding unknown unicast or multicast packets to other ports.

Note

With multicast traffic, the port blocking feature blocks only pure Layer 2 packets. Multicast packets that contain IPv4 or IPv6 information in the header are not blocked.

How to Configure Port Blocking

Blocking Flooded Traffic on an Interface

Before you begin

The interface can be a physical interface or an EtherChannel group. When you block multicast or unicast traffic for a port channel, it is blocked on all ports in the port-channel group.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport block multicast`
5. `switchport block unicast`
6. `end`
7. `show interfaces interface-id switchport`
**Blocking Flooded Traffic on an Interface**

8. `show running-config`
9. `copy running-config startup-config`

---

### Prerequisites for Port Security

**Note**  
If you try to set the maximum value to a number less than the number of secure addresses already configured on an interface, the command is rejected.

---

### Restrictions for Port Security

The maximum number of secure MAC addresses that you can configure on a switch or switch stack is set by the maximum number of available MAC addresses allowed in the system. This number is determined by the active Switch Database Management (SDM) template. This number is the total of available MAC addresses, including those used for other Layer 2 functions and any other secure MAC addresses configured on interfaces.
Information About Port Security

Port Security

You can use the port security feature to restrict input to an interface by limiting and identifying MAC addresses of the stations allowed to access the port. When you assign secure MAC addresses to a secure port, the port does not forward packets with source addresses outside the group of defined addresses. If you limit the number of secure MAC addresses to one and assign a single secure MAC address, the workstation attached to that port is assured the full bandwidth of the port.

If a port is configured as a secure port and the maximum number of secure MAC addresses is reached, when the MAC address of a station attempting to access the port is different from any of the identified secure MAC addresses, a security violation occurs. Also, if a station with a secure MAC address configured or learned on one secure port attempts to access another secure port, a violation is flagged.

Related Topics
- Enabling and Configuring Port Security, on page 1861
- Configuration Examples for Port Security, on page 1879

Types of Secure MAC Addresses

The switch supports these types of secure MAC addresses:

- Static secure MAC addresses—These are manually configured by using the `switchport port-security mac-address mac-address` interface configuration command, stored in the address table, and added to the switch running configuration.

- Dynamic secure MAC addresses—These are dynamically configured, stored only in the address table, and removed when the switch restarts.

- Sticky secure MAC addresses—These can be dynamically learned or manually configured, stored in the address table, and added to the running configuration. If these addresses are saved in the configuration file, when the switch restarts, the interface does not need to dynamically reconfigure them.

Sticky Secure MAC Addresses

You can configure an interface to convert the dynamic MAC addresses to sticky secure MAC addresses and to add them to the running configuration by enabling sticky learning. The interface converts all the dynamic secure MAC addresses, including those that were dynamically learned before sticky learning was enabled, to sticky secure MAC addresses. All sticky secure MAC addresses are added to the running configuration.

The sticky secure MAC addresses do not automatically become part of the configuration file, which is the startup configuration used each time the switch restarts. If you save the sticky secure MAC addresses in the configuration file, when the switch restarts, the interface does not need to relearn these addresses. If you do not save the sticky secure addresses, they are lost.

If sticky learning is disabled, the sticky secure MAC addresses are converted to dynamic secure addresses and are removed from the running configuration.
Security Violations

It is a security violation when one of these situations occurs:

- The maximum number of secure MAC addresses have been added to the address table, and a station whose MAC address is not in the address table attempts to access the interface.

- An address learned or configured on one secure interface is seen on another secure interface in the same VLAN.

- Running diagnostic tests with port security enabled.

You can configure the interface for one of three violation modes, based on the action to be taken if a violation occurs:

- **protect**—when the number of secure MAC addresses reaches the maximum limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses to drop below the maximum value or increase the number of maximum allowable addresses. You are not notified that a security violation has occurred.

  **Note**  
  We do not recommend configuring the protect violation mode on a trunk port. The protect mode disables learning when any VLAN reaches its maximum limit, even if the port has not reached its maximum limit.

- **restrict**—when the number of secure MAC addresses reaches the maximum limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses to drop below the maximum value or increase the number of maximum allowable addresses. In this mode, you are notified that a security violation has occurred. An SNMP trap is sent, a syslog message is logged, and the violation counter increments.

- **shutdown**—a port security violation causes the interface to become error-disabled and to shut down immediately, and the port LED turns off. When a secure port is in the error-disabled state, you can bring it out of this state by entering the `errdisable recovery cause psecure-violation` global configuration command, or you can manually re-enable it by entering the `shutdown` and `no shutdown` interface configuration commands. This is the default mode.

- **shutdown vlan**—Use to set the security violation mode per-VLAN. In this mode, the VLAN is error disabled instead of the entire port when a violation occurs

This table shows the violation mode and the actions taken when you configure an interface for port security.

<table>

Table 151: Security Violation Mode Actions
Port Security Aging

You can use port security aging to set the aging time for all secure addresses on a port. Two types of aging are supported per port:

- **Absolute**—The secure addresses on the port are deleted after the specified aging time.
- **Inactivity**—The secure addresses on the port are deleted only if the secure addresses are inactive for the specified aging time.

Related Topics

[Enabling and Configuring Port Security Aging](#), on page 1866

Port Security and Switch Stacks

When a switch joins a stack, the new switch will get the configured secure addresses. All dynamic secure addresses are downloaded by the new stack member from the other stack members.

When a switch (either the active switch or a stack member) leaves the stack, the remaining stack members are notified, and the secure MAC addresses configured or learned by that switch are deleted from the secure MAC address table.

</tbody>
</table>
### Port Security Configuration Guidelines

- Port security can only be configured on static access ports or trunk ports. A secure port cannot be a dynamic access port.

- A secure port cannot be a destination port for Switched Port Analyzer (SPAN).

- **Note**
  Voice VLAN is only supported on access ports and not on trunk ports, even though the configuration is allowed.

- When you enable port security on an interface that is also configured with a voice VLAN, set the maximum allowed secure addresses on the port to two. When the port is connected to a Cisco IP phone, the IP phone requires one MAC address. The Cisco IP phone address is learned on the voice VLAN, but is not learned on the access VLAN. If you connect a single PC to the Cisco IP phone, no additional MAC addresses are required. If you connect more than one PC to the Cisco IP phone, you must configure enough secure addresses to allow one for each PC and one for the phone.

- When a trunk port configured with port security and assigned to an access VLAN for data traffic and to a voice VLAN for voice traffic, entering the `switchport voice` and `switchport priority extend` interface configuration commands has no effect.

  When a connected device uses the same MAC address to request an IP address for the access VLAN and then an IP address for the voice VLAN, only the access VLAN is assigned an IP address.

- When you enter a maximum secure address value for an interface, and the new value is greater than the previous value, the new value overwrites the previously configured value. If the new value is less than the previous value and the number of configured secure addresses on the interface exceeds the new value, the command is rejected.

- The switch does not support port security aging of sticky secure MAC addresses.

This table summarizes port security compatibility with other port-based features.

25 You must set the maximum allowed secure addresses on the port to two plus the maximum number of secure addresses allowed on the access VLAN.

**Overview of Port-Based Traffic Control**

Port-based traffic control is a set of Layer 2 features on the Cisco Catalyst switches used to filter or block packets at the port level in response to specific traffic conditions. The following port-based traffic control features are supported in the Cisco IOS Release for which this guide is written:

- Storm Control
- Protected Ports
- Port Blocking
- Port Security
- Protocol Storm Protection
How to Configure Port Security

Enabling and Configuring Port Security

Before you begin
This task restricts input to an interface by limiting and identifying MAC addresses of the stations allowed to access the port:

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. switchport mode {access | trunk}
5. switchport voice vlan vlan-id
6. switchport port-security
7. switchport port-security [maximum value [vlan {vlan-list | {access | voice}]}]]
8. switchport port-security violation {protect | restrict | shutdown | shutdown vlan}
9. switchport port-security [mac-address mac-address {vlan {vlan-id | {access | voice} }}]
10. switchport port-security mac-address sticky
11. switchport port-security mac-address sticky [mac-address | vlan {vlan-id | {access | voice}}]
12. end
13. show port-security
14. show running-config
15. copy running-config startup-config

<tr>
<td><strong>Example:</strong></td>
<td>(Optional) Sets the maximum number of secure MAC addresses for the interface. The maximum number of secure MAC addresses that you can configure on a switch or switch stack is set by the maximum number of available MAC addresses allowed in the system. This number is set by the active Switch Database Management (SDM) template. This number is the total of available MAC addresses, including those used for other Layer 2 functions and any other secure MAC addresses configured on interfaces. (Optional) vlan—sets a per-VLAN maximum value Enter one of these options after you enter the vlan keyword:</td>
</tr>
<tr>
<td>Device(config-if)# switchport port-security maximum 20</td>
<td></td>
</tr>
</tbody>
</table>

• **vlan-list**—On a trunk port, you can set a per-VLAN maximum value on a range of VLANs separated by a hyphen or a series of VLANs separated by commas. For nonspecified VLANs, the per-VLAN maximum value is used.

• **access**—On an access port, specifies the VLAN as an access VLAN.

• **voice**—On an access port, specifies the VLAN as a voice VLAN.
The `voice` keyword is available only if a voice VLAN is configured on a port and if that port is not the access VLAN. If an interface is configured for voice VLAN, configure a maximum of two secure MAC addresses.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 8</strong></td>
<td>(Optional) Sets the violation mode, the action to be taken when a security violation is detected, as one of these:</td>
</tr>
</tbody>
</table>
| `switchport port-security violation {protect | restrict | shutdown | shutdown vlan}` | • **protect**—When the number of port secure MAC addresses reaches the maximum limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses to drop below the maximum value or increase the number of maximum allowable addresses. You are not notified that a security violation has occurred.  
  **Note** We do not recommend configuring the protect mode on a trunk port. The protect mode disables learning when any VLAN reaches its maximum limit, even if the port has not reached its maximum limit.  
  • **restrict**—When the number of secure MAC addresses reaches the limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses or increase the number of maximum allowable addresses. An SNMP trap is sent, a syslog message is logged, and the violation counter increments.  
  • **shutdown**—The interface is error-disabled when a violation occurs, and the port LED turns off. An SNMP trap is sent, a syslog message is logged, and the violation counter increments.  
  • **shutdown vlan**—Use to set the security violation mode per VLAN. In this mode, the VLAN is error disabled instead of the entire port when a violation occurs. |
### Command or Action

| Step 9 | `switchport port-security [mac-address mac-address [vlan {vlan-id | {access | voice}]}}` |
|---|---|
| **Example:** | Device(config-if)# `switchport port-security mac-address 00:A0:C7:12:C9:25 vlan 3 voice` |

(Optional) Enters a secure MAC address for the interface. You can use this command to enter the maximum number of secure MAC addresses. If you configure fewer secure MAC addresses than the maximum, the remaining MAC addresses are dynamically learned.

**Note** If you enable sticky learning after you enter this command, the secure addresses that were dynamically learned are converted to sticky secure MAC addresses and are added to the running configuration.

(Optional) `vlan`—sets a per-VLAN maximum value. Enter one of these options after you enter the `vlan` keyword:

- `vlan-id`—On a trunk port, you can specify the VLAN ID and the MAC address. If you do not specify a VLAN ID, the native VLAN is used.
- `access`—On an access port, specifies the VLAN as an access VLAN.
- `voice`—On an access port, specifies the VLAN as a voice VLAN.

**Note** The `voice` keyword is available only if a voice VLAN is configured on a port and if that port is not the access VLAN. If an interface is configured for voice VLAN, configure a maximum of two secure MAC addresses.

<table>
<thead>
<tr>
<th>Step 10</th>
<th><code>switchport port-security mac-address sticky</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config-if)# <code>switchport port-security mac-address sticky</code></td>
</tr>
</tbody>
</table>

(Optional) Enables sticky learning on the interface.

Enabling and Configuring Port Security Aging

Use this feature to remove and add devices on a secure port without manually deleting the existing secure MAC addresses and to still limit the number of secure addresses on a port. You can enable or disable the aging of secure addresses on a per-port basis.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport port-security aging {static | time time | type {absolute | inactivity}}`
5. `end`
6. `show port-security [interface interface-id] [address]`
7. `show running-config`
8. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>interface interface-id</code></td>
<td>Specifies the interface to be configured, and enter interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Device(config)# interface gigabitethernet1/0/1</code></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>--------</td>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Example:** | `switchport port-security aging {static | time time | type 
| | `{absolute | inactivity}}` | Enables or disable static aging for the secure port, or set the aging time or type. |
| **Note** | The switch does not support port security aging of sticky secure addresses. |
| **Enter static to enable aging for statically configured secure addresses on this port.** |
| **For time, specifies the aging time for this port. The valid range is from 0 to 1440 minutes.** |
| **For type, select one of these keywords:** |
| • **absolute**—Sets the aging type as absolute aging. All the secure addresses on this port age out exactly after the time (minutes) specified lapses and are removed from the secure address list. |
| • **inactivity**—Sets the aging type as inactivity aging. The secure addresses on this port age out only if there is no data traffic from the secure source addresses for the specified time period. |

| Step 5 | end | Returns to privileged EXEC mode. |
| **Example:** | `Device(config-if)# end` |

| Step 6 | show port-security [interface interface-id] [address] | Verifies your entries. |
| **Example:** | `Device# show port-security interface gigabitethernet1/0/1` |

| Step 7 | show running-config | Verifies your entries. |
| **Example:** | `Device# show running-config` |

| Step 8 | copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| **Example:** | `Device# copy running-config startup-config` |

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Storm Control

Storm Control

Storm control prevents traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on one of the physical interfaces. A LAN storm occurs when packets flood the LAN, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation, mistakes in network configurations, or users issuing a denial-of-service attack can cause a storm.

Storm control (or traffic suppression) monitors packets passing from an interface to the switching bus and determines if the packet is unicast, multicast, or broadcast. The switch counts the number of packets of a specified type received within the 1-second time interval and compares the measurement with a predefined suppression-level threshold.

How Traffic Activity is Measured

Storm control uses one of these methods to measure traffic activity:

- Bandwidth as a percentage of the total available bandwidth of the port that can be used by the broadcast, multicast, or unicast traffic
- Traffic rate in packets per second at which broadcast, multicast, or unicast packets are received
- Traffic rate in bits per second at which broadcast, multicast, or unicast packets are received
- Traffic rate in packets per second and for small frames. This feature is enabled globally. The threshold for small frames is configured for each interface.

With each method, the port blocks traffic when the rising threshold is reached. The port remains blocked until the traffic rate drops below the falling threshold (if one is specified) and then resumes normal forwarding. If the falling suppression level is not specified, the switch blocks all traffic until the traffic rate drops below the rising suppression level. In general, the higher the level, the less effective the protection against broadcast storms.

Note

When the storm control threshold for multicast traffic is reached, all multicast traffic except control traffic, such as bridge protocol data unit (BDPU) and Cisco Discovery Protocol (CDP) frames, are blocked. However, the switch does not differentiate between routing updates, such as OSPF, and regular multicast data traffic, so both types of traffic are blocked.
Traffic Patterns

Figure 118: Broadcast Storm Control Example

This example shows broadcast traffic patterns on an interface over a given period of time.

Broadcast traffic being forwarded exceeded the configured threshold between time intervals T1 and T2 and between T4 and T5. When the amount of specified traffic exceeds the threshold, all traffic of that kind is dropped for the next time period. Therefore, broadcast traffic is blocked during the intervals following T2 and T5. At the next time interval (for example, T3), if broadcast traffic does not exceed the threshold, it is again forwarded.

The combination of the storm-control suppression level and the 1-second time interval controls the way the storm control algorithm works. A higher threshold allows more packets to pass through. A threshold value of 100 percent means that no limit is placed on the traffic. A value of 0.0 means that all broadcast, multicast, or unicast traffic on that port is blocked.

Note

Because packets do not arrive at uniform intervals, the 1-second time interval during which traffic activity is measured can affect the behavior of storm control.

You use the storm-control interface configuration commands to set the threshold value for each traffic type.

How to Configure Storm Control

Configuring Storm Control and Threshold Levels

You configure storm control on a port and enter the threshold level that you want to be used for a particular type of traffic.

However, because of hardware limitations and the way in which packets of different sizes are counted, threshold percentages are approximations. Depending on the sizes of the packets making up the incoming traffic, the actual enforced threshold might differ from the configured level by several percentage points.

Note

Storm control is supported on physical interfaces. You can also configure storm control on an EtherChannel. When storm control is configured on an EtherChannel, the storm control settings propagate to the EtherChannel physical interfaces.
Follow these steps to storm control and threshold levels:

Before you begin
Storm control is supported on physical interfaces. You can also configure storm control on an EtherChannel. When storm control is configured on an EtherChannel, the storm control settings propagate to the EtherChannel physical interfaces.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. storm-control {broadcast | multicast | unicast} level {level [level-low] | bps bps [bps-low] | pps pps [pps-low]}
5. storm-control action {shutdown | trap}
6. end
7. show storm-control [interface-id] [broadcast | multicast | unicast]
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>
| **Step 4** storm-control {broadcast | multicast | unicast} level {level [level-low] | bps bps [bps-low] | pps pps [pps-low]} | Configures broadcast, multicast, or unicast storm control. By default, storm control is disabled. The keywords have these meanings:
- For level, specifies the rising threshold level for broadcast, multicast, or unicast traffic as a percentage (up to two decimal places) of the bandwidth. The port blocks traffic when the rising threshold is reached. The range is 0.00 to 100.00. |
<p>| Example: Device(config-if)# storm-control unicast level 87 65 |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) For level-low, specifies the falling threshold level as a percentage (up to two decimal places) of the bandwidth. This value must be less than or equal to the rising suppression value. The port forwards traffic when traffic drops below this level. If you do not configure a falling suppression level, it is set to the rising suppression level. The range is 0.00 to 100.00. If you set the threshold to the maximum value (100 percent), no limit is placed on the traffic. If you set the threshold to 0.0, all broadcast, multicast, and unicast traffic on that port is blocked.</td>
<td></td>
</tr>
<tr>
<td>• For bps bps, specifies the rising threshold level for broadcast, multicast, or unicast traffic in bits per second (up to one decimal place). The port blocks traffic when the rising threshold is reached. The range is 0.0 to 10000000000.0.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) For bps-low, specifies the falling threshold level in bits per second (up to one decimal place). It can be less than or equal to the rising threshold level. The port forwards traffic when traffic drops below this level. The range is 0.0 to 10000000000.0.</td>
<td></td>
</tr>
<tr>
<td>• For pps pps, specifies the rising threshold level for broadcast, multicast, or unicast traffic in packets per second (up to one decimal place). The port blocks traffic when the rising threshold is reached. The range is 0.0 to 10000000000.0.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) For pps-low, specifies the falling threshold level in packets per second (up to one decimal place). It can be less than or equal to the rising threshold level. The port forwards traffic when traffic drops below this level. The range is 0.0 to 10000000000.0.</td>
<td></td>
</tr>
</tbody>
</table>

For BPS and PPS settings, you can use metric suffixes such as k, m, and g for large number thresholds.

Step 5  storm-control action {shutdown | trap}
**Example:**
```
Device(config-if)# storm-control action trap
```

Step 6  end
**Example:**
```
```

Specifies the action to be taken when a storm is detected. The default is to filter out the traffic and not to send traps.

• Select the shutdown keyword to error-disable the port during a storm.

• Select the trap keyword to generate an SNMP trap when a storm is detected.

Returns to privileged EXEC mode.
### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

### Information About Protected Ports

**Protected Ports**

Some applications require that no traffic be forwarded at Layer 2 between ports on the same switch so that one neighbor does not see the traffic generated by another neighbor. In such an environment, the use of protected ports ensures that there is no exchange of unicast, broadcast, or multicast traffic between these ports on the switch.

Protected ports have these features:

- A protected port does not forward any traffic (unicast, multicast, or broadcast) to any other port that is also a protected port. Data traffic cannot be forwarded between protected ports at Layer 2; only control traffic, such as PIM packets, is forwarded because these packets are processed by the CPU and forwarded in software. All data traffic passing between protected ports must be forwarded through a Layer 3 device.

- Forwarding behavior between a protected port and a nonprotected port proceeds as usual.

Because a switch stack represents a single logical switch, Layer 2 traffic is not forwarded between any protected ports in the switch stack, whether they are on the same or different switches in the stack.

### Default Protected Port Configuration

The default is to have no protected ports defined.
Protected Ports Guidelines

You can configure protected ports on a physical interface (for example, Gigabit Ethernet port 1) or an EtherChannel group (for example, port-channel 5). When you enable protected ports for a port channel, it is enabled for all ports in the port-channel group.

How to Configure Protected Ports

Configuring a Protected Port

Before you begin

Protected ports are not pre-defined. This is the task to configure one.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. switchport protected
5. end
6. show interfaces interface-id switchport
7. show running-config
8. copy running-config startup-config

Information About Port Blocking

Port Blocking

By default, the switch floods packets with unknown destination MAC addresses out of all ports. If unknown unicast and multicast traffic is forwarded to a protected port, there could be security issues. To prevent unknown unicast or multicast traffic from being forwarded from one port to another, you can block a port (protected or nonprotected) from flooding unknown unicast or multicast packets to other ports.

Note

With multicast traffic, the port blocking feature blocks only pure Layer 2 packets. Multicast packets that contain IPv4 or IPv6 information in the header are not blocked.

How to Configure Port Blocking

Blocking Flooded Traffic on an Interface

Before you begin

The interface can be a physical interface or an EtherChannel group. When you block multicast or unicast traffic for a port channel, it is blocked on all ports in the port-channel group.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface interface-id
4. switchport block multicast
5. switchport block unicast
6. end
7. show interfaces interface-id switchport
8. show running-config
9. copy running-config startup-config

Monitoring Port Security

This table displays port security information.

*Table 156: Commands for Displaying Port Security Status and Configuration*

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show port-security [interface interface-id]</code></td>
<td>Displays port security settings for the switch or for the specified interface, including the maximum allowed number of secure MAC addresses for each interface, the number of secure MAC addresses on the interface, the number of security violations that have occurred, and the violation mode.</td>
</tr>
<tr>
<td><code>show port-security [interface interface-id] address</code></td>
<td>Displays all secure MAC addresses configured on all switch interfaces or on a specified interface with aging information for each address.</td>
</tr>
<tr>
<td><code>show port-security interface interface-id vlan</code></td>
<td>Displays the number of secure MAC addresses configured per VLAN on the specified interface.</td>
</tr>
</tbody>
</table>

Configuration Examples for Port Security

This example shows how to enable port security on a port and to set the maximum number of secure addresses to 50. The violation mode is the default, no static secure MAC addresses are configured, and sticky learning is enabled.
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# switchport mode access
Device(config-if)# switchport port-security
Device(config-if)# switchport port-security maximum 50
Device(config-if)# switchport port-security mac-address sticky

This example shows how to configure a static secure MAC address on VLAN 3 on a port:

Device(config)# interface gigabitethernet1/0/2
Device(config-if)# switchport mode trunk
Device(config-if)# switchport port-security
Device(config-if)# switchport port-security mac-address 0000.0200.0004 vlan 3

This example shows how to enable sticky port security on a port, to manually configure MAC addresses for data VLAN and voice VLAN, and to set the total maximum number of secure addresses to 20 (10 for data VLAN and 10 for voice VLAN).

Device(config)# interface tengigabitethernet1/0/1
Device(config-if)# switchport access vlan 21
Device(config-if)# switchport mode access
Device(config-if)# switchport voice vlan 22
Device(config-if)# switchport port-security
Device(config-if)# switchport port-security maximum 20
Device(config-if)# switchport port-security violation restrict
Device(config-if)# switchport port-security mac-address sticky
Device(config-if)# switchport port-security mac-address 0000.0000.0002
Device(config-if)# switchport port-security mac-address 0000.0000.0003
Device(config-if)# switchport port-security mac-address 0000.0000.0001 vlan voice
Device(config-if)# switchport port-security mac-address 0000.0000.0004 vlan voice
Device(config-if)# switchport port-security maximum 10 vlan access
Device(config-if)# switchport port-security maximum 10 vlan voice

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for First Hop Security in IPv6

- You have configured the necessary IPv6 enabled SDM template.
- You should be familiar with the IPv6 neighbor discovery feature.
Restrictions for First Hop Security in IPv6

- The following restrictions apply when applying FHS policies to EtherChannel interfaces (Port Channels):
  - A physical port with an FHS policy attached cannot join an EtherChannel group.
  - An FHS policy cannot be attached to a physical port when it is a member of an EtherChannel group.

- By default, a snooping policy has a security-level of guard. When such a snooping policy is configured on an access switch, external IPv6 Router Advertisement (RA) or Dynamic Host Configuration Protocol server packets are blocked, even though the uplink port facing the router or DHCP server/relay is configured as a trusted port. To allow IPv6 RA or DHCPv6 server messages, do the following:
  - Apply an IPv6 RA-guard policy (for RA) or IPv6 DHCP-guard policy (for DHCP server messages) on the uplink port.
  - Configure a snooping policy with a lower security-level, for example glean or inspect. However; configuring a lower security level is not recommended with such a snooping policy, because benefits of First Hop security features are not effective.

Information about First Hop Security in IPv6

First Hop Security in IPv6 (FHS IPv6) is a set of IPv6 security features, the policies of which can be attached to a physical interface, an EtherChannel interface, or a VLAN. An IPv6 software policy database service stores and accesses these policies. When a policy is configured or modified, the attributes of the policy are stored or updated in the software policy database, then applied as was specified. The following IPv6 policies are currently supported:

- IPv6 FHS Binding Table Content—A database table of IPv6 neighbors connected to the switch is created from information sources such as Neighbor Discovery (ND) protocol snooping. This database, or binding table is used by various IPv6 guard features (such as IPv6 ND Inspection) to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors to prevent spoofing and redirect attacks.

- IPv6 Neighbor Discovery Inspection—IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables. IPv6 ND inspection analyzes neighbor discovery messages in order to build a trusted binding table database and IPv6 neighbor discovery messages that do not conform are dropped. An ND message is considered trustworthy if its IPv6-to-Media Access Control (MAC) mapping is verifiable.

  This feature mitigates some of the inherent vulnerabilities of the ND mechanism, such as attacks on DAD, address resolution, router discovery, and the neighbor cache.

- IPv6 Router Advertisement Guard—The IPv6 Router Advertisement (RA) guard feature enables the network administrator to block or reject unwanted or rogue RA guard messages that arrive at the network switch platform. RAs are used by routers to announce themselves on the link. The RA Guard feature analyzes the RAs and filters out bogus RAs sent by unauthorized routers. In host mode, all router
advertisement and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 device with the information found in the received RA frame. Once the Layer 2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.

- IPv6 DHCP Guard—The IPv6 DHCP Guard feature blocks reply and advertisement messages that come from unauthorized DHCPv6 servers and relay agents. IPv6 DHCP guard can prevent forged messages from being entered in the binding table and block DHCPv6 server messages when they are received on ports that are not explicitly configured as facing a DHCPv6 server or DHCP relay. To use this feature, configure a policy and attach it to an interface or a VLAN. To debug DHCP guard packets, use the `debug ipv6 snooping dhcp-guard` privileged EXEC command.

- IPv6 Source Guard—Like IPv4 Source Guard, IPv6 Source Guard validates the source address or prefix to prevent source address spoofing.

A source guard programs the hardware to allow or deny traffic based on source or destination addresses. It deals exclusively with data packet traffic.

The IPv6 source guard feature provides the ability to store entries in the hardware TCAM table to prevent a host from sending packets with an invalid IPv6 source address.

To debug source-guard packets, use the `debug ipv6 snooping source-guard` privileged EXEC command.

---

**Note**

The IPv6 source guard and prefix guard features are supported only in the ingress direction; it is not supported in the egress direction.

---

The following restrictions apply:

- An FHS policy cannot be attached to a physical port when it is a member of an EtherChannel group.

- When IPv6 source guard is enabled on a switch port, NDP or DHCP snooping must be enabled on the interface to which the switch port belongs. Otherwise, all data traffic from this port will be blocked.

- An IPv6 source guard policy cannot be attached to a VLAN. It is supported only at the interface level.

- You cannot use IPv6 Source Guard and Prefix Guard together. When you attach the policy to an interface, it should be "validate address" or "validate prefix" but not both.

- PVLAN and Source/Prefix Guard cannot be applied together.

- IPv6 Source Guard and Prefix Guard is supported on EtherChannels

For more information on IPv6 Source Guard, see the [IPv6 Source Guard](#) chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Prefix Guard—The IPv6 prefix guard feature works within the IPv6 source guard feature, to enable the device to deny traffic originated from non-topologically correct addresses. IPv6 prefix guard is often used when IPv6 prefixes are delegated to devices (for example, home gateways) using DHCP prefix delegation. The feature discovers ranges of addresses assigned to the link and blocks any traffic sourced with an address outside this range.
For more information on IPv6 Prefix Guard, see the IPv6 Prefix Guard chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Destination Guard—The IPv6 destination guard feature works with IPv6 neighbor discovery to ensure that the device performs address resolution only for those addresses that are known to be active on the link. It relies on the address glean functionality to populate all destinations active on the link into the binding table and then blocks resolutions before they happen when the destination is not found in the binding table.

Note
IPv6 Destination Guard is recommended to apply on Layer 2 VLAN with an SVI configured

For more information about IPv6 Destination Guard, see the IPv6 Destination Guard chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

How to Configure an IPv6 Snooping Policy

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Snooping Policy:
SUMMARY STEPS

1. configure terminal
2. ipv6 snooping policy policy-name
3. {
   [default ] | [device-role {node | switch}] | [limit address-count value] | [no ] | [protocol {dhcp | ndp} ] | [security-level {glean | guard | inspect}] | [tracking {disable | stale-lifetime [seconds | infinite] | enable | reachable-lifetime [seconds | infinite]}] | [trusted-port ]
}
4. end
5. show ipv6 snooping policy policy-name

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td>Purpose</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>ipv6 snooping policy policy-name</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ipv6 snooping policy example_policy</td>
</tr>
<tr>
<td>Purpose</td>
<td>Creates a snooping policy and enters IPv6 Snooping Policy Configuration mode.</td>
</tr>
</tbody>
</table>
| **Step 3** | {
   [default ] | [device-role {node | switch}] | [limit address-count value] | [no ] | [protocol {dhcp | ndp} ] | [security-level {glean | guard | inspect}] | [tracking {disable | stale-lifetime [seconds | infinite] | enable | reachable-lifetime [seconds | infinite]}] | [trusted-port ]
}
| Example: | Device(config-ipv6-snooping)# security-level inspect |
| Example: | Device(config-ipv6-snooping)# trusted-port |
| Purpose | Enables data address gleaning, validates messages against various criteria, specifies the security level for messages. |
|   | * (Optional) default—Sets all to default options. |
|   | * (Optional) device-role {node | switch}—Specifies the role of the device attached to the port. Default is node. |
|   | * (Optional) limit address-count value—Limits the number of addresses allowed per target. |
|   | * (Optional) no—Negates a command or sets it to defaults. |
|   | * (Optional) protocol {dhcp | ndp}—Specifies which protocol should be redirected to the snooping feature for analysis. The default, is dhcp and ndp. To change the default, use the no protocol command. |
|   | * (Optional) security-level {glean | guard | inspect}—Specifies the level of security enforced by the feature. Default is guard. |
|   | glean—Gleans addresses from messages and populates the binding table without any verification. |
|   | guard—Gleans addresses and inspects messages. In addition, it rejects RA and DHCP server messages. This is the default option. |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>inspect</td>
<td>Gleans addresses, validates messages for consistency and conformance, and enforces address ownership.</td>
</tr>
<tr>
<td>(Optional) tracking {disable</td>
<td>enable}</td>
</tr>
<tr>
<td>(Optional) trusted-port</td>
<td>Sets up a trusted port. It disables the guard on applicable targets. Bindings learned through a trusted port have preference over bindings learned through any other port. A trusted port is given preference in case of a collision while making an entry in the table.</td>
</tr>
</tbody>
</table>

### Step 4

**Step 4**

Exits configuration modes to Privileged EXEC mode.

**Example:**

Device(config-ipv6-snooping)# `exit`

### Step 5

**Step 5**

Displays the snooping policy configuration.

**Example:**

Device#`show ipv6 snooping policy example_policy`

### What to do next

Attach an IPv6 Snooping policy to interfaces or VLANs.

How to Configure the IPv6 Binding Table Content

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content:

**SUMMARY STEPS**

1. `configure terminal`
2. `[no] ipv6 neighbor binding [vlan vlan-id] [ipv6-address interface interface_type stack/module/port hw_address [reachable-lifetimevalue [seconds | default | infinite] | [tracking] [default | disable] [reachable-lifetimevalue [seconds | default | infinite] | [enable] [reachable-lifetimevalue [seconds | default | infinite] | [retry-interval [seconds | default] [reachable-lifetimevalue [seconds | default | infinite] } ]]
3. `[no] ipv6 neighbor binding max-entries number [mac-limit number] [port-limit number [mac-limit number] | vlan-limit number [mac-limit number] | [port-limit number [mac-limit number] ] ]
4. `ipv6 neighbor binding logging`
5. `exit`
6. `show ipv6 neighbor binding`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td><code>configure terminal</code></td>
</tr>
<tr>
<td></td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>
| **Step 2** | `[no] ipv6 neighbor binding [vlan vlan-id] [ipv6-address interface interface_type stack/module/port hw_address [reachable-lifetimevalue [seconds | default | infinite] | [tracking] [default | disable] [reachable-lifetimevalue [seconds | default | infinite] | [enable] [reachable-lifetimevalue [seconds | default | infinite] | [retry-interval [seconds | default] [reachable-lifetimevalue [seconds | default | infinite] } ]]
| Example: | `ipv6 neighbor binding` |
| | Adds a static entry to the binding table database. |
| **Note** | Switch adds small variance to configured reachable-time value to improve system stability during timer expiry of binding entries. |
| **Step 3** | `[no] ipv6 neighbor binding max-entries number [mac-limit number] [port-limit number [mac-limit number] | vlan-limit number [mac-limit number] | [port-limit number [mac-limit number] ] ]
| Example: | `ipv6 neighbor binding max-entries 30000` |
| | Specifies the maximum number of entries that are allowed to be inserted in the binding table cache. |
| **Step 4** | `ipv6 neighbor binding logging` |
| Example: | `ipv6 neighbor binding logging` |
| | Enables the logging of binding table main events. |
How to Configure an IPv6 Neighbor Discovery Inspection Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 ND Inspection Policy:

### SUMMARY STEPS

1. `configure terminal`  
   **Example:**
   ```bash
   Device# configure terminal
   ```
2. `[no]ipv6 nd inspection policy policy-name`  
   **Example:**
   ```bash
   Device(config)# ipv6 nd inspection policy example_policy
   ```
3. `device-role {host | monitor | router | switch}`
4. `drop-unsecure`
5. `limit address-count value`
6. `sec-level minimum value`
7. `tracking {enable [reachable-lifetime {value | infinite}] | disable [stale-lifetime {value | infinite}]}`
8. `trusted-port`
9. `validate source-mac`
10. `no {device-role | drop-unsecure | limit address-count | sec-level minimum | tracking | trusted-port | validate source-mac}`
11. `default {device-role | drop-unsecure | limit-address-count | sec-level minimum | tracking | trusted-port | validate source-mac}`
12. `do show ipv6 nd inspection policy policy_name`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
</tbody>
</table>
|      | **Example:**
|      | `Device# configure terminal` | |
| 2    | `[no]ipv6 nd inspection policy policy-name` | Specifies the ND inspection policy name and enters ND Inspection Policy configuration mode. |
|      | **Example:**
<p>|      | <code>Device(config)# ipv6 nd inspection policy example_policy</code> | |
| 3    | <code>device-role {host | monitor | router | switch}</code> | Specifies the role of the device attached to the port. The default is <code>host</code>. |
|      | <strong>Example:</strong> | |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-nd-inspection)# device-role switch</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**

**drop-unsecure**

**Example:**
Device(config-nd-inspection)# drop-unsecure

Drops messages with no or invalid options or an invalid signature.

**Step 5**

**limit address-count** `value`

**Example:**
Device(config-nd-inspection)# limit address-count 1000

Enter 1–10,000.

**Step 6**

**sec-level minimum** `value`

**Example:**
Device(config-nd-inspection)# limit address-count 1000

Specify the minimum security level parameter value when Cryptographically Generated Address (CGA) options are used.

**Step 7**

**tracking {enable [reachable-lifetime {value | infinite}] | disable [stale-lifetime {value | infinite}]}}**

**Example:**
Device(config-nd-inspection)# tracking disable stale-lifetime infinite

Overrides the default tracking policy on a port.

**Step 8**

**trusted-port**

**Example:**
Device(config-nd-inspection)# trusted-port

Configures a port to become a trusted port.

**Step 9**

**validate source-mac**

**Example:**
Device(config-nd-inspection)# validate source-mac

Checks the source media access control (MAC) address against the link-layer address.

**Step 10**

**no** `{device-role | drop-unsecure | limit address-count | sec-level minimum | tracking | trusted-port | validate source-mac}`

**Example:**
Device(config-nd-inspection)# no validate source-mac

Remove the current configuration of a parameter with the no form of the command.

**Step 11**

**default** `{device-role | drop-unsecure | limit address-count | sec-level minimum | tracking | trusted-port | validate source-mac}`

**Example:**
Device(config-nd-inspection)# default limit address-count

Restores configuration to the default values.

**Step 12**

**do show ipv6 nd inspection policy** `policy_name`

**Example:**

Verifies the ND Inspection Configuration without exiting ND inspection configuration mode.
How to Attach an IPv6 Neighbor Discovery Inspection Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 ND Inspection policy to an interface or VLANs on an interface:

**SUMMARY STEPS**

1. `configure terminal`
2. `interface Interface_type stack/module/port`
3. `ipv6 nd inspection [attach-policy policy_name [ vlan vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all ] | vlan [ {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all] ]`
4. `do show running-config`

**DETAILED STEPS**

How to Attach an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Neighbor Discovery Inspection policy on an EtherChannel interface or VLAN:

**SUMMARY STEPS**

1. **configure terminal**
2. **interface range Interface_name**
3. **ipv6 nd inspection [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all} | vlan [ {vlan_ids | add vlan_ids | exceptvlan_ids | none | remove vlan_ids | all} ] | vlan_ids | add vlan_ids | exceptvlan_ids | none | remove vlan_ids | all} ]**
4. **do show running-config interface portchannel_interface_name**

**DETAILED STEPS**

**Step 1**

**configure terminal**

**Example:**
Device# configure terminal

**Step 2**

**interface range Interface_name**

**Example:**
Device(config)# interface Port1

**Step 3**

**ipv6 nd inspection [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all} | vlan [ {vlan_ids | add vlan_ids | exceptvlan_ids | none | remove vlan_ids | all} ] | vlan_ids | add vlan_ids | exceptvlan_ids | none | remove vlan_ids | all} ]**

**Example:**
Device#(config-if)# do show running-config

Verifies the policy is attached to the specified interface without exiting the interface configuration mode.

### How to Attach an IPv6 Neighbor Discovery Inspection Policy to VLANs Globally

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 ND Inspection policy to VLANs across multiple interfaces:

**SUMMARY STEPS**

1. configure terminal
2. vlan configuration vlan_list
3. ipv6 nd inspection [attach-policy policy_name]
4. do show running-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
| configure terminal | Enters the global configuration mode. |
| Example:
| Device# configure terminal | |
| **Step 2**
| vlan configuration vlan_list | Specifies the VLANs to which the IPv6 Snooping policy will be attached; enters the VLAN interface configuration mode. |
| Example:
| Device(config)# vlan configuration 334 | |
| **Step 3**
| ipv6 nd inspection [attach-policy policy_name] | Attaches the IPv6 Neighbor Discovery policy to the specified VLANs across all switch and stack interfaces. The default policy is attached if the attach-policy option is not used. |
| Example:
| Device(config-vlan-config)#ipv6 nd inspection attach-policy example_policy | |
How to Configure an IPv6 Router Advertisement Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 Router Advertisement policy:

SUMMARY STEPS

1. configure terminal
2. [no]ipv6 nd raguard policy policy-name
3. [no]device-role {host | monitor | router | switch}
4. [no]hop-limit {maximum | minimum} value
5. [no]managed-config-flag {off | on}
6. [no]match {ipv6 access-list list | ra prefix-list list}
7. [no]other-config-flag {on | off}
8. [no]router-preference maximum {high | medium | low}
9. [no]trusted-port
10. default {device-role | hop-limit {maximum | minimum} | managed-config-flag | match {ipv6 access-list | ra prefix-list } | other-config-flag | router-preference maximum | trusted-port}
11. do show ipv6 nd raguard policy policy_name

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>

### How to Configure an IPv6 Router Advertisement Guard Policy

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Device(config-nd-raguard)# device-role switch</code></td>
<td>For a network with both host-facing ports and router-facing ports, along with a RA guard policy configured with <code>device-role host</code> on host-facing ports or vlan, it is mandatory to configure a RA guard policy with <code>device-role router</code> on router-facing ports to allow the RA Guard feature to work properly.</td>
</tr>
</tbody>
</table>

**Note**

(1–255) Range for Maximum and Minimum Hop Limit values.

Enables filtering of Router Advertisement messages by the Hop Limit value. A rogue RA message may have a low Hop Limit value (equivalent to the IPv4 Time to Live) that when accepted by the host, prevents the host from generating traffic to destinations beyond the rogue RA message generator. An RA message with an unspecified Hop Limit value is blocked.

If not configured, this filter is disabled. Configure `minimum` to block RA messages with Hop Limit values lower than the value you specify. Configure `maximum` to block RA messages with Hop Limit values greater than the value you specify.

**Step 4**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`[no] hop-limit {maximum</td>
<td>minimum} value`</td>
</tr>
<tr>
<td><strong>Example:</strong></td>

How to Configure an IPv6 DHCP Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 DHCP (DHCPv6) Guard policy:

**SUMMARY STEPS**

1. configure terminal
2. [no]ipv6 dhcp guard policy policy-name
3. [no]device-role {client | server}
4. [no] match server access-list ipv6-access-list-name
5. `[no] match reply prefix-list ipv6-prefix-list-name`
6. `[no] preference { max limit | min limit }
7. `[no] trusted-port
8. default {device-role | trusted-port}
9. do show ipv6 dhcp guard policy policy_name

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** configure terminal  
Example: Device# configure terminal | Enters the global configuration mode. |
| **Step 2** `[no]ipv6 dhcp guard policy policy-name`  
Example: Device(config)# ipv6 dhcp guard policy example_policy | Specifies the DHCPv6 Guard policy name and enters DHCPv6 Guard Policy configuration mode. |
| **Step 3** `[no]device-role {client | server}`  
Example: Device(config-dhcp-guard)# device-role server | (Optional) Filters out DHCPv6 replies and DHCPv6 advertisements on the port that are not from a device of the specified role. Default is `client`.  
- `client`—Default value, specifies that the attached device is a client. Server messages are dropped on this port.  
- `server`—Specifies that the attached device is a DHCPv6 server. Server messages are allowed on this port. |
| **Step 4** `[no] match server access-list ipv6-access-list-name`  
Example:  
```bash
;;Assume a preconfigured IPv6 Access List as follows:  
Device(config)# ipv6 access-list my_acls  
Device(config-ipv6-acl)# permit host FE80::A8BB:CCFF:FE01:F700 any  
;;configure DHCPv6 Guard to match approved access list.  
Device(config-dhcp-guard)# match server access-list my_acls
``` | (Optional). Enables verification that the advertised DHCPv6 server or relay address is from an authorized server access list (The destination address in the access list is 'any'). If not configured, this check will be bypassed. An empty access list is treated as a permit all. |
| **Step 5** `[no] match reply prefix-list ipv6-prefix-list-name`  
Example:  
```bash
;;Assume a preconfigured IPv6 prefix list as follows:  
Device(config)# ipv6 prefix-list my_prefix permit 2001:0DB8::/64 le 128
``` | (Optional) Enables verification of the advertised prefixes in DHCPv6 reply messages from the configured authorized prefix list. If not configured, this check will be bypassed. An empty prefix list is treated as a permit. |
### Command or Action

<table>
<thead>
<tr>
<th>Description</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure DCHPv6 Guard to match prefix</td>
<td><code>match reply prefix-list my_prefix</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>`[no] preference { max limit</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><code>[no] trusted-port</code> &lt;br&gt;<strong>Example:</strong> &lt;br&gt;Device(config-dhcp-guard)# <code>trusted-port</code> &lt;br&gt;(Optional) <code>trusted-port</code>—Sets the port to a trusted mode. No further policing takes place on the port. &lt;br&gt;Note If you configure a trusted port then the device-role option is not available.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>`default {device-role</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td><code>do show ipv6 dhcp guard policy policy_name</code> &lt;br&gt;<strong>Example:</strong> &lt;br&gt;Device(config-dhcp-guard)# <code>do show ipv6 dhcp guard policy example_policy</code> &lt;br&gt;(Optional) Displays the configuration of the IPv6 DHCP guard policy without leaving the configuration submode. Omitting the <code>policy_name</code> variable displays all DHCPv6 policies.</td>
</tr>
</tbody>
</table>

### Example of DHCPv6 Guard Configuration

```
enable
configure terminal
ipv6 access-list acl1
     permit host FE80::A0BB:CCFF:FE01:F700 any
ipv6 prefix-list abc permit 2001:0DB8::/64 le 128
ipv6 dhcp guard policy pol1
device-role server
match server access-list acl1
match reply prefix-list abc
preference min 0
preference max 255
trusted-port
interface GigabitEthernet 0/2/0
     switchport
     ipv6 dhcp guard attach-policy pol1 vlan add 1
     vlan 1
     ipv6 dhcp guard attach-policy pol1
show ipv6 dhcp guard policy pol1
```
How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content:

### SUMMARY STEPS

1. configure terminal
2. interface Interface_type stack/module/port
3. ipv6 dhcp guard [attach-policy policy_name [ vlan {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ] | vlan [ {vlan_ids | add vlan_ids | except vlan_ids | none | remove vlan_ids | all } ]]
4. do show running-config interface Interface_type stack/module/port

## How to Configure IPv6 Source Guard

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no ipv6 source-guard policy policy_name`
4. `[deny global-autoconf] [permit link-local] [default{...}] [exit] [no{...}]`
5. `end`
6. `show ipv6 source-guard policy policy_name`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
</tr>
</tbody>
</table>

Enables privileged EXEC mode. Enter your password if prompted.

| **Step 2** | configure terminal |
| **Example:** | Device# configure terminal |

Enters the global configuration mode.

| **Step 3** | `no ipv6 source-guard policy policy_name` |
| **Example:** | Device(config)# ipv6 source-guard policy example_policy |

Specifies the IPv6 Source Guard policy name and enters IPv6 Source Guard policy configuration mode.

| **Step 4** | `[deny global-autoconf] [permit link-local] [default{...}] [exit] [no{...}]` |
| **Example:** | Device(config-sisf-sourceguard)# deny global-autoconf |

(Optional) Defines the IPv6 Source Guard policy.
- *deny global-autoconf*—Denies data traffic from auto-configured global addresses. This is useful when all global addresses on a link are DHCP-assigned and the administrator wants to block hosts with self-configured addresses to send traffic.
How to Attach an IPv6 Source Guard Policy to an Interface

### SUMMARY STEPS

1. `enable`
2. `configure terminal`

How to Configure IPv6 Prefix Guard

**Note**
To allow routing protocol control packets sourced by a link-local address when prefix guard is applied, enable the permit link-local command in the source-guard policy configuration mode.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. [no] ipv6 source-guard policy source-guard-policy
4. [no] validate address
5. validate prefix
6. exit
7. show ipv6 source-guard policy [source-guard-policy]

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

### Configuration Examples for IPv6 First Hop Security

#### Examples: How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface

The following example shows how to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface:

```
Switch# configure terminal  
Switch(config)# ipv6 source-guard policy POL  
Switch(config-sisf-sourceguard) # validate address  
switch(config-sisf-sourceguard)# exit  
Switch(config)# interface Po4  
Switch(config)# ipv6 snooping  
Switch(config-if)# ipv6 source-guard attach-policy POL  
Switch(config-if)# exit  
switch(config)#
```

Configuring Cisco TrustSec

- Information about Cisco TrustSec, on page 1917
- Finding Feature Information, on page 1917
- Cisco TrustSec Features, on page 1918
- Feature Information for Cisco TrustSec, on page 1920

Information about Cisco TrustSec

Cisco TrustSec provides security improvements to Cisco network devices based on the capability to strongly identify users, hosts, and network devices within a network. TrustSec provides topology-independent and scalable access controls by uniquely classifying data traffic for a particular role. TrustSec ensures data confidentiality and integrity by establishing trust among authenticated peers and encrypting links with those peers.

The key component of Cisco TrustSec is the Cisco Identity Services Engine (ISE). Cisco ISE can provision switches with TrustSec Identities and Security Group ACLs (SGACLs), though these may be configured manually on the switch.

Finding Feature Information

To configure Cisco Trustsec on the switch, see the Cisco TrustSec Switch Configuration Guide at the following URL:

Release notes for Cisco TrustSec General Availability releases are at the following URL:

Additional information about the Cisco TrustSec solution, including overviews, datasheets, features by platform matrix, and case studies, is available at the following URL:

## Cisco TrustSec Features

The table below lists the TrustSec features to be eventually implemented on TrustSec-enabled Cisco switches. Successive general availability releases of TrustSec will expand the number of switches supported and the number of TrustSec features supported per switch.

<table>
<thead>
<tr>
<th>Cisco TrustSec Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>802.1AE Tagging (MACsec)</td>
<td>Protocol for IEEE 802.1AE-based wire-rate hop-to-hop Layer 2 encryption. Between MACsec-capable devices, packets are encrypted on egress from the transmitting device, decrypted on ingress to the receiving device, and in the clear within the devices. This feature is only available between TrustSec hardware-capable devices.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This feature is not supported on Catalyst 3850 and Catalyst 3650 switches with Cisco IOS XE Denali 16.1.1</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This feature is not supported on Catalyst 2960x.</td>
</tr>
<tr>
<td>Endpoint Admission Control (EAC)</td>
<td>EAC is an authentication process for an endpoint user or a device connecting to the TrustSec domain. Usually EAC takes place at the access level switch. Successful authentication and authorization in the EAC process results in Security Group Tag assignment for the user or device. Currently EAC can be 802.1X, MAC Authentication Bypass (MAB), and Web Authentication Proxy (WebAuth).</td>
</tr>
<tr>
<td>Network Device Admission Control (NDAC)</td>
<td>NDAC is an authentication process where each network device in the TrustSec domain can verify the credentials and trustworthiness of its peer device. NDAC utilizes an authentication framework based on IEEE 802.1X port-based authentication and uses EAP-FAST as its EAP method. Successful authentication and authorization in NDAC process results in Security Association Protocol negotiation for IEEE 802.1AE encryption.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This feature is not supported on Catalyst 2960x.</td>
</tr>
<tr>
<td>Security Group Access Control List (SGACL)</td>
<td>A Security Group Access Control List (SGACL) associates a Security Group Tag with a policy. The policy is enforced upon SGT-tagged traffic egressing the TrustSec domain.</td>
</tr>
</tbody>
</table>
### Cisco TrustSec Features

<table>
<thead>
<tr>
<th>Cisco TrustSec Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Association Protocol (SAP)</td>
<td>After NDAC authentication, the Security Association Protocol (SAP) automatically negotiates keys and the cipher suite for subsequent MACSec link encryption between TrustSec peers. SAP is defined in IEEE 802.11i.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: This feature is not supported on Catalyst 3850 and Catalyst 3650 switches with Cisco IOS XE Denali 16.1.1.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: This feature is not supported on Catalyst 2960x.</td>
</tr>
<tr>
<td>Security Group Tag (SGT)</td>
<td>An SGT is a 16-bit single label indicating the security classification of a source in the TrustSec domain. It is appended to an Ethernet frame or an IP packet.</td>
</tr>
<tr>
<td>SGT Exchange Protocol (SXP)</td>
<td>Security Group Tag Exchange Protocol (SXP). With SXP, devices that are not TrustSec-hardware-capable can receive SGT attributes for authenticated users and devices from the Cisco Identity Services Engine (ISE) or the Cisco Secure Access Control System (ACS). The devices can then forward a source IP-to-SGT binding to a TrustSec-hardware-capable device will tag the source traffic for SGACL enforcement.</td>
</tr>
</tbody>
</table>

When both ends of a link support 802.1AE MACsec, SAP negotiation occurs. An EAPOL-key exchange occurs between the supplicant and the authenticator to negotiate a cipher suite, exchange security parameters, and manage keys. Successful completion of these tasks results in the establishment of a security association (SA).

Depending on your software version and licensing and link hardware support, SAP negotiation can use one of these modes of operation:

- Galois Counter Mode (GCM)—authentication and encryption
- GCM authentication (GMAC)—GCM authentication, no encryption
- No Encapsulation—no encapsulation (clear text)
- Null—encapsulation, no authentication or encryption

Configuring Control Plane Policing

• Finding Feature Information, on page 1921
• Restrictions for CoPP, on page 1921
• Information About Control Plane Policing, on page 1922
• How to Configure CoPP, on page 1925
• Examples for Configuring CoPP, on page 1929
• Monitoring CoPP, on page 1932
• Additional References for CoPP, on page 1933
• Feature History and Information For CoPP, on page 1934

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for CoPP

Restrictions for control plane policing (CoPP) include the following:

• Only ingress CoPP is supported. The **system-cpp-policy** policy-map is available on the control place interface, only in the ingress direction.

• Only the **system-cpp-policy** policy-map can be installed on the control plane interface.

• The **system-cpp-policy** policy-map and the seventeen system-defined classes cannot be modified or deleted.

• Only the **police** action is allowed under the **system-cpp-policy** policy-map. Further, the **police rate** can be configured only in packets per second (pps).
• One or more CPU queues are part of each class-map. Where multiple CPU queues belong to one class-map, changing the policer rate of a class-map affects all CPU queues that belong to that class-map. Similarly, disabling a class-map disables all queues that belong to that class-map. See Table 158: System-Defined Values for CoPP, on page 1923 for information about which CPU queues belong to each class-map.

Information About Control Plane Policing

This chapter describes how control plane policing (CoPP) works on your device and how to configure it.

CoPP Overview

The CoPP feature improves security on your device by protecting the CPU from unnecessary traffic, or DoS traffic, and by prioritizing control plane and management traffic.

Your device is typically segmented into three planes of operation, each with its own objective:

- The data plane, to forward data packets.
- The control plane, to route data correctly.
- The management plane, to manage network elements.

You can use CoPP to protect most of the CPU-bound traffic and ensure routing stability, reachability, and packet delivery. Most importantly, you can use CoPP to protect the CPU from a DoS attack.

CoPP uses the modular QoS command-line interface (MQC) and CPU queues to achieve these objectives. Different types of control plane traffic are grouped together based on certain criteria, and assigned to a CPU queue. You can manage these CPU queues by configuring dedicated policers in hardware. For example, you can modify the policer rate for certain CPU queues (traffic-type), or you can disable the policer for a certain type of traffic.

Although the policers are configured in hardware, CoPP does not affect CPU performance or the performance of the data plane. But since it limits the number of packets going to CPU, the CPU load is controlled. This means that services waiting for packets from hardware may see a more controlled rate of incoming packets (the rate being user-configurable).

System-Defined Aspects of CoPP

When you power-up the device for the first time, the system automatically performs the following tasks:

- It looks for policy-map system-cpp-policy. If it does not detect this policy-map, it creates and installs it on the control-plane.
- It creates seventeen class-maps under system-cpp-policy.
The next time you power-up the device, the system detects the policy and class maps that have already been created.

- Once the policy is installed, sixteen (out of the thirty-two) CPU queues are enabled by default with their respective default rate. The CPU queues enabled by default and their default rates are indicated in Table 158: System-Defined Values for CoPP, on page 1923.

The following table lists the class-maps that the system creates when you load the device. It lists the policer that corresponds to each class-map and one or more CPU queues that are grouped under each class-map. There is a one-to-one mapping of class-maps to policers; and one or more CPU queues map to a class-map.

**Table 158: System-Defined Values for CoPP**

## User-Configurable Aspects of CoPP

You can perform these tasks to manage control plane traffic:

- Enable or disable CPU queues.

Enable a CPU queue, by configuring a policer action (in packets per second) under the corresponding class-map, within the `system-cpp-policy` policy-map.

Disable a CPU queue, by removing the policer action under the corresponding class-map, within the `system-cpp-policy` policy-map.

</table>
• Change the policer rate, by configuring a policer rate action (in packets per second) under the corresponding class-map, within the system-cpp-policy policy-map.

• Set the CPU queues to their default values, by entering the cpp system-default command in global configuration mode.

How to Configure CoPP

Enabling a CPU Queue or Changing the Policer Rate

The procedure to enable a CPU queue and change the policer rate of a CPU queue is the same. Follow these steps:

SUMMARY STEPS

1. enable
2. configure terminal
3. policy-map policy-map-name
4. class class-name
5. service-policy input policy-name
6. police rate rate pps
7. end
8. show running-config | begin system-cpp-policy

</table>

### Step 3

**policy-map policy-map-name**

**Example:**

Device(config)# policy-map system-cpp-policy
Device(config-pmap)#

#### Purpose

Enters the policy map configuration mode.

### Step 4

**class class-name**

**Example:**

Device(config-pmap)# class system-cpp-police-protocol-snooping
Device(config-pmap-c)#

#### Purpose

Enters the class action configuration mode. Enter the name of the class that corresponds to the CPU queue you want to enable. See Table 158: System-Defined Values for CoPP, on page 1923

### Step 5

**service-policy input policy-name**

**Example:**

Device(config)# control-plane
Device(config-cp)# service-policy input system-cpp-policy
Device(config-cp)#

#### Purpose

Installs system-cpp-policy in FED. This command is required for you to see the FED policy. Not configuring this command will lead to an error.

### Step 6

**police rate rate pps**

**Example:**

Device(config-pmap-c)# police rate 100 pps

#### Note

The rate you specify is applied to all CPU queues that belong to the class-map you have specified.

### Step 7

**end**

**Example:**

Device(config-pmap-c)# end

#### Purpose

Returns to the privileged EXEC mode.

### Step 8

**show running-config | begin system-cpp-policy**

**Example:**

Device# show running-config | begin system-cpp-policy

#### Purpose

Displays the rates configured for the various traffic types.

Device# configure terminal | Enters the global configuration mode. |
### Examples for Configuring CoPP

#### Example: Enabling a CPU Queue or Changing the Policer Rate of a CPU Queue

This example shows how to enable a CPU queue or to change the policer rate of a CPU queue. Here the `class system-cpp-police-protocol-snooping` CPU queue is enabled with the policer rate of 100 pps.

```
Device> enable
Device# configure terminal
Device(config)# policy-map system-cpp-policy
Device(config-pmap)# class system-cpp-police-protocol-snooping
Device(config-pmap-c)# police rate 100 pps
Device(config-pmap-c)# end

Device# show running-config | begin system-cpp-policy
policy-map system-cpp-policy
```
Example: Disabling a CPU Queue

This example shows how to disable a CPU queue. Here the class system-cpp-police-protocol-snooping CPU queue is disabled.

Example: Disabling a CPU Queue
Example: Setting the Default Policer Rates for All CPU Queues

This example shows how to set the policer rates for all CPU queues to their default and then verify the setting:

```
Device> enable
Device# configure terminal
Device(config)# cpp system-default
Defaulting CPP : Policer rate for all classes will be set to their defaults
Device(config)# end

Device# show platform hardware fed switch 1 qos queue stats internal cpu policer
```

• Feature History and Information for Guest Access, on page 1959

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Guest Access

• All mobility peers should be configured for hierarchical mobility architecture.
• For Guest Controller Mobility Anchor configuration on WLAN is must on Mobility Agent and Guest Controller.
• Guest Access can be a 3 box solution or 2 box solution. The mobility tunnel link status should be up between:
  • Mobility Agent, Mobility Controller and Guest Controller.
  or
  • Mobility Agent/Mobility Controller and Guest Controller
Restrictions for Guess Access

Information about Wireless Guest Access

Ideally, the implementation of a wireless guest network uses as much of an enterprise’s existing wireless and wired infrastructure as possible to avoid the cost and complexity of building a physical overlay network. Assuming this is the case, the following additional elements and functions are needed:

- A dedicated guest WLAN/SSID—Implemented throughout the campus wireless network wherever guest access is required. A guest WLAN is identified by a WLAN with mobility anchor (Guest Controller) configured.
- Guest traffic segregation—Requires implementing Layer 2 or Layer 3 techniques across the campus network to restrict where guests are allowed to go.
- Access control—Involves using imbedded access control functionality within the campus network or implementing an external platform to control guest access to the Internet from the enterprise network.
- Guest user credential management—A process by which a sponsor or lobby administrator can create temporary credentials in behalf of a guest. This function might be resident within an access control platform or it might be a component of AAA or some other management system.

Fast Secure Roaming

Fast secure roaming can be achieved by caching the Pairwise Master Key (PMK) information for Cisco Centralized Key Management (CCKM), and 802.11i clients. Cisco Centralized Key Management (CCKM) helps to improve roaming. Only the client can initiate the roaming process, which depends on factors such as:

- Overlap between APs
- Distance between APs
- Channel, signal strength, and load on the AP
- Data rates and output power

Whenever a fast-roaming client 802.11i, [CCKM]) roams to a new device, after fast-roaming the clients go through mobility "handoff" procedure. And new AAA attributes learned through mobility "handoff" procedure get re-applied.

Full L2 authentication must be avoided during roaming if the client uses the 802.11i WPA2, CCKM, to achieve the full requirements of fast secure roaming. The PMK cache (802.11i, CCKM) is used to authenticate and derive the keys for roaming clients to avoid full L2 authentication. This requires all Mobility Anchors (MA) and Mobility Controllers (MC) in the mobility group to have the same PMK cache values.

The session timeout defines when a PMK cache will expire. A PMK cache can also be deleted when a client fails to re-authenticate or when it is manually deleted them from the CLI. The deletion on the original controller or switch shall be propagated to other controllers or switches in the same mobility group.
How to Configure Guest Access

Creating a Lobby Administrator Account

SUMMARY STEPS

1. `configure terminal`
2. `user-name user-name`
3. `type lobby-admin`
4. `password 0 password`
5. `end`
6. `show running-config | section user-name` (or) `show running-config | section configured lobby admin username`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `configure terminal`  
*Example:*  
Device # `configure terminal` | Enters global configuration mode. |
| Step 2 | `user-name user-name`  
*Example:*  
Device (config)# `user-name lobby` | Creates a user account. |
| Step 3 | `type lobby-admin`  
*Example:*  
Device (config-user-name)# `type lobby-admin` | Specifies the account type as lobby admin. |
| Step 4 | `password 0 password`  
*Example:*  
Device(config-user-name)# `password 0 lobby` | Creates a password for the lobby administrator account. |
| Step 5 | `end`  
*Example:*  
Device (config-user-name)# `end` | Returns to privileged EXEC mode. |
| Step 6 | `show running-config | section user-name` (or) `show running-config | section configured lobby admin username`  
*Example:*  
Device # `show running-config | section lobby` | Displays the configuration details. |
## Configuring Guest User Accounts

### SUMMARY STEPS

1. `configure terminal`
2. `user-name user-name`
3. `password unencrypted/hidden-password password`
4. `type network-user description description guest-user lifetime year 0-1 month 0-11 day 0-30 hour 0-23 minute 0-59 second 0-59`
5. `end`
6. `show aaa local netuser all`
7. `show running-config | section user-name`

## Displaying a Web Authentication Certificate

**SUMMARY STEPS**

1. show crypto ca certificate verb
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>show crypto ca certificate verb</td>
</tr>
<tr>
<td>Example:</td>
<td>Device # show crypto ca certificate verb</td>
</tr>
</tbody>
</table>

**Example**

### Choosing the Default Web Authentication Login Page

AAA override flag should be enabled on the WLAN for web authentication using local or remote AAA server.

### SUMMARY STEPS

1. configure terminal
2. parameter-map type webauth parameter-map name
3. wlan wlan-name
4. shutdown
5. security web-auth
6. security web-auth authentication-list authentication list name
7. security web-auth parameter-map parameter-map name
8. no shutdown
9. end
10. show running-config | section wlan-name
11. show running-config | section parameter-map type webauth parameter-map

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Device # configure terminal</td>
</tr>
</tbody>
</table>

| **Step 2** | parameter-map type webauth parameter-map name |
| Example: | Device (config) # parameter-map type webauth test |

| **Step 3** | wlan wlan-name |
| Example: | Device (config) # wlan wlan10 |

| **Step 4** | shutdown |
| Example: | |

For the wlan-name, enter the profile name. The range is 1-32 characters.

Disables WLAN.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device (config) # shutdown</td>
<td>Enables web-auth on WLAN.</td>
</tr>
</tbody>
</table>

**Step 5**

`security web-auth`  
**Example:**
Controller (config-wlan) # security web-auth

**Step 6**

`security web-auth authentication-list authentication-list name`  
**Example:**
Controller (config-wlan) # security web-auth authentication-list test

**Step 7**

`security web-auth parameter-map parameter-map name`  
**Example:**
Device (config) # security web-auth parameter-map test

**Step 8**

`no shutdown`  
**Example:**
Device (config) # no shutdown

**Step 9**

`end`  
**Example:**
Device (config) # end

**Step 10**

`show running-config | section wlan-name`  
**Example:**
Device# show running-config | section mywlan

**Step 11**

`show running-config | section parameter-map type webauth parameter-map`  
**Example:**
Device# show running-config | section parameter-map type webauth test

### Example

**Choosing a Customized Web Authentication Login Page from an External Web Server**

AAA override flag should be enabled on the WLAN for web authentication using local or remote AAA server.
**SUMMARY STEPS**

1. configure terminal
2. parameter-map type webauth global
3. virtual-ip {ipv4 | ipv6} ip-address
4. parameter-map type webauth parameter-map name
5. type {authbypass | consent | webauth | webconsent}
6. redirect [for-login|on-success|on-failure] URL
7. redirect portal {ipv4 | ipv6} ip-address
8. end
9. show running-config | section parameter-map

**DETAILED STEPS**

end  
**Example:**
Device (config-params-parameter-map) # end | Returns to privileged EXEC mode.
**Step 5**
show running-config | section parameter-map type webauth parameter-map  
**Example:**
Device (config) # show running-config | section parameter-map type webauth test | Displays the configuration details.

### Example

## Configuration Examples for Guest Access

### Example: Creating a Lobby Ambassador Account

This example shows how to configure a lobby ambassador account.

```
Device# configure terminal  
Device(config)# user-name lobby  
Device(config)# type lobby-admin  
Device(config)# password 0 lobby  
Device(config)# end  
Device# show running-config | section lobby  
    user-name lobby  
    creation-time 1351118727  
    password 0 lobby  
    type lobby-admin
```

### Example: Obtaining Web Authentication Certificate

This example shows how to obtain web authentication certificate.

```
Device# configure terminal  
Device(config)# crypto pki import cert pkcs12 tftp://9.1.0.100/ldapserver-cert.p12 cisco  
Device(config)# end  
Device# show crypto pki trustpoints cert
```
Trustpoint cert:

Example: Choosing a Customized Web Authentication Login Page from an External Web Server

This example shows how to choose a customized web authentication login page from an external web server.

Device# configure terminal
Device(config)# parameter-map type webauth global
Device(config-params-parameter-map)# virtual-ip ipv4 1.1.1.1
Device(config-params-parameter-map)# parameter-map type webauth test
Device(config-params-parameter-map)# type webauth
Device(config-params-parameter-map)# redirect for-login http://9.1.0.100/login.html
Device(config-params-parameter-map)# redirect portal ipv4 23.0.0.1
Device(config-params-parameter-map)# end

Device# show running-config | section parameter-map
type webauth
virtual-ip ipv4 1.1.1.1
parameter-map type webauth test
type webauth
redirect for-login http://9.1.0.100/login.html
redirect portal ipv4 23.0.0.1
security web-auth parameter-map rasagna-auth-map
security web-auth parameter-map test

Example: Assigning Login, Login Failure, and Logout Pages per WLAN

This example shows how to assign login, login failure and logout pages per WLAN.

Device# configure terminal
Device(config)# parameter-map type webauth test
Device(config-params-parameter-map)# custom-page login device flash:loginsantosh.html
Device(config-params-parameter-map)# custom-page login expired device flash:loginexpire.html
Example: Configuring AAA-Override

This example shows how to configure aaa-override.

```
Device# configure terminal
Device(config)# wlan fff
Device(config-wlan)# aaa-override
Device(config-wlan)# end
Device# show running-config | section fff
wlan fff 44 fff
aaa-override
shutdown
```

Example: Configuring Client Load Balancing

This example shows how to configure client load balancing.

```
Device# configure terminal
Device(config)# wlan fff
Device(config-wlan)# shutdown
Device(config-wlan)# mobility anchor 9.7.136.15
Device(config-wlan)# mobility anchor 9.7.136.16
Device(config-wlan)# no shutdown wlan
Device(config-wlan)# end
Device# show running-config | section fff
wlan fff 44 fff
aaa-override
shutdown
```

Example: Configuring Preauthentication ACL

This example shows how to configure preauthentication ACL.

```
Device# configure terminal
Device(config)# wlan fff
Device(config-wlan)# shutdown
Device(config-wlan)# ip access-group web preauthrule
Device(config-wlan)# no shutdown
Device(config-wlan)# end
Device# show wlan name fff
```
Example: Configuring IOS ACL Definition

This example shows how to configure IOS ACL definition.

```
Device# configure terminal
Device(config)# ip access-list extended 102
Device(config-ext-nacl)# permit udp any eq 8080 any
Device(config-ext-nacl)# end
Device# show access-lists 102
Extended IP access list 102
  10 permit udp any eq 8080 any
```

Example: Configuring Webpassthrough

This example shows how to configure webpassthrough.

```
Device# configure terminal
Device(config)# parameter-map type webauth webparalocal
Device(config-params-parameter-map)# type consent
Device(config-params-parameter-map)# end
Device# show running-config | section parameter-map type webauth test
parameter-map type webauth test
  type webauth
  redirect for-login http://9.1.0.100/login.html
  redirect portal ipv4 23.0.0.1
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Rogue Devices

Rogue access points can disrupt wireless LAN operations by hijacking legitimate clients and using plain-text or other denial-of-service or man-in-the-middle attacks. That is, a hacker can use a rogue access point to capture sensitive information, such as usernames and passwords. The hacker can then transmit a series of Clear to Send (CTS) frames. This action mimics an access point, informing a particular client to transmit, and instructing all the other clients to wait, which results in legitimate clients being unable to access network resources. Wireless LAN service providers have a strong interest in banning rogue access points from the air space.

Because rogue access points are inexpensive and readily available, employees sometimes plug unauthorized rogue access points into existing LANs and build ad hoc wireless networks without their IT department's knowledge or consent. These rogue access points can be a serious breach of network security because they can be plugged into a network port behind the corporate firewall. Because employees generally do not enable any security settings on the rogue access point, it is easy for unauthorized users to use the access point to
intercept network traffic and hijack client sessions. Even more alarming, wireless users frequently publish unsecured access point locations, increasing the odds of having enterprise security breached.

The following are some guidelines to manage rogue devices:

- The containment frames are sent immediately after the authorization and associations are detected. The enhanced containment algorithm provides more effective containment of ad hoc clients.

- The local mode access points are designed to serve associated clients. These access points spend relatively less time performing off-channel scanning: about 50 milliseconds on each channel. If you want to perform high rogue detection, a monitor mode access point must be used. Alternatively, you can reduce the scan intervals from 180 seconds to a lesser value, for example, 120 or 60 seconds, ensuring that the radio goes off-channel more frequently, which improves the chances of rogue detection. However, the access point will still spend about 50 milliseconds on each channel.

- Rogue detection is disabled by default for OfficeExtend access points because these access points, which are deployed in a home environment, are likely to detect a large number of rogue devices.

- Client card implementations might mitigate the effectiveness of ad hoc containment.

- It is possible to classify and report rogue access points through the use of rogue states and user-defined classification rules that enable rogues to automatically move between states.

- Each controller limits the number of rogue containment to three per radio (or six per radio for access points in the monitor mode).

- Rogue Location Discovery Protocol (RLDP) detects rogue access points that are configured for open authentication.

- RLDP detects rogue access points that use a broadcast Basic Service Set Identifier (BSSID), that is, the access point broadcasts its Service Set Identifier in beacons.

- RLDP detects only those rogue access points that are on the same network. If an access list in the network prevents the sending of RLDP traffic from the rogue access point to the controller, RLDP does not work.

- RLDP does not work on 5-GHz dynamic frequency selection (DFS) channels. However, RLDP works when the managed access point is in the monitor mode on a DFS channel.

- If RLDP is enabled on mesh APs, and the APs perform RLDP tasks, the mesh APs are dissociated from the controller. The workaround is to disable RLDP on mesh APs.

- If RLDP is enabled on nonmonitor APs, client connectivity outages occur when RLDP is in process.

- If the rogue is manually contained, the rogue entry is retained even after the rogue expires.

- If the rogue is contained by any other means, such as auto, rule, and AwIPS prevents, the rogue entry is deleted when it expires.

- The controller will request to AAA server for rogue client validation only once. As a result, if rogue client validation fails on the first attempt then the rogue client will not be detected as a threat any more. To avoid this, add the valid client entries in the authentication server before enabling Validate Rogue Clients Against AAA.

- In the 7.4 and earlier releases, if a rogue that was already classified by a rule was not reclassified. In the 7.5 release, this behavior is enhanced to allow reclassification of rogues based on the priority of the rogue rule. The priority is determined by using the rogue report that is received by the controller.
- The rogue detector AP fails to co-relate and contain the wired rogue AP on a 5Mhz channel because the MAC address of the rogue AP for WLAN, LAN, 11a radio and 11bg radio are configured with a difference of +/-1 of the rogue BSSID. In the 8.0 release, this behavior is enhanced by increasing the range of MAC address, that the rogue detector AP co-relates the wired ARP MAC and rogue BSSID, by +/-3.
- The rogue access points with open authentication can be detected on wire. The NAT wired or rogue wired detection is not supported in by WLC (both RLDP and rogue detector AP). The non-adjacent MAC address is supported by rogue detector mode of AP and not by RLDP.

---

**Note**
A rogue AP or client or adhoc containment configuration is not saved after the reload. You have to configure all the rogues again after the reload.

---

**Note**
No separate command exists for controlling rogue client traps. However, you can enable or disable rogue client traps using the `config trapflags rogueap {enable | disable}` command, which is also used for rogue APs. In GUI configuration also, you should use the rogue AP flag under **Management->SNMP->TrapControl->Security->Rogue AP** to control rogue clients.

---

**Rogue Location Discovery Protocol**

Rogue Location Discovery Protocol (RLDP) is an active approach, which is used when rogue AP has no authentication (Open Authentication) configured. This mode, which is disabled by default, instructs an active AP to move to the rogue channel and connect to the rogue as a client. During this time, the active AP sends de-authentication messages to all connected clients and then shuts down the radio interface. Then, it associates to the rogue AP as a client. The AP then tries to obtain an IP address from the rogue AP and forwards a User Datagram Protocol (UDP) packet (port 6352) that contains the local AP and rogue connection information to the controller through the rogue AP. If the controller receives this packet, the alarm is set to notify the network administrator that a rogue AP was discovered on the wired network with the RLDP feature.

RLDP has 100% accuracy in rogue AP detection. It detects Open APs and NAT APs.

---

**Note**
Use the `debug dot11 rldp enable` command in order to check if the Lightweight AP associates and receives a DHCP address from the rogue AP. This command also displays the UDP packet sent by the Lightweight AP to the controller.

---

A sample of a UDP (destination port 6352) packet sent by the Lightweight AP is shown here: 0020 0a 01 01 0d 0a 01 .......(.*...... 0030 01 1e 00 07 85 92 78 01 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00

The first 5 bytes of the data contain the DHCP address given to the local mode AP by the rogue AP. The next 5 bytes are the IP address of the controller, followed by 6 bytes that represent the rogue AP MAC address. Then, there are 18 bytes of zeroes.

Steps of how RLDP works are listed here:
1. Identify the closest Unified AP to the rogue using signal strength values.
2. The AP then connects to the rogue as a WLAN client, attempting three associations before timing out.
3. If association is successful, the AP then uses DHCP to obtain an IP address.

4. If an IP address was obtained, the AP (acting as a WLAN client) sends a UDP packet to each of the controller's IP addresses.

5. If the controller receives even one of the RLDP packets from the client, that rogue is marked as on-wire with a severity of critical.

---

**Note**

The RLDP packets are unable to reach the controller if filtering rules are placed between the controller's network and the network where the rogue device is located.

---

Caveats of RLDP:

- RLDP only works with open rogue APs broadcasting their SSID with authentication and encryption disabled.
- RLDP requires that the Managed AP acting as a client is able to obtain an IP address via DHCP on the rogue network.
- Manual RLDP can be used to attempt an RLDP trace on a rogue multiple number of times.
- During RLDP process, the AP is unable to serve clients. This negatively impacts performance and connectivity for local mode APs. To avoid this case, RLDP can be selectively enabled for Monitor Mode AP only.
- RLDP does not attempt to connect to a rogue AP operating in a 5GHz DFS channel.

---

**Note**

RLDP is not supported for use with Cisco autonomous rogue access points. These access points drop the DHCP Discover request sent by the RLDP client. Also, RLDP is not supported if the rogue access point channel requires dynamic frequency selection (DFS). If the automatic RLDP attempt does not detect the rogue (due to a noisy RF environment, for example), the controller does not retry. However, you can initiate RLDP manually on a rogue device.

---

**Detecting Rogue Devices**

The controller continuously monitors all the nearby access points and automatically discovers and collects information on rogue access points and clients. When the controller discovers a rogue access point, it uses the Rogue Location Discovery Protocol (RLDP) and the rogue detector mode access point is connected to determine if the rogue is attached to your network.

Controller initiates RLDP on rogue devices that have open authenticated and configured. If RLDP uses Flexconnect or local mode access points, then clients are disconnected for that moment. After the RLDP cycle, the clients are reconnected to the access points. As and when rogue access points are seen (auto-configuration), the RLDP process is initiated.

You can configure the controller to use RLDP on all the access points or only on the access points configured for the monitor (listen-only) mode. The latter option facilitates automated rogue access point detection in a crowded radio frequency (RF) space, allowing monitoring without creating unnecessary interference and without affecting the regular data access point functionality. If you configure the controller to use RLDP on all the access points, the controller always chooses the monitor access point for RLDP operation if a monitor...
access point and a local (data) access point are both nearby. If RLDP determines that the rogue is on your network, you can choose to contain the detected rogue either manually or automatically.

RLDP detects on wire presence of the rogue access points that are configured with open authentication only once, which is the default retry configuration. Retries can be configured using the `config rogue ap rldp retries` command.

You can initiate or trigger RLDP from controller in three ways:

1. Enter the RLDP initiation command manually from the controller CLI. The equivalent GUI option for initiating RLDP is not supported.

   ```
   config rogue ap rldp initiate mac-address
   ```

2. Schedule RLDP from the controller CLI. The equivalent GUI option for scheduling RLDP is not supported.

   ```
   config rogue ap rldp schedule
   ```

3. Auto RLDP. You can configure auto RLDP on controller either from controller CLI or GUI but keep in mind the following guidelines:

   - The auto RLDP option can be configured only when the rogue detection security level is set to custom.
   - Either auto RLDP or schedule of RLDP can be enabled at a time.

A rogue access point is moved to a contained state either automatically or manually. The controller selects the best available access point for containment and pushes the information to the access point. The access point stores the list of containments per radio. For auto containment, you can configure the controller to use only the monitor mode access point. The containment operation occurs in the following two ways:

   - The container access point goes through the list of containments periodically and sends unicast containment frames. For rogue access point containment, the frames are sent only if a rogue client is associated.

   - Whenever a contained rogue activity is detected, containment frames are transmitted.

Individual rogue containment involves sending a sequence of unicast disassociation and deauthentication frames.

**Cisco Prime Infrastructure Interaction and Rogue Detection**

Cisco Prime Infrastructure supports rule-based classification and uses the classification rules configured on the controller. The controller sends traps to Cisco Prime Infrastructure after the following events:

- If an unknown access point moves to the Friendly state for the first time, the controller sends a trap to Cisco Prime Infrastructure only if the rogue state is Alert. It does not send a trap if the rogue state is Internal or External.

- If a rogue entry is removed after the timeout expires, the controller sends a trap to Cisco Prime Infrastructure for rogue access points categorized as Malicious (Alert, Threat) or Unclassified (Alert). The controller does not remove rogue entries with the following rogue states: Contained, Contained Pending, Internal, and External.
# How to Configure Rogue Detection

## Configuring Rogue Detection (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `wireless wps rogue detection min-rssi rssi in dBm`
3. `wireless wps rogue detection min-transient-time time in seconds`
4. `wireless wps rogue client {aaa | mse}`
5. `wireless wps rogue ap valid-client auto-contain`
6. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><em>Example:</em></td>
<td>Device# <code>configure terminal</code></td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td><code>wireless wps rogue detection min-rssi rssi in dBm</code></td>
</tr>
<tr>
<td><em>Example:</em></td>
<td>Device(config)# <code>wireless wps rogue detection min-rssi 100</code></td>
</tr>
<tr>
<td></td>
<td>Specify the minimum RSSI value that rogues should have for APs to detect and for rogue entry to be created in the device.</td>
</tr>
<tr>
<td></td>
<td>Valid range for the rssi in dBm parameter is -128 dBm to -70 dBm, and the default value is -128 dBm.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> This feature is applicable to all the AP modes.</td>
</tr>
<tr>
<td></td>
<td>There can be many rogues with very weak RSSI values that do not provide any valuable information in rogue analysis. Therefore, you can use this option to filter rogues by specifying the minimum RSSI value at which APs should detect rogues.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td><code>wireless wps rogue detection min-transient-time time in seconds</code></td>
</tr>
<tr>
<td><em>Example:</em></td>
<td>Device(config)# <code>wireless wps rogue detection min-transient-time</code></td>
</tr>
<tr>
<td></td>
<td>Specify the time interval at which rogues have to be consistently scanned for by APs after the first time the rogues are scanned.</td>
</tr>
<tr>
<td></td>
<td>Valid range for the time in sec parameter is 120 seconds to 1800 seconds, and the default value is 0.</td>
</tr>
</tbody>
</table>
This feature is applicable to APs that are in monitor mode only. Using the transient interval values, you can control the time interval at which APs should scan for rogues. APs can also filter the rogues based on their transient interval values. This feature has the following advantages:

- Rogue reports from APs to the controller are shorter
- Transient rogue entries are avoided in the controller
- Unnecessary memory allocation for transient rogues are avoided

Note

Set the AAA server or local database, or the MSE to validate if rogue clients are valid clients.

Example:

Step 4

```
Device(config)# wireless wps rogue client { aaa | mse }
Device(config)# wireless wps rogue client aaa
Device(config)# wireless wps rogue client mse
```

Set the AAA server or local database, or the MSE to validate if rogue clients are valid clients.

Step 5

```
Device(config)# wireless wps rogue ap valid-client auto-contain
```

Specify to automatically contain a rogue access point to which trusted clients are associated.

Step 6

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Monitoring Rogue Detection

This section describes the new command for rogue detection.

The following command can be used to monitor rogue detection on the.

**Table 159: Monitoring Rogue Detection Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show wireless wps rogue ap summary</td>
<td>Displays a list of all rogue access points detected by the</td>
</tr>
<tr>
<td>show wireless wps rogue client detailed client-mac</td>
<td>Displays detailed information for a specific rogue client.</td>
</tr>
</tbody>
</table>
Examples: Rogue Detection Configuration

This example shows how to configure the minimum RSSI that a detected rogue AP needs to be at, to have an entry created at the:

```
Device# configure terminal
Device(config)# wireless wps rogue detection min-rssi -100
Device(config)# end
Device# show wireless wps rogue client detailed/show wireless wps rogue ap summary
```

This example shows how to configure the classification interval:

```
Device# configure terminal
Device(config)# wireless wps rogue detection min-transient-time 500
Device(config)# end
Device# show wireless wps rogue client detailed/show wireless wps rogue ap summary
```

This example shows how to configure the MSE to validate if rogue clients are valid clients:

```
Device# configure terminal
Device(config)# wireless wps rogue client mse
Device(config)# end
Device# show wireless wps rogue client summary
```

This example shows how to automatically contain a rogue access point to which trusted clients are associated:

```
Device# configure terminal
Device(config)# wireless wps rogue ap valid-client auto-contain
Device(config)# end
Device# show wireless wps rogue ap summary
Device# show nmsp capability
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Classifying Rogue Access Points

The controller software enables you to create rules that can organize and display rogue access points as Friendly, Malicious, or Unclassified.

By default, none of the classification rules are enabled. Therefore, all unknown access points are categorized as Unclassified. When you create a rule, configure conditions for it, and enable the rule, the unclassified access points are reclassified. Whenever you change a rule, it is applied to all access points (friendly, malicious, and unclassified) in the Alert state only.

Note

Rule-based rogue classification does not apply to ad hoc rogues and rogue clients.
You can configure up to 64 rogue classification rules per controller.

When the controller receives a rogue report from one of its managed access points, it responds as follows:

1. The controller verifies that the unknown access point is in the friendly MAC address list. If it is, the controller classifies the access point as Friendly.

2. If the unknown access point is not in the friendly MAC address list, the controller starts applying rogue classification rules.

3. If the rogue is already classified as Malicious, Alert or Friendly, Internal or External, the controller does not reclassify it automatically. If the rogue is classified differently, the controller reclassifies it automatically only if the rogue is in the Alert state.

4. The controller applies the first rule based on priority. If the rogue access point matches the criteria specified by the rule, the controller classifies the rogue according to the classification type configured for the rule.

5. If the rogue access point does not match any of the configured rules, the controller classifies the rogue as Unclassified.

6. The controller repeats the previous steps for all rogue access points.

7. If RLDP determines that the rogue access point is on the network, the controller marks the rogue state as Threat and classifies it as Malicious automatically, even if no rules are configured. You can then manually contain the rogue (unless you have configured RLDP to automatically contain the rogue), which would change the rogue state to Contained. If the rogue access point is not on the network, the controller marks the rogue state as Alert, and you can manually contain the rogue.

8. If desired, you can manually move the access point to a different classification type and rogue state.

Table 160: Classification Mapping

<table>
<thead>
<tr>
<th>Rule-Based Classification Type</th>
<th>Rogue States</th>
</tr>
</thead>
</table>
| Friendly                      | • Internal—If the unknown access point is inside the network and poses no threat to WLAN security, you would manually configure it as Friendly, Internal. An example is the access points in your lab network.  
• External—If the unknown access point is outside the network and poses no threat to WLAN security, you would manually configure it as Friendly, External. An example is an access point that belongs to a neighboring coffee shop.  
• Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list. |
Rogue States

**Rule-Based Classification Type**

<table>
<thead>
<tr>
<th>Malicious</th>
<th>Rogue States</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.</td>
<td></td>
</tr>
<tr>
<td>Threat—The unknown access point is found to be on the network and poses a threat to WLAN security.</td>
<td></td>
</tr>
<tr>
<td>Contained—The unknown access point is contained.</td>
<td></td>
</tr>
<tr>
<td>Contained Pending—The unknown access point is marked Contained, but the action is delayed due to unavailable resources.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Unclassified</th>
<th>Rogue States</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pending—On first detection, the unknown access point is put in the Pending state for 3 minutes. During this time, the managed access points determine if the unknown access point is a neighbor access point.</td>
<td></td>
</tr>
<tr>
<td>Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.</td>
<td></td>
</tr>
<tr>
<td>Contained—The unknown access point is contained.</td>
<td></td>
</tr>
<tr>
<td>Contained Pending—The unknown access point is marked Contained, but the action is delayed due to unavailable resources.</td>
<td></td>
</tr>
</tbody>
</table>

The classification and state of the rogue access points are configured as follows:

- From Known to Friendly, Internal
- From Acknowledged to Friendly, External
- From Contained to Malicious, Contained

As mentioned previously, the controller can automatically change the classification type and rogue state of an unknown access point based on user-defined rules, or you can manually move the unknown access point to a different classification type and rogue state.

**Table 161: Allowable Classification Type and Rogue State Transitions**

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Friendly (Internal, External, Alert)</td>
<td>Malicious (Alert)</td>
</tr>
<tr>
<td>Friendly (Internal, External, Alert)</td>
<td>Unclassified (Alert)</td>
</tr>
<tr>
<td>Friendly (Alert)</td>
<td>Friendly (Internal, External)</td>
</tr>
<tr>
<td>Malicious (Alert, Threat)</td>
<td>Friendly (Internal, External)</td>
</tr>
<tr>
<td>Malicious (Contained, Contained Pending)</td>
<td>Malicious (Alert)</td>
</tr>
<tr>
<td>Unclassified (Alert, Threat)</td>
<td>Friendly (Internal, External)</td>
</tr>
<tr>
<td>Unclassified (Contained, Contained Pending)</td>
<td>Unclassified (Alert)</td>
</tr>
<tr>
<td>Unclassified (Alert)</td>
<td>Malicious (Alert)</td>
</tr>
</tbody>
</table>
If the rogue state is Contained, you have to uncontain the rogue access point before you can change the classification type. If you want to move a rogue access point from Malicious to Unclassified, you must delete the access point and allow the controller to reclassify it.

**Restrictions for Classifying Rogue Access Points**

The following rules apply to this feature:

- Classifying Custom type rogues is tied to rogue rules. Therefore, it is not possible to manually classify a rogue as Custom. Custom class change can occur only using rogue rules.

- There are traps that are sent for containment by rule and for every 30 minutes for rogue classification change. For custom classification, the first trap does not contain the severity score because the trap has existed before the custom classification. The severity score is obtained from the subsequent trap that is generated after 30 minutes if the rogue is classified.

- Rogue rules are applied on every incoming new rogue report in the controller in the order of their priority.

- Once a rogue satisfies a higher priority rule and classified, it does not move down the priority list for the same report.

- Previously classified rogue gets re-classified on every new rogue report with the following restrictions:
  - Rogues which are classified as friendly by rule and whose state is set to ALERT, go through re-classification on receiving the new rogue report.
  - If a rogue is classified as friendly by the administrator manually, then the state is INTERNAL and it does not get re-classified on successive rogue reports.
  - If rogue is classified as malicious, irrespective of the state it does not get re-classified on subsequent rogue reports.

- Transition of the rogue's state from friendly to malicious is possible by multiple rogue rules if some attribute is missing in new rogue report.

- Transition of the rogue's state from malicious to any other classification is not possible by any rogue rule.

- When service set identifiers (SSIDs) are defined as part of a rogue rule, and details of the rogue rule are displayed using the `show wireless wps rogue rule detailed` command, the output differs in Cisco IOS XE Release 3.6E and prior releases and Cisco IOS XE Denali 16.1.1 and later releases.

The following is sample output from the `show wireless wps rogue rule detailed` command in Cisco IOS XE Release 3.6E and prior releases:

```
Switch# show wireless wps rogue rule detailed test

Priority : 1
Rule Name : wpstest
State : Disabled
Type : Pending
Match Operation : Any
Hit Count : 0
Total Conditions : 1
Condition :
  type : Ssid
  SSID Count : 2 ! SSID count differs.
```
The following is sample output from the `show wireless wps rogue rule detailed` command in Cisco IOS XE Denali 16.1.1 and later releases:

```
Switch# show wireless wps rogue rule detailed test

Priority               : 1
Rule Name              : wpstest
State                  : Disabled
Type                   : Pending
Match Operation        : Any
Hit Count              : 0
Total Conditions       : 1
Condition :
  type                  : Ssid
  SSID Count           : 2  ! SSID count differs.
  SSID                 : ssid1
  SSID                 : ssid2
```

## How to Classify Rogue Access Points

### Configuring Rogue Classification Rules (CLI)

#### SUMMARY STEPS

1. `configure terminal`
2. `wireless wps rogue rule rule-name priority priority`
3. `classify {friendly | malicious}`
4. `condition {client-count | duration | encryption | infrastructure | rssi | ssid}`
5. `match {all | any}`
6. `default`
7. `exit`
8. `shutdown`
9. `end`
10. `configure terminal`
11. `wireless wps rogue rule shutdown`
12. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td>Creates or enables a rule. While creating a rule, you must enter priority for the rule.</td>
</tr>
<tr>
<td>wireless wps rogue rule <em>rule-name priority priority</em></td>
<td>After creating the rule, if you are editing the rule, you can change the priority only for the rogue rules that are disabled. You cannot change priority for the rogue rules that are enabled. While editing, changing the priority for a rogue rule is optional.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# wireless wps rogue rule rule_3 priority 3</td>
<td></td>
</tr>
<tr>
<td>Device(config-rule)#</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 3** | Classifies a rule. |
| classify {friendly | malicious} | |
| **Example:**| |
| Device(config)# wireless wps rogue rule rule_3 priority 3 | |
| Device(config-rule)# classify friendly | |

| **Step 4** | Specifies to add the following conditions to a rule that the rogue access point must meet. |
| condition {client-count | duration | encryption | infrastructure | rssi | ssid} | |
| **Example:**| |
| Device(config)# wireless wps rogue rule rule_3 priority 3 | |
| Device(config-rule)# condition client-count 5 | |

- **client-count**—Requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum number of clients to be associated to the rogue access point for the *condition_value parameter*. The valid range is 1 to 10 (inclusive), and the default value is 0.

- **duration**—Requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period for the *condition_value parameter*. The valid range is 0 to 3600 seconds (inclusive), and the default value is 0 seconds.

- **encryption**—Requires that the advertised WLAN does not have encryption enabled.

- **infrastructure**—Requires the SSID to be known to the controller.

- **rssi**—Requires that the rogue access point have a minimum RSSI value. For example, if the rogue access point has an RSSI that is greater than the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum RSSI value for the *condition_value parameter*. The valid range is –95 to –50 dBm (inclusive), and the default value is 0 dBm.
### Command or Action | Purpose
--- | ---
- ssid—Requires that the rogue access point have a specific SSID. You should add SSIDs that are not managed by the controller. If you choose this option, enter the SSID for the `condition_value` parameter. The SSID is added to the user-configured SSID list.

**Step 5**

```bash
match {all | any}
```

**Example:**

```
Device(config)# wireless wps rogue rule rule_3
    priority 3
Device(config-rule)# match all
```

Specifies whether a detected rogue access point must meet all or any of the conditions specified by the rule in order for the rule to be matched and the rogue access point to adopt the classification type of the rule.

**Step 6**

```bash
default
```

**Example:**

```
Device(config)# wireless wps rogue rule rule_3
    priority 3
Device(config-rule)# default
```

Specifies to set a command to its default.

**Step 7**

```bash
exit
```

**Example:**

```
Device(config)# wireless wps rogue rule rule_3
    priority 3
Device(config-rule)# exit
Device(config)#
```

Specifies to exit the sub-mode.

**Step 8**

```bash
shutdown
```

**Example:**

```
Device(config)# wireless wps rogue rule rule_3
    priority 3
Device(config-rule)# shutdown
```

Specifies to disable a particular rogue rule. For example, the rule `rule_3` is disabled.

**Step 9**

```bash
end
```

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

**Step 10**

```bash
configure terminal
```

**Example:**

```
Device# configure terminal
```

Enters global configuration mode.

**Step 11**

```bash
wireless wps rogue rule shutdown
```

**Example:**

```
Device(config)# wireless wps rogue rule shutdown
```

Specifies to disable all the rogue rules.

**Step 12**

```bash
end
```

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.
Examples: Classifying Rogue Access Points

This example shows how to create rule that can organize and display rogue access points as Friendly:

```
Device# configure terminal
Device(config)# wireless wps rogue rule ap1 priority 1
Device(config-rule)# classify friendly
Device(config-rule)# end
```

This example shows how to apply condition that the rogue access point must meet:

```
Device# configure terminal
Device(config)# wireless wps rogue rule ap1 priority 1
Device(config-rule)# condition client-count 5
Device(config-rule)# condition duration 1000
Device(config-rule)# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About wIPS

The Cisco Adaptive Wireless Intrusion Prevention System (wIPS) uses an advanced approach to wireless threat detection and performance management. It combines network traffic analysis, network device and topology information, signature-based techniques, and anomaly detection to deliver highly accurate and complete wireless threat prevention. With a fully infrastructure-integrated solution, you can continually monitor wireless traffic on both the wired and wireless networks and use that network intelligence to analyze attacks from many sources to accurately pinpoint and proactively prevent attacks, rather than wait until damage or exposure has occurred.

Cisco Adaptive wIPS is a part of the Cisco 3300 Series Mobility Services Engine (MSE), which centralizes the processing of intelligence collected by the continuous monitoring of Cisco Aironet APs. With Cisco Adaptive wIPS functionalities and Cisco Prime Infrastructure integration into the Cisco MSE, the wIPS can configure and monitor wIPS policies and alarms and report threats.
If your wIPS deployment consists of a Cisco WLC, access point, and Cisco MSE, you must set all the three entities to the UTC time zone.

Cisco Adaptive wIPS is not configured on the Cisco WLC. Instead, the Cisco Prime Infrastructure forwards the profile configuration to the wIPS service, which forwards the profile to the Cisco WLC. The profile is stored in flash memory on the Cisco WLC and sent to APs when they join the Cisco WLC. When an access point disassociates and joins another Cisco WLC, it receives the wIPS profile from the new Cisco WLC.

Local-mode APs with a subset of wIPS capabilities are referred to as Enhanced Local Mode access point or ELM AP. You can configure an access point to work in the wIPS mode if the AP is in any of the following modes:

- Monitor
- Local

The regular local mode AP is extended with a subset of wIPS capabilities. This feature enables you to deploy your APs to provide protection without needing a separate overlay network.

wIPS ELM has the limited capability of detecting off-channel alarms. AN AP periodically goes off-channel, and monitors the nonserving channels for a short duration, and triggers alarms if any attack is detected on the channel. But off-channel alarm detection is best effort, and it takes a longer time to detect attacks and trigger alarms, which might cause the ELM AP to intermittently detect an alarm and clear it because it is not visible.

APs in any of the above modes can periodically send alarms based on the policy profile to the wIPS service through the Cisco WLC. The wIPS service stores and processes the alarms and generates SNMP traps. Cisco Prime Infrastructure configures its IP address as a trap destination to receive SNMP traps from the Cisco MSE.

This table lists all the SNMP trap controls and their respective traps. When a trap control is enabled, all the traps of that trap control are also enabled.

The Cisco WLC uses only SNMPv2 for SNMP trap transmission.

</table>
The following are the trap descriptions for the traps mentioned in the *SNMP Trap Controls and Their Respective Traps* table:

- **General Traps**
  - SNMP Authentication—The SNMPv2 entity has received a protocol message that is not properly authenticated.

  **Note** When a user who is configured in SNMP V3 mode tries to access the Cisco WLC with an incorrect password, the authentication fails and a failure message is displayed. However, no trap logs are generated for the authentication failure.

- **Link (Port) Up/Down**—Link changes status from up or down.
- **Link (Port) Up/Down**—Link changes status from up or down.
- **Multiple Users**—Two users log in with the same ID.
- **Rogue AP**—Whenever a rogue access point is detected, this trap is sent with its MAC address; when a rogue access point that was detected earlier no longer exists, this trap is sent.
- **Config Save**—Notification that is sent when the Cisco WLC configuration is modified.
• Cisco AP Traps
  • AP Register—Notification sent when an access point associates or disassociates with the Cisco WLC.
  • AP Interface Up/Down—Notification sent when an access point interface (802.11X) status goes up or down.

• Client-Related Traps
  • 802.11 Association—Associate notification that is sent when a client sends an association frame.
  • 802.11 Disassociation—Disassociate notification that is sent when a client sends a disassociation frame.
  • 802.11 Deauthentication—Deauthenticate notification that is sent when a client sends a deauthentication frame.
  • 802.11 Failed Authentication—Authenticate failure notification that is sent when a client sends an authentication frame with a status code other than successful.
  • 802.11 Failed Association—Associate failure notification that is sent when the client sends an association frame with a status code other than successful.
  • Exclusion—Associate failure notification that is sent when a client is exclusion listed (blacklisted).
  • Authentication—Authentication notification that is sent when a client is successfully authenticated.
  • Max Clients Limit Reached—Notification that is sent when the maximum number of clients, defined in the Threshold field, are associated with the Cisco WLC.

• NAC Alert—Alert that is sent when a client joins an SNMP NAC-enabled WLAN.
  This notification is generated when a client on NAC-enabled SSIDs completes Layer2 authentication to inform the NAC appliance about the client's presence. cldcClientWlanProfileName represents the profile name of the WLAN that the 802.11 wireless client is connected to, cldcClientIPAddress represents the unique IP address of the client, cldcApMacAddress represents the MAC address of the AP to which the client is associated, cldcClientQuarantineVLAN represents the quarantine VLAN for the client, cldcClientAccessVLAN represents the access VLAN for the client.

• Association with Stats—Associate notification that is sent with data statistics when a client is associated with the Cisco WLC, or roams. Data statistics include transmitted and received bytes and packets.

• Disassociation with Stats—Disassociate notification that is sent with data statistics when a client disassociates from the Cisco WLC. Data statistics include transmitted and received bytes and packets, SSID, and session ID.

---

**Note**

When you downgrade to Release 7.4 from a higher release, if a trap that was not supported in Release 7.4 (for example, NAC Alert trap) is enabled before the downgrade, all traps are disabled. After the downgrade, you must enable all the traps that were enabled before the downgrade. We recommend that you disable the new traps before the downgrade so that all the other traps are not disabled.

---

• Security Traps
  • User Auth Failure—This trap informs that a client RADIUS Authentication failure has occurred.
  • RADIUS Server No Response—This trap is to indicate that no RADIUS servers are responding to authentication requests sent by the RADIUS client.
• WEP Decrypt Error—Notification sent when the Cisco WLC detects a WEP decrypting error.
• Rogue AP—Whenever a rogue access point is detected, this trap is sent with its MAC address; when a rogue access point that was detected earlier no longer exists, this trap is sent.
• SNMP Authentication—The SNMPv2 entity has received a protocol message that is not properly authenticated.

---

**Note**

When a user who is configured in SNMP V3 mode tries to access the Cisco WLC with an incorrect password, authentication fails and a failure message is displayed. However, no trap logs are generated for the authentication failure.

---

• Multiple Users—Two users log in with the same ID.

• SNMP Authentication
  • Load Profile—Notification sent when the Load Profile state changes between PASS and FAIL.
  • Noise Profile—Notification sent when the Noise Profile state changes between PASS and FAIL.
  • Interference Profile—Notification sent when the Interference Profile state changes between PASS and FAIL.
  • Coverage Profile—Notification sent when the Coverage Profile state changes between PASS and FAIL.

• Auto RF Profile Traps
  • Load Profile—Notification sent when the Load Profile state changes between PASS and FAIL.
  • Noise Profile—Notification sent when the Noise Profile state changes between PASS and FAIL.
  • Interference Profile—Notification sent when the Interference Profile state changes between PASS and FAIL.
  • Coverage Profile—Notification sent when the Coverage Profile state changes between PASS and FAIL.

• Auto RF Update Traps
  • Channel Update—Notification sent when the access point dynamic channel algorithm is updated.
  • Tx Power Update—Notification sent when the access point dynamic transmit power algorithm is updated.

• Mesh Traps
  • Child Excluded Parent—Notification that is sent when a defined number of failed association to the Cisco WLC occurs through a parent mesh node.
  • Notification sent when a child mesh node exceeds the threshold limit of the number of discovery response timeouts. The child mesh node does not try to associate an excluded parent mesh node for the interval defined. The child mesh node remembers the excluded parent MAC address when it joins the network, and informs the Cisco WLC.
  • Parent Change—Notification is sent by the agent when a child mesh node changes its parent. The child mesh node remembers previous parent and informs the Cisco WLC about the change of parent when it rejoins the network.
  • Child Moved—Notification sent when a parent mesh node loses connection with its child mesh node.
• Excessive Parent Change—Notification sent when the child mesh node changes its parent frequently. Each mesh node keeps a count of the number of parent changes in a fixed time. If it exceeds the defined threshold, the child mesh node informs the Cisco WLC.

• Excessive Children—Notification sent when the child count exceeds for a RAP and a MAP.

• Poor SNR—Notification sent when the child mesh node detects a lower SNR on a backhaul link. For the other trap, a notification is sent to clear a notification when the child mesh node detects an SNR on a backhaul link that is higher then the object defined by 'clMeshSNRThresholdAbate'.

• Console Login—Notification is sent by the agent when a login on a MAP console is either successful or fail after three attempts.

• Default Bridge Group Name—Notification sent when the MAP mesh node joins its parent using the default bridge group name.

The remaining traps do not have trap controls. These traps are not generated too frequently and do not require any trap control. Any other trap that is generated by the Cisco WLC cannot be turned off.

In all of the above cases, the Cisco WLC functions solely as a forwarding device.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the <TBD>

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Intrusion Detection System

The Cisco Intrusion Detection System/Intrusion Prevention System (CIDS/CIPS) instructs devices to block certain clients from accessing the wireless network when attacks involving these clients are detected at Layer 3 through Layer 7. This system offers significant network protection by helping to detect, classify, and stop threats including worms, spyware/adware, network viruses, and application abuse. Two methods are available to detect potential attacks:

- IDS sensors
- IDS signatures

IDS sensors can be configured to detect various types of IP-level attacks in the network. When the sensors identify an attack, they can alert the device to shun the offending client. When a new IDS sensor is added, the IDS sensor should be registered with the device so that the device can query the sensor to get the list of shunned clients.

When an IDS sensor detects a suspicious client, it alerts the device to shun this client. The shun entry is distributed to all devices within the same mobility group. If the client to be shunned is currently joined to a device in this mobility group, the anchor device adds this client to the dynamic exclusion list, and the foreign...
device removes the client. The next time that the client tries to connect to a device, the anchor device rejects the handoff and informs the foreign device that the client is being excluded.

How to Configure Intrusion Detection System

Configuring IDS Sensors

SUMMARY STEPS

1. configure terminal
2. wireless wps cids-sensor index [ip-address ip-addr username username password password_type password]
3. wireless wps cids-sensor index

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Switch Stacks

All the switches in the switch stack need to be running the same license level as the active switch. For information about license levels, see the System Management Configuration Guide (Catalyst 3850 Switches).

All switches in the switch stack need to be running compatible software versions.

Restrictions for Switch Stacks

The following are restrictions for your switch stack configuration:

- Switch stacks running the LAN Base license level do not support Layer 3 features.
• A switch stack can have up to nine stacking-capable switches connected through their StackWise-480 ports.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

• You cannot have a switch stack containing a mix of different license levels.

---

**Information About Switch Stacks**

**Switch Stack Overview**

A switch stack can have up to nine stacking-capable switches connected through their StackWise-480 ports. The stack members work together as a unified system. Layer 2 and Layer 3 protocols present the entire switch stack as a single entity to the network.

A switch stack always has one active switch and one standby switch. If the active switch becomes unavailable, the standby switch assumes the role of the active switch, and continues to keep the stack operational.

The active switch controls the operation of the switch stack, and is the single point of stack-wide management. From the active switch, you configure:

- System-level (global) features that apply to all stack members
- Interface-level features for each stack member

The active switch contains the saved and running configuration files for the switch stack. The configuration files include the system-level settings for the switch stack and the interface-level settings for each stack member. Each stack member has a current copy of these files for back-up purposes.

A switch stack can have up to nine stacking-capable switches connected through their StackWise-480 ports. The switches in the stack must be homogeneous and must have the same license level.

**Supported Features in a Switch Stack**

The system-level features supported on the active switch are supported on the entire switch stack.

**Encryption Features**

If the active switch is running the cryptographic universal software image (supports encryption), the encryption features are available on the switch stack.

**StackWise-480**

The stack members use the StackWise-480 technology to work together as a unified system. Layer 2 and Layer 3 protocols support the entire switch stack as a single entity in the network.
Note
Switch stacks running the LAN Base image do not support Layer 3 features.

StackWise-480 has a stack bandwidth of 480 Gbps, and uses stateful switchover (SSO) to provide resiliency within the stack. The stack behaves as a single switching unit that is managed by an active switch elected by the member switches. The active switch automatically elects a standby switch within the stack. The active switch creates and updates all the switching, routing and wireless information and constantly synchronizes that information with the standby switch. If the active switch fails, the standby switch assumes the role of the active switch and continues to keep the stack operational. Access points continue to remain connected during an active-to-standby switchover unless the access point is directly connected to the active switch. In this case the access point will lose power and reboot. A working stack can accept new members or delete old ones without service interruption.

Fast Stack Convergence
When a single link in a full ring stack becomes inoperable, there is a disruption in the forwarding of packets, and the stack moves to a half ring. With Catalyst 3850 switches this disruption of traffic (or stack convergence time) takes milliseconds.

StackPower
StackPower allows the power supplies in a stack to be shared as a common resource among all the switches in the stack. StackPower unifies the individual power supplies installed in the switches and creates a pool of power, directing that power where it is needed. Up to four switches can be configured in a StackPower stack using the StackPower cable.

For more information about StackPower, see the Interface and Hardware Component Configuration Guide (Catalyst 3850 Switches).

Switch Stack Membership
A standalone device is a device stack with one stack member that also operates as the active switch. You can connect one standalone device to another to create a device stack containing two stack members, with one of them as the active switch. You can connect standalone devices to an existing device stack to increase the stack membership.

Hello messages are sent and received by all stack members.
• If a stack member does not respond, that member is removed from the stack.
• If the standby device does not respond, a new standby device is elected.
• If the active device does not respond, the standby device becomes the active device.

In addition, keepalive messages are sent and received between the active and standby devicees.
• If the standby device does not respond, a new standby device is elected.
• If the active device does not respond, the standby device becomes the active device.
Changes to Switch Stack Membership

If you replace a stack member with an identical model, the new switch functions with exactly the same configuration as the replaced switch, assuming that the new switch (referred to as the provisioned switch) is using the same member number as the replaced switch.

The operation of the switch stack continues uninterrupted during membership changes unless you remove the active switch or you add powered-on standalone switches or switch stacks.

- Adding powered-on switches (merging) causes all switches to reload and elect a new active switch from among themselves. The newly elected active switch retains its role and configuration. All other switches retain their stack member numbers and use the stack configuration of the newly elected active switch.

- Removing powered-on stack members causes the switch stack to divide (partition) into two or more switch stacks, each with the same configuration. This can cause:
  - An IP address conflict in your network. If you want the switch stacks to remain separate, change the IP address or addresses of the newly created switch stacks.
  - A MAC address conflict between two members in the stack. You can use the `stack-mac update force` command to resolve the conflict.

If a newly created switch stack does not have an active switch or standby switch, the switch stack will reload and elect a new active switch.

Note

Make sure that you power off the switches that you add to or remove from the switch stack.

After adding or removing stack members, make sure that the switch stack is operating at full bandwidth (480 Gbps). Press the Mode button on a stack member until the Stack mode LED is on. The last two right port LEDs on all switches in the stack should be green. Depending on the switch model, the last two right ports are 10-Gigabit Ethernet ports or small form-factor pluggable (SFP) module ports (10/100/1000 ports). If one or both of these LEDs are not green on any of the switches, the stack is not operating at full bandwidth.

If you remove powered-on members but do not want to partition the stack:

- Power off the switches in the newly created switch stacks.
- Reconnect them to the original switch stack through their stack ports.
- Power on the switches.

For cabling and power considerations that affect switch stacks, see the Catalyst 3850 Switch Hardware Installation Guide.

Stack Member Numbers

The stack member number (1 to 9) identifies each member in the Device stack. The member number also determines the interface-level configuration that a stack member uses. You can display the stack member number by using the `show switch` EXEC command.

A new, out-of-the-box Device (one that has not joined a Device stack or has not been manually assigned a stack member number) ships with a default stack member number of 1. When it joins a Device stack, its default stack member number changes to the lowest available member number in the stack.
Stack members in the same Device stack cannot have the same stack member number. Every stack member, including a standalone Device, retains its member number until you manually change the number or unless the number is already being used by another member in the stack.

- If you manually change the stack member number by using the `switch current-stack-member-number renumber new-stack-member-number` EXEC command, the new number goes into effect after that stack member resets (or after you use the `reload slot stack-member-number` privileged EXEC command) and only if that number is not already assigned to any other members in the stack. Another way to change the stack member number is by changing the Device_NUMBER environment variable.

If the number is being used by another member in the stack, the Device selects the lowest available number in the stack.

If you manually change the number of a stack member and no interface-level configuration is associated with that new member number, that stack member resets to its default configuration.

You cannot use the `switch current-stack-member-number renumber new-stack-member-number` EXEC command on a provisioned Device. If you do, the command is rejected.

- If you move a stack member to a different Device stack, the stack member retains its number only if the number is not being used by another member in the stack. If it is being used, the Device selects the lowest available number in the stack.

- If you merge Device stacks, the Device that join the Device stack of a new active switch select the lowest available numbers in the stack.

As described in the hardware installation guide, you can use the Device port LEDs in Stack mode to visually determine the stack member number of each stack member.

In the default mode Stack LED will blink in green color only on the stack master. However, when we scroll the Mode button to Stack option - Stack LED will glow green on all the stack members.

When mode button is scrolled to Stack option, the switch number of each stack member will be displayed as LEDs on the first five ports of that switch. The switch number is displayed in binary format for all stack members. On the switch, the amber LED indicates value 0 and green LED indicates value 1.

Example for switch number 5 (Binary - 00101):

First five LEDs will glow in below color combination on stack member with switch number 5.

- Port-1 : Amber
- Port-2 : Amber
- Port-3 : Green
- Port-4 : Amber
- Port-5 : Green

Similarly first five LEDs will glow in amber or green, depending on the switch number on all stack members.
Stack Member Priority Values

A higher priority value for a stack member increases the probability of it being elected active switch and retaining its stack member number. The priority value can be 1 to 15. The default priority value is 1. You can display the stack member priority value by using the `show switch` EXEC command.

Note: We recommend assigning the highest priority value to the device that you prefer to be the active switch. This ensures that the device is reelected as the active switch if a reelection occurs.

To change the priority value for a stack member, use the `switch stack-member-number priority new priority-value` EXEC command. For more information, see the “Setting the Stack Member Priority Value” section.

The new priority value takes effect immediately but does not affect the current active switch. The new priority value helps determine which stack member is elected as the new active switch when the current active switch or the switch stack resets.

Switch Stack Bridge ID and MAC Address

A switch stack is identified in the network by its bridge ID and, if it is operating as a Layer 3 device, its router MAC address. The bridge ID and router MAC address are determined by the MAC address of the active switch.

If the active switch changes, the MAC address of the new active switch determines the new bridge ID and router MAC address.

If the entire switch stack reloads, the switch stack uses the MAC address of the active switch.

Persistent MAC Address on the Switch Stack

You can use the persistent MAC address feature to set a time delay before the stack MAC address changes. During this time period, if the previous active switch rejoins the stack, the stack continues to use its MAC address as the stack MAC address, even if the switch is now a stack member and not an active switch. If the previous active switch does not rejoin the stack during this period, the switch stack takes the MAC address of the new active switch as the stack MAC address. By default, the stack MAC address will be the MAC address of the first active switch, even if a new active switch takes over.
You can use the persistent MAC address feature to set a time delay before the stack MAC address changes to the MAC address of the new stack master. When this feature is enabled, the stack MAC address changes in approximately 4 minutes. During this time, if the previous stack master rejoins the stack, the stack continues to use its MAC address as the stack MAC address, even if the switch is now a stack member and not a stack master. If the previous stack master does not rejoin the stack during this period, the switch stack takes the MAC address of the new stack master as the stack MAC address.

You can also configure stack MAC persistency so that the stack MAC address never changes to the new active switch MAC address.

### Active and Standby Switch Election and Reelection

All stack members are eligible to be the active switch or the standby switch. If the active switch becomes unavailable, the standby switch becomes the active switch.

An active switch retains its role unless one of these events occurs:

- The switch stack is reset.
- The active switch is removed from the switch stack.
- The active switch is reset or powered off.
- The active switch fails.
- The switch stack membership is increased by adding powered-on standalone switches or switch stacks.

All stack members are eligible stack masters. If the stack master becomes unavailable, the remaining members elect a new stack master from among themselves.

The active switch is elected or reelected based on one of these factors and in the order listed:

1. The switch that is currently the active switch.
2. The switch with the highest stack member priority value.

---

**Note**

We recommend assigning the highest priority value to the switch that you prefer to be the active switch. This ensures that the switch is reelected as active switch if a reelection occurs.

3. The switch with the shortest start-up time. Differences in start-up times between the feature image licenses determine the active switch. For example, a switch running the IP Services license level has a higher priority than the switch running the IP Base license level, but the switch running the IP Base license level becomes the active switch because the other switch takes 120 seconds longer to start. To avoid this problem, upgrade the switch running the IP Base license level to the same licensed feature set and software image as the other switch, or manually start the active switch and wait at least 8 seconds before starting the new member switch that is running the IP Base license level.

4. The switch that has the configuration file.

5. The switch with the lowest MAC address.
The factors for electing or reelecting a new standby switch are same as those for the active switch election or reelection, and are applied to all participating switches except the active switch.

After election, the new active switch becomes available after a few seconds. In the meantime, the switch stack uses the forwarding tables in memory to minimize network disruption. The physical interfaces on the other available stack members are not affected during a new active switch election and reset.

When the previous active switch becomes available, it does not resume its role as the active switch.

If you power on or reset an entire switch stack, some stack members might not participate in the active switch election. Stack members that are powered on within the same 2-minute timeframe participate in the active switch election and have a chance to become the active switch. Stack members that are powered on after the 120-second timeframe do not participate in this initial election and become stack members. For powering considerations that affect active-switch elections, see the switch hardware installation guide.

As described in the hardware installation guide, you can use the ACTV LED on the switch to see if the switch is the active switch.

A stack master retains its role unless one of these events occurs:

- The switch stack is reset.*
- The stack master is removed from the switch stack.
- The stack master is reset or powered off.
- The stack master fails.
- The switch stack membership is increased by adding powered-on standalone switches or switch stacks.*

In the events marked by an asterisk (*), the current stack master might be reelected based on the listed factors.

When you power on or reset an entire switch stack, some stack members might not participate in the stack master election. Stack members that are powered on within the same 20-second time frame participate in the stack master election and have a chance to become the stack master. Stack members that are powered on after the 20-second time frame do not participate in this initial election and become stack members. All stack members participate in reelections. For all powering considerations that affect stack-master elections, see the “Switch Installation” chapter in the hardware installation guide.

The new stack master becomes available after a few seconds. In the meantime, the switch stack uses the forwarding tables in memory to minimize network disruption. The physical interfaces on the other available stack members are not affected during a new stack master election and reset.

After a new stack master is elected and the previous stack master becomes available, the previous stack master does not resume its role as stack master.

**Switch Stack Configuration Files**

The active switch has the saved and running configuration file for the switch stack. The standby switch automatically receives the synchronized running configuration file. Stack members receive synchronized copies when the running configuration file is saved into the startup configuration file. If the active switch becomes unavailable, the standby switch takes over with the current running configuration.
The active switch has the saved and running configuration files for the switch stack. All stack members periodically receive synchronized copies of the configuration files from the active switch. If the active switch becomes unavailable, any stack member assuming the role of active switch has the latest configuration files.

The configuration files record these settings:

- System-level (global) configuration settings such as IP, STP, VLAN, and SNMP settings that apply to all stack members
- Stack member interface-specific configuration settings that are specific for each stack member

The interface-specific settings of the active switch are saved if the active switch is replaced without saving the running configuration to the startup configuration.

A new, out-of-box device joining a switch stack uses the system-level settings of that switch stack. If a device is moved to a different switch stack before it is powered on, that device loses its saved configuration file and uses the system-level configuration of the new switch stack. If the device is powered on as a standalone device before it joins the new switch stack, the stack will reload. When the stack reloads, the new device may become the active switch, retain its configuration and overwrite the configuration files of the other stack members.

The interface-specific configuration of each stack member is associated with the stack member number. Stack members retain their numbers unless they are manually changed or they are already used by another member in the same switch stack. If the stack member number changes, the new number goes into effect after that stack member resets.

- If an interface-specific configuration does not exist for that member number, the stack member uses its default interface-specific configuration.
- If an interface-specific configuration exists for that member number, the stack member uses the interface-specific configuration associated with that member number.

If you replace a failed member with an identical model, the replacement member automatically uses the same interface-specific configuration as the failed device. You do not need to reconfigure the interface settings. The replacement device (referred to as the provisioned device) must have the same stack member number as the failed device.

You back up and restore the stack configuration in the same way as you would for a standalone device configuration.

### Offline Configuration to Provision a Stack Member

You can use the offline configuration feature to provision (to supply a configuration to) a new switch before it joins the switch stack. You can configure the stack member number, the switch type, and the interfaces associated with a switch that is not currently part of the stack. The configuration that you create on the switch stack is called the provisioned configuration. The switch that is added to the switch stack and that receives this configuration is called the provisioned switch.

You manually create the provisioned configuration through the switch stack-member-number provision type global configuration command. You must change the stack-member-number on the provisioned switch before you add it to the stack, and it must match the stack member number that you created for the new switch on the switch stack. The switch type in the provisioned configuration must match the switch type of the newly
added switch. The provisioned configuration is automatically created when a switch is added to a switch stack and when no provisioned configuration exists.

When you configure the interfaces associated with a provisioned switch, the switch stack accepts the configuration, and the information appears in the running configuration. However, as the switch is not active, any configuration on the interface is not operational and the interface associated with the provisioned switch does not appear in the display of the specific feature. For example, VLAN configuration information associated with a provisioned switch does not appear in the `show vlan` user EXEC command output on the switch stack.

The switch stack retains the provisioned configuration in the running configuration whether or not the provisioned switch is part of the stack. You can save the provisioned configuration to the startup configuration file by entering the `copy running-config startup-config` privileged EXEC command. The startup configuration file ensures that the switch stack can reload and can use the saved information whether or not the provisioned switch is part of the switch stack.

### Effects of Adding a Provisioned Switch to a Switch Stack

When you add a provisioned Device to the switch stack, the stack applies either the provisioned configuration or the default configuration. This table lists the events that occur when the switch stack compares the provisioned configuration with the provisioned switch.

#### Table 165: Results of Comparing the Provisioned Configuration with the Provisioned Switch

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>The stack member numbers and the Device types match.</td>
<td>The switch stack applies the provisioned configuration to the provisioned switch and adds it to the stack.</td>
</tr>
<tr>
<td></td>
<td>1. If the stack member number of the provisioned switch matches the stack member number in the provisioned configuration on the stack, and</td>
</tr>
<tr>
<td></td>
<td>2. If the Device type of the provisioned switch matches the Device type in the provisioned configuration on the stack.</td>
</tr>
<tr>
<td>The stack member numbers match but the Device types do not match.</td>
<td>The switch stack applies the default configuration to the provisioned switch and adds it to the stack. The provisioned configuration is changed to reflect the new information.</td>
</tr>
<tr>
<td></td>
<td>1. If the stack member number of the provisioned switch matches the stack member number in the provisioned configuration on the stack, but</td>
</tr>
<tr>
<td></td>
<td>2. The Device type of the provisioned switch does not match the Device type in the provisioned configuration on the stack.</td>
</tr>
<tr>
<td>The stack member number is not found in the provisioned configuration.</td>
<td>The switch stack applies the default configuration to the provisioned switch and adds it to the stack. The provisioned configuration is changed to reflect the new information.</td>
</tr>
</tbody>
</table>
Effects of Replacing a Provisioned Switch in a Switch Stack

When a provisioned switch in a switch stack fails, it is removed from the stack, and is replaced with another Device, the stack applies either the provisioned configuration or the default configuration to it. The events that occur when the switch stack compares the provisioned configuration with the provisioned switch are the same as those when you add a provisioned switch to a stack.

Effects of Removing a Provisioned Switch from a Switch Stack

If you remove a provisioned switch from the switch stack, the configuration associated with the removed stack member remains in the running configuration as provisioned information. To completely remove the configuration, use the no switch stack-member-number provision global configuration command.

Upgrading a Switch Running Incompatible Software

The auto-upgrade and auto-advice features enable a switch with software packages that are incompatible with the switch stack to be upgraded to a compatible software version so that it can join the switch stack.

Auto-Upgrade

The purpose of the auto-upgrade feature is to allow a switch to be upgraded to a compatible software image, so that the switch can join the switch stack.

When a new switch attempts to join a switch stack, each stack member performs compatibility checks with itself and the new switch. Each stack member sends the results of the compatibility checks to the active switch, which uses the results to determine whether the switch can join the switch stack. If the software on the new switch is incompatible with the switch stack, the new switch enters version-mismatch (VM) mode.
If the auto-upgrade feature is enabled on the existing switch stack, the active switch automatically upgrades the new switch with the same software image running on a compatible stack member. Auto-upgrade starts a few minutes after the mismatched software is detected before starting.

Auto-upgrade is disabled by default.

Auto-upgrade includes an auto-copy process and an auto-extract process.

- Auto-copy automatically copies the software image running on any stack member to the new switch to automatically upgrade it. Auto-copy occurs if auto-upgrade is enabled, if there is enough flash memory in the new switch, and if the software image running on the switch stack is suitable for the new switch.

  **Note**
  
  A switch in VM mode might not run all released software. For example, new switch hardware is not recognized in earlier versions of software.

  - Automatic extraction (auto-extract) occurs when the auto-upgrade process cannot find the appropriate software in the stack to copy to the new switch. In that case, the auto-extract process searches all switches in the stack for the bin file needed to upgrade the switch stack or the new switch. The bin file can be in any flash file system in the switch stack or in the new switch. If a bin file suitable for the new switch is found on a stack member, the process extracts the file and automatically upgrades the new switch.

The auto-upgrade feature is not available in bundle mode. The switch stack must be running in installed mode. If the switch stack is in bundle mode, use the `software expand` privileged EXEC command to change to installed mode.

You can enable auto-upgrade by using the `software auto-upgrade enable` global configuration command on the new switch. You can check the status of auto-upgrade by using the `show running-config` privileged EXEC command and by checking the `Auto upgrade` line in the display.

You can configure auto-upgrade to upgrade the new switch with a specific software bundle by using the `software auto-upgrade source url` global configuration command. If the software bundle is invalid, the new switch is upgraded with the same software image running on a compatible stack member.

When the auto-upgrade process is complete, the new switch reloads and joins the stack as a fully functioning member. If you have both stack cables connected during the reload, network downtime does not occur because the switch stack operates on two rings.

For more information about upgrading a switch running incompatible software see the *Cisco IOS File System, Configuration Files, and Bundle Files Appendix, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*.

### Auto-Advise

The auto-advise feature is triggered when:

- The auto-upgrade feature is disabled.

- The new switch is in bundle mode and the stack is in installed mode. Auto-advise displays syslog messages about using the `software auto-upgrade` privileged EXEC command to change the new switch to installed mode.

- The stack is in bundle mode. Auto-advise displays syslog messages about booting the new switch in bundle mode so that it can join the stack.
• An auto-upgrade attempt fails because the new switch is running incompatible software. After the switch stack performs compatibility checks with the new switch, auto-advice displays syslog messages about whether the new switch can be auto-upgraded.

Auto-advice cannot be disabled. It does not give suggestions when the switch stack software and the software of the switch in version-mismatch (VM) mode do not contain the same license level.

Automatic advise (auto-advice) occurs when the auto-upgrade process cannot find appropriate stack member software to copy to the new switch. This process tells you the command (archive copy-sw or archive download-sw privileged EXEC command) and the image name (tar filename) needed to manually upgrade the switch stack or the new switch. The recommended image can be the running switch stack image or a tar file in any flash file system in the switch stack (including the new switch). If an appropriate image is not found in the stack flash file systems, the auto-advice process tells you to install new software on the switch stack. Auto-advice cannot be disabled, and there is no command to check its status.

Examples of Auto-Advise Messages

**Auto-Upgrade Is Disabled and Incompatible Switch Attempting to Join: Example**

This sample auto-advice output shows the system messages displayed when the auto-upgrade feature is disabled and an incompatible switch 1 tries to join the switch stack:

*Oct 18 08:36:19.379: %INSTALLER-6-AUTO_ADVISE_SW_INITIATED: 2 installer: Auto advise initiated for switch 1
*Oct 18 08:36:19.380: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: Searching stack for software to upgrade switch 1
*Oct 18 08:36:19.382: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: Switch 1 with incompatible software has been
*Oct 18 08:36:19.382: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: added to the stack. The software running on
*Oct 18 08:36:19.382: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: all stack members was scanned and it has been
*Oct 18 08:36:19.382: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: determined that the 'software auto-upgrade' command can be used to install compatible

**Auto-Upgrade is Disabled and New Switch is in Bundle Mode: Example**

This sample auto-advice output shows the system messages displayed when auto-upgrade is disabled and a switch running in bundle mode tries to join the stack that is running in installed mode:

*Oct 18 11:09:47.005: %INSTALLER-6-AUTO_ADVISE_SW_INITIATED: 2 installer: Auto advise initiated for switch 1
*Oct 18 11:09:47.005: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: Switch 1 running bundled software has been added
*Oct 18 11:09:47.005: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: to the stack that is running installed software.
*Oct 18 11:09:47.005: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: The 'software auto-upgrade' command can be used to
*Oct 18 11:09:47.005: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: convert switch 1 to the installed running mode by
*Oct 18 11:09:47.005: %INSTALLER-6-AUTO_ADVISE_SW: 2 installer: installing its running software.
Switch Stack Management Connectivity

You manage the switch stack and the stack member interfaces through the active switch. You can use the CLI, SNMP, and supported network management applications such as CiscoWorks. You cannot manage stack members on an individual Device basis.

Note

Use SNMP to manage network features across the stack that are defined by supported MIBs. The switch does not support MIBs to manage stacking-specific features such as stack membership and election.

Connectivity to the Switch Stack Through an IP Address

The switch stack is managed through a single IP address. The IP address is a system-level setting and is not specific to the active switch or to any other stack member. You can still manage the stack through the same IP address even if you remove the active switch or any other stack member from the stack, provided there is IP connectivity.

Note

Stack members retain their IP addresses when you remove them from a switch stack. To avoid a conflict by having two devices with the same IP address in your network, change the IP addresses of any Device that you remove from the switch stack.

For related information about switch stack configurations, see the Switch Stack Configuration Files section.

Connectivity to the Switch Stack Through Console Ports or Ethernet Management Ports

You can connect to the active switch by using one of these methods:

- You can connect a terminal or a PC to the active switch through the console port of one or more stack members.

- You can connect a PC to the active switch through the Ethernet management ports of one or more stack members. For more information about connecting to the switch stack through Ethernet management ports, see the Using the Ethernet Management Port section.

You can connect to the active switch by connecting a terminal or a PC to the stack master through the console port of one or more stack members.

Be careful when using multiple CLI sessions to the active switch. Commands that you enter in one session are not displayed in the other sessions. Therefore, it is possible that you might not be able to identify the session from which you entered a command.

We recommend using only one CLI session when managing the switch stack.
How to Configure a Switch Stack

Enabling the Persistent MAC Address Feature

Note: When you enter the command to configure this feature, a warning message appears with the consequences of your configuration. You should use this feature cautiously. Using the old active switch MAC address elsewhere in the same domain could result in lost traffic.

Follow these steps to enable persistent MAC address:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `stack-mac persistent timer [0 | time-value]`
4. `end`
5. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; <code>enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables a time delay after an active-switch change before the stack MAC address changes to that of the new active switch. If the previous active switch rejoins the stack during this period, the stack uses that MAC address as the stack MAC address.</td>
</tr>
<tr>
<td>`stack-mac persistent timer [0</td>
<td>time-value]`</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# <code>stack-mac persistent timer 7</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Enter the command with no value or with a value of 0 to continue using the MAC address of the current active switch indefinitely.</td>
</tr>
<tr>
<td></td>
<td>• Enter a <code>time-value</code> from 1 to 60 minutes to configure the time period before the stack MAC address changes to the new active switch.</td>
</tr>
</tbody>
</table>
Assigning a Stack Member Number

This optional task is available only from the active switch.

Follow these steps to assign a member number to a stack member:

SUMMARY STEPS

1. enable
2. configure terminal
3. switch current-stack-member-number renumber new-stack-member-number
4. end
5. reload slot stack-member-number
6. show switch
7. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

What to do next

Use the **no stack-mac persistent timer** global configuration command to disable the persistent MAC address feature.
### Setting the Stack Member Priority Value

This optional task is available only from the active switch.

Follow these steps to assign a priority value to a stack member:

#### SUMMARY STEPS

1. `enable`
2. `switch stack-member-number priority new-priority-number`
3. `end`
4. `show switch stack-member-number`
5. `copy running-config startup-config`
**Provisioning a New Member for a Switch Stack**

This optional task is available only from the active switch.

**SUMMARY STEPS**

1. show switch
2. configure terminal
3. switch stack-member-number provision type
4. end
5. copy running-config startup-config

---

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device&gt; enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>switch stack-member-number priority new-priority-number&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# switch 3 priority 2</td>
<td>Specifies the stack member number and the new priority for the stack member. The stack member number range is 1 to 9. The priority value range is 1 to 15. You can display the current priority value by using the <code>show switch</code> user EXEC command. The new priority value takes effect immediately but does not affect the current active switch. The new priority value helps determine which stack member is elected as the new active switch when the current active switch or switch stack resets.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>end&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>show switch stack-member-number&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# show switch</td>
<td>Verify the stack member priority value.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>copy running-config startup-config&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> show switch</td>
<td>Displays summary information about the switch stack.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show switch</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> switch stack-member-number provision type</td>
<td>Specifies the stack member number for the preconfigured switch. By default, no switches are provisioned.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# switch 3 provision WS-xxxx</td>
<td>Specifies a stack member number that is not already used in the switch stack. See Step 1.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

### Removing Provisioned Switch Information

Before you begin, you must remove the provisioned switch from the stack. This optional task is available only from the active switch.

### SUMMARY STEPS

1. configure terminal
2. no switch stack-member-number provision
3. end
4. copy running-config startup-config
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> no switch stack-member-number provision</td>
<td>Removes the provisioning information for the specified member.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# no switch 3 provision</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

If you are removing a provisioned switch in a stack with this configuration:

- The stack has four members
- Stack member 1 is the active switch
- Stack member 3 is a provisioned switch

and want to remove the provisioned information and to avoid receiving an error message, you can remove power from stack member 3, disconnect the StackWise-480 stack cables between the stack member 3 and switches to which it is connected, reconnect the cables between the remaining stack members, and enter the `no switch stack-member-number provision` global configuration command.

Displaying Incompatible Switches in the Switch Stack

**SUMMARY STEPS**

1. show switch
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  * show switch
    
  **Example:**
  Device# show switch |
  Displays any incompatible switches in the switch stack (indicated by a 'Current State' of 'V-Mismatch'). The V-Mismatch state identifies the switches with incompatible software. The output displays Lic-Mismatch for switches that are not running the same license level as the active switch.
  For information about managing license levels, see the *System Management Configuration Guide (Catalyst 3850 Switches)*.

Upgrading an Incompatible Switch in the Switch Stack

**SUMMARY STEPS**

1. software auto-upgrade
2. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  * software auto-upgrade
    
  **Example:**
  Device# software auto-upgrade |
  Upgrades incompatible switches in the switch stack, or changes switches in bundle mode to installed mode.

| **Step 2**
  * copy running-config startup-config
    
  **Example:**
  Device# copy running-config startup-config |
  (Optional) Saves your entries in the configuration file.

Troubleshooting the Switch Stack

Temporarily Disabling a Stack Port

If a stack port is flapping and causing instability in the stack ring, to disable the port, enter the `switch stack-member-number stack port port-number disable` privileged EXEC command. To reenable the port, enter the `switch stack-member-number stack port port-number enable` command.

**Note**

Be careful when using the `switch stack-member-number stack port port-number disable` command. When you disable the stack port, the stack operates at half bandwidth.
A stack is in the full-ring state when all members are connected through the stack ports and are in the ready state.

The stack is in the partial-ring state when the following occurs:

- All members are connected through their stack ports but some are not in the ready state.
- Some members are not connected through the stack ports.

### SUMMARY STEPS

1. `switch stack-member-number stack port port-number disable`
2. `switch stack-member-number stack port port-number enable`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>switch stack-member-number stack port port-number disable</code></td>
<td>Disables the specified stack port.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# <code>switch 2 stack port 1 disable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**                                  |                                              |
| `switch stack-member-number stack port port-number enable` | Reenables the stack port.                    |
| **Example:**                                |                                              |
| Device# `switch 2 stack port 1 enable`      |                                              |

When you disable a stack port and the stack is in the full-ring state, you can disable only one stack port. This message appears:

`Enabling/disabling a stack port may cause undesired stack changes. Continue?[confirm]`

When you disable a stack port and the stack is in the partial-ring state, you cannot disable the port. This message appears:

`Disabling stack port not allowed with current stack configuration.`

### Reenabling a Stack Port While Another Member Starts

Stack Port 1 on Switch 1 is connected to Port 2 on Switch 4. If Port 1 is flapping, you can disable Port 1 with the `switch 1 stack port 1 disable` privileged EXEC command. While Port 1 on Switch 1 is disabled and Switch 1 is still powered on, follow these steps to reenable a stack port:

1. **Step 1** Disconnect the stack cable between Port 1 on Switch 1 and Port 2 on Switch 4.
2. **Step 2** Remove Switch 4 from the stack.
3. **Step 3** Add a switch to replace Switch 4 and assign it switch-number 4.
4. **Step 4** Reconnect the cable between Port 1 on Switch 1 and Port 2 on Switch 4 (the replacement switch).
Step 5  Reenable the link between the switches. Enter the `switch 1 stack port 1 enable` privileged EXEC command to enable Port 1 on Switch 1.

Step 6  Power on Switch 4.

**Caution**

Powering on Switch 4 before enabling the Port 1 on Switch 1 might cause one of the switches to reload.

If Switch 4 is powered on first, you might need to enter the `switch 1 stack port 1 enable` and the `switch 4 stack port 2 enable` privileged EXEC commands to bring up the link.

### Monitoring the Device Stack

**Table 166: Commands for Displaying Stack Information**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show switch</code></td>
<td>Displays summary information about the stack, including the status of provisioned switches and switches in version-mismatch mode.</td>
</tr>
<tr>
<td><code>show switch stack-member-number</code></td>
<td>Displays information about a specific member.</td>
</tr>
<tr>
<td><code>show switch detail</code></td>
<td>Displays detailed information about the stack.</td>
</tr>
<tr>
<td><code>show switch neighbors</code></td>
<td>Displays the stack neighbors.</td>
</tr>
<tr>
<td><code>show switch stack-ports [summary]</code></td>
<td>Displays port information for the stack. Use the <code>summary</code> keyword to display the stack cable length, the stack link status, and the loopback status.</td>
</tr>
<tr>
<td><code>show redundancy</code></td>
<td>Displays the redundant system and the current processor information. The redundant system information includes the system uptime, standby failures, switchover reason, hardware, configured and operating redundancy mode. The current processor information displayed includes the active location, the software state, the uptime in the current state and so on.</td>
</tr>
<tr>
<td><code>show redundancy state</code></td>
<td>Displays all the redundancy states of the active and standby devices.</td>
</tr>
</tbody>
</table>
Configuration Examples for Switch Stacks

Switch Stack Configuration Scenarios

Most of these switch stack configuration scenarios assume that at least two devices are connected through their StackWise-480 stack ports.

Table 167: Configuration Scenarios

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect two powered-on switch stacks through the StackWise-480 stack ports.</td>
<td>Only one of the two active switches becomes the new active switch.</td>
</tr>
</tbody>
</table>
| Activeswitch election specifically determined by existing active switches | 1. Connect two switches through their StackWise-480 stack ports.  
2. Use the `switch stack-member-number priority new-priority-number` EXEC command to set one stack member with a higher member priority value.  
3. Restart both stack members at the same time. | The stack member with the higher priority value is elected active switch. |
| Activeswitch election specifically determined by the stack member priority value | Assuming that both stack members have the same priority value:  
1. Make sure that one stack member has a default configuration and that the other stack member has a saved (nondefault) configuration file.  
2. Restart both stack members at the same time. | The stack member with the saved configuration file is elected active switch. |
| Activeswitch election specifically determined by the configuration file | Assuming that both stack members have the same priority value, configuration file, and license level, restart both stack members at the same time. | The stack member with the lower MAC address is elected active switch. |
| Activeswitch election specifically determined by the MAC address | | |
### Stack Manager and High Availability

**Enabling the Persistent MAC Address Feature: Example**

This example shows how to configure the persistent MAC address feature for a 7-minute time delay and to verify the configuration:

```bash
Device(config)# stack-mac persistent timer 7
WARNING: The stack continues to use the base MAC of the old Master
WARNING: as the stack MAC after a master switchover until the MAC
WARNING: persistency timer expires. During this time the Network
WARNING: Administrators must make sure that the old stack-mac does
WARNING: not appear elsewhere in this network domain. If it does,
WARNING: user traffic may be blackholed.
Device(config)# end
Device# show switch
Switch/Stack Mac Address : 0016.4727.a900
Mac persistency wait time: 7 mins
```

### Table

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stack member number conflict</td>
<td>The stack member with the higher priority value retains its stack member number. The other stack member has a new stack member number.</td>
</tr>
<tr>
<td>Add a stack member</td>
<td>The active switch is retained. The new switch is added to the switch stack.</td>
</tr>
<tr>
<td>Active switch failure</td>
<td>The standby switch becomes the new active switch. All other stack members in the stack remain as stack members and do not reboot.</td>
</tr>
<tr>
<td>Add more than nine stack members</td>
<td>Two device become active switches. One active switch has nine stack members. The other active switch remains as a standalone device. Use the Mode button and port LEDs on the device to identify which device are active switches and which device belong to each active switch.</td>
</tr>
</tbody>
</table>

---

**Result Scenario**

The stack member with the higher priority value retains its stack member number. The other stack member has a new stack member number.

1. Ensure that both stack members have the same stack member number. If necessary, use the `switch current-stack-member-number renumber new-stack-member-number` EXEC command.
2. Restart both stack members at the same time.

**Assuming that one stack member has a higher priority value than the other stack member:**

1. Ensure that both stack members have the same stack member number. If necessary, use the `switch current-stack-member-number renumber new-stack-member-number` EXEC command.
2. Restart both stack members at the same time.

**Add a stack member**

1. Power off the new switch.
2. Through their StackWise-480stack ports, connect the new switch to a powered-on switch stack.
3. Power on the new switch.

**Active switch failure**

Remove (or power off) the active switch.

**Add more than nine stack members**

1. Through their StackWise-480stack ports, connect ten device.
2. Power on all device.
Provisioning a New Member for a Switch Stack: Example

This example shows how to provision a switch with a stack member number of 2 for the switch stack. The `show running-config` command output shows the interfaces associated with the provisioned switch:

```
Device(config)# switch 2 provision switch_PID
Device(config)# end
Device# show running-config | include switch 2
! interface GigabitEthernet2/0/1
! interface GigabitEthernet2/0/2
! interface GigabitEthernet2/0/3
<output truncated>
```

**show switch stack-ports summary Command Output: Example**

Only Port 1 on stack member 2 is disabled.

```
Device# show switch stack-ports summary
Device#/ Stack Neighbor Cable Link Link Sync # In
Port# Port Length OK Active OK Changes Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
1/1 OK 3 50 cm Yes Yes Yes 1 No
1/2 Down None 3 m Yes No Yes 1 No
2/1 Down None 3 m Yes No Yes 1 No
2/2 OK 3 50 cm Yes Yes Yes 1 No
3/1 OK 2 50 cm Yes Yes Yes 1 No
3/2 OK 1 50 cm Yes Yes Yes 1 No
```

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch#/Port#</td>
<td>Member number and its stack port number.</td>
</tr>
<tr>
<td>Stack Port Status</td>
<td>Status of the stack port.</td>
</tr>
<tr>
<td>Neighbor</td>
<td>Switch number of the active member at the other end of the stack cable.</td>
</tr>
</tbody>
</table>

- **Absent**—No cable is detected on the stack port.
- **Down**—A cable is detected, but either no connected neighbor is up, or the stack port is disabled.
- **OK**—A cable is detected, and the connected neighbor is up.
**Field** | **Description**
---|---
Cable Length | Valid lengths are 50 cm, 1 m, or 3 m. If the switch cannot detect the cable length, the value is *no cable*. The cable might not be connected, or the link might be unreliable.
Link OK | Whether the stack cable is connected and functional. There may or may not be a neighbor connected on the other end. The *link partner* is a stack port on a neighbor switch.
  - No—There is no stack cable connected to this port or the stack cable is not functional.
  - Yes—There is a functional stack cable connected to this port.
Link Active | Whether a neighbor is connected on the other end of the stack cable.
  - No—No neighbor is detected on the other end. The port cannot send traffic over this link.
  - Yes—A neighbor is detected on the other end. The port can send traffic over this link.
Sync OK | Whether the link partner sends valid protocol messages to the stack port.
  - No—The link partner does not send valid protocol messages to the stack port.
  - Yes—The link partner sends valid protocol messages to the port.
# Changes to Link OK | The relative stability of the link.
  - If a large number of changes occur in a short period of time, link flapping can occur.
In Loopback | Whether a stack cable is attached to a stack port on the member.
  - No—At least one stack port on the member has an attached stack cable.
  - Yes—None of the stack ports on the member has an attached stack cable.

### Software Loopback: Examples

In a stack with three members, stack cables connect all the members:

```device# show switch stack-ports summary
Sw#/Port#  Port Status  Neighbor ID  Cable Length  Link OK  Link Active  Sync OK  #Changes to Link OK  In Loopback
---------  ----------  ---------  ----------  ------  ----------  ------  --------------  --------
1/1       OK         3         50 cm      Yes     Yes        Yes     1           No
1/2       OK         2         3 m        Yes     Yes        Yes     1           No
2/1       OK         1         3 m        Yes     Yes        Yes     1           No
2/2       OK         3         50 cm      Yes     Yes        Yes     1           No
3/1       OK         2         50 cm      Yes     Yes        Yes     1           No
3/2       OK         1         50 cm      Yes     Yes        Yes     1           No
```
If you disconnect the stack cable from Port 1 on Switch 1, these messages appear:

01:09:55: %STACKMGR-4-STACK_LINK_CHANGE: Stack Port 2 Switch 3 has changed to state DOWN
01:09:56: %STACKMGR-4-STACK_LINK_CHANGE: Stack Port 1 Switch 1 has changed to state DOWN

```
Device# show switch stack-ports summary
Device:
Sw#/Port# Port Neighbor Cable Link Link Sync #Changes In
Status Length OK Active OK To LinkOK Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
1/1 Absent None No cable No No No 1 No
1/2 OK 2 3 m Yes Yes Yes 1 No
2/1 OK 1 3 m Yes Yes Yes 1 No
2/2 OK 3 50 cm Yes Yes Yes 1 No
3/1 OK 2 50 cm Yes Yes Yes 1 No
3/2 Down None 50 cm No No No 1 No
```

If you disconnect the stack cable from Port 2 on Switch 1, the stack splits.

Switch 2 and Switch 3 are now in a two-member stack connected through stack cables:

```
Device# show sw stack-ports summary
Device:
Sw#/Port# Port Neighbor Cable Link Link Sync #Changes In
Status Length OK Active OK To LinkOK Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
2/1 Down None 3 m No No No 1 No
2/2 OK 3 50 cm Yes Yes Yes 1 No
3/1 OK 2 50 cm Yes Yes Yes 1 No
3/2 Down None 50 cm No No No 1 No
```

Switch 1 is a standalone switch:

```
Device# show switch stack-ports summary
Device:
Sw#/Port# Port Neighbor Cable Link Link Sync #Changes In
Status Length OK Active OK To LinkOK Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
1/1 Absent None No cable No No No 1 Yes
1/2 Absent None No cable No No No 1 Yes
```

**Software Loopback with Connected Stack Cables: Examples**

- **On Port 1 on Switch 1, the port status is Down, and a cable is connected.**

On Port 2 on Switch 1, the port status is Absent, and no cable is connected.

```
Device# show switch stack-ports summary
Device:
Sw#/Port# Port Neighbor Cable Link Link Sync #Changes In
Status Length OK Active OK To LinkOK Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
1/1 Down None 50 Cm No No No 1 No
1/2 Absent None No cable No No No 1 No
```
• In a physical loopback, a cable connects both stack ports on a switch. You can use this configuration to test
  • Cables on a switch that is running properly
  • Stack ports with a cable that works properly

Device# `show switch stack-ports summary`

<table>
<thead>
<tr>
<th>Sw#/Port#</th>
<th>Port Status</th>
<th>Neighbor</th>
<th>Cable Length</th>
<th>Link OK</th>
<th>Link Active</th>
<th>Sync OK</th>
<th>#Changes</th>
<th>In Loopback</th>
</tr>
</thead>
<tbody>
<tr>
<td>2/1</td>
<td>OK</td>
<td>2</td>
<td>50 cm</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
<td>No</td>
</tr>
<tr>
<td>2/2</td>
<td>OK</td>
<td>2</td>
<td>50 cm</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
<td>No</td>
</tr>
</tbody>
</table>

The port status shows that
  • Switch 2 is a standalone switch.
  • The ports can send and receive traffic.

Software Loopback with no Connected Stack Cable: Example

Device# `show switch stack-ports summary`

<table>
<thead>
<tr>
<th>Sw#/Port#</th>
<th>Port Status</th>
<th>Neighbor</th>
<th>Cable Length</th>
<th>Link OK</th>
<th>Link Active</th>
<th>Sync OK</th>
<th>#Changes</th>
<th>In Loopback</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/1</td>

Finding a Disconnected Stack Cable: Example

Stack cables connect all stack members. Port 2 on Switch 1 connects to Port 1 on Switch 2.

This is the port status for the members:

Device# `show switch stack-ports summary`

<table>
<thead>
<tr>
<th>Sw#/Port#</th>
<th>Port Status</th>
<th>Neighbor</th>
<th>Cable Length</th>
<th>Link OK</th>
<th>Link Active</th>
<th>Sync OK</th>
<th>#Changes</th>
<th>In Loopback</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/1</td>
<td>OK</td>
<td>2</td>
<td>50 cm</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>1/2</td>
<td>OK</td>
<td>2</td>
<td>50 cm</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>2/1</td>
<td>OK</td>
<td>1</td>
<td>50 cm</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>0</td>
<td>No</td>
</tr>
<tr>
<td>2/2</td>
<td>OK</td>
<td>1</td>
<td>50 cm</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>0</td>
<td>No</td>
</tr>
</tbody>
</table>

If you disconnect the cable from Port 2 on Switch 1, these messages appear:
%STACKMGR-4-STACK_LINK_CHANGE: Stack Port 1 Switch 2 has changed to state DOWN
%STACKMGR-4-STACK_LINK_CHANGE: Stack Port 2 Switch 1 has changed to state DOWN
This is now the port status:

```
Device# show switch stack-ports summary
Device#
Sw#/Port# Port Neighbor Cable Link Link Sync #Changes In
Status Length OK Active OK OK OK Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
1/1 OK 2 50 cm Yes Yes Yes 1 No
1/2 Absent None None No No No 2 No
2/1 Down None 50 cm No No No 2 No
2/2 OK 1 50 cm Yes Yes Yes 1 No
```

Only one end of the cable connects to a stack port, Port 1 on Switch 2.

- The `Stack Port Status` value for Port 2 on Switch 1 is `Absent`, and the value for Port 1 on Switch 2 is `Down`.
- The `Cable Length` value is `No cable`.

Diagnosing the problem:
- Verify the cable connection for Port 2 on Switch 1.
- Port 2 on Switch 1 has a port or cable problem if
  - The `In Loopback` value is `Yes`.
  - or
  - The `Link OK`, `Link Active`, or `Sync OK` value is `No`.

**Fixing a Bad Connection Between Stack Ports: Example**

Stack cables connect all members. Port 2 on Switch 1 connects to Port 1 on Switch 2.

This is the port status:

```
Device# show switch stack-ports summary
Device#
Sw#/Port# Port Neighbor Cable Link Link Sync #Changes In
Status Length OK Active OK OK OK Loopback
-------- ------ -------- -------- ---- ------ ---- --------- --------
1/1 OK 2 50 cm Yes Yes Yes 1 No
1/2 Down None 50 cm No No No 2 No
2/1 Down None 50 cm No No No 2 No
2/2 OK 1 50 cm Yes Yes Yes 1 No
```

Diagnosing the problem:
- The `Stack Port Status` value is `Down`.
- Link OK, Link Active, and Sync OK values are `No`.
- The Cable Length value is `50 cm`. The switch detects and correctly identifies the cable.
The connection between Port 2 on Switch 1 and Port 1 on Switch 2 is unreliable on at least one of the connector pins.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for NSF with SSO

The following are prerequisites and considerations for configuring NSF with SSO.

- Use of the routing protocols requires the IP Services license level. EIGRP-stub and OSPF for routed access are supported on IP Base license level.

- BGP support in NSF requires that neighbor networking devices be NSF-aware; that is, the devices must have the graceful restart capability and advertise that capability in their OPEN message during session establishment. If an NSF-capable router discovers that a particular BGP neighbor does not have graceful restart capability, it does not establish an NSF-capable session with that neighbor. All other neighbors that have graceful restart capability continue to have NSF-capable sessions with this NSF-capable networking device.

- OSPF support in NSF requires that all neighbor networking devices be NSF-aware. If an NSF-capable router discovers that it has non-NSF-aware neighbors on a particular network segment, it disables NSF capabilities for that segment. Other network segments composed entirely of NSF-capable or NSF-aware routers continue to provide NSF capabilities.
Restrictions for NSF with SSO

The following are restrictions for configuring NSF with SSO:

- NSF capability is supported for IPv4 routing protocols only. NSF capability is not supported for IPv6 routing protocols.
- NSF does not support IP Multicast Routing, as it is not SSO-aware.
- NSF is not supported if the IOS-XE software is running in the LAN Base mode.
- For NSF operation, you must have SSO configured on the device.
- NSF with SSO supports IP Version 4 traffic and protocols only; NSF with SSO does not support IPv6 traffic.
- All Layer 3 neighboring devices must be NSF Helper or NSF-capable to support graceful restart capability.
- For IETF, all neighboring devices must be running an NSF-aware software image.

Information About NSF with SSO

Overview of NSF with SSO

The switch supports fault resistance by allowing a standby switch to take over if the active switch becomes unavailable. Cisco nonstop forwarding (NSF) works with stateful switchover (SSO) to minimize the amount of time a network is unavailable.

NSF provides these benefits:

- Improved network availability—NSF continues forwarding network traffic and application state information so that user session information is maintained after a switchover.
- Overall network stability—Network stability may be improved with the reduction in the number of route flaps, which were created when routers in the network failed and lost their routing tables.
- Neighboring routers do not detect a link flap—Because the interfaces remain up during a switchover, neighboring routers do not detect a link flap (the link does not go down and come back up).
- Prevents routing flaps—Because SSO continues forwarding network traffic during a switchover, routing flaps are avoided.
- Maintains user sessions established prior to the switchover.

Keepalive messages are sent and received between the active and standby switches.

- If the standby switch does not respond, a new standby switch is elected.
- If the active switch does not respond, the standby switch becomes the active switch.

In addition, hello messages are sent and received by all stack members.

- If a stack member does not respond, that member is removed from the stack.
• If the standby switch does not respond, a new standby switch is elected.
• If the active switch does not respond, the standby switch becomes the active switch.

**SSO Operation**

When a standby switch runs in SSO mode, the standby switch starts up in a fully-initialized state and synchronizes with the persistent configuration and the running configuration of the active switch. It subsequently maintains the state on the protocols listed below, and all changes in hardware and software states for features that support stateful switchover are kept in synchronization. Consequently, it offers minimum interruption to Layer 2 sessions in a redundant active switch configuration.

If the active switch fails, the standby switch becomes the active switch. This new active switch uses existing Layer 2 switching information to continue forwarding traffic. Layer 3 forwarding will be delayed until the routing tables have been repopulated in the newly active switch.

---

**Note**

SSO Layer 2 Only is supported if the IOS-XE software is running the LAN Base license level.

The state of these features is preserved between both the active and standby switches:

- 802.3
- 802.3u
- 802.3x (Flow Control)
- 802.3ab (GE)
- 802.3z (Gigabit Ethernet including CWDM)
- 802.3ad (LACP)
- 802.1p (Layer 2 QoS)
- 802.1q
- 802.1X (Authentication)
- 802.1D (Spanning Tree Protocol)
- 802.3af (Inline power)
- PAgP
- VTP
- Dynamic ARP Inspection
- DHCP
- DHCP snooping
- IP source guard
- IGMP snooping (versions 1 and 2)
• DTP (802.1q and ISL)
• MST
• PVST+
• Rapid-PVST
• PortFast/UplinkFast/BackboneFast
• BPDU guard and filtering
• Voice VLAN
• Port security
• Unicast MAC filtering
• ACL (VACLs, PACLs, RACLs)
• QOS (DBL)
• Multicast storm control/broadcast storm control

SSO is compatible with the following list of features. However, the protocol database for these features is not synchronized between the standby and active switches:
  • 802.1Q tunneling with Layer 2 Protocol Tunneling (L2PT)
  • Baby giants
  • Jumbo frame support
  • CDP
  • Flood blocking
  • UDLD
  • SPAN/RSPAN
  • NetFlow

All Layer 3 protocols on a switch are learned on the standby switch if SSO is enabled.

**NSF Operation**

Cisco IOS Nonstop Forwarding (NSF) always runs with stateful switchover (SSO) and provides redundancy for Layer 3 traffic. NSF is supported by the BGP, OSPF, and EIGRP routing protocols and is supported by Cisco Express Forwarding (CEF) for forwarding. The routing protocols have been enhanced with NSF-capability and awareness, which means that routers running these protocols can detect a switchover and take the necessary actions to continue forwarding network traffic and to recover route information from the peer devices.

Each protocol depends on CEF to continue forwarding packets during switchover while the routing protocols rebuild the Routing Information Base (RIB) tables. After the routing protocols have converged, CEF updates the FIB table and removes stale route entries. CEF then updates the hardware with the new FIB information.

If the active switch is configured for BGP (with the `graceful-restart` command), OSPF, or EIGRP routing protocols, routing updates are automatically sent during the active switch election.
The switch supports NSF-awareness and NSF-capability for the BGP, OSPF, and EIGRP protocols in IP Services license level and NSF-awareness for the EIGRP-stub in IP Base license level.

NSF has two primary components:

- **NSF-awareness**
  A networking device is NSF-aware if it is running NSF-compatible software. If neighboring router devices detect that an NSF router can still forward packets when an active switch election happens, this capability is referred to as NSF-awareness. Cisco IOS enhancements to the Layer 3 routing protocols (BGP, OSPF, and EIGRP) are designed to prevent route-flapping so that the CEF routing table does not time out or the NSF router does not drop routes. An NSF-aware router helps to send routing protocol information to the neighboring NSF router. NSF-awareness is enabled by default for EIGRP-stub, EIGRP, and OSPF protocols. NSF-awareness is disabled by default for BGP.

- **NSF-capability**
  A device is NSF-capable if it has been configured to support NSF; it rebuilds routing information from NSF-aware or NSF-capable neighbors. NSF works with SSO to minimize the amount of time that a Layer 3 network is unavailable following an active switch election by continuing to forward IP packets. Reconvergence of Layer 3 routing protocols (BGP, OSPFv2, and EIGRP) is transparent to the user and happens automatically in the background. The routing protocols recover routing information from neighbor devices and rebuild the Cisco Express Forwarding (CEF) table. 

---

**Cisco Express Forwarding**

A key element of Cisco IOS Nonstop Forwarding (NSF) is packet forwarding. In a Cisco networking device, packet forwarding is provided by Cisco Express Forwarding (CEF). CEF maintains the FIB and uses the FIB information that was current at the time of the switchover to continue forwarding packets during a switchover. This feature reduces traffic interruption during the switchover.

During normal NSF operation, CEF on the active supervisor switch synchronizes its current FIB and adjacency databases with the FIB and adjacency databases on the standby switch. Upon switchover, the standby switch initially has FIB and adjacency databases that are mirror images of those that were current on the active switch. CEF keeps the forwarding engine on the standby switch current with changes that are sent to it by CEF on the active switch. The forwarding engine can continue forwarding after a switchover as soon as the interfaces and a data path are available.

As the routing protocols start to repopulate the RIB on a prefix-by-prefix basis, the updates cause prefix-by-prefix updates to CEF, which it uses to update the FIB and adjacency databases. Existing and new entries receive the new version (“epoch”) number, indicating that they have been refreshed. The forwarding information is updated on the forwarding engine during convergence. The switch signals when the RIB has converged. The software removes all FIB and adjacency entries that have an epoch older than the current switchover epoch. The FIB now represents the newest routing protocol forwarding information.

**BGP Operation**

When an NSF-capable router begins a BGP session with a BGP peer, it sends an OPEN message to the peer. Included in the message is a statement that the NSF-capable device has “graceful” restart capability. Graceful
restart is the mechanism by which BGP routing peers avoid a routing flap following a switchover. If the BGP peer has received this capability, it is aware that the device sending the message is NSF-capable. Both the NSF-capable router and its BGP peers need to exchange the graceful restart capability in their OPEN messages at the time of session establishment. If both the peers do not exchange the graceful restart capability, the session will not be capable of a graceful restart.

If the BGP session is lost during the active switch switchover, the NSF-aware BGP peer marks all the routes associated with the NSF-capable router as stale; however, it continues to use these routes to make forwarding decisions for a set period of time. This functionality prevents packets from being lost while the newly active switch is waiting for convergence of the routing information with the BGP peers.

After an active switch switchover occurs, the NSF-capable router reestablishes the session with the BGP peer. In establishing the new session, it sends a new graceful restart message that identifies the NSF-capable router as having restarted.

At this point, the routing information is exchanged between the two BGP peers. After this exchange is complete, the NSF-capable device uses the routing information to update the RIB and the FIB with the new forwarding information. The NSF-aware device uses the network information to remove stale routes from its BGP table; the BGP protocol then is fully converged.

If a BGP peer does not support the graceful restart capability, it ignores the graceful restart capability in an OPEN message but establishes a BGP session with the NSF-capable device. This function allows interoperability with non-NSF-aware BGP peers (and without NSF functionality), but the BGP session with non-NSF-aware BGP peers is not capable of a graceful restart.

---

**Note**

BGP support in NSF requires that neighbor networking devices be NSF-aware; that is, the devices must have the graceful restart capability and advertise that capability in their OPEN message during session establishment. If an NSF-capable router discovers that a particular BGP neighbor does not have graceful restart capability, it does not establish an NSF-capable session with that neighbor. All other neighbors that have graceful restart capability continue to have NSF-capable sessions with this NSF-capable networking device.

### OSPF Operation

When an OSPF NSF-capable router performs an active switch switchover, it must perform the following tasks in order to resynchronize its link state database with its OSPF neighbors:

- Relearn the available OSPF neighbors on the network without causing a reset of the neighbor relationship
- Reacquire the contents of the link state database for the network

As quickly as possible after an active switch switchover, the NSF-capable router sends an OSPF NSF signal to neighboring NSF-aware devices. Neighbor networking devices recognize this signal as an indicator that the neighbor relationship with this router should not be reset. As the NSF-capable router receives signals from other routers on the network, it can begin to rebuild its neighbor list.

After neighbor relationships are reestablished, the NSF-capable router begins to resynchronize its database with all of its NSF-aware neighbors. At this point, the routing information is exchanged between the OSPF neighbors. Once this exchange is complete, the NSF-capable device uses the routing information to remove stale routes, update the RIB, and update the FIB with the new forwarding information. The OSPF protocols are then fully converged.
OSPF support in NSF requires that all neighbor networking devices be NSF-aware. If an NSF-capable router discovers that it has non-NSF-aware neighbors on a particular network segment, it disables NSF capabilities for that segment. Other network segments composed entirely of NSF-capable or NSF-aware routers continue to provide NSF capabilities.

Note

EIGRP Operation

When an EIGRP NSF-capable router initially re-boots after an NSF restart, it has no neighbor and its topology table is empty. The router is notified by the standby (now active) switch when it needs to bring up the interfaces, reacquire neighbors, and rebuild the topology and routing tables. The restarting router and its peers must accomplish these tasks without interrupting the data traffic directed toward the restarting router. EIGRP peer routers maintain the routes learned from the restarting router and continue forwarding traffic through the NSF restart process.

To prevent an adjacency reset by the neighbors, the restarting router uses a new Restart (RS) bit in the EIGRP packet header to indicate a restart. The RS bit is set in the hello packets and in the initial INIT update packets during the NSF restart period. The RS bit in the hello packets allows the neighbors to be quickly notified of the NSF restart. Without seeing the RS bit, the neighbor can only detect an adjacency reset by receiving an INIT update or by the expiration of the hello hold timer. Without the RS bit, a neighbor does not know if the adjacency reset should be handled using NSF or the normal startup method.

When the neighbor receives the restart indication, either by receiving the hello packet or the INIT packet, it recognizes the restarting peer in its peer list and maintains the adjacency with the restarting router. The neighbor then sends its topology table to the restarting router with the RS bit set in the first update packet indicating that it is NSF-aware and is helping out the restarting router. The neighbor does not set the RS bit in their hello packets, unless it is also a NSF restarting neighbor.

Note

A router may be NSF-aware but may not be helping the NSF restarting neighbor because booting from a cold start.

If at least one of the peer routers is NSF-aware, the restarting router would then receive updates and rebuild its database. The restarting router must then find out if it had converged so that it can notify the routing information base (RIB). Each NSF-aware router is required to send an end of table (EOT) marker in the last update packet to indicate the end of the table content. The restarting router knows it has converged when it receives the EOT marker. The restarting router can then begin sending updates.

An NSF-aware peer would know when the restarting router had converged when it receives an EOT indication from the restarting router. The peer then scans its topology table to search for the routes with the restarted neighbor as the source. The peer compares the route timestamp with the restart event timestamp to determine if the route is still available. The peer then goes active to find alternate paths for the routes that are no longer available through the restarted router.

When the restarting router has received all EOT indications from its neighbors or when the NSF converge timer expires, EIGRP notifies the RIB of convergence. EIGRP waits for the RIB convergence signal and then floods its topology table to all awaiting NSF-aware peers.
How to Configure Cisco NSF with SSO

Configuring SSO

You must configure SSO in order to use NSF with any supported protocol.

SUMMARY STEPS

1. redundancy
2. mode sso
3. end
4. show running-config
5. show redundancy states

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Enters redundancy configuration mode.</td>
</tr>
<tr>
<td>redundancy</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# redundanty</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Configures SSO. When this command is entered, the standby switch is reloaded and begins to work in SSO mode.</td>
</tr>
<tr>
<td>mode sso</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-red)# mode sso</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Returns to EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config-red)# end</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>Verifies that SSO is enabled.</td>
</tr>
<tr>
<td>show running-config</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show running-config</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>Displays the operating redundancy mode.</td>
</tr>
<tr>
<td>show redundancy states</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show redundancy states</td>
<td></td>
</tr>
</tbody>
</table>

Configuring SSO Example

This example shows how to configure the system for SSO and display the redundancy state:

Device(config)# redundancy
Device(config)# mode sso
Device(config)# end
Device# show redundancy states
my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
Mode = Duplex
Unit = Primary
Unit ID = 5
Redundancy Mode (Operational) = sso
Redundancy Mode (Configured) = sso
Split Mode = Disabled
Manual Swact = Enabled
Communications = Up
client count = 29
client_notification_TMR = 30000 milliseconds
keep_alive TMR = 9000 milliseconds
keep_alive count = 1
keep_alive threshold = 18
RF debug mask = 0x0

Verifying CEF NSF

To verify CEF NSF, use the show cef state privileged EXEX command.

Device# show cef state
CEF Status:
RF instance
common CEF enabled
IPv4 CEF Status:
CEF enabled/running
dCEF enabled/running
CEF switching enabled/running
universal per-destination load sharing algorithm, id DEA83012
IPv6 CEF Status:
CEF disabled/not running
dCEF disabled/not running
universal per-destination load sharing algorithm, id DEA83012
RRP state:
I am standby RRP: no
RF Peer Presence: yes
RF PeerComm reached: yes
RF Progression blocked: never
Redundancy mode: rpr(1)
CEF NSF sync: disabled/not running
CEF ISSU Status:
FIBHWD broker
No slots are ISSU capable.
FIBIDB broker
No slots are ISSU capable.
FIBHWD Subblock broker
No slots are ISSU capable.
FIBIDB Subblock broker
No slots are ISSU capable.
Adjacency update
No slots are ISSU capable.
IPv4 table broker
No slots are ISSU capable.
CEF push
No slots are ISSU capable.
Configuring BGP for NSF

You must configure BGP graceful restart on all peer devices participating in BGP NSF.

**SUMMARY STEPS**

1. configure terminal
2. router bgp as-number
3. bgp graceful-restart

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enables a BGP routing process, which places the switch in switch configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# configure terminal</td>
<td>Enables the BGP graceful restart capability, starting BGP NSF. If you enter this command after the BGP session has been established, you must restart the session for the capability to be exchanged with the BGP neighbor. Use this command on the restarting switch and all of its peers.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enables a BGP routing process, which places the switch in switch configuration mode.</td>
</tr>
<tr>
<td>router bgp as-number</td>
<td>Enables the BGP graceful restart capability, starting BGP NSF. If you enter this command after the BGP session has been established, you must restart the session for the capability to be exchanged with the BGP neighbor. Use this command on the restarting switch and all of its peers.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# router bgp 300</td>
<td>Enables a BGP routing process, which places the switch in switch configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables the BGP graceful restart capability, starting BGP NSF. If you enter this command after the BGP session has been established, you must restart the session for the capability to be exchanged with the BGP neighbor. Use this command on the restarting switch and all of its peers.</td>
</tr>
<tr>
<td>bgp graceful-restart</td>
<td>Enables a BGP routing process, which places the switch in switch configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# bgp graceful-restart</td>
<td>Enables a BGP routing process, which places the switch in switch configuration mode.</td>
</tr>
</tbody>
</table>

Verifying BGP NSF

To verify BGP NSF, you must check that BGP graceful restart is configured on the SSO-enabled networking device and on the neighbor devices. To verify, follow these steps:

**Step 1**

Verify that “bgp graceful-restart” appears in the BGP configuration of the SSO-enabled switch by entering the `show running-config` command:

**Example:**

Device# show running-config
... router bgp 120...
.... bgp graceful-restart
neighbor 192.0.2.0 remote-as 300...
...
Step 2  Repeat Step 1 on each of the BGP neighbors.

Step 3  On the SSO device and the neighbor device, verify that the graceful restart function is shown as both advertised and received, and confirm the address families that have the graceful restart capability. If no address families are listed, BGP NSF does not occur either:

Example:

```
Device# show ip bgp neighbors
BGP neighbor is 192.0.2.3, remote AS 1, internal link
BGP version 4, remote router ID 192.0.2.4
BGP state = Established, up for 00:02:38
Last read 00:00:38, last write 00:00:35, hold time is 180, keepalive interval is 60 seconds
Neighbor capabilities:
Route refresh: advertised and received(new)
Address family IPv4 Unicast: advertised and received
Message statistics:
InQ depth is 0
OutQ depth is 0
Sent Rcvd
Opens: 1 1
Notifications: 0 0
Updates: 0 0
Keepalives: 4 4
Route Refresh: 0 0
Total: 5 5
Default minimum time between advertisement runs is 0 seconds
............................................................
```

---

**Configuring OSPF NSF**

All peer devices participating in OSPF NSF must be made OSPF NSF-aware, which happens automatically when you install an NSF software image on the device.

**SUMMARY STEPS**

1. `configure terminal`
2. `router ospf processID`
3. `nsf`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>Example:</code> <code>Device(config)# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>router ospf processID</code></td>
<td>Enables an OSPF routing process, which places the switch in router configuration mode.</td>
</tr>
<tr>
<td><code>Example:</code> <code>Device(config)# router ospf processID</code></td>
<td></td>
</tr>
</tbody>
</table>
Verifying OSPF NSF

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>nsf</td>
<td>Enables NSF operations for OSPF.</td>
</tr>
</tbody>
</table>

Example:

Device(config)# nsf

Verifying OSPF NSF

Step 1
Verify that ‘nsf’ appears in the OSPF configuration of the SSO-enabled device by entering the `show running-config` command:

Example:

Device(config)# show running-config
route ospf 120
log-adjacency-changes
nsf
network 192.0.2.0 192.0.2.255 area 0
network 192.0.2.1 192.0.2.255 area 1
network 192.0.2.2 192.0.2.255 area 2
.
.
.

Step 2
Enter the `show ip ospf` command to verify that NSF is enabled on the device:

Example:

Device show ip ospf
Routing Process "ospf 1" with ID 192.0.2.1
Start time: 00:02:07.532, Time elapsed: 00:39:05.052
Supports only single TOS(TOS0) routes
Supports opaque LSA
Supports Link-local Signaling (LLS)
transit capable is 0
External flood list length 0
IETF Non-Stop Forwarding enabled
restart-interval limit: 120 sec
IETF NSF helper support enabled
Cisco NSF helper support enabled
Reference bandwidth unit is 100 mbps
Area Backbone(0)
Number of interfaces in this area is 3 (1 loopback)
Area has no authentication
SPF algorithm last executed 00:08:53.760 ago
SPF algorithm executed 2 times
Area ranges are
Number of LSA 3. Checksum Sum 0x025BE0
Number of opaque link LSA 0. Checksum Sum 0x000000
Number of DCbitless LSA 0
Number of Indication LSA 0
Number of DoNotAge LSA 0
Flood list length 0
Configuring EIGRP NSF

SUMMARY STEPS

1. configure terminal
2. router eigrp as-number
3. nsf

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 router eigrp as-number</td>
<td>Enables an EIGRP routing process, which places the switch in router configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# router eigrp as-number</td>
<td></td>
</tr>
<tr>
<td>Step 3 nsf</td>
<td>Enables EIGRP NSF. Use this command on the “restarting” switch and all of its peers.</td>
</tr>
<tr>
<td>Example: Device(config-router)# nsf</td>
<td></td>
</tr>
</tbody>
</table>

Verifying EIGRP NSF

Step 1 Verify that “nsf” appears in the EIGRP configuration of the SSO-enabled device by entering the show running-config command:

Example:

Device show running-config
.. .
router eigrp 100
auto-summary
nsf
.. .

Step 2 Enter the show ip protocols command to verify that NSF is enabled on the device:

Example:

Device show ip protocols
*** IP Routing is NSF aware ***
Routing Protocol is "ospf 1"
Outgoing update filter list for all interfaces is not set
Incoming update filter list for all interfaces is not set
Router ID 192.0.2.3
Number of areas in this router is 1. 1 normal 0 stub 0 nssa

- Information about High Availability, on page 2043
- Information About Redundancy, on page 2044
- Information about Access Point Stateful Switch Over, on page 2046
- Initiating Graceful Switchover, on page 2046
- Configuring EtherChannels for High Availability, on page 2046
- Configuring LACP, on page 2047
- Troubleshooting High Availability, on page 2048

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information about High Availability

The high availability feature is enabled by default when the devices are connected using the stack cable and the Cisco StackWise-480 technology is enabled. You cannot disable it; however, you can initiate a manual graceful-switchover using the command line interface to use the high availability feature enabled in the .

In Cisco Wireless LAN Controllers, high availability is achieved with redundancy.

In Cisco Wireless LAN Controllers, redundancy is achieved in two ways— n+1 and AP SSO redundancy.

Keepalive messages are sent and received between the active and standby controllers.

- If the standby controller does not respond, a new standby controller is elected.
- If the active controller does not respond, the standby controller becomes the active controller.

In addition, hello messages are sent and received by all stack members.

- If a stack member does not respond, that member is removed from the stack.
- If the standby controller does not respond, a new standby controller is elected.
- If the active controller does not respond, the standby controller becomes the active controller.

## Information About Redundancy

In case of n+1 redundancy, access points are configured with primary, secondary, and tertiary controllers. When the primary controller fails, depending upon the number of access points managed by a controller, the access point fails over to the secondary controller. In case of AP SSO redundancy, once the primary controller is unavailable, the access points re-discovers the controller and reestablishes the CAPWAP tunnel with the secondary controller. However, all clients must disconnect and a re-authentication is performed to rejoin the controller.

You can configure primary, secondary, and tertiary controllers for a selected access point and a selected controller.

In an ideal high availability deployment, you can have access points connected to primary and secondary controllers and one controller can remain without connection to any access points. This way the controller that does not have any access points can take over when a failure occurs and resume services of active controller.

## Configuring Redundancy in Access Points

You must use the commands explained in this section to configure primary, secondary, or tertiary controllers for a selected access point.

### Before you begin

<table>
<thead>
<tr>
<th>SUMMARY STEPS</th>

</tr>
</tbody>
</table>

**Example:**

Controller # conf t

| **Step 2**    |
| Command or Action | Purpose |
| ap capwap backup primary | Configures the primary controller for the selected access point. |

**Example:**

Controller # ap capwap backup primary
WLAN-Controller-A

| **Step 3**    |
| Command or Action | Purpose |
| ap capwap backup secondary | Configures the secondary controller for the selected access point. |

**Example:**
## Configuring Heartbeat Messages

Hearbeat messages enable you to reduce the controller failure detection time. When a failure occurs, a switchover from active to hot standby happens after the controller waits for the heartbeat timer. If the controller does not function within the heartbeat time, then the standby takes over as the active controller. Ideally the access point generates three heartbeat messages within the time out value specified, and when the controller does not respond within the timeout value, the standby controller takes over as active. You can specify the timeout value depending on your network. Ideally the timer value is not a higher value as some chaos will occur while performing a switchover. This section explains on how to configure heartbeat interval between the controller and the access points using a timeout value to reduce the controller failure detection time.

### Before you begin

#### SUMMARY STEPS

1. `conf t`
2. `ap capwap timers heartbeat-timeout`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Configures the terminal.</td>
</tr>
<tr>
<td><code>conf t</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>controller # conf t</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Configures the heartbeat interval between the controller and access points. The timeout value ranges from 1 to 30.</td>
</tr>
<tr>
<td><code>ap capwap timers heartbeat-timeout</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>controller # ap capwap timers heartbeat-timeout</code></td>
<td></td>
</tr>
</tbody>
</table>

### What to do next

Once you complete configuration of the primary, secondary, and tertiary controllers for a selected access point, you must verify the configuration using the `show ap name AP-NAME` command. For more details on, `show ap name AP-NAME` command, see the Lightweight Access Point Configuration Guide for Cisco Wireless LAN Controller.
Information about Access Point Stateful Switch Over

An Access Point Stateful Switch Over (AP SSO) implies that all the access point sessions are switched over state-fully and the user session information is maintained during a switchover, and access points continue to operate in network with no loss of sessions, providing improved network availability. The active in the stack is equipped to perform all network functions, including IP functions and routing information exchange. The supports 1000 access points and 12000 clients.

However, all the clients are de-authenticated and need to be re-associated with the new active except for the locally switched clients in FlexConnect mode when a switchover occurs.

Once a redundancy pair is formed while in a stack, high availability is enabled, which includes that access points continue to remain connected during an active-to-standby switchover.

Note: You can not disable AP SSO while in a stack once the devices form a redundant pair.

Note: After switchover new standby gets reloaded during stack formation, this is due to bulk sync failure. This is seen after reload, 2nd attempt to formed stack successfully. To avoid this execute the command exception dump device second flash which is used to enable, dump crashfile on flash when crashinfo directory is full. When crash occurs and if there is no space left in crashinfo, it will proceed to store the full core/crash files into flash.

Initiating Graceful Switchover

To perform a manual switchover and to use the high availability feature enabled in the, execute the redundancy force-switchover command. This command initiates a graceful switchover from the active to the standby.

Device# redundancy force-switchover
System configuration has been modified. Save ? [yes/no] : yes
Building configuration ...
Preparing for switchover ...
Compressed configuration from 14977 bytes to 6592 bytes[OK]This will reload the active unit
and force switchover to standby[confirm] : y

Configuring EtherChannels for High Availability

The LAG, or an EtherChannel, bundles all the existing ports in both the standby and active units into a single logical port to provide an aggregate bandwidth of 60 Gbps. The creation of an EtherChannel enables protection against failures. The EtherChannels or LAGs created are used for link redundancy to ensure high availability of access points.

For more details on configuring EtherChannel, and Etherchannel modes, see the Layer 2 (Link Aggregation) Configuration Guide, Cisco IOS XE Release 3SE (Cisco WLC 5700 Series)
Step 1  Connect two devices that are in powered down state using the stack cable.
Step 2  Power up and perform a boot on both devices simultaneously or power and boot one. The devices boot up successfully, and form a high availability pair.
Step 3  Configure EtherChannel or LAG on the units.
Step 4  Use the `show etherchannel summary` command to view the status of the configured EtherChannel. On successful configuration, all the specified ports will be bundled in a single channel and listed in the command output of `show etherchannel summary`.
Step 5  Execute the `show ap uptime` command to verify the connected access points.

Configuring LACP

**SUMMARY STEPS**

1. configure terminal
2. interface port-channel number
3. lACP max-bundle number
4. lACP port-priority number
5. switchport backup interface po2
6. end
7. show etherchannel summary
8. show interfaces switchport backup

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>interface port-channel number</td>
<td>Enters port-channel interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface Port-channel Po2</td>
<td></td>
</tr>
<tr>
<td>lACP max-bundle number</td>
<td>Defines the maximum number of active bundled LACP ports allowed in a port channel. The value ranges from 1 to 8.</td>
</tr>
<tr>
<td>Example: Device(config-if)# lACP max-bundle 6</td>
<td></td>
</tr>
<tr>
<td>lACP port-priority number</td>
<td>Specifies port priority to be configured on the port using LACP. The value ranges from 0 to 65535.</td>
</tr>
<tr>
<td>Example: Device(config-if)# lACP port-priority 4</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

**Step 5**

- `switchport backup interface po2`

  **Example:**
  ```
  Device(config-if)# switchport backup interface Po2
  ```

**Step 6**

- `end`

**Step 7**

- `show etherchannel summary`

  **Example:**
  ```
  Device# show etherchannel summary
  ```

**Step 8**

- `show interfaces switchport backup`

  **Example:**
  ```
  Device# show interfaces switchport backup
  ```

### Troubleshooting High Availability

#### Access the Standby Console

You can only access the console of the active in a stack. To access the standby, use the following commands.

**Before you begin**

Use this functionality only under supervision of Cisco Support.

**SUMMARY STEPS**

1. `configure terminal`
2. `service internal`
3. `redundancy`
4. `main-cpu`
5. `standby console enable`
6. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>service internal</code></td>
<td>Enables Cisco IOS debug commands.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# service internal</code></td>
<td></td>
</tr>
</tbody>
</table>
Before a Switchover

A switchover happens when the active fails; however, while performing a manual switchover, you can execute these commands to initiate a successful switchover:

**SUMMARY STEPS**

1. show redundancy states  
2. show switch detail  
3. show platform ses states  
4. show ap summary  
5. show capwap detail  
6. show dtls database-brief  
7. show power inline

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> show redundancy states</td>
<td>Displays the high availability role of the active and standby devices.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show redundancy states</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> show switch detail</td>
<td>Display physical property of the stack. Verify if the physical states of the stacks are &quot;Ready&quot; or &quot;Port&quot;.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show switch detail</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> show platform ses states</td>
<td>Displays the sequences of the stack manager.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# show platform ses states</td>
<td></td>
</tr>
</tbody>
</table>

---

**Purpose Command or Action**

**Step 3** redundancy  
Example:  
Device(config)# redundancy  

**Step 4** main-cpu  
Example:  
Device(config)# main-cpu  

**Step 5** standby console enable  
Example:  
Device(config)# standby console enable  

**Step 6** exit  
Example:  
Device(config)# exit
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Displays all the access points in the active and standby devices.</td>
</tr>
</tbody>
</table>

### Step 4

**show ap summary**

**Example:**

```bash
Device# show ap summary
```

**Example:**

```bash
Device# show ap summary
```

### Step 5

**show capwap detail**

**Example:**

```bash
Device# show capwap detail
```

**Example:**

```bash
Device# show capwap detail
```

### Step 6

**show dtls database-brief**

**Example:**

```bash
Device# show dtls database-brief
```

**Example:**

```bash
Device# show dtls database-brief
```

### Step 7

**show power inline**

**Example:**

```bash
Device# show power inline
```

**Example:**

```bash
Device# show power inline
```

**Note**

When a failover occurs, the standby controller must be in a standby-hot state and the redundant port in a terminal state in SSO for successful switchover to occur.

---

### After a Switchover

This section defines the steps that you must perform to ensure that successful switchover from the active to standby is performed. On successful switchover of the standby as active, all access points connected to the active need to re-join the standby (then active).

#### SUMMARY STEPS

1. show ap uptime
2. show wireless summary
3. show wcdb database all
4. show power inline

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> show ap uptime</td>
<td>Verify if the uptime of the access point after the switchover is large enough.</td>
</tr>
</tbody>
</table>

**Example:**

```bash
Device# show ap uptime
```

**Step 2** show wireless summary

**Example:**

```bash
Device# show wireless summary
```

**Example:**

```bash
Device# show wireless summary
```
Display if the client has reached the uptime.

**Example:**

```
Device# show wcdb database all
```

### Step 4

**Command or Action:**

`show power inline`

**Example:**

```
Device# show power inline
```

### Purpose

Display the power over Ethernet power state.

---

## Monitoring the Device Stack

### Table 169: Commands for Displaying Stack Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show switch</code></td>
<td>Displays summary information about the stack, including the status of provisioned switches and switches in version-mismatch mode.</td>
</tr>
<tr>
<td><code>show switch stack-member-number</code></td>
<td>Displays information about a specific member.</td>
</tr>
<tr>
<td><code>show switch detail</code></td>
<td>Displays detailed information about the stack.</td>
</tr>
<tr>
<td><code>show switch neighbors</code></td>
<td>Displays the stack neighbors.</td>
</tr>
<tr>
<td><code>show switch stack-ports {summary}</code></td>
<td>Displays port information for the stack. Use the <code>summary</code> keyword to display the stack cable length, the stack link status, and the loopback status.</td>
</tr>
<tr>
<td><code>show redundancy</code></td>
<td>Displays the redundant system and the current processor information. The redundant system information includes the system uptime, standby failures, switchover reason, hardware, configured and operating redundancy mode. The current processor information displayed includes the active location, the software state, the uptime in the current state and so on.</td>
</tr>
<tr>
<td><code>show redundancy state</code></td>
<td>Displays all the redundancy states of the active and standby devices.</td>
</tr>
</tbody>
</table>

## LACP Configuration: Example

This example shows how to configure LACP and to verify creation of the LACP bundle and the status:

```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Administering the Device

System Time and Date Management

You can manage the system time and date on your device using automatic configuration methods (RTC and NTP), or manual configuration methods.

Note

For complete syntax and usage information for the commands used in this section, see the Cisco IOS Configuration Fundamentals Command Reference on Cisco.com.
System Clock

The basis of the time service is the system clock. This clock runs from the moment the system starts up and keeps track of the date and time.

The system clock can then be set from these sources:

- NTP
- Manual configuration

The system clock can provide time to these services:

- User `show` commands
- Logging and debugging messages

The system clock keeps track of time internally based on Coordinated Universal Time (UTC), also known as Greenwich Mean Time (GMT). You can configure information about the local time zone and summer time (daylight saving time) so that the time appears correctly for the local time zone.

The system clock keeps track of whether the time is authoritative or not (that is, whether it has been set by a time source considered to be authoritative). If it is not authoritative, the time is available only for display purposes and is not redistributed.

Network Time Protocol

The NTP is designed to time-synchronize a network of devices. NTP runs over User Datagram Protocol (UDP), which runs over IP. NTP is documented in RFC 1305.

An NTP network usually gets its time from an authoritative time source, such as a radio clock or an atomic clock attached to a time server. NTP then distributes this time across the network. NTP is extremely efficient; no more than one packet per minute is necessary to synchronize two devices to within a millisecond of one another.

NTP uses the concept of a stratum to describe how many NTP hops away a device is from an authoritative time source. A stratum 1 time server has a radio or atomic clock directly attached, a stratum 2 time server receives its time through NTP from a stratum 1 time server, and so on. A device running NTP automatically chooses as its time source the device with the lowest stratum number with which it communicates through NTP. This strategy effectively builds a self-organizing tree of NTP speakers.

NTP avoids synchronizing to a device whose time might not be accurate by never synchronizing to a device that is not synchronized. NTP also compares the time reported by several devices and does not synchronize to a device whose time is significantly different than the others, even if its stratum is lower.

The communications between devices running NTP (known as associations) are usually statically configured; each device is given the IP address of all devices with which it should form associations. Accurate timekeeping is possible by exchanging NTP messages between each pair of devices with an association. However, in a LAN environment, NTP can be configured to use IP broadcast messages instead. This alternative reduces configuration complexity because each device can simply be configured to send or receive broadcast messages. However, in that case, information flow is one-way only.

The time kept on a device is a critical resource; you should use the security features of NTP to avoid the accidental or malicious setting of an incorrect time. Two mechanisms are available: an access list-based restriction scheme and an encrypted authentication mechanism.
Cisco’s implementation of NTP does not support stratum 1 service; it is not possible to connect to a radio or atomic clock. We recommend that the time service for your network be derived from the public NTP servers available on the IP Internet.

The Figure shows a typical network example using NTP. Device A is the NTP master, with the Device B, C, and D configured in NTP server mode, in server association with Device A. Device E is configured as an NTP peer to the upstream and downstream Device, Device B and Device F, respectively.

Figure 119: Typical NTP Network Configuration

If the network is isolated from the Internet, Cisco’s implementation of NTP allows a device to act as if it is synchronized through NTP, when in fact it has learned the time by using other means. Other devices then synchronize to that device through NTP.

When multiple sources of time are available, NTP is always considered to be more authoritative. NTP time overrides the time set by any other method.

Several manufacturers include NTP software for their host systems, and a publicly available version for systems running UNIX and its various derivatives is also available. This software allows host systems to be time-synchronized as well.

**NTP Stratum**

NTP uses the concept of a *stratum* to describe how many NTP hops away a device is from an authoritative time source. A stratum 1 time server has a radio or atomic clock directly attached, a stratum 2 time server receives its time through NTP from a stratum 1 time server, and so on. A device running NTP automatically chooses as its time source the device with the lowest stratum number with which it communicates through NTP. This strategy effectively builds a self-organizing tree of NTP speakers.

NTP avoids synchronizing to a device whose time might not be accurate by never synchronizing to a device that is not synchronized. NTP also compares the time reported by several devices and does not synchronize to a device whose time is significantly different than the others, even if its stratum is lower.
NTP Associations

The communications between devices running NTP (known as associations) are usually statically configured; each device is given the IP address of all devices with which it should form associations. Accurate timekeeping is possible by exchanging NTP messages between each pair of devices with an association. However, in a LAN environment, NTP can be configured to use IP broadcast messages instead. This alternative reduces configuration complexity because each device can simply be configured to send or receive broadcast messages. However, in that case, information flow is one-way only.

NTP Security

The time kept on a device is a critical resource; you should use the security features of NTP to avoid the accidental or malicious setting of an incorrect time. Two mechanisms are available: an access list-based restriction scheme and an encrypted authentication mechanism.

NTP Implementation

Implementation of NTP does not support stratum 1 service; it is not possible to connect to a radio or atomic clock. We recommend that the time service for your network be derived from the public NTP servers available on the IP Internet.

Figure 120: Typical NTP Network Configuration

The following figure shows a typical network example using NTP. Switch A is the NTP master, with the Switch B, C, and D configured in NTP server mode, in server association with Switch A. Switch E is configured as an NTP peer to the upstream and downstream switches, Switch B and Switch F,
If the network is isolated from the Internet, NTP allows a device to act as if it is synchronized through NTP, when in fact it has learned the time by using other means. Other devices then synchronize to that device through NTP.

When multiple sources of time are available, NTP is always considered to be more authoritative. NTP time overrides the time set by any other method.

Several manufacturers include NTP software for their host systems, and a publicly available version for systems running UNIX and its various derivatives is also available. This software allows host systems to be time-synchronized as well.

**NTP Version 4**

NTP version 4 is implemented on the device. NTPv4 is an extension of NTP version 3. NTPv4 supports both IPv4 and IPv6 and is backward-compatible with NTPv3.

NTPv4 provides these capabilities:

- Support for IPv6.
- Improved security compared to NTPv3. The NTPv4 protocol provides a security framework based on public key cryptography and standard X509 certificates.
- Automatic calculation of the time-distribution hierarchy for a network. Using specific multicast groups, NTPv4 automatically configures the hierarchy of the servers to achieve the best time accuracy for the lowest bandwidth cost. This feature leverages site-local IPv6 multicast addresses.

For details about configuring NTPv4, see the *Implementing NTPv4 in IPv6* chapter of the *Cisco IOS IPv6 Configuration Guide, Release 12.4T*.

**System Name and Prompt**

You configure the system name on the Device to identify it. By default, the system name and prompt are Device.

If you have not configured a system prompt, the first 20 characters of the system name are used as the system prompt. A greater-than symbol [>] is appended. The prompt is updated whenever the system name changes.

For complete syntax and usage information for the commands used in this section, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.4* and the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

**Stack System Name and Prompt**

If you are accessing a stack member through the active switch, you must use the `session stack-member-number` privileged EXEC command. The stack member number range is from 1 through 4. When you use this command, the stack member number is appended to the system prompt. For example, Switch-2# is the prompt in privileged EXEC mode for stack member 2, and the system prompt for the switch stack is Switch.

**Default System Name and Prompt Configuration**

The default switch system name and prompt is `Switch`. 
DNS

The DNS protocol controls the Domain Name System (DNS), a distributed database with which you can map hostnames to IP addresses. When you configure DNS on your device, you can substitute the hostname for the IP address with all IP commands, such as `ping`, `telnet`, `connect`, and related Telnet support operations.

IP defines a hierarchical naming scheme that allows a device to be identified by its location or domain. Domain names are pieced together with periods (.) as the delimiting characters. For example, Cisco Systems is a commercial organization that IP identifies by a `com` domain name, so its domain name is `cisco.com`. A specific device in this domain, for example, the File Transfer Protocol (FTP) system is identified as `ftp.cisco.com`.

To keep track of domain names, IP has defined the concept of a domain name server, which holds a cache (or database) of names mapped to IP addresses. To map domain names to IP addresses, you must first identify the hostnames, specify the name server that is present on your network, and enable the DNS.

Default DNS Settings

Table 170: Default DNS Settings

<table>
<thead>
<tr>

<tbody>
<tr>
<td>DNS enable state</td>
<td>Enabled.</td>
</tr>
<tr>
<td>DNS default domain name</td>
<td>None configured.</td>
</tr>
<tr>
<td>DNS servers</td>
<td>No name server addresses are configured.</td>
</tr>
</tbody>
</table>

Login Banners

You can configure a message-of-the-day (MOTD) and a login banner. The MOTD banner is displayed on all connected terminals at login and is useful for sending messages that affect all network users (such as impending system shutdowns).

The login banner is also displayed on all connected terminals. It appears after the MOTD banner and before the login prompts.

For complete syntax and usage information for the commands used in this section, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.4*.

Default Banner Configuration

The MOTD and login banners are not configured.

MAC Address Table

The MAC address table contains address information that the device uses to forward traffic between ports. All MAC addresses in the address table are associated with one or more ports. The address table includes these types of addresses:

- Dynamic address—A source MAC address that the device learns and then ages when it is not in use.
• Static address—A manually entered unicast address that does not age and that is not lost when the device resets.

The address table lists the destination MAC address, the associated VLAN ID, and port number associated with the address and the type (static or dynamic).

Note
For complete syntax and usage information for the commands used in this section, see the command reference for this release.

MAC Address Table Creation

With multiple MAC addresses supported on all ports, you can connect any port on the device to other network devices. The device provides dynamic addressing by learning the source address of packets it receives on each port and adding the address and its associated port number to the address table. As devices are added or removed from the network, the device updates the address table, adding new dynamic addresses and aging out those that are not in use.

The aging interval is globally configured. However, the device maintains an address table for each VLAN, and STP can accelerate the aging interval on a per-VLAN basis.

The device sends packets between any combination of ports, based on the destination address of the received packet. Using the MAC address table, the device forwards the packet only to the port associated with the destination address. If the destination address is on the port that sent the packet, the packet is filtered and not forwarded. The device always uses the store-and-forward method: complete packets are stored and checked for errors before transmission.

MAC Addresses and VLANs

All addresses are associated with a VLAN. An address can exist in more than one VLAN and have different destinations in each. Unicast addresses, for example, could be forwarded to port 1 in VLAN 1 and ports 9, 10, and 1 in VLAN 5.

Each VLAN maintains its own logical address table. A known address in one VLAN is unknown in another until it is learned or statically associated with a port in the other VLAN.

MAC Addresses and Device Stacks

The MAC address tables on all stack members are synchronized. At any given time, each stack member has the same copy of the address tables for each VLAN. When an address ages out, the address is removed from the address tables on all stack members. When a Device joins a switch stack, that Device receives the addresses for each VLAN learned on the other stack members. When a stack member leaves the switch stack, the remaining stack members age out or remove all addresses learned by the former stack member.
Default MAC Address Table Settings

The following table shows the default settings for the MAC address table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aging time</td>
<td>300 seconds</td>
</tr>
<tr>
<td>Dynamic addresses</td>
<td>Automatically learned</td>
</tr>
<tr>
<td>Static addresses</td>
<td>None configured</td>
</tr>
</tbody>
</table>

ARP Table Management

To communicate with a device (over Ethernet, for example), the software first must learn the 48-bit MAC address or the local data link address of that device. The process of learning the local data link address from an IP address is called address resolution.

The Address Resolution Protocol (ARP) associates a host IP address with the corresponding media or MAC addresses and the VLAN ID. Using an IP address, ARP finds the associated MAC address. When a MAC address is found, the IP-MAC address association is stored in an ARP cache for rapid retrieval. Then the IP datagram is encapsulated in a link-layer frame and sent over the network. Encapsulation of IP datagrams and ARP requests and replies on IEEE 802 networks other than Ethernet is specified by the Subnetwork Access Protocol (SNAP). By default, standard Ethernet-style ARP encapsulation (represented by the arpa keyword) is enabled on the IP interface.

ARP entries added manually to the table do not age and must be manually removed.

For CLI procedures, see the Cisco IOS Release 12.4 documentation on Cisco.com.

How to Administer the Device

Configuring the Time and Date Manually

System time remains accurate through restarts and reboot, however, you can manually configure the time and date after the system is restarted.

We recommend that you use manual configuration only when necessary. If you have an outside source to which the device can synchronize, you do not need to manually set the system clock.

Note

You must reconfigure this setting if you have manually configured the system clock before the active switch fails and a different stack member assumes the role of active switch.
Setting the System Clock

If you have an outside source on the network that provides time services, such as an NTP server, you do not need to manually set the system clock.

Follow these steps to set the system clock:

**SUMMARY STEPS**

1. enable
2. Use one of the following:
   - `clock set hh:mm:ss day month year`
   - `clock set hh:mm:ss month day year`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example: enable</td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td>Step 2</td>
<td>Use one of the following:</td>
<td>Manually set the system clock using one of these formats:</td>
</tr>
<tr>
<td></td>
<td>• clock set hh:mm:ss day month year</td>
<td>• <code>hh:mm:ss</code>—Specifies the time in hours (24-hour format), minutes, and seconds. The time specified is relative to the configured time zone.</td>
</tr>
<tr>
<td></td>
<td>• clock set hh:mm:ss month day year</td>
<td>• <code>day</code>—Specifies the day by date in the month.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>• <code>month</code>—Specifies the month by name.</td>
</tr>
<tr>
<td></td>
<td>Device# clock set 13:32:00 23 March 2013</td>
<td>• <code>year</code>—Specifies the year (no abbreviation).</td>
</tr>
</tbody>
</table>

Configuring the Time Zone

Follow these steps to manually configure the time zone:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `clock timezone zone hours-offset [minutes-offset]`
4. end
5. show running-config
6. copy running-config startup-config
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        |        |
| `configure terminal` | Enters the global configuration mode. |
| Example:          |        |
| `Device# configure terminal` | |

| **Step 3**        |        |
| `clock timezone zone hours-offset [minutes-offset]` | Sets the time zone. |
| Example:          |        |
| `Device(config)# clock timezone AST -3 30` | Internal time is kept in Coordinated Universal Time (UTC), so this command is used only for display purposes and when the time is manually set. |
|                  | • *zone*—Enters the name of the time zone to be displayed when standard time is in effect. The default is UTC. |
|                  | • *hours-offset*—Enters the hours offset from UTC. |
|                  | • (Optional) *minutes-offset*—Enters the minutes offset from UTC. This available where the local time zone is a percentage of an hour different from UTC. |

| **Step 4**        |        |
| `end`             | Returns to privileged EXEC mode. |
| Example:          |        |
| `Device(config)# end` | |

| **Step 5**        |        |
| `show running-config` | Verifies your entries. |
| Example:          |        |
| `Device# show running-config` | |

| **Step 6**        |        |
| `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
| Example:          |        |
| `Device# copy running-config startup-config` | |

## Configuring Summer Time (Daylight Saving Time)

To configure summer time (daylight saving time) in areas where it starts and ends on a particular day of the week each year, perform this task:
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `clock summer-time zone date date month year hh:mm date month year hh:mm [offset]`
4. `clock summer-time zone recurring [week day month hh:mm week day month hh:mm [offset]]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong> clock summer-time zone date date month year hh:mm date month year hh:mm [offset]]</td>
<td>Configures summer time to start and end on specified days every year.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# clock summer-time PDT date 10 March 2013 2:00 3 November 2013 2:00</td>
</tr>
<tr>
<td><strong>Step 4</strong> clock summer-time zone recurring [week day month hh:mm week day month hh:mm [offset]]</td>
<td>Configures summer time to start and end on the specified days every year. All times are relative to the local time zone. The start time is relative to standard time. The end time is relative to summer time. Summer time is disabled by default. If you specify clock summer-time zone recurring without parameters, the summer time rules default to the United States rules. If the starting month is after the ending month, the system assumes that you are in the southern hemisphere.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device(config)# clock summer-time PDT recurring 10 March 2013 2:00 3 November 2013 2:00</td>
</tr>
</tbody>
</table>

- `zone`—Specifies the name of the time zone (for example, PDT) to be displayed when summer time is in effect.
- (Optional) `week`—Specifies the week of the month (1 to 4, first, or last).
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• (Optional) <em>day</em>—Specifies the day of the week (Sunday, Monday...).</td>
<td></td>
</tr>
<tr>
<td>• (Optional) <em>month</em>—Specifies the month (January, February...).</td>
<td></td>
</tr>
<tr>
<td>• (Optional) <em>hh:mm</em>—Specifies the time (24-hour format) in hours and minutes.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) <em>offset</em>—Specifies the number of minutes to add during summer time. The default is 60.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 5**

```
end
```

*Example:*

```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 6**

```
show running-config
```

*Example:*

```
Device# show running-config
```

Verifies your entries.

**Step 7**

```
copy running-config startup-config
```

*Example:*

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

Follow these steps if summer time in your area does not follow a recurring pattern (configure the exact date and time of the next summer time events):

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `clock summer-time [zone date] [month date year hh:mm month date year hh:mm] [offset]` or `clock summer-time [date month year hh:mm date month year hh:mm] [offset]`
4. end
5. show running-config
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>

# Configuring a System Name

Follow these steps to manually configure a system name:

## SUMMARY STEPS

1. enable
2. configure terminal
3. hostname name
4. end
5. show running-config
6. copy running-config startup-config

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> hostname name</td>
<td>Configures a system name. When you set the system name, it is also used as the system prompt. The default setting is Device. The name must follow the rules for ARPANET hostnames. They must start with a letter, end with a letter or digit, and have as interior characters only letters, digits, and hyphens. Names can be up to 63 characters.</td>
</tr>
<tr>
<td>Example: Device(config)# hostname remote-users</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example: Device# show running-config</td>
<td></td>
</tr>
</tbody>
</table>
Setting Up DNS

If you use the device IP address as its hostname, the IP address is used and no DNS query occurs. If you configure a hostname that contains no periods (.), a period followed by the default domain name is appended to the hostname before the DNS query is made to map the name to an IP address. The default domain name is the value set by the `ip domain-name` global configuration command. If there is a period (.) in the hostname, the Cisco IOS software looks up the IP address without appending any default domain name to the hostname.

Follow these steps to set up your switch to use the DNS:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip domain-name name
4. ip name-server server-address1 [server-address2 ... server-address6]
5. ip domain-lookup [nsap | source-interface interface]
6. end
7. show running-config
8. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip domain-name name</td>
<td>Defines a default domain name that the software uses to complete unqualified hostnames (names without a dotted-decimal domain name).</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# ip domain-name Cisco.com</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

Do not include the initial period that separates an unqualified name from the domain name.

At boot time, no domain name is configured; however, if the device configuration comes from a BOOTP or Dynamic Host Configuration Protocol (DHCP) server, then the default domain name might be set by the BOOTP or DHCP server (if the servers were configured with this information).

**Step 4**

*ip name-server* server-address1 [server-address2 ... server-address6]*

**Example:**

Device(config)# ip name-server 192.168.1.100 192.168.1.200 192.168.1.300

Specifies the address of one or more name servers to use for name and address resolution.

You can specify up to six name servers. Separate each server address with a space. The first server specified is the primary server. The device sends DNS queries to the primary server first. If that query fails, the backup servers are queried.

**Step 5**

*ip domain-lookup [nsap | source-interface interface]*

**Example:**

Device(config)# ip domain-lookup

(Optional) Enables DNS-based hostname-to-address translation on your device. This feature is enabled by default.

If your network devices require connectivity with devices in networks for which you do not control name assignment, you can dynamically assign device names that uniquely identify your devices by using the global Internet naming scheme (DNS).

**Step 6**

*end*

**Example:**

Device(config)# end

Returns to privileged EXEC mode.

**Step 7**

*show running-config*

**Example:**

Device# show running-config

Verifies your entries.

**Step 8**

*copy running-config startup-config*

**Example:**

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

### Configuring a Message-of-the-Day Login Banner

You can create a single or multiline message banner that appears on the screen when someone logs in to the device.
Follow these steps to configure a MOTD login banner:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. banner motd $message$
4. end
5. show running-config
6. copy running-config startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>banner motd $message$</td>
<td>Specifies the message of the day.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# banner motd # This is a secure site. Only authorized users are allowed. For access, contact technical support. #</td>
<td></td>
</tr>
<tr>
<td></td>
<td>c—Enters the delimiting character of your choice, for example, a pound sign (#), and press the Return key. The delimiting character signifies the beginning and end of the banner text. Characters after the ending delimiter are discarded.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>message—Enters a banner message up to 255 characters. You cannot use the delimiting character in the message.</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show running-config</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring a Login Banner

You can configure a login banner to be displayed on all connected terminals. This banner appears after the MOTD banner and before the login prompt.

Follow these steps to configure a login banner:

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **banner login** `c message c`
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>enable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; <strong>enable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><strong>configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# <strong>configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Specifies the login message.</td>
</tr>
<tr>
<td><strong>banner login</strong> <code>c message c</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# <strong>banner login</strong> <code>$</code></td>
<td></td>
</tr>
<tr>
<td>Access for authorized users only. Please enter your username and password. <code>$</code></td>
<td></td>
</tr>
</tbody>
</table>

`c`—Enters the delimiting character of your choice, for example, a pound sign (#), and press the Return key. The delimiting character signifies the beginning and end of the banner text. Characters after the ending delimiter are discarded.

`message`—Enters a login message up to 255 characters. You cannot use the delimiting character in the message.
Managing the MAC Address Table

Changing the Address Aging Time

Follow these steps to configure the dynamic address table aging time:

SUMMARY STEPS

1. enable
2. configure terminal
3. mac address-table aging-time \([0 \mid 10-1000000] \)[ routed-mac | vlan vlan-id]\)
4. end
5. show running-config
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 1 Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Step 2 Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>

### Configuring MAC Address Change Notification Traps

Follow these steps to configure the switch to send MAC address change notification traps to an NMS host:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. snmp-server host host-addr community-string notification-type { informs | traps } { version { 1 | 2c | 3 } } { vrf vrf instance name }
4. snmp-server enable traps mac-notification change
5. mac address-table notification change
6. mac address-table notification change [interval value] [history-size value]
7. interface interface-id
8. snmp trap mac-notification change { added | removed }
9. end
10. show running-config
11. copy running-config startup-config

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Purpose</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Sets the length of time that a dynamic entry remains in the MAC address table after the entry is used or updated. The range is 10 to 1000000 seconds. The default is 300. You can also enter 0, which disables aging. Static address entries are never aged or removed from the table.</td>
</tr>
<tr>
<td>mac address-table aging-time [0</td>
<td>10-1000000] [routed-mac</td>

<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# copy running-config startup-config</td>
</tr>
</tbody>
</table>

**Configuring MAC Address Move Notification Traps**

When you configure MAC-move notification, an SNMP notification is generated and sent to the network management system whenever a MAC address moves from one port to another within the same VLAN.

Follow these steps to configure the device to send MAC address-move notification traps to an NMS host:
SUMMARY STEPS

1. enable
2. configure terminal
3. snmp-server host host-addr {traps | informs} {version {1 | 2c | 3}} community-string notification-type
4. snmp-server enable traps mac-notification move
5. mac address-table notification mac-move
6. end
7. show running-config
8. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal | Enters the global configuration mode. |
| **Example:** Device# configure terminal |

| **Step 3** snmp-server host host-addr {traps | informs} {version {1 | 2c | 3}} community-string notification-type | Specifies the recipient of the trap message. |
| **Example:** Device(config)# snmp-server host 172.20.10.10 traps private mac-notification |

- *host-addr*—Specifies the name or address of the NMS.
- *traps* (the default)—Sends SNMP traps to the host.
- *informs*—Sends SNMP informs to the host.
- *version*—Specifies the SNMP version to support. Version 1, the default, is not available with informs.
- *community-string*—Specifies the string to send with the notification operation. Though you can set this string by using the `snmp-server host` command, we recommend that you define this string by using the `snmp-server community` command before using the `snmp-server host` command.
- *notification-type*—Uses the `mac-notification` keyword.

| **Step 4** snmp-server enable traps mac-notification move | Enables the device to send MAC address move notification traps to the NMS. |
| **Example:** Device(config)# snmp-server enable traps mac-notification move |
### Configuring MAC Threshold Notification Traps

When you configure MAC threshold notification, an SNMP notification is generated and sent to the network management system when a MAC address table threshold limit is reached or exceeded.

Follow these steps to configure the switch to send MAC address table threshold notification traps to an NMS host:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. snmp-server host host-addr {traps | informs} {version {1 | 2c | 3}} community-string notification-type
4. snmp-server enable traps mac-notification threshold
5. mac address-table notification threshold
6. mac address-table notification threshold [limit percentage] | [interval time]

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong></td>
<td>mac address-table notification mac-move</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# mac address-table notification mac-move</td>
</tr>
<tr>
<td></td>
<td>Enables the MAC address move notification feature.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>end</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# show running-config</td>
</tr>
<tr>
<td></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>copy running-config startup-config</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

---

**What to do next**

To disable MAC address-move notification traps, use the `no snmp-server enable traps mac-notification move` global configuration command. To disable the MAC address-move notification feature, use the `no mac address-table notification mac-move` global configuration command.

You can verify your settings by entering the `show mac address-table notification mac-move` privileged EXEC commands.

---

**Configuring MAC Threshold Notification Traps**

When you configure MAC threshold notification, an SNMP notification is generated and sent to the network management system when a MAC address table threshold limit is reached or exceeded.

Follow these steps to configure the switch to send MAC address table threshold notification traps to an NMS host:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. snmp-server host host-addr {traps | informs} {version {1 | 2c | 3}} community-string notification-type
4. snmp-server enable traps mac-notification threshold
5. mac address-table notification threshold
6. mac address-table notification threshold [limit percentage] | [interval time]
7. end
8. show running-config
9. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

</tbody>
</table>
### Adding and Removing Static Address Entries

Follow these steps to add a static address:

#### SUMMARY STEPS

1. enable
2. configure terminal
3. `mac address-table static mac-addr vlan vlan-id interface interface-id`
4. end
5. show running-config
6. copy running-config startup-config

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 <code>mac address-table static mac-addr vlan vlan-id interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td>Step 4 end</td>
<td></td>
</tr>
<tr>
<td>Step 5 show running-config</td>
<td></td>
</tr>
<tr>
<td>Step 6 copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Purpose

Command or Action | Purpose
---|---
Device> enable | 

Step 2 | configure terminal
Example:
Device# configure terminal |

Step 3 | mac address-table static mac-addr vlan vlan-id interface interface-id
Example:
Device(config)# mac address-table static c2f3.220a.12f4 vlan 4 interface gigabitethernet 1/0/1 |

- **mac-addr**—Specifies the destination MAC unicast address to add to the address table. Packets with this destination address received in the specified VLAN are forwarded to the specified interface.
- **vlan-id**—Specifies the VLAN for which the packet with the specified MAC address is received. Valid VLAN IDs are 1 to 4094.
- **interface-id**—Specifies the interface to which the received packet is forwarded. Valid interfaces include physical ports or port channels. For static multicast addresses, you can enter multiple interface IDs. For static unicast addresses, you can enter only one interface at a time, but you can enter the command multiple times with the same MAC address and VLAN ID.

Step 4 | end
Example:
Device(config)# end |

Step 5 | show running-config
Example:
Device# show running-config |

Step 6 | copy running-config startup-config
Example:
Device# copy running-config startup-config |

(Optional) Saves your entries in the configuration file.

Configuring Unicast MAC Address Filtering

Follow these steps to configure the Device to drop a source or destination unicast static address:
SUMMARY STEPS

1. enable
2. configure terminal
3. mac address-table static mac-addr vlan vlan-id drop
4. end
5. show running-config
6. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal              | Enters the global configuration mode.                                  |
| Example:                                   |                                                                         |
| Device# configure terminal                 |                                                                         |

| **Step 3** mac address-table static mac-addr vlan vlan-id drop | Enables unicast MAC address filtering and configure the device to drop a packet with the specified source or destination unicast static address. |
| Example:                                                   | *mac-addr*—Specifies a source or destination unicast MAC address (48-bit). Packets with this MAC address are dropped. |
|                                                          | *vlan-id*—Specifies the VLAN for which the packet with the specified MAC address is received. Valid VLAN IDs are 1 to 4094. |
| Device(config)# mac address-table static c2f3.220a.12f4 vlan 4 drop |                                                                         |

| **Step 4** end                                      | Returns to privileged EXEC mode.                                        |
| Example:                                           |                                                                         |
| Device(config)# end                               |                                                                         |

| **Step 5** show running-config                    | Verifies your entries.                                                 |
| Example:                                          |                                                                         |
| Device# show running-config                      |                                                                         |

| **Step 6** copy running-config startup-config    | (Optional) Saves your entries in the configuration file.                |
| Example:                                         |                                                                         |
|                                                   |                                                                         |

Configuration Examples for Device Administration

Example: Setting the System Clock

This example shows how to manually set the system clock:

Device# clock set 13:32:00 23 July 2013

Examples: Configuring Summer Time

This example (for daylight savings time) shows how to specify that summer time starts on March 10 at 02:00 and ends on November 3 at 02:00:

Device(config)# clock summer-time PDT recurring PST date
10 March 2013 2:00 3 November 2013 2:00

This example shows how to set summer time start and end dates:

Device(config)# clock summer-time PST date
20 March 2013 2:00 20 November 2013 2:00

Example: Configuring a MOTD Banner

This example shows how to configure a MOTD banner by using the pound sign (#) symbol as the beginning and ending delimiter:

Device(config)# banner motd #
This is a secure site. Only authorized users are allowed.
For access, contact technical support.
#
Device(config)#

This example shows the banner that appears from the previous configuration:

Unix> telnet 192.0.2.15
Trying 192.0.2.15...
Connected to 192.0.2.15.
Escape character is '^]'.
This is a secure site. Only authorized users are allowed.
For access, contact technical support.
User Access Verification

Password:

**Example: Configuring a Login Banner**

This example shows how to configure a login banner by using the dollar sign ($) symbol as the beginning and ending delimiter:

```
Device(config)# banner login $
Access for authorized users only. Please enter your username and password.
$
Device(config)#
```

**Example: Configuring MAC Address Change Notification Traps**

This example shows how to specify 172.20.10.10 as the NMS, enable MAC address notification traps to the NMS, enable the MAC address-change notification feature, set the interval time to 123 seconds, set the history-size to 100 entries, and enable traps whenever a MAC address is added on the specified port:

```
Device(config)# snmp-server host 172.20.10.10 traps private mac-notification
Device(config)# snmp-server enable traps mac-notification change
Device(config)# mac address-table notification change
Device(config)# mac address-table notification change interval 123
Device(config)# mac address-table notification change history-size 100
Device(config)# interface gigabitethernet1/2/1
Device(config-if)# snmp trap mac-notification change added
```

**Example: Configuring MAC Threshold Notification Traps**

This example shows how to specify 172.20.10.10 as the NMS, enable the MAC address threshold notification feature, set the interval time to 123 seconds, and set the limit to 78 percent:

```
Device(config)# snmp-server host 172.20.10.10 traps private mac-notification
Device(config)# snmp-server enable traps mac-notification threshold
Device(config)# mac address-table notification threshold
Device(config)# mac address-table notification threshold interval 123
Device(config)# mac address-table notification threshold limit 78
```

**Example: Adding the Static Address to the MAC Address Table**

This example shows how to add the static address c2f3.220a.12f4 to the MAC address table. When a packet is received in VLAN 4 with this MAC address as its destination address, the packet is forwarded to the specified port:
Example: Configuring Unicast MAC Address Filtering

This example shows how to enable unicast MAC address filtering and how to configure drop packets that have a source or destination address of c2f3.220a.12f4. When a packet is received in VLAN 4 with this MAC address as its source or destination, the packet is dropped:

```
Device(config)# mac address-table static c2f3.220a.12f4 vlan 4 drop
```

CHAPTER 104

Performing Device Setup Configuration

• Finding Feature Information, on page 2091
• Information About Performing Device Setup Configuration, on page 2091
• How to Perform Device Setup Configuration, on page 2103
• Monitoring Device Setup Configuration, on page 2119
• Configuration Examples for Performing Device Setup, on page 2123
• Additional References For Performing Device Setup, on page 2125
• Installing WCM Sub-Package, on page 2126
• Feature History and Information For Performing Device Setup Configuration, on page 2127

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Performing Device Setup Configuration

Review the sections in this module before performing your initial device configuration tasks that include IP address assignments and DHCP autoconfiguration.

Device Boot Process

To start your device, you need to follow the procedures in the hardware installation guide for installing and powering on the device and setting up the initial device configuration (IP address, subnet mask, default gateway, secret and Telnet passwords, and so forth).

The normal boot process involves the operation of the boot loader software and includes these activities:

• Performs low-level CPU initialization. It initializes the CPU registers, which control where physical memory is mapped, its quantity, its speed, and so forth.
• Performs power-on self-test (POST) for the CPU subsystem and tests the system DRAM.
• Initializes the file systems on the system board.
• Loads a default operating system software image into memory and boots up the device.

The boot loader provides access to the file systems before the operating system is loaded. Normally, the boot loader is used only to load, decompress, and start the operating system. After the boot loader gives the operating system control of the CPU, the boot loader is not active until the next system reset or power-on.

The boot loader also provides trap-door access into the system if the operating system has problems serious enough that it cannot be used. The trap-door mechanism provides enough access to the system so that if it is necessary, you can reinstall the operating system software image by using the Xmodem Protocol, recover from a lost or forgotten password, and finally restart the operating system.

Before you can assign device information, make sure you have connected a PC or terminal to the console port or a PC to the Ethernet management port, and make sure you have configured the PC or terminal-emulation software baud rate and character format to match these of the device console port:

- Baud rate default is 9600.
- Data bits default is 8.

  **Note**  
  If the data bits option is set to 8, set the parity option to none.

- Stop bits default is 2 (minor).
- Parity settings default is none.

### Software Installer Features

The following software installer features are supported on your switch:

- Software bundle installation on a standalone switch, a switch stack, or a subset of switches in a stack. The default is installation on all the switches if a switch stack is configured.
- In a stack of switches, Cisco recommends all switches in install mode.
- Software rollback to a previously installed package set.
- Emergency installation in the event that no valid installed packages reside on the boot flash.
- Auto-upgrade of a switch that joins the switch stack with incompatible software.
- Installation using packages on one switch as the source for installing packages on another switch in the switch stack.

**Note**  
Software installation and rollback must be performed while running only in installed mode. You can use the **software expand** EXEC command to convert bundle boot mode to install mode.
Software Boot Modes

Your device supports two modes to boot the software packages:

- Installed mode
- Bundle mode

Related Topics

Examples: Displaying Software Bootup in Install Mode, on page 2120
Example: Emergency Installation, on page 2122

Installed Boot Mode

You can boot your device in installed mode by booting the software package provisioning file that resides in flash:

device: boot flash:packages.conf

The provisioning file contains a list of software packages to boot, mount, and run. The ISO file system in each installed package is mounted to the root file system directly from flash.

Note

The packages and provisioning file used to boot in installed mode must reside in flash. Booting in installed mode from usbflash0: or tftp: is not supported.

Related Topics

Examples: Displaying Software Bootup in Install Mode, on page 2120
Example: Emergency Installation, on page 2122

Bundle Boot Mode

You can boot your device in bundle boot mode by booting the bundle (.bin) file:

switch: boot flash:cat3850-universalk9.SSA.03.08.83.EMD.150-8.83.EMD.bin

The provisioning file contained in a bundle is used to decide which packages to boot, mount, and run. Packages are extracted from the bundle and copied to RAM. The ISO file system in each package is mounted to the root file system.

Unlike install boot mode, additional memory that is equivalent to the size of the bundle is used when booting in bundle mode.

Unlike install boot mode, bundle boot mode is available from several locations:

- flash:
- usbflash0:
- tftp:

Note

Auto install and smart install functionality is not supported in bundle boot mode.
Note

The AP image pre-download feature is not supported in bundle boot mode. For more information about the pre-download feature see the Cisco WLC 5700 Series Preloading an Image to Access Points chapter.

Related Topics

Examples: Displaying Software Bootup in Install Mode, on page 2120
Example: Emergency Installation, on page 2122

Boot Mode for a Switch Stack

All the switches in a stack must be running in installed mode or bundle boot mode. A mixed mode stack is not supported. If a new switch tries to join the stack in a different boot mode then the active switch, the new switch is given a V-mismatch state.

If a mixed mode switch stack is booted at the same time, then all the switches except for the active switch is given a V-mismatch state. If the boot mode does not support auto-upgrade, then the switch stack members must be re-booted in the same boot mode as the active switch.

If the stack is running in installed mode, the auto-upgrade feature can be used to automatically upgrade the new switch that is attempting to join the switch stack.

The auto-upgrade feature changes the boot mode of the new switch to installed mode. If the stack is running in bundle boot mode, the auto-upgrade feature is not available. You will be required to use the bundle mode to boot the new switch so that it can join the switch stack.

This is an example of the state of a switch that attempts to join the switch stack when the boot mode is not compatible with the active switch:

```
Device# show switch

Switch/Stack Mac Address : 6400.f125.1100 - Local Mac Address
Mac persistency wait time: Indefinite
H/W Current
Switch# Role Mac Address Priority Version State
----------------------------------------------
 1 Member 6400 f125.1a00 1 0 V-Mismatch
*2 Active 6400.f125.1100 1 V01 Ready
```

Devices Information Assignment

You can assign IP information through the device setup program, through a DHCP server, or manually.

Use the device setup program if you want to be prompted for specific IP information. With this program, you can also configure a hostname and an enable secret password.

It gives you the option of assigning a Telnet password (to provide security during remote management) and configuring your switch as a command or member switch of a cluster or as a standalone switch.

Use a DHCP server for centralized control and automatic assignment of IP information after the server is configured.
If you are using DHCP, do not respond to any of the questions in the setup program until the device receives the dynamically assigned IP address and reads the configuration file.

If you are an experienced user familiar with the device configuration steps, manually configure the device. Otherwise, use the setup program described in the Boot Process section.

**DHCP-Based Autoconfiguration Overview**

DHCP provides configuration information to Internet hosts and internetworking devices. This protocol consists of two components: one for delivering configuration parameters from a DHCP server to a device and an operation for allocating network addresses to devices. DHCP is built on a client-server model, in which designated DHCP servers allocate network addresses and deliver configuration parameters to dynamically configured devices. The device can act as both a DHCP client and a DHCP server.

During DHCP-based autoconfiguration, your device (DHCP client) is automatically configured at startup with IP address information and a configuration file.

With DHCP-based autoconfiguration, no DHCP client-side configuration is needed on your device. However, you need to configure the DHCP server for various lease options associated with IP addresses.

If you want to use DHCP to relay the configuration file location on the network, you might also need to configure a Trivial File Transfer Protocol (TFTP) server and a Domain Name System (DNS) server.

**Note**

We recommend a redundant connection between a switch stack and the DHCP, DNS, and TFTP servers. This is to help ensure that these servers remain accessible in case one of the connected stack members is removed from the switch stack.
The DHCP server for your device can be on the same LAN or on a different LAN than the device. If the DHCP server is running on a different LAN, you should configure a DHCP relay device between your device and the DHCP server. A relay device forwards broadcast traffic between two directly connected LANs. A router does not forward broadcast packets, but it forwards packets based on the destination IP address in the received packet.

DHCP-based autoconfiguration replaces the BOOTP client functionality on your device.

### DHCP Client Request Process

When you boot up your device, the DHCP client is invoked and requests configuration information from a DHCP server when the configuration file is not present on the device. If the configuration file is present and the configuration includes the `ip address dhcp` interface configuration command on specific routed interfaces, the DHCP client is invoked and requests the IP address information for those interfaces.

This is the sequence of messages that are exchanged between the DHCP client and the DHCP server.

**Figure 121: DHCP Client and Server Message Exchange**

The client, Device A, broadcasts a DHCPDISCOVER message to locate a DHCP server. The DHCP server offers configuration parameters (such as an IP address, subnet mask, gateway IP address, DNS IP address, a lease for the IP address, and so forth) to the client in a DHCPOFFER unicast message.

In a DHCPREQUEST broadcast message, the client returns a formal request for the offered configuration information to the DHCP server. The formal request is broadcast so that all other DHCP servers that received the DHCPDISCOVER broadcast message from the client can reclaim the IP addresses that they offered to the client.

The DHCP server confirms that the IP address has been allocated to the client by returning a DHCPACK unicast message to the client. With this message, the client and server are bound, and the client uses configuration information received from the server. The amount of information the device receives depends on how you configure the DHCP server.

If the configuration parameters sent to the client in the DHCPOFFER unicast message are invalid (a configuration error exists), the client returns a DHCPDECLINE broadcast message to the DHCP server.

The DHCP server sends the client a DHCPNAK denial broadcast message, which means that the offered configuration parameters have not been assigned, that an error has occurred during the negotiation of the parameters, or that the client has been slow in responding to the DHCPOFFER message (the DHCP server assigned the parameters to another client).

A DHCP client might receive offers from multiple DHCP or BOOTP servers and can accept any of the offers; however, the client usually accepts the first offer it receives. The offer from the DHCP server is not a guarantee that the IP address is allocated to the client; however, the server usually reserves the address until the client has had a chance to formally request the address. If the device accepts replies from a BOOTP server and configure itself, the device broadcasts, instead of unicasts, TFTP requests to obtain the device configuration file.

The DHCP hostname option allows a group of devices to obtain hostnames and a standard configuration from the central management DHCP server. A client (device) includes in its DHCPDISCOVER message an option
12 field used to request a hostname and other configuration parameters from the DHCP server. The configuration files on all clients are identical except for their DHCP-obtained hostnames.

If a client has a default hostname (the **hostname** name global configuration command is not configured or the **no hostname** global configuration command is entered to remove the hostname), the DHCP hostname option is not included in the packet when you enter the **ip address dhcp** interface configuration command. In this case, if the client receives the DCHP hostname option from the DHCP interaction while acquiring an IP address for an interface, the client accepts the DHCP hostname option and sets the flag to show that the system now has a hostname configured.

**DHCP-based Autoconfiguration and Image Update**

You can use the DHCP image upgrade features to configure a DHCP server to download both a new image and a new configuration file to one or more devices in a network. Simultaneous image and configuration upgrade for all switches in the network helps ensure that each new device added to a network receives the same image and configuration.

There are two types of DHCP image upgrades: DHCP autoconfiguration and DHCP auto-image update.

**Restrictions for DHCP-based Autoconfiguration**

- The DHCP-based autoconfiguration with a saved configuration process stops if there is not at least one Layer 3 interface in an up state without an assigned IP address in the network.
- Unless you configure a timeout, the DHCP-based autoconfiguration with a saved configuration feature tries indefinitely to download an IP address.
- The auto-install process stops if a configuration file cannot be downloaded or if the configuration file is corrupted.
- The configuration file that is downloaded from TFTP is merged with the existing configuration in the running configuration but is not saved in the NVRAM unless you enter the **write memory** or **copy running-configuration startup-configuration** privileged EXEC command. If the downloaded configuration is saved to the startup configuration, the feature is not triggered during subsequent system restarts.

**DHCP Autoconfiguration**

DHCP autoconfiguration downloads a configuration file to one or more devices in your network from a DHCP server. The downloaded configuration file becomes the running configuration of the device. It does not over write the bootup configuration saved in the flash, until you reload the device.

**DHCP Auto-Image Update**

You can use DHCP auto-image upgrade with DHCP autoconfiguration to download both a configuration and a new image to one or more devices in your network. The device (or devices) downloading the new configuration and the new image can be blank (or only have a default factory configuration loaded).

If the new configuration is downloaded to a switch that already has a configuration, the downloaded configuration is appended to the configuration file stored on the switch. (Any existing configuration is not overwritten by the downloaded one.)

To enable a DHCP auto-image update on the device, the TFTP server where the image and configuration files are located must be configured with the correct option 67 (the configuration filename), option 66 (the DHCP
server hostname) option 150 (the TFTP server address), and option 125 (description of the Cisco IOS image file) settings.

After you install the device in your network, the auto-image update feature starts. The downloaded configuration file is saved in the running configuration of the device, and the new image is downloaded and installed on the device. When you reboot the device, the configuration is stored in the saved configuration on the device.

**DHCP Server Configuration Guidelines**

Follow these guidelines if you are configuring a device as a DHCP server:

- You should configure the DHCP server with reserved leases that are bound to each device by the device hardware address.
- If you want the device to receive IP address information, you must configure the DHCP server with these lease options:
  - IP address of the client (required)
  - Subnet mask of the client (required)
  - DNS server IP address (optional)
  - Router IP address (default gateway address to be used by the device) (required)
- If you want the device to receive the configuration file from a TFTP server, you must configure the DHCP server with these lease options:
  - TFTP server name (required)
  - Boot filename (the name of the configuration file that the client needs) (recommended)
  - Hostname (optional)
- Depending on the settings of the DHCP server, the device can receive IP address information, the configuration file, or both.
- If you do not configure the DHCP server with the lease options described previously, it replies to client requests with only those parameters that are configured. If the IP address and the subnet mask are not in the reply, the device is not configured. If the router IP address or the TFTP server name are not found, the device might send broadcast, instead of unicast, TFTP requests. Unavailability of other lease options does not affect autoconfiguration.
- The device can act as a DHCP server. By default, the Cisco IOS DHCP server and relay agent features are enabled on your device but are not configured. (These features are not operational.)

**Purpose of the TFTP Server**

Based on the DHCP server configuration, the device attempts to download one or more configuration files from the TFTP server. If you configured the DHCP server to respond to the device with all the options required for IP connectivity to the TFTP server, and if you configured the DHCP server with a TFTP server name, address, and configuration filename, the device attempts to download the specified configuration file from the specified TFTP server.

If you did not specify the configuration filename, the TFTP server, or if the configuration file could not be downloaded, the device attempts to download a configuration file by using various combinations of filenames.
and TFTP server addresses. The files include the specified configuration filename (if any) and these files:

- network-config
- ciscoetaf.cfg
- hostname.cfg
- hostname

Where hostname is the device’s current hostname. The TFTP server addresses used include the specified TFTP server address (if any) and the broadcast address (255.255.255.255).

For the device to successfully download a configuration file, the TFTP server must contain one or more configuration files in its base directory. The files can include these files:

- The configuration file named in the DHCP reply (the actual device configuration file).
- The network-config or the ciscoetaf.cfg file (known as the default configuration files).
- The router-config or the ciscortr.cfg file (These files contain commands common to all devices. Normally, if the DHCP and TFTP servers are properly configured, these files are not accessed.)

If you specify the TFTP server name in the DHCP server-lease database, you must also configure the TFTP server name-to-IP-address mapping in the DNS-server database.

If the TFTP server to be used is on a different LAN from the device, or if it is to be accessed by the device through the broadcast address (which occurs if the DHCP server response does not contain all the required information described previously), a relay must be configured to forward the TFTP packets to the TFTP server. The preferred solution is to configure the DHCP server with all the required information.

**Purpose of the DNS Server**

The DHCP server uses the DNS server to resolve the TFTP server name to an IP address. You must configure the TFTP server name-to-IP address map on the DNS server. The TFTP server contains the configuration files for the device.

You can configure the IP addresses of the DNS servers in the lease database of the DHCP server from where the DHCP replies will retrieve them. You can enter up to two DNS server IP addresses in the lease database.

The DNS server can be on the same LAN or on a different LAN from the device. If it is on a different LAN, the device must be able to access it through a router.

**How to Obtain Configuration Files**

Depending on the availability of the IP address and the configuration filename in the DHCP reserved lease, the device obtains its configuration information in these ways:

- The IP address and the configuration filename is reserved for the device and provided in the DHCP reply (one-file read method).

The device receives its IP address, subnet mask, TFTP server address, and the configuration filename from the DHCP server. The device sends a unicast message to the TFTP server to retrieve the named configuration file from the base directory of the server and upon receipt, it completes its boot up process.

- The IP address and the configuration filename is reserved for the device, but the TFTP server address is not provided in the DHCP reply (one-file read method).

The device receives its IP address, subnet mask, and the configuration filename from the DHCP server. The device sends a broadcast message to a TFTP server to retrieve the named configuration file from the base directory of the server, and upon receipt, it completes its boot-up process.

- Only the IP address is reserved for the device and provided in the DHCP reply. The configuration filename is not provided (two-file read method).
The device receives its IP address, subnet mask, and the TFTP server address from the DHCP server. The device sends a unicast message to the TFTP server to retrieve the network-config or cisco-config default configuration file. (If the network-config file cannot be read, the device reads the cisco-config file.)

The default configuration file contains the hostnames-to-IP-address mapping for the device. The device fills its host table with the information in the file and obtains its hostname. If the hostname is not found in the file, the device uses the hostname in the DHCP reply. If the hostname is not specified in the DHCP reply, the device uses the default Switch as its hostname.

After obtaining its hostname from the default configuration file or the DHCP reply, the device reads the configuration file that has the same name as its hostname (hostname-config or hostname.cfg, depending on whether network-config or cisco-config was read earlier) from the TFTP server. If the cisco-config file is read, the filename of the host is truncated to eight characters.

If the device cannot read the network-config, cisco-config, or the hostname file, it reads the router-config file. If the device cannot read the router-config file, it reads the ciscortr.cfg file.

Note

The device broadcasts TFTP server requests if the TFTP server is not obtained from the DHCP replies, if all attempts to read the configuration file through unicast transmissions fail, or if the TFTP server name cannot be resolved to an IP address.

How to Control Environment Variables

With a normally operating device, you enter the boot loader mode only through the console connection configured for 9600 bps. Unplug the device power cord, and press the Mode button while reconnecting the power cord. You can release the Mode button after all the amber system LEDs turn on and remain solid. The boot loader device prompt then appears.

The device boot loader software provides support for nonvolatile environment variables, which can be used to control how the boot loader, or any other software running on the system, operates. Boot loader environment variables are similar to environment variables that can be set on UNIX or DOS systems.

Environment variables that have values are stored in flash memory outside of the flash file system.

Each line in these files contains an environment variable name and an equal sign followed by the value of the variable. A variable has no value if it is not present; it has a value if it is listed even if the value is a null string. A variable that is set to a null string (for example, “” ) is a variable with a value. Many environment variables are predefined and have default values.

You can change the settings of the environment variables by accessing the boot loader or by using Cisco IOS commands. Under normal circumstances, it is not necessary to alter the setting of the environment variables.
Common Environment Variables

This table describes the function of the most common environment variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Boot Loader Command</th>
<th>Cisco IOS Global Configuration Command</th>
</tr>
</thead>
</table>
| BOOT           | set BOOT filesystem :/file-url ... | boot system {filesystem :/file-url ... | switch {number | all} | Specifies the Cisco IOS image to load during the next boot cycle and the stack members on which the image is loaded. This command changes the setting of the BOOT environment variable. The package provisioning file, also referred to as the packages.conf file, is used by the system to determine which software packages to activate during boot up.

- When booting in installed mode, the package provisioning file specified in the boot command is used to determine which packages to activate. For example: boot flash:packages.conf.

- When booting in bundle mode, the package provisioning file contained in the booted bundle is used to activate the packages included in the bundle. For example: boot flash:image.bin.

| MANUAL_BOOT    | set MANUAL_BOOT yes | boot manual
<table>
<thead>
<tr>
<th></th>
<th></th>

**Environment Variables for TFTP**

When the switch is connected to a PC through the Ethernet management port, you can download or upload a configuration file to the boot loader by using TFTP. Make sure the environment variables in this table are configured.

*Table 174: Environment Variables for TFTP*

<table>
<thead>
<tr>
<th>Variable</th>

<tr>
<td></td>
<td>However, if you modify this variable after the boot loader is up or the value is different from the saved value, enter this command before using TFTP.</td>
</tr>
<tr>
<td>IP_ADDR</td>
<td>Specifies the IP address and the subnet mask for the associated IP subnet of the switch.</td>
</tr>
<tr>
<td>DEFAULT_ROUTER</td>
<td>Specifies the IP address and subnet mask of the default gateway.</td>
</tr>
</tbody>
</table>
Scheduled Reload of the Software Image

You can schedule a reload of the software image to occur on the device at a later time (for example, late at night or during the weekend when the device is used less), or you can synchronize a reload network-wide (for example, to perform a software upgrade on all devices in the network).

A scheduled reload must take place within approximately 24 days.

You have these reload options:

- Reload of the software to take affect in the specified minutes or hours and minutes. The reload must take place within approximately 24 hours. You can specify the reason for the reload in a string up to 255 characters in length.

- Reload of the software to take place at the specified time (using a 24-hour clock). If you specify the month and day, the reload is scheduled to take place at the specified time and date. If you do not specify the month and day, the reload takes place at the specified time on the current day (if the specified time is later than the current time) or on the next day (if the specified time is earlier than the current time). Specifying 00:00 schedules the reload for midnight.

The reload command halts the system. If the system is not set to manually boot up, it reboots itself.

If your device is configured for manual booting, do not reload it from a virtual terminal. This restriction prevents the device from entering the boot loader mode and then taking it from the remote user’s control.

If you modify your configuration file, the device prompts you to save the configuration before reloading. During the save operation, the system requests whether you want to proceed with the save if the CONFIG_FILE environment variable points to a startup configuration file that no longer exists. If you proceed in this situation, the system enters setup mode upon reload.

To cancel a previously scheduled reload, use the reload cancel privileged EXEC command.

How to Perform Device Setup Configuration

Using DHCP to download a new image and a new configuration to a device requires that you configure at least two devices. One device acts as a DHCP and TFTP server and the second device (client) is configured to download either a new configuration file or a new configuration file and a new image file.

Configuring DHCP Autoconfiguration (Only Configuration File)

This task describes how to configure DHCP autoconfiguration of the TFTP and DHCP settings on an existing device in the network so that it can support the autoconfiguration of a new device.

SUMMARY STEPS

1. configure terminal
2. ip dhcp pool poolname
3. boot filename
4. network network-number mask prefix-length
5. default-router address
6. option 150 address
7. exit
8. tftp-server flash:filename.text
9. interface interface-id
10. no switchport
11. ip address address mask
12. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>ip dhcp pool poolname</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ip dhcp pool pool</td>
</tr>
<tr>
<td></td>
<td>Creates a name for the DHCP server address pool, and enters DHCP pool configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>boot filename</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(dhcp-config)# boot config-boot.text</td>
</tr>
<tr>
<td></td>
<td>Specifies the name of the configuration file that is used as a boot image.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>network network-number mask prefix-length</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(dhcp-config)# network 10.10.10.0 255.255.255.0</td>
</tr>
<tr>
<td>Note</td>
<td>The prefix length specifies the number of bits that comprise the address prefix. The prefix is an alternative way of specifying the network mask of the client. The prefix length must be preceded by a forward slash (/).</td>
</tr>
<tr>
<td></td>
<td>Specifies the subnet network number and mask of the DHCP address pool.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>default-router address</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(dhcp-config)# default-router 10.10.1</td>
</tr>
<tr>
<td></td>
<td>Specifies the IP address of the default router for a DHCP client.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>option 150 address</td>
</tr>
<tr>
<td>Example:</td>
<td>Specifies the IP address of the TFTP server.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device(dhcp-config)# option 150 10.10.1</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 7** exit | Returns to global configuration mode.  
| **Example:** |  
| Device(dhcp-config)# exit | |
| **Step 8** tftp-server flash:filename.text | Specifies the configuration file on the TFTP server.  
| **Example:** |  
| Device(config)# tftp-server flash:config-boot.text |  
| **Step 9** interface interface-id | Specifies the address of the client that will receive the configuration file.  
| **Example:** |  
| Device(config)# interface gigabitethernet1/0/4 |  
| **Step 10** no switchport | Puts the interface into Layer 3 mode.  
| **Example:** |  
| Device(config-if)# no switchport |  
| **Step 11** ip address address mask | Specifies the IP address and mask for the interface.  
| **Example:** |  
| Device(config-if)# ip address 10.10.10.1 255.255.255.0 |  
| **Step 12** end | Returns to privileged EXEC mode.  
| **Example:** |  
| Device(config-if)# end | |

**Configuring DHCP Auto-Image Update (Configuration File and Image)**

This task describes DHCP autoconfiguration to configure TFTP and DHCP settings on an existing device to support the installation of a new switch.
Before you begin

You must first create a text file (for example, autoinstall dhcp) that will be uploaded to the device. In the text file, put the name of the image that you want to download (for example, c3750e-ipservices-mz.122-44.3.SE.tarc3750x-ipservices-mz.122-53.3.SE2.tar). This image must be a tar and not a bin file.

SUMMARY STEPS

1. configure terminal
2. ip dhcp pool poolname
3. boot filename
4. network network-number mask prefix-length
5. default-router address
6. option 150 address
7. option 125 hex
8. copy tftp flash filename.txt
9. copy tftp flash imagename.bin
10. exit
11. tftp-server flash: config.text
12. tftp-server flash: imagename.bin
13. tftp-server flash: filename.txt
14. interface interface-id
15. no switchport
16. ip address address mask
17. end
18. copy running-config startup-config

Modifying the Device Startup Configuration

Specifying the Filename to Read and Write the System Configuration

By default, the Cisco IOS software uses the config.text file to read and write a nonvolatile copy of the system configuration. However, you can specify a different filename, which will be loaded during the next boot cycle.

Before you begin

Use a standalone device for this task.

SUMMARY STEPS

1. configure terminal
2. boot flash:/file-url
3. end
4. show boot
5. copy running-config startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>

<td></td>
</tr>
<tr>
<td><code>Device# show boot</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
Manually Booting the Switch

By default, the switch automatically boots up; however, you can configure it to manually boot up.

**Before you begin**

Use a standalone switch for this task.

**SUMMARY STEPS**

1. `configure terminal`
2. `boot manual`
3. `end`
4. `show boot`
5. `copy running-config startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
| **Example:**

Device# `configure terminal` |

| **Step 2** `boot manual` | Enables the switch to manually boot up during the next boot cycle. |
| **Example:**

Device(config)# `boot manual` |

| **Step 3** `end` | Returns to privileged EXEC mode. |
| **Example:**

Device(config)# `end` |

| **Step 4** `show boot` | Verifies your entries. |
| **Example:**

Device# `show boot` |

The `boot manual` global command changes the setting of the MANUAL_BOOT environment variable.

The next time you reboot the system, the switch is in boot loader mode, shown by the `switch:` prompt. To boot up the system, use the `boot filesystem:/file-url` boot loader command.
Booting the Device in Installed Mode

SUMMARY STEPS

1. `cp source_file_path destination_file_path`
2. `software expand file source_file_path`
3. `reload`
4. `boot flash:packages.conf`
5. `show version`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>cp source_file_path destination_file_path</code></td>
<td>(Optional) Copies the bin file (<code>image.bin</code>) from the FTP or TFTP server to flash or USB flash.</td>
</tr>
<tr>
<td>Example: Device# <code>copy tftp://10.0.0.6/cat3k_caa-universalk9.SSA.03.12.02.EXP.150-12.02.EXP.150-12.02.EXP.bin flash:</code></td>
<td></td>
</tr>
</tbody>
</table>

| Step 2 `software expand file source_file_path` | Expands the bin file stored in flash, FTP, TFTP, HTTP, or HTTPS server on the booted device. |
| Example: Expanding the bin file from the TFTP server: Switch# `software expand file tftp://10.0.0.2/cat3k_caa-universalk9.SSA.03.09.37.EXP.150-9.37.EXP.bin to flash:` | Note Ensure that the `packages.conf` file is available in the expanded list. |

### Booting the Device in Bundle Mode

There are several methods by which you can boot the device—either by copying the bin file from the TFTP server and then boot the device, or by booting the device straight from flash or USB flash using the commands `boot flash:<image.bin>` or `boot usbflash0:<image.bin>`.

The following procedure explains how to boot the device from the TFTP server in the bundle mode.

</tbody>
</table>

---

**Step 3**

**Example:**

Device: `reload`

Reloads the device.

**Note**

You can boot the device manually or automatically using the `packages.conf` file. If you are booting manually, you can proceed to Step 4. Otherwise, the device boots up automatically.

**Step 4**

**Example:**

`switch: boot flash:packages.conf`

Boots the device with the `packages.conf` file.

**Step 5**

**Example:**

`switch# show version`

Verifies that the device is in the **INSTALL** mode.

---

### Booting the Device in Bundle Mode

There are several methods by which you can boot the device—either by copying the bin file from the TFTP server and then boot the device, or by booting the device straight from flash or USB flash using the commands `boot flash:<image.bin>` or `boot usbflash0:<image.bin>`.

The following procedure explains how to boot the device from the TFTP server in the bundle mode.
Booting a Specific Software Image On a Switch Stack

By default, the switch attempts to automatically boot up the system using information in the BOOT environment variable. If this variable is not set, the switch attempts to load and execute the first executable image it can by performing a recursive, depth-first search throughout the flash file system. In a depth-first search of a directory, each encountered subdirectory is completely searched before continuing the search in the original directory. However, you can specify a specific image to boot up.

SUMMARY STEPS

1. configure terminal
2. boot system switch {number | all}
3. end
4. show boot system
5. copy running-config startup-config

### Configuring a Scheduled Software Image Reload

This task describes how to configure your device to reload the software image at a later time.
### SUMMARY STEPS

1. configure terminal
2. copy running-config startup-config
3. reload in [hh:]mm [text]
4. reload slot [stack-member-number]
5. reload at hh:mm [month day | day month] [text]
6. reload cancel
7. show reload

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | configure terminal  
Example:  
Device# configure terminal | Enters global configuration mode. |
| Step 2 | copy running-config startup-config  
Example:  
copy running-config startup-config | Saves your device configuration information to the startup configuration before you use the **reload** command. |
| Step 3 | reload in [hh:]mm [text]  
Example:  
Device(config)# reload in 12  
System configuration has been modified. Save? [yes/no]: y | Schedules a reload of the software to take affect in the specified minutes or hours and minutes. The reload must take place within approximately 24 days. You can specify the reason for the reload in a string up to 255 characters in length. |
| Step 4 | reload slot [stack-member-number]  
Example:  
Device(config)# reload slot 6  
Proceed with reload? [confirm] y | Schedules a reload of the software in a switch stack. |
| Step 5 | reload at hh:mm [month day | day month] [text]  
Example:  
Device(config)# reload at 14:00 | Specifies the time in hours and minutes for the reload to occur.  
**Note** Use the **at** keyword only if the device system clock has been set (through Network Time Protocol (NTP), the hardware calendar, or manually). The time is relative to the configured time zone on the device. To schedule reloads across several devices to occur simultaneously, the time on each device must be synchronized with NTP. |
<table>

Example: Configuring a Device to Download Configurations from a DHCP Server

This example uses a Layer 3 SVI interface on VLAN 99 to enable DHCP-based autoconfiguration with a saved configuration:

```
Device# configure terminal
Device(config)# boot host dhcp
Device(config)# boot host retry timeout 300
Device(config)# banner config-save "Caution - Saving Configuration File to NVRAM May Cause You to No longer Automatically Download Configuration Files at Reboot"
Device(config)# vlan 99
Device(config-vlan)# interface vlan 99
Device(config-if)# no shutdown
Device(config-if)# end
Device# show boot
BOOT path-list:
 Config file: flash:/config.text
 Private Config file: flash:/private-config.text
 Enable Break: no
 Manual Boot: no
 HELPER path-list:
 NVRAM/Config file
 buffer size: 32768
 Timeout for Config Download: 300 seconds
 Config Download via DHCP: enabled (next boot: enabled)
Device#
```

Installing WCM Sub-Package

This document explains the process to install wireless control module (WCM) sub-package in Cisco Catalyst 3850 and 3650 Series Switches.

The WCM sub-package, which consists of WCM module and AP images, upgrades features, supports new APs, and fixes known issues. It eliminates the need for a full image upgrade and the resulting network downtime by upgrading only the WCM portion of the image. For example, if the WCM fails to allow a new AP to join the network due to image version mis-match, you can upgrade only the WCM portion of the image to add support for the new AP. When the WCM is upgraded, all the APs in the network are automatically upgraded to the newer image.

Benefits

• Fixes WCM bugs
• Supports new APs
• Updates features available in WCM

Prerequisites

• The controller must be booted in install mode.
• WCM sub-package should be available in any of the sources supported by installer. For example, flash or TFTP or USB.

Restrictions

• WCM sub-package can only be installed on previous minor versions of the 16.1 image (for example, WCM package from 16.01.YY(cat3k_caa-wcm.16.01.YY.SSA.pkg) can be installed on 16.01.01 to 16.01.YY super package (cat3k_caa-universalk9.16.01.[01-to-YY].SSA.bin).
• You should reboot the switch after an upgrade.
Installing WCM Sub-Package

Step 1
Upgrade controller WCM package.
request platform software package install switch all file flash: wcm_sub_package.pkg auto-copy

Step 2
(Optional) Download and install the AP image. This procedure reduces network downtime by pre-downloading and pre-programming APs with new image. Otherwise, when the controller reloads there will be a version mis-match between controller and APs and the APs will start to upgrade themselves using the new AP image, which may lead to longer downtime on the network.

Note After the download and install, wait for 30 seconds to ensure that the CLIs reach the AP.

a) Push the new image to all connected APs.
   ap image predownload
b) Monitor the progress of the download.
   show ap image
c) Point the boot variable of all APs to the new image.
   ap image swap
d) Reset the APs.
   ap image reset

Step 3
Reload the controller. After the reload, the controller reloads with new WCM package and APs reloads with new AP image and they will start joining the upgraded controller.
reload

CHAPTER 105

Configuring Right-To-Use Licenses

- Finding Feature Information, on page 2129
- Restrictions for Configuring RTU Licenses, on page 2129
- Information About Configuring RTU Licenses, on page 2130
- How to Configure RTU Licenses, on page 2133
- Monitoring and Maintaining RTU Licenses, on page 2138
- Configuration Examples for RTU Licensing, on page 2138
- Additional References for RTU Licensing, on page 2143
- Feature History and Information for RTU Licensing, on page 2144

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring RTU Licenses

The following are the restrictions for configuring and using RTU licenses.

- AP count licenses can be ordered and pre-activated on your switch.
- Imaged based licenses can be upgraded. AP count licenses can be deactivated and moved between switches and controllers.
- To activate a permanent license, you must reboot your switch after configuring the new image level. The AP-count license does not require a reboot to activate.
- An expired image based evaluation license cannot be reactivated after reboot.
- Stack members of a switch stack must run the same license level.
• Your switch is pre-installed with the image that you ordered. If an image was not pre-ordered, then the switch is booted with a LAN base image by default.

• Adder AP-count licenses are installed in the factory.

Related Topics
Activating an Image Based License, on page 2133
Examples: Activating RTU Image Based Licenses, on page 2138

Information About Configuring RTU Licenses

Right-To-Use Licensing

Right-to-use (RTU) licensing allows you to order and activate a specific license type and level, and then to manage license usage on your switch. The types of licenses available to order are:

• Permanent licenses—Purchased with a specific feature set with no expiration date.

• Evaluation licenses—Pre-installed on the switch and is valid for only a 90 day in-use period.

To activate a permanent or evaluation license, you are required to accept the End-User License Agreement (EULA).

A permanent license can be moved from one device to another. To activate a license, you must reboot your switch.

If you activate the evaluation license, it will expire in 90 days. An evaluation license is a manufacturing image on your switch and is not transferable to another switch. Once activated, this type of license cannot be deactivated until it expires. After your evaluation period expires, at the next reload your switch image will return to its default license.

Related Topics
Activating an Image Based License, on page 2133
Examples: Activating RTU Image Based Licenses, on page 2138

Right-To-Use Image-Based Licenses

Right-to-use image licenses support a set of features based on a specific image-based license:

• LAN Base—Layer 2 features.

• IP Base—Layer 2 and Layer 3 features.

• IP Services—Layer 2, Layer 3, and IPv6 features. (Applicable only to switches and not controllers.)

Right-To-Use License States

After you configure a specific license type and level, you can manage your licenses by monitoring the license state.
### Table 175: RTU License States

<td>EULA was accepted and the switch is ready to use when the license is enabled.</td>
</tr>
<tr>
<td>Not Activated</td>
<td>EULA was not accepted.</td>
</tr>
</tbody>
</table>

Guidelines to follow when monitoring your image based license state:

- A purchased permanent license is set to **Active, In Use** state only after a switch reboot.
- If more than one license was purchased, a reboot will activate the license with the highest feature set. For instance, the IP Services license is activated and not the LAN Base license.
- Remaining licenses purchased after switch reboot, stay in **Active, Not In Use** state.

**Note**  
For the AP count license, to change the state to Active, In Use, you must first make sure that the evaluation AP count license is deactivated.

### License Activation for Switch Stacks

Right-to-use licensing is supported on switch stacks. A switch is a set of up to nine stacking-capable switches connected through their StackWise-480 ports. You can connect only one switch type in a stack. One switch in the stack is identified as the active switch and the remaining switches are standby switches. The active switch is the switch that is activated with an RTU license and from its active console, the license level for the standby switches in the stack can be activated at the same time.

A new switch is allowed to join the switch stack if its license level matches. If there is a mismatch, then the active switch can reconfigure the license level and reboot it to allow it to join the stack.

### Mobility Controller Mode

AP-count licenses are used only when the switch is in Mobility Controller mode. The MC is the gatekeeper for tracking the AP-count licenses and allows an access point to join or not.

Management of AP-count licenses is performed by the mobility controller mode configurable through the CLI.

- Changing Mobility Mode, on page 2136

### Right-To-Use AP-Count Licensing

Right-to-use licensing (RTU) allows you to order and activate a specific license type, and then to manage license usage on your system.
You can order your device with support for a specific number of adder access point count licenses, but the total number of licenses ordered should not exceed 50. You can also order your adder access point count licenses after receiving the device.

For example, if you have ordered 50 new adder licenses, you can add only those ordered adder licenses to the device. The licenses can be added in increments of 1, but the total number of licenses added for the device should not exceed 50.

You can configure your switch to manage the access point count licenses and view the number of access points currently in use from the CLI.

The following are two different types of access point licenses:

1. Permanent licenses for the access points
   - Adder access point count license—You can purchase the adder license to increase the device capacity at a later time. You can transfer the adder access point count license from one device to another.

2. Evaluation licenses for the access points
   - You can activate these licenses to evaluate more access points before purchasing the licenses.
   - The maximum number of access points that can be evaluated is 50.
   - The evaluation period for using the access point licenses is 90 days.
   - You can activate and deactivate the evaluation licenses from the CLI.

Rehosting a License, on page 2136

**Right-to-Use AP-Count Evaluation Licenses**

If you are considering upgrading to a license with a higher access point count, you can try an evaluation license before upgrading to a permanent version of the license. For example, if you are using a permanent license with a 50-access-point count and want to try an evaluation license with a 100-access-point count, you can try out the evaluation license for 90 days. For example, if you are using a permanent license with a 10 access-point count and want to try an evaluation license with a 15-access-point count, you can try out the evaluation license for 90 days.

When an evaluation license is activated, the permanent AP-count licenses are ignored. The maximum supported licenses of 1000 access points are available for 90 days. The maximum supported licenses of 25 access points are available for 90 days.

To prevent disruptions in operation, the device does not change licenses when an evaluation license expires. A warning expiry message is displayed daily starting five days prior to the expiry date. After 90 days, the evaluation license expires with a warning message. You must disable the evaluation license and then purchase the permanent license.

When the device reboots after the evaluation license expiry, the license defaults to a permanent license.

Right-To-Use Adder AP-Count Rehosting Licenses

Revoking a license from one device and installing it on another is called rehosting. You might want to rehost a license to change the purpose of a device. For example, if you want to move your Office Extend or indoor access points to a different device, you could transfer the adder ap-count license from one device to another.

To rehost a license, you must deactivate the adder ap-count license from one device and activate the same license on another device.

Evaluation licenses cannot be rehosted.

How to Configure RTU Licenses

Activating an Imaged Based License

SUMMARY STEPS

1. `license right-to-use activate {ipbase | ipservices | lanbase} {all | evaluation all} [slot slot-number] [ acceptEULA]`
2. `reload [ LINE | at | cancel | in | slot stack-member-number | standby-cpu ]`
3. `show license right-to-use usage [ slot slot-number ]`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

Configuration Examples for RTU Licensing

Examples: Activating RTU Image Based Licenses

This example shows how to activate an IP Services image license and accept the EULA for a specific slot:

```
Switch# license right-to-use activate ipservices slot 1 acceptEULA
% switch-1:stack-mgr:Reboot the switch to invoke the highest activated License level
```

This example shows how to activate a license for evaluation:

```
Switch# license right-to-use activate ipservices evaluation acceptEULA
```
% switch-1:stack-mgr:Reboot the switch to invoke the highest activated License level

Example: Displaying RTU License Details

This example shows all the detailed information for the RTU licenses on slot 1:

Switch# `show license right-to-use detail slot 1`

Index 1: License Name: ipservices
Period left: Lifetime
License Type: permanent
License State: Active, In use
License Count: Non-Counted
License Location: Slot 1

Index 2: License Name: ipservices
Period left: 90
License Type: evaluation
License State: Not Activated
License Count: Non-Counted
License Location: Slot 1

Index 3: License Name: ipbase
    Period left: Lifetime
    License Type: permanent
    License State: Active, Not In use
    License Count: Non-Counted
    License Location: Slot 1

Index 4: License Name: ipbase
    Period left: 90
    License Type: evaluation
    License State: Not Activated
    License Count: Non-Counted
    License Location: Slot 1
    License Location: Standby Switch 1

Index 5: License Name: lanbase
    Period left: Lifetime
    License Type: permanent
    License State: Not Activated
    License Count: Non-Counted
    License Location: Slot 1

Index 6: License Name: apcount
    Period left: 90
    License Type: evaluation
    License State: Active, In use
    License Count: 50
    License Location: Slot 1

Index 7: License Name: apcount
    Period left: Lifetime
    License Type: base
    License State: Active, Not In use
    License Count: 0
    License Location: Slot 1

Index 8: License Name: apcount
    Period left: Lifetime
    License Type: adder
    License State: Active, Not In use
    License Count: 10
    License Location: Slot 1

Controller# show license right-to-use detail slot 1
Index 6: License Name: apcount
    Period left: Expired
    License Type: evaluation
    License State: Active, In use
    License Count: 1000
    License Location: Slot 1

Index 7: License Name: apcount
    Period left: Lifetime
    License Type: base
    License State: Active, Not In use
    License Count: 0
    License Location: Slot 1

Index 8: License Name: apcount
    Period left: Lifetime
    License Type: adder
    License State: Active, Not In use
    License Count: 0
    License Location: Slot 1
Example: Displaying RTU License Mismatch

This example shows the license information of the switches in a stack and a mismatch state of a member switch. The member must match the active.

Switch# show switch

Switch/Stack Mac Address : 6400.f125.0c80

<table>
<thead>
<tr>
<th>Switch#</th>
<th>Role</th>
<th>Mac Address</th>
<th>Priority</th>
<th>Version</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Standby</td>
<td>6400.f125.1b00</td>
<td>1</td>
<td>0</td>
<td>Ready</td>
</tr>
<tr>
<td>2</td>
<td>Active</td>
<td>6400.f125.0c80</td>
<td>1</td>
<td>V01</td>
<td>Ready</td>
</tr>
<tr>
<td>3</td>
<td>Member</td>
<td>6400.f125.1780</td>
<td>1</td>
<td>0</td>
<td>Lic-Mismatch</td>
</tr>
</tbody>
</table>

Note: To resolve the license mismatch, first check the RTU license summary:

Switch# show switch right-to-use summary

Then change the license level of the mismatched switch so that it is the same license level of the active switch. This example shows that the IP Base license was activated for the member switch to match the active switch.

Switch# license right-to-use activate ipbase slot 1 acceptEULA

Example: Displaying RTU Licensing Usage

This example shows the detailed licensing usage on your switch stack. The IP Services license in Slot 1 is permanent and usage is one day. An AP-count license in Slot 2 is ready for evaluation. EULA was accepted and state shows in use, but after reboot the evaluation license will be deactivated.

Switch# show license right-to-use usage

<table>

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Administrator Usernames and Passwords

You can configure administrator usernames and passwords to prevent unauthorized users from reconfiguring the device and viewing configuration information. This section provides instructions for initial configuration and for password recovery.

You can also set administrator usernames and passwords to manage and configure one or more access points that are associated with the device.

Strong Passwords

You can set strong administrator passwords such as encrypted passwords with ASCII keys for the administrator user for managing access points.

Use the following guidelines while creating strong passwords:
• There should be at least three of the following categories—lowercase letters, uppercase letters, and digits, and special characters.

Note Special characters are not supported for username and password for GUI login.

• The new password should not be the same as that of the associated username and the username should not be reversed.

• The characters in the password should not be repeated more than three times consecutively.

• The password should not be cisco, ocsic, admin, nimda, or any variant obtained by changing the capitalization of letters therein, or by substituting "1" for "i", or "1" for i, and/or substituting "0" for "o", and/or substituting "$" for "s".

• The maximum number of characters accepted for the username and password is 32.

Encrypted Passwords
You can set three types of keys for the password:

• Randomly generated key—This key is generated randomly and it is the most secure option. To export the configuration file from one system to another, the key should also be exported.

• Static key—The simplest option is to use a fixed (static) encryption key. By using a fixed key, no key management is required, but if the key is somehow discovered, the data can be decrypted by anyone with the knowledge of that key. This is not a secure option and it is called obfuscation in the CLI.

• User defined key—You can define the key by yourself. To export the configuration file from one system to another, both systems should have the same key configured.

Configuring Administrator Usernames and Passwords

SUMMARY STEPS

1. configure terminal
2. wireless security strong-password
3. username admin-username password {0 unencrypted_password | 7 hidden_password | unencrypted_text}
4. username admin-username secret {0 unencrypted_secret_text | 4 SHA256 encrypted_secret_text | 5 MD5 encrypted_secret_text | LINE}
5. ap mgmtuser username password {0 unencrypted_password | 8 AES encrypted password | secret {0 unencrypted_password | 8 AES encrypted password }
6. ap dot1x username password {0 unencrypted_password | 8 AES encrypted password }
7. end

### Examples: Administrator Usernames and Passwords Configuration

This example shows how to configure administrator usernames and passwords with the strong password policy in configuration mode:

```
Device# configure terminal
Device(config)# wireless security strong-password
Device(config)# username adminuser1 password 0 QSsek239@
Device(config)# ap mgmtuser username cisco password 0 Qwci12@ secret 0 Qwci14@
Device(config)# ap dot1x username cisco password 0 Qwci12@
Device# end
```

This example shows how to configure administrator usernames and passwords for an access point in global EXEC mode:

```
Device# wireless security strong-password
Device# ap name APf0f7.55c7.7b23 mgmtuser username cisco password Qwci12@ secret Qwci14@
Device# ap name APf0f7.55c7.7b23 dot1x-user username cisco password Qwci12@
Device# end
```

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Aggressive Load Balancing

- You can configure aggressive load balancing only from the command-line interface.
- Aggressive load balancing is disabled by default, you must enable it manually.
- You can enable load balancing either separately or together with the band select configurations.
- When the band select is enabled on the dual-band clients, the load balancing parameter selects only the lowest load radio from 5-GHz radios. For the 2.4-GHz clients, there is no probe information of the client on 5 GHz and therefore the load balancing algorithm can only be selected between radio on 2.4 GHz.
- You can operate load balancing of clients between access points on the same device but not for the clients between access points on the different device.
- The load balancing uses an existing association denial mechanism based on the number of client on the radio and the band select is implemented by the distributed probe response suppression on the access point only.
Information for Configuring Aggressive Load Balancing Parameters

Aggressive Load Balancing

Enabling aggressive load balancing on the controller allows lightweight access points to load balance wireless clients across access points. You can enable aggressive load balancing using the controller.

When a wireless client attempts to associate to a lightweight access point, association response packets are sent to the client with an 802.11 response packet including status code 17. The code 17 indicates that the AP is busy. The AP responds with an association response bearing 'success' if the AP threshold is not met, and with code 17 (AP busy) if the AP utilization threshold is reached or exceeded and another less busy AP heard the client request.

For example, if the number of clients on AP1 is more than the number of clients on AP2 plus the load-balancing window, then AP1 is considered to be busier than AP2. When a client attempts to associate to AP1, it receives an 802.11 response packet with status code 17, indicating that the access point is busy, and the client attempts to associate to a different access point.

You can configure the controller to deny client associations up to 10 times (if a client attempted to associate 11 times, it would be allowed to associate on the 11th try). You can also enable or disable load balancing on a particular WLAN, which is useful if you want to disable load balancing for a select group of clients (such as time-sensitive voice clients).

---

**Note**

Voice Client does not authenticate when delay is configured more than 300 ms. To avoid this configure a Central-Auth, Local Switching WLAN with CCKM, configure a Pagent Router between AP and WLC with a delay of 600 ms (300 ms UP and 300 ms DOWN and try associating the voice client.

The maximum number of client associations that the access points can support is dependent upon the following factors:

- The maximum number of client associations differs for lightweight and autonomous Cisco IOS access points.
- There may be a limit per radio and an overall limit per AP.
- AP hardware (the 16-MB APs have a lower limit than the 32-MB and higher APs)

The Client Association Limits for Lightweight Access Points are as follows:

- For 16-MB APs, the limit is 128 clients per AP. This limit is applicable to 1100 and 1200 series APs.
- For 32-MB and higher APs, there is no per-AP limit.

The maximum Client Association Limits per-radio for all of the Cisco IOS APs is 200 associations.
With 32- MB and higher lightweight Cisco IOS APs, with two radios, up to $200 + 200 = 400$ associations are supported.

The maximum Client Association Limits per Autonomous Cisco IOS access point is around 80 to 127 clients per AP. This number varies depending on the following factors:

- AP model (whether it is 16 MB or 32 MB or higher)
- Cisco IOS software release
- Hardware configuration (two radios use more memory than one)
- Enabled features (WDS functionality in particular)

The per-radio limit is about 200 associations. One association will likely hit the per-AP limit first. Unlike Cisco Unified Wireless Network, autonomous Cisco IOS supports per-SSID/per-AP association limits. This limit is configured using the max-associations CLI, under dot11 SSID. The maximum number is 255 associations (which is also the default number).

For a FlexConnect AP the association is locally handled. The load-balancing decisions are taken at the Cisco WLC. A FlexConnect AP initially responds to the client before knowing the result of calculations at the Cisco WLC. Load-balancing doesn't take effect when the FlexConnect AP is in standalone mode.

FlexConnect AP does not send (re)association response with status 17 for Load-Balancing as Local mode APs do; instead, it first sends (re)association with status 0 (success) and then deauth with reason 5.

How to Configure Aggressive Load Balancing

Configuring Aggressive Load Balancing (CLI)

**SUMMARY STEPS**

1. Set the client window for aggressive load balancing by entering this command:
2. Set the denial count for load balancing by entering this command:
3. Save your changes by entering this command:
4. Enter WLAN configuration mode by entering this command:
5. Enable load balancing on the specific WLAN by entering this command:
6. Verify your settings by entering this command:
7. Save your changes by entering this command:

**DETAILED STEPS**

**Step 1**
Set the client window for aggressive load balancing by entering this command:
**Monitoring Aggressive Load Balancing**

This section describes the new command for aggressive load balancing. The following command can be used to monitor aggressive load balancing on the.

---

**Table 176: Monitoring Aggressive Load Balancing Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>

---

**Step 1**
Set the denial count for load balancing by entering this command:

**wireless load-balancing denial denial_count**

You can enter a value between 1 and 10 for the `denial_count` parameter.

**Step 3**
Save your changes by entering this command:

**write memory**

**Step 4**
Enter WLAN configuration mode by entering this command:

**wlan profile-name wlan_ID SSID**

You can enter a profile name with up to 32 alphanumeric characters for `profile-name`. You can enter a value between 1 and 512 for `wlan_ID` parameter. You can enter a network name of up to 32 alphanumeric characters for `SSID` parameter.

**Step 5**
Enable load balancing on the specific WLAN by entering this command:

**load-balance**

You can use **no load-balance** command to disable load balancing.

**Step 6**
Verify your settings by entering this command:

**show wireless load-balancing**

---

**Monitoring Aggressive Load Balancing**

This section describes the new command for aggressive load balancing. The following command can be used to monitor aggressive load balancing on the.
show wireless load-balancing

Displays the status of the load-balancing feature.

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Configuring Client Roaming

The following are the restrictions that you should be aware while configuring client roaming:
- Cisco Compatible Extensions (CCX) support is enabled automatically for every WLAN on the device and cannot be disabled. The device stores the CCX version of the client in its client database and uses it to generate and respond to CCX frames appropriately. Clients must support CCXv4 or v5 (or CCXv2 for access point assisted roaming) to utilize these roaming enhancements.
- Client roaming between 600 Series Access points is not supported.

Information About Client Roaming

The controllers deliver high-end wireless services to the clients roaming across wireless network. Now, the wireless services are integrated with the switches, thus delivering a value-added Cisco unified new mobility
architecture. This unified architecture enables client-roaming services to both wireless and wired clients with seamless, fast-roaming services.

The new mobility architecture supports fast client roaming services using logical categorization of network into Mobility Domains (MDs), Mobility Groups (MGs), Mobility Subdomains (MSDs), and Switch Peer Groups (SPGs) using systems such as Mobility Oracle (MO), Mobility Controller (MC), and Mobility Agent (MA).

- **A Mobility Domain** is the entire domain across which client roaming is supported. It is a collection of mobility groups. For example, a campus network can be considered as a mobility domain.

- **A Mobility Group** is a collection of mobility subdomains across which fast roaming is supported. The mobility group can be one or more buildings within a campus across which frequent roaming is supported.

- **A Mobility Subdomain** is an autonomous portion of the mobility domain network. Each mobility subdomain contains one mobility controller (MC) and a collection of SPGs. A subdomain is equivalent to an 802.11r key domain.

- **A Switch Peer Group** is a collection of mobility agents.

- The **Mobility Oracle** acts as the point of contact for mobility events that occur across mobility subdomains. The mobility oracle also maintains a local database of each client in the entire mobility domain, their home and current subdomain. There is only one MO for an entire mobility domain. The Cisco WLC 5700 Series Controllers or Cisco Unified Wireless Networking Solution controller can act as MO.

- The **Mobility Controller** provides mobility management services for inter-SPG roaming events. The MC sends the configuration like SPG name and SPG peer member list to all of the mobility agents under its subdomain. The Cisco WLC 5700 Series Controllers, Cisco Catalyst 3850 Switch, or Cisco Unified Wireless Networking Solution controller can act as MC. The MC has MC functionality and MA functionality that is running internally into it.

- **The Mobility Agent** is the component that maintains client mobility state machine for a mobile client. All APs are connected to the mobility agent.

The New mobility architecture supports seamless roaming in the following scenarios:

- **Intra-switch roaming**—The client roaming between APs managed by same mobility agent.

- **Intra-SPG roaming**—The client roaming between mobility agents in the same SPG.

- **Inter-SPG, Intra-subdomain roaming**—The client roaming between mobility agents in different SPGs within the same subdomain.

- **Inter-subdomain roaming**—The client roaming between mobility agents across a subdomain.

**Fast Roaming**

New mobility architecture supports fast roaming when clients roam within a mobility group by eliminating the need for full authentication. Security polices should be same across the switches for fast roaming.

**Local, anchor, foreign MAs and MCs**

When a client joins an MA initially and its point of attachment has not changed, that MA is referred as local or associated MA. The MC to which this MA is associated is referred as local or associated MC.

When a client roams between two MAs, the MA to which the client was previously associated is the anchor MA (point of attachment) and the MA to which the client is currently associated is the foreign or associated
MA (point of presence). The MCs to which these MAs are associated are referred as anchor, foreign, or associated MCs, respectively.

**Inter-Subnet Roaming**

Multiple-controller deployments support client roaming across access points managed by controllers in the same mobility group on different subnets. This roaming is transparent to the client because the session is sustained and a tunnel between the controllers allows the client to continue using the same DHCP-assigned or client-assigned IP address as long as the session remains active. The tunnel is torn down, and the client must reauthenticate when the client sends a DHCP Discover with a 0.0.0.0 client IP address or a 169.254.*.* client auto-IP address or when the operator-set user timeout is exceeded.

**Voice-over-IP Telephone Roaming**

802.11 voice-over-IP (VoIP) telephones actively seek out associations with the strongest RF signal to ensure the best quality of service (QoS) and the maximum throughput. The minimum VoIP telephone requirement of 20-millisecond or shorter latency time for the roaming handover is easily met by the Cisco Wireless solution, which has an average handover latency of 5 or fewer milliseconds when open authentication is used. This short latency period is controlled by controllers rather than allowing independent access points to negotiate roaming handovers.

The Cisco Wireless solution supports 802.11 VoIP telephone roaming across lightweight access points managed by controllers on different subnets, as long as the controllers are in the same mobility group. This roaming is transparent to the VoIP telephone because the session is sustained and a tunnel between controllers allows the VoIP telephone to continue using the same DHCP-assigned IP address as long as the session remains active. The tunnel is torn down, and the VoIP client must reauthenticate when the VoIP telephone sends a DHCP Discover with a 0.0.0.0 VoIP telephone IP address or a 169.254.*.* VoIP telephone auto-IP address or when the operator-set user timeout is exceeded.

**CCX Layer 2 Client Roaming**

The controller supports five CCX Layer 2 client roaming enhancements:

- **Access point assisted roaming**—This feature helps clients save scanning time. When a CCXv2 client associates to an access point, it sends an information packet to the new access point listing the characteristics of its previous access point. Roaming time decreases when the client recognizes and uses an access point list built by compiling all previous access points to which each client was associated and sent (unicast) to the client immediately after association. The access point list contains the channels, BSSID of neighbor access points that support the client’s current SSID(s), and time elapsed since disassociation.

- **Enhanced neighbor list**—This feature focuses on improving a CCXv4 client’s roam experience and network edge performance, especially when servicing voice applications. The access point provides its associated client information about its neighbors using a neighbor-list update unicast message.

- **Enhanced neighbor list request (E2E)**—The End-2-End specification is a Cisco and Intel joint program that defines new protocols and interfaces to improve the overall voice and roaming experience. It applies only to Intel clients in a CCX environment. Specifically, it enables Intel clients to request a neighbor list at will. When this occurs, the access point forwards the request to the controller. The controller receives the request and replies with the current CCX roaming sublist of neighbors for the access point to which the client is associated.
How to Configure Layer 2 or Layer 3 Roaming

Configuring Layer 2 or Layer 3 Roaming

Before you begin

To configure the mobility agent for Layer 2 or Layer 3 roaming, the following requisites should be considered:

- SSID and security polices should be same across MAs for Layer 2 and Layer 3 roaming.
- Client VLAN ID should be same for Layer 2 roaming and different for Layer 3 roaming.
- Bridge domain ID and client VLAN IDs should be same for Layer 2 roaming. Either one or both of the bridge domain ID and client VLAN ID should be different for Layer 3 roaming.

SUMMARY STEPS

1. `configure terminal`
2. `wlan wlan_profile_name wlan_ID SSID_network_name`
3. `no mobility anchor sticky`
4. `end`

DETAILED STEPS

<tr>
<td></td>
<td>ap dot11 {5ghz</td>
<td>24ghz} l2roam rf-params {default</td>
</tr>
<tr>
<td></td>
<td>Example: Device#ap dot11 5ghz l2roam rf-params custom -80</td>
<td>To choose the default RF parameters, enter the <strong>default</strong> option.</td>
</tr>
</tbody>
</table>

To fine-tune the RF parameters that affect client roaming, enter the **custom** option and then enter any one of the following options:

- **Minimum RSSI**—Indicates minimum Received Signal Strength Indicator (RSSI) required for the client to associate to an access point.

  If the client’s average received signal power dips below this threshold, reliable communication is usually impossible. Therefore, clients must already have found and roamed to another access point with a stronger signal before the minimum RSSI value is reached.

  You can configure the minimum RSSI range from –50 through –90 dBm and the default value is –85 dBm.

- **Hysteresis**—Indicates how much greater the signal strength of a neighboring access point must be for the client to roam to it.
### Configuring CCX Client Roaming Parameters (CLI)

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This parameter is intended to reduce the amount of roaming between access points if the client is physically located on or near the border between two access points. You can configure the hysteresis range from 3 through 20 dB and the default is 3 dB.</td>
</tr>
<tr>
<td>• Scan Threshold—Indicates a minimum RSSI that is allowed before the client should roam to a better access point. When the RSSI drops below the specified value, the client must be able to roam to a better access point within the specified transition time. This parameter also provides a power-save method to minimize the time that the client spends in active or passive scanning. For example, the client can scan slowly when the RSSI is above the threshold and scan more rapidly when the RSSI is below the threshold. You can configure the RSSI range from –50 through –90 dBm and the default value is –72 dBm.</td>
<td></td>
</tr>
<tr>
<td>• Transition Time—Indicates the maximum time allowed for the client to detect a suitable neighboring access point to roam to and to complete the roam, whenever the RSSI from the client’s associated access point is below the scan threshold. The Scan Threshold and Transition Time parameters guarantee a minimum level of client roaming performance. Together with the highest expected client speed and roaming hysteresis, these parameters make it possible to design a wireless LAN network that supports roaming simply by ensuring a certain minimum overlap distance between access points. You can configure the time period in the range from 1 through 5 seconds and the default time is 5 seconds.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 3**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

**switch-peer-group-name**  
**Example:**  
Device(config)# wireless mobility controller peer-group SPG1 | Configures a switch peer group name. You can enter up to 31 case-sensitive ASCII printable characters for the group name. Spaces are not allowed in mobility group.  
**Note** The No form of the command deletes the switch peer group. |
| **Step 4** | **wireless mobility controller peer-group**  
**switch-peer-group-name**  
**member ip**  
**ip-address**  
**public-ip public-ip-address**  
**Example:**  
Device(config)# wireless mobility controller peer-group SPG1 member ip 10.0.0.1 | Adds a mobility group member to a switch peer group.  
**Note** The No form of the command deletes the member from the switch peer group. |
| **Step 5** | **wireless mobility controller peer-group**  
**switch-peer-group-name**  
**multicast**  
**Example:**  
Device(config)# wireless mobility controller peer-group SPG1 multicast | Configures the multicast mode within a switch peer group. |
| **Step 6** | **wireless mobility controller peer-group**  
**switch-peer-group-name**  
**multicast ip**  
**peer-group-multicast-ip-addr**  
**Example:**  
Device(config)# wireless mobility controller peer-group SPG1 multicast ip 10.0.0.4 | Configures the multicast IP address for a switch peer group.  
**Note** The No form of the command deletes the multicast IP for the switch peer group. |
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 7    | wireless mobility controller peer-group switch-peer-group-name bridge-domain-id id | Configures the bridge domain ID for a switch peer group. The default is zero.  
**Example:**  
Device(config)# wireless mobility controller peer-group SPG bridge-domain-id 10.0.0.5 |
| 8    | wireless mobility group member ip ip-address [public-ip public-ip-address] [group group-name] | Adds a mobility group member.  
**Note** The No form of the command removes the member from the group. The default group name is the group name of MC.  
**Example:**  
Device(config)# wireless mobility group member ip 10.0.0.1 |
| 9    | wireless mobility dscp value | Sets the DSCP value for mobility control packet.  
You can configure the DSCP value in a range from 0 through 63. The default value is 46.  
**Example:**  
Device(config)# wireless mobility dscp 46 |
| 10   | wireless mobility group keepalive {count | interval} | Configures the wireless mobility group keepalive count which is the number of keepalive retries before a member status is termed DOWN and keepalive interval which is interval between two keepalives.  
**Example:**  
Device(config)# wireless mobility group keepalive count |
| 11   | wireless mobility group name name | Specifies the case sensitive wireless mobility group name which can be ASCII printable string up to 31 characters.  
**Example:**  
Device(config)# wireless mobility group name group1 |
| 12   | wireless mobility oracle ip mo-ip-address | Configures the mobility oracle IP address.  
**Example:**  
Device(config)# wireless mobility oracle ip 10.0.0.5 |
| 13   | wireless management interface interface-name | Configures the wireless management interface.  
**Example:**  
Device(config)# wireless management interface Vlan21 |
| 14   | end | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.  
**Example:**  
Device(config)# end |
Configuring Mobility Agent

SUMMARY STEPS

1. configure terminal
2. wireless mobility controller ip ip-address
3. wireless mobility load-balance
4. wireless mobility load-balance threshold threshold-value
5. wireless management interface interface-name
6. end

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Application Visibility and Control

Application Visibility and Control (AVC) classifies applications using deep packet inspection techniques with the Network-Based Application Recognition engine, and provides application-level visibility and control (QoS) in wireless networks. After the applications are recognized, the AVC feature enables you to either drop, mark, or police the data traffic.

AVC is configured by defining a class map in a QoS client policy to match a protocol.

Using AVC, we can detect more than 1000 applications. AVC enables you to perform real-time analysis and create policies to reduce network congestion, costly network link usage, and infrastructure upgrades.
You can view list of 30 applications in Top Applications in Monitor Summary section of the UI.

Traffic flows are analyzed and recognized using the NBAR2 engine at the access point. For more information about the NBAR2 Protocol Library, see [http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/qos_nbar/prot_lib/config_library/nbar-prot-pack-library.html](http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/qos_nbar/prot_lib/config_library/nbar-prot-pack-library.html). The specific flow is marked with the recognized protocol or application, such as WebEx. This per-flow information can be used for application visibility using Flexible NetFlow (FNF).

AVC QoS actions are applied with AVC filters in both upstream and downstream directions. The QoS actions supported for upstream flow are drop, mark, and police, and for downstream flow are mark and police. AVC QoS is applicable only when the application is classified correctly and matched with the class map filter in the policy map. For example, if the policy has a filter based on an application name, and the traffic has also been classified to the same application name, then the action specified for this match in the policy will be applied. For all QoS actions, refer Supported AVC Class Map and Policy Map Formats, on page 2172.

**Application Visibility and Control Protocol Packs**

Protocol packs are a means to distribute protocol updates outside the controller software release trains, and can be loaded on the controller without replacing the controller software.

The Application Visibility and Control Protocol Pack (AVC Protocol Pack) is a single compressed file that contains multiple Protocol Description Language (PDL) files and a manifest file. A set of required protocols can be loaded, which helps AVC to recognize additional protocols for classification on your network. The manifest file gives information about the protocol pack, such as the protocol pack name, version, and some information about the available PDLs in the protocol pack.

The AVC Protocol Packs are released to specific AVC engine versions. You can load a protocol pack if the engine version on the controller platform is the same or higher than the version required by the protocol pack.

**Supported AVC Class Map and Policy Map Formats**

### Supported AVC Class Map Format

<table>
<thead>
<tr>
<th>Class Map Format</th>
<th>Class Map Example</th>
<th>Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>match protocol protocol name</strong></td>
<td>class-map match-any webex-class match protocol webex-media</td>
<td>Both upstream and downstream</td>
</tr>
<tr>
<td><strong>match protocol attribute category-name</strong></td>
<td>class-map match-any IM match protocol attribute category instant-messaging</td>
<td>Both upstream and downstream</td>
</tr>
<tr>
<td><strong>match protocol attribute sub-category sub-category-name</strong></td>
<td>class-map match-any realtimeconferencing match protocol attribute sub-category voice-video-chat-collaboration</td>
<td>Both upstream and downstream</td>
</tr>
</tbody>
</table>
### Supported AVC Class Map and Policy Map Formats

#### Class Map Format

<table>
<thead>
<tr>
<th>Direction</th>
<th>Class Map Example</th>

  set dscp ef  
  class class-webex-category  
  police 200000  
  set dscp af31 | |
| Drop action                       | Any of the above examples apply to this format with this additional example:  
  policy-map webex-policy  
  class webex-class  
  drop  
  class netflix  
  set dscp ef //or set up,cos  
  police 6000000  
  class class-default  
  set dscp <> | Upstream only |

### Prerequisites for Application Visibility and Control

- The access points should be AVC capable.
- For the control part of AVC (QoS) to work, the application visibility feature with FNF has to be configured.
Guidelines for Inter-Device Roaming with Application Visibility and Control

Follow these guidelines to prevent clients from getting excluded due to malformed QoS policies:

- When a new QoS policy is added to the device, a QoS policy with the same name should be added to other device within the same roam or mobility domain.

- When a device is loaded with a software image of a later release, the new policy formats are supported. If you have upgraded the software image from an earlier release to a later release, you should save the configuration separately. When an earlier release image is loaded, some QoS policies might show as not supported, and you should restore those QoS policies to supported policy formats.

Restrictions for Application Visibility and Control

- AVC is supported only on the following access points:
  - Cisco Aironet 1260 Series Access Points
  - Cisco Aironet 1600 Series Access Points
  - Cisco Aironet 2600 Series Access Point
  - Cisco Aironet 2600 Series Wireless Access Points
  - Cisco Aironet 2700 Series Access Point
  - Cisco Aironet 3500 Series Access Points
  - Cisco Aironet 3600 Series Access Points

- AVC is not supported on Cisco Aironet 702W, 702I (128 M memory), and 1530 Series Access Points.

- Dropping or marking of the data traffic (control part) is not supported for software Release 3.3.

- Dropping or marking of the data traffic (control part) is supported in software Release 3E.

- Only the applications that are recognized with application visibility can be used for applying QoS control.

- Multicast traffic classification is not supported.

- Only the applications that are recognized with App visibility can be used for applying QoS control.

- IPv6 including ICMPv6 traffic classifications are not supported.

- Datalink is not supported for NetFlow fields for AVC.

- The following commands are not supported for AVC flow records:

  - `collect flow username`
  - `collect interface { input | output }
  - `collect wireless client ipv4 address`
  - `match interface { input | output }
  - `match transport igmp type`

- The template timeout cannot be modified on exporters configured with AVC. Even if the template timeout value is configured to a different value, only the default value of 600 seconds is used.
• For the username information in the AVC-based record templates, ensure that you configure the options records to get the user MAC address to username mapping. For more information, refer Creating a Flow Exporter (Optional), on page 2179.

• When there is a mix of AVC-enabled APs such as 3600, and non-AVC-enabled APs such as 1140, and the chosen policy for the client is AVC-enabled, the policy will not be sent to the APs that cannot support AVC.

• Only ingress AVC statistics are supported. The frequency of statistics updates depends on the number of clients loaded at the AP at that time. Statistics are not supported for very large policy format sizes.

• The total number of flows for which downstream AVC QoS supported per client is 1000.

• The maximum number of flows supported for Catalyst 3850 Series Switch is 48 K.

• These are some class map and policy map-related restrictions. For supported policy formats, see Supported AVC Class Map and Policy Map Formats, on page 2172.
  • AVC and non-AVC classes cannot be defined together in a policy in a downstream direction. For example, when you have a class map with match protocol, you cannot use any other type of match filter in the policy map in the downstream direction.
  • Drop action is not applicable for the downstream AVC QoS policy.
  • Match protocol is not supported in ingress or egress for SSID policy.

• Google shares resources among several of their services because of which for some of the traffic it is not possible to say it is unique to one application. Therefore we added google-services for traffic that cannot be distinguished. The behavior you experience is expected.

How to Configure Application Visibility and Control

Configuring Application Visibility and Control (CLI)

To configure Application Visibility, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.
2. Create an optional flow exporter by specifying the flow record as an option.
3. Create a flow monitor based on the flow record and flow exporter.
4. Configure WLAN to apply flow monitor in IPv4 input or output direction.

To configure Application Control, follow these general steps:

1. Create an AVC QoS policy.
2. Attach AVC QoS policy to the client in one of three ways: configuring WLAN, using ACS or ISE, or adding local policies.

Creating a Flow Record

By default, wireless avc basic (flow record) is available. When you click Apply from the GUI, then the record is mapped to the flow monitor.
Default flow record cannot be edited or deleted. If you require a new flow record, you need to create one and map it to the flow monitor from CLI.

### SUMMARY STEPS

1. configure terminal
2. flow record *flow_record_name*
3. description *string*
4. match ipv4 protocol
5. match ipv4 source address
6. match ipv4 destination address
7. match transport source-port
8. match transport destination-port
9. match flow direction
10. match application name
11. match wireless ssid
12. collect counter bytes long
13. collect counter packets long
14. collect wireless ap mac address
15. collect wireless client mac address
16. end

</tbody>
</table>
### Creating a Flow Exporter (Optional)

You can create a flow export to define the export parameters for a flow. This is an optional procedure for configuring flow parameters.

#### SUMMARY STEPS

1. `configure terminal`
2. `flow exporter flow_exporter_name`
3. `description string`
4. `destination {hostname | ip-address}`
5. `transport udp port-value`
6. `option application-table timeout seconds (optional)`
7. `option usermac-table timeout seconds (optional)`
8. `end`
9. `show flow exporter`
10. `end`

## Creating a Flow Monitor

You can create a flow monitor and associate it with a flow record and a flow exporter.

### SUMMARY STEPS

1. `configure terminal`
2. `flow monitor monitor-name`
3. `description description`
4. `record record-name`
5. `exporter exporter-name`
6. `cache timeout {active | inactive} (Optional)`
7. `end`
8. `show flow monitor`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> flow monitor monitor-name</td>
<td>Creates a flow monitor and enters flow monitor</td>
</tr>
<tr>
<td>Example:</td>
<td>configuration mode.</td>
</tr>
<tr>
<td>Device (config)# flow monitor flow-monitor-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> description description</td>
<td>Creates a description for the flow monitor.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device (config-flow-monitor)# description flow-monitor-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> record record-name</td>
<td>Specifies the name of a recorder that was created</td>
</tr>
<tr>
<td>Example:</td>
<td>previously.</td>
</tr>
<tr>
<td>Device (config-flow-monitor)# record flow-record-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> exporter exporter-name</td>
<td>Specifies the name of an exporter that was created</td>
</tr>
<tr>
<td>Example:</td>
<td>previously.</td>
</tr>
<tr>
<td>Device (config-flow-monitor)# exporter flow-exporter-1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> cache timeout (active</td>
<td>in inactive) (Optional)</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device (config-flow-monitor)# cache timeout active 1800</td>
<td>You can configure for a time period of 1 to 604800 seconds (optional).</td>
</tr>
<tr>
<td>Device (config-flow-monitor)# cache timeout inactive 200</td>
<td>Note  To achieve optimal result for the AVC flow monitor, we recommend you to configure the inactive cache timeout value to be greater than 90 seconds.</td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> show flow monitor</td>
<td>Verifies your configuration.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device # show flow monitor</td>
<td></td>
</tr>
</tbody>
</table>

### Creating AVC QoS Policy

To create AVC QoS policy, perform these general steps:

1. Create a class map with match protocol filters.
2. Create a policy map.
3. Apply a policy map to the client in one of the following ways:
   1. Apply a policy map over WLAN either from the CLI or GUI.
   2. Apply a policy map through the AAA server (ACS server or ISE) from the CLI.
      For more information, refer to the Cisco Identity Services Engine User Guide and Cisco Secure Access
      Control System User Guide.
   3. Apply local policies either from the CLI or GUI.

Creating a Class Map

You need to create a class map before configuring any match protocol filter. The QoS actions such as marking,
policing, and dropping can be applied to the traffic. The AVC match protocol filters are applied only for the
wireless clients. Refer 8.0 protocol pack for the protocols supported.

SUMMARY STEPS

1. configure terminal
2. class-map class-map-name
3. match protocol { application-name | attribute category category-name | attribute sub-category sub-category-name | attribute application-group application-group-name }
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> class-map class-map-name</td>
<td>Creates a class map.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# class-map webex-class</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> match protocol { application-name</td>
<td>attribute category category-name</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config)# class-map webex-class</td>
<td></td>
</tr>
<tr>
<td>Device(config-cmap)# match protocol webex-media</td>
<td></td>
</tr>
<tr>
<td>Device(config)# class-map class-webex-category</td>
<td></td>

</tbody>
</table>
Creating a Policy Map

**SUMMARY STEPS**

1. `configure terminal`
2. `policy-map policy-map-name`
3. `class [class-map-name | class-default]`
4. `police rate-bps burst-byte [exceed-action {drop | policed-dscp-transmit}]`
5. `set {dscp new-dscp | cos cos-value}`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>policy-map policy-map-name</code></td>
<td>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</td>
</tr>
</tbody>
</table>
|  | Example: `Device(config)# policy-map webex-policy`
  `Device(config-pmap)#` | By default, no policy maps are defined. The default behavior of a policy map is to set the DSCP to 0 if the packet is an IP packet and to set the CoS to 0 if the packet is tagged. No policing is performed. |
| **Step 3** | `class [class-map-name | class-default]` | Defines a traffic classification, and enters policy-map class configuration mode. |
|  | Example: `Device(config-pmap)# class-map webex-class`
  `Device(config-pmap-c)#` | By default, no policy map and class maps are defined. If a traffic class has already been defined by using the `class-map` global configuration command, specify its name for `class-map-name` in this command. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>A class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any is included in the class-default class, all packets that have not already matched the other traffic classes will match class-default.</td>
<td></td>
</tr>
<tr>
<td>Note: To delete an existing class map, use the no class class-map-name policy-map configuration command.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>**police rate-bps burst-byte [exceed-action {drop</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-pmap-c)# police 100000 80000 drop</td>
</tr>
<tr>
<td>Defines a policer for the classified traffic. By default, no policer is defined.</td>
<td></td>
</tr>
<tr>
<td>• For rate-bps, specify an average traffic rate in bits per second (b/s). The range is 8000 to 10000000000.</td>
<td></td>
</tr>
<tr>
<td>• For burst-byte, specify the normal burst size in bytes. The range is 8000 to 1000000.</td>
<td></td>
</tr>
<tr>
<td>• (Optional) Specifies the action to take when the rates are exceeded. Use the exceed-action drop keywords to drop the packet. Use the exceed-action policed-dscp-transmit keywords to mark down the DSCP value (by using the policed-DSCP map) and to send the packet.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>**set {dscp new-dscp</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-pmap-c)# set dscp 45</td>
</tr>
<tr>
<td>Classifies IP traffic by setting a new value in the packet.</td>
<td></td>
</tr>
<tr>
<td>• For dscp new-dscp, enter a new DSCP value to be assigned to the classified traffic. The range is 0 to 63.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>end</strong></td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
</tr>
<tr>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
<td></td>
</tr>
</tbody>
</table>

**What to do next**

After creating your policy maps, attach the traffic policy or polices to an interface using the service-policy command.

**Configuring Local Policies (CLI)**

**Configuring Local Policies (CLI)**

To configure local policies, complete these procedures:

1. Create a service template.
2. Create an interface template.
3. Create a parameter map.
4. Create a policy map.
5. Apply a local policy on a WLAN.

Creating a Service Template (CLI)

**SUMMARY STEPS**

1. `configure terminal`
2. `service-template service-template-name`
3. `access-group acl_list`
4. `vlan vlan_id`
5. `absolute-timer seconds`
6. `service-policy qos {input | output}`
7. `end`

**DETAILED STEPS**

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
Creating a Parameter Map (CLI)

Parameter map is preferred to use than class map.

SUMMARY STEPS

1. configure terminal
2. parameter-map type subscriber attribute-to-service parameter-map-name
3. map-index map { device-type | mac-address | oui | user-role | username } { eq | not-eq | regex filter-name }
4. interface-template interface-template-name
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> parameter-map type subscriber attribute-to-service parameter-map-name</td>
<td>Specifies the parameter map type and name.</td>
</tr>
<tr>
<td>Example: Device(config)# parameter-map type subscriber attribute-to-service Aironet-Policy-para</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> map-index map { device-type</td>
<td>mac-address</td>
</tr>
<tr>
<td>Example: Device(config-parameter-map-filter)# 10 map device-type eq “WindowsXP-Workstation”</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface-template interface-template-name</td>
<td>Enters service template configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config-parameter-map-filter-submode)#</td>
<td></td>
</tr>
</tbody>
</table>
## Creating a Policy Map (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `policy-map type control subscriber policy-map-name`
3. `event identity-update {match-all | match-first}`
4. `class_number class {class_map_name | always } {do-all | do-until-failure | do-until-success}`
5. `action-index map attribute-to-service table parameter-map-name`
6. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: <code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>policy-map type control subscriber policy-map-name</code></td>
<td>Specifies the policy map type.</td>
</tr>
<tr>
<td>Example: <code>Device(config)# policy-map type control subscriber Aironet-Policy</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> `event identity-update {match-all</td>
<td>match-first}`</td>
</tr>
<tr>
<td>Example: <code>Device(config-policy-map)# event identity-update match-all</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> `class_number class {class_map_name</td>
<td>always } {do-all</td>
</tr>
</tbody>
</table>

<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
| Device(config-class-control-policymap)# 1 class local_policy1_class do-until-success | **• always**—Executes without doing any matching but return success.  
**• do-all**—Executes all the actions.  
**• do-until-failure**—Execute all the actions until any match failure is encountered. This is the default value.  
**• do-until-success**—Execute all the actions until any match success happens. |

**Step 5**

action-index map attribute-to-service table parameter-map-name

Example:

Device(config-policy-map)# 10 map attribute-to-service table Aironet-Policy-para

Specifies parameter map table to be used.

**Step 6**

end

Example:

Device(config)# end

Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

### Configuring WLAN to Apply Flow Monitor in IPV4 Input/Output Direction

**SUMMARY STEPS**

1. configure terminal
2. wlan wlan-id
3. ip flow monitor monitor-name {input | output}
### Monitoring Application Visibility and Control

#### Monitoring Application Visibility and Control (CLI)

This section describes the new commands for application visibility.

The following commands can be used to monitor application visibility on the access points.

**Table 182: Monitoring Application Visibility Commands on the**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show avc client client-mac top n application [aggregate</td>
<td>upstream</td>
</tr>
<tr>
<td>`show avc wlan ssid top n application [aggregate</td>
<td>upstream</td>
</tr>
<tr>
<td>`avc top user [enable</td>
<td>disable]`</td>
</tr>
<tr>
<td>`show avc wlan wlan-id application app name top N [aggregate</td>
<td>upstream</td>
</tr>
</tbody>
</table>
show wlan id wlan-id
Displays information whether AVC is enabled or disabled on a particular WLAN.

show flow monitor flow_monitor_name cache
Displays information about flow monitors.

show wireless client mac-address mac-address service-policy { input | output }
Displays information about policy mapped to the wireless clients.

show ip nbar protocol-discovery [interface interface-type interface-number] [stats [byte-count | bit-rate | packet-count | max-bit-rate] [protocol protocol-name | top-n number]]
Displays the statistics gathered by the NBAR Protocol Discovery feature.
  • (Optional) Enter keywords and arguments to fine-tune the statistics displayed. For more information on each of the keywords, refer to the show ip nbar protocol-discovery command in Cisco IOS Quality of Service Solutions Command Reference.

Note: When you configure NBAR, you must enable Protocol Discovery on the interface.

show policy-map target
show policy-map
show policy-map policy-name
show policy-map interface interface-type interface-number
Displays information about policy map.

Table 183: Clearing Application Visibility Statistics Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear avc client mac stats</td>
<td>Clears the statistics per client.</td>
</tr>
<tr>
<td>clear avc wlan wlan-name stats</td>
<td>Clears the statistics per WLAN.</td>
</tr>
</tbody>
</table>

Examples: Application Visibility and Control

Examples: Application Visibility Configuration

This example shows how to create a flow record, create a flow monitor, apply the flow record to the flow monitor, and apply the flow monitor on a WLAN:

Device# configure terminal
Device(config)# flow record fr_v4
Device(config-flow-record)# match ipv4 protocol
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Examples: Application Visibility and Control QoS Configuration

This example shows how to create class maps with apply match protocol filters for application name, category, and subcategory:

```
Device# configure terminal
Device(config)# class-map cat-browsing
Device(config-cmap)# match protocol attribute category browsing
Device(config-cmap)# end

Device# configure terminal
Device(config)# class-map cat-fileshare
Device(config-cmap)# match protocol attribute category file-sharing
Device(config-cmap)# end

Device# configure terminal
Device(config)# class-map match-any subcat-terminal
Device(config-cmap)# match protocol attribute sub-category terminal
Device(config-cmap)# end

Device# configure terminal
Device(config)# class-map match-any webex-meeting
Device(config-cmap)# match protocol webex-meeting
Device(config-cmap)# end
```

This example shows how to create policy maps and define existing class maps for upstream QoS:

```
Device# configure terminal
Device(config)# policy-map test-avc-up
Device(config-pmap)# class cat-browsing
Device(config-pmap-c)# police 150000
Device(config-pmap-c)# set dscp 12
Device(config-pmap-c)# end

Device# configure terminal
Device(config)# policy-map test-avc-up
```
This example shows how to create policy maps and define existing class maps for downstream QoS:

```
Device# configure terminal
Device(config)# policy-map test-avc-down
Device(config-pmap)# class cat-browsing
Device(config-pmap-c)# police 200000
Device(config-pmap-c)# set dscp 10
Device(config-pmap-c)#end

Device# configure terminal
Device(config)# policy-map test-avc-up
Device(config-pmap)# class webex-meeting
Device(config-pmap-c)# police 60000000
Device(config-pmap-c)# set dscp 41
Device(config-pmap-c)#end

This example shows how to apply defined QoS policy on a WLAN:

```
Device# configure terminal
Device(config)# wlan alpha
Device(config-wlan)# shut
Device(config-wlan)#end
Device(config-wlan)# service-policy client input test-avc-up
```
Example: Configuring QoS Attribute for Local Profiling Policy

The following example shows how to configure QoS attribute for a local profiling policy:

```
Device(config)# class-map type control subscriber match-all local_policy1_class
Device(config-filter-control-classmap)# match device-type android
Device(config)# service-template local_policy1_template
Device(config-service-template)# vlan 40
Device(config-service-template)# service-policy qos output local_policy1
Device(config)# policy-map type control subscriber local_policy1
Device(config-event-control-policymap)# event identity-update match-all
Device(config-class-control-policymap)# 1 class local_policy1_class do-until-success
Device(config-action-control-policymap)# 1 activate service-template local_policy1_template
Device(config)# wlan open_auth 9
Device(config-wlan)# client vlan VLAN40
Device(config-wlan)# service-policy type control subscriber local_policy1
```

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Voice and Video Parameters

You can confirm the following points before configuring voice and video parameters:

- Ensure that the device has access points connected to it.
- Configure SSID.

Restrictions for Voice and Video Parameters

The following are the restrictions that you should keep in mind while configuring voice and video parameters:

- SIP CAC can be used for the 9971 Cisco phones that support TSPEC-based admission control. You can also use the phones that support Status code 17.
• SIP snooping is supported for providing voice priority to the non-TSPEC SIP phones.
• TSPEC for video CAC is not supported.
• Cisco 792x IP phones that are admitted as non-WMM devices with 11K enabled will experience audio problems with the phones.

Note
Disable 11K for voice WLAN for all 792x Cisco IP phones that are admitted as non-WMM devices with 11K enabled. Upgrade the firmware on Cisco Unified Call Manager to 1.4.5 to resolve this issue. Refer to the Cisco Unified Call Manager configuration guide for more information.

Information About Configuring Voice and Video Parameters

Three parameters on the device affect voice and/or video quality:

• Call Admission Control
• Expedited bandwidth requests
• Unscheduled automatic power save delivery

Call Admission Control (CAC) and UAPSD are supported on Cisco Compatible Extensions (CCX) v4 and v5; however, these parameters are also supported even without CCX but on any device implementing WMM (that supports 802.1e). Expedited bandwidth requests are supported only on CCXv5.

Traffic stream metrics (TSM) can be used to monitor and report issues with voice quality.

Call Admission Control

Call Admission Control (CAC) enables an access point to maintain controlled quality of service (QoS) when the wireless LAN is experiencing congestion. The WMM protocol deployed in CCXv4 maintains QoS under differing network loads.

Two types of Over The Air (OTA) CAC are available: static-based CAC and load-based CAC.

The device supports the following QoS policies:

• User-defined policies: You can define your own QoS policies. You can have more control over these policies than the existing metal policies.
• System-defined precious metal policies: To support backward compatibility.
  • Platinum: Used for VoIP clients.
  • Gold: Used for video clients.
  • Silver: Used for best effort traffic.
  • Bronze: Used for NRT traffic.
Static-Based CAC

Voice over WLAN applications supporting WMM and TSPEC can specify how much bandwidth or shared medium time is required to initiate a call. Bandwidth-based, or static, CAC enables the access point to determine whether it is capable of accommodating a particular call. The access point rejects the call if necessary in order to maintain the maximum allowed number of calls with acceptable quality.

The QoS setting for a WLAN determines the level of bandwidth-based CAC support. To use bandwidth-based CAC with voice applications, the WLAN must be configured for Platinum QoS. With bandwidth-based CAC, the access point bandwidth availability is determined based on the amount of bandwidth currently used by the access point clients, to which the bandwidth requested by the Voice over WLAN applications is added. If this total exceeds a configured bandwidth threshold, the new call is rejected.

Note: You must enable admission control (ACM) for CCXv4 clients that have WMM enabled. Otherwise, bandwidth-based CAC does not operate properly for these CCXv4 clients.

Load-Based CAC

Load-based CAC incorporates a measurement scheme that takes into account the bandwidth consumed by all traffic types (including that from clients), cochannel access point loads, and coallocated channel interference, for voice and video applications. Load-based CAC also covers the additional bandwidth consumption resulting from PHY and channel impairment.

In load-based CAC, the access point continuously measures and updates the utilization of the RF channel (that is, the mean time of bandwidth that has been exhausted), channel interference, and the additional calls that the access point can admit. The access point admits a new call only if the channel has enough unused bandwidth to support that call. By doing so, load-based CAC prevents oversubscription of the channel and maintains QoS under all conditions of WLAN loading and interference.

Note: If you disable load-based CAC, the access points start using bandwidth-based CAC.

IOSd Call Admission Control

IOSd Call Admission Control (CAC) controls bandwidth availability from device to access point.

You can configure class-based, unconditional packet marking features on your switch for CAC.

CAC is a concept that applies to voice and video traffic only—not data traffic. If an influx of data traffic oversubscribes a particular link in the network, queueing, buffering, and packet drop decisions resolve the congestion. The extra traffic is simply delayed until the interface becomes available to send the traffic, or, if traffic is dropped, the protocol or the end user initiates a timeout and requests a retransmission of the information.

Network congestion cannot be resolved in this manner when real-time traffic, sensitive to both latency and packet loss, is present, without jeopardizing the quality of service (QoS) expected by the users of that traffic. For real-time delay-sensitive traffic such as voice, it is better to deny network access under congestion conditions than to allow traffic onto the network to be dropped and delayed, causing intermittent impaired QoS and resulting in customer dissatisfaction.
CAC is therefore a deterministic and informed decision that is made before a voice call is established and is based on whether the required network resources are available to provide suitable QoS for the new call.

Based on the admit CAC CLI configuration in addition to the existing CAC algorithm, device allows either voice or video with TSPEC or SIP snooping. The admit cac CLI is mandatory for the voice call to pass through.

If the BSSID policer is configured for the voice or video traffic, then additional checks are performed on the packets.

**Expedited Bandwidth Requests**

The expedited bandwidth request feature enables CCXv5 clients to indicate the urgency of a WMM traffic specifications (TSPEC) request (for example, an e911 call) to the WLAN. When the controller receives this request, it attempts to facilitate the urgency of the call in any way possible without potentially altering the quality of other TSPEC calls that are in progress.

You can apply expedited bandwidth requests to both bandwidth-based and load-based CAC. Expedited bandwidth requests are disabled by default. When this feature is disabled, the controller ignores all expedited requests and processes TSPEC requests as normal TSPEC requests.

The following table lists examples of TSPEC request handling for normal TSPEC requests and expedited bandwidth requests.

**Table 184: TSPEC Request Handling Examples**

<table>
<thead>
<tr>
<th>CAC Mode</th>
<th>Reserved bandwidth for voice calls</th>
<th>Usage</th>
<th>Normal TSPEC Request</th>
<th>TSPEC with Expedited Bandwidth Request</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bandwidth-based CAC</td>
<td>75% (default setting)</td>
<td>Less than 75%</td>
<td>Admitted</td>
<td>Admitted</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Between 75% and 90% (reserved bandwidth for voice calls exhausted)</td>
<td>Rejected</td>
<td>Admitted</td>
</tr>
<tr>
<td></td>
<td></td>
<td>More than 90%</td>
<td>Rejected</td>
<td>Rejected</td>
</tr>
<tr>
<td>Load-based CAC</td>

<td>Rejected</td>
<td>Admitted</td>
</tr>
<tr>
<td></td>
<td></td>
<td>More than 85%</td>
<td>Rejected</td>
<td>Rejected</td>
</tr>
</tbody>
</table>

26 For bandwidth-based CAC, the voice call bandwidth usage is per access point radio and does not take into account cochannel access points. For load-based CAC, the voice call bandwidth usage is measured for the entire channel.

27 Bandwidth-based CAC (consumed voice and video bandwidth) or load-based CAC (channel utilization [Pb]).
Admission control for TSPEC G711-20ms and G711-40 ms codec types are supported.

**U-APSD**

Unscheduled automatic power save delivery (U-APSD) is a QoS facility defined in IEEE 802.11e that extends the battery life of mobile clients. In addition to extending battery life, this feature reduces the latency of traffic flow delivered over the wireless media. Because U-APSD does not require the client to poll each individual packet buffered at the access point, it allows delivery of multiple downlink packets by sending a single uplink trigger packet. U-APSD is enabled automatically when WMM is enabled.

**Traffic Stream Metrics**

In a voice-over-wireless LAN (VoWLAN) deployment, traffic stream metrics (TSM) can be used to monitor voice-related metrics on the client-access point air interface. It reports both packet latency and packet loss. You can isolate poor voice quality issues by studying these reports.

The metrics consist of a collection of uplink (client side) and downlink (access point side) statistics between an access point and a client device that supports CCX v4 or later releases. If the client is not CCX v4 or CCXv5 compliant, only downlink statistics are captured. The client and access point measure these metrics. The access point also collects the measurements every 5 seconds, prepares 90-second reports, and then sends the reports to the controller. The controller organizes the uplink measurements on a client basis and the downlink measurements on an access point basis and maintains an hour's worth of historical data. To store this data, the controller requires 32 MB of additional memory for uplink metrics and 4.8 MB for downlink metrics.

TSM can be configured through either the GUI or the CLI on a per radio-band basis (for example, all 802.11a radios). The controller saves the configuration in flash memory so that it persists across reboots. After an access point receives the configuration from the controller, it enables TSM on the specified radio band.

This table shows the upper limit for TSM entries in different controller series.

<table>
<thead>
<tr>
<th>TSM Entries</th>
<th>5700</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX AP TSM entries</td>
<td>100</td>
</tr>
<tr>
<td>MAX Client TSM entries</td>
<td>250</td>
</tr>
<tr>
<td>MAX TSM entries</td>
<td>100*250=25000</td>
</tr>
</tbody>
</table>

Once the upper limit is reached, additional TSM entries cannot be stored and sent to WCS or NCS. If client TSM entries are full and AP TSM entries are available, then only the AP entries are stored, and vice versa. This leads to partial output. TSM cleanup occurs every one hour. Entries are removed only for those APs and clients that are not in the system.
Information About Configuring Voice Prioritization Using Preferred Call Numbers

You can configure a device to provide support for SIP calls from VoWLAN clients that do not support TSPEC-based calls. This feature is known as SIP CAC support. If bandwidth is available in the configured voice pool, the SIP call uses the normal flow and the device allocates the bandwidth to those calls.

You can also prioritize up to six preferred call numbers. When a call comes to one of the configured preferred numbers, the device does not check the configured maximum voice bandwidth. The device allocates the bandwidth needed for the call, even if it exceeds the maximum bandwidth for voice configured for voice CAC. The preferred call will be rejected if bandwidth allocation exceeds 85% of the radio bandwidth. The bandwidth allocation is 85 percent of the entire bandwidth pool, not just from the maximum configured voice pool. The bandwidth allocation is the same even for roaming calls.

You must configure the following parameters before configuring voice prioritization:

• Set WLAN QoS to allow voice calls to pass through.
• Enable ACM for the radio.
• Enable SIP call snooping on the WLAN.

Information About EDCA Parameters

Enhanced distributed channel access (EDCA) parameters are designed to provide preferential wireless channel access for voice, video, and other quality-of-service (QoS) traffic.

How to Configure Voice and Video Parameters

Configuring Voice Parameters (CLI)

Before you begin

Ensure that you have configured SIP-based CAC.

You should have created a class map for CAC before beginning this procedure.

SUMMARY STEPS

1. show wlan summary
2. show wlan wlan_id
3. configure terminal
4. policy-map policy-map name
5. class {class-name | class-default}
6. admit cac wmm-tspec
7. service-policy policy-map name
8. end
9. wlan wlan_profile_name wlan_ID SSID_network_name wlan shutdown
10. `wlan wlan_profile_name wlan_ID SSID_network_name`
11. `wlan wlan_name call-snoop`
12. `wlan wlan_name service-policy input input_policy_name`
13. `wlan wlan_name service-policy output output_policy_name`
14. `wlan wlan_name service-policy input ingress_policy_name`
15. `wlan wlan_name service-policy output egress_policy_name`
16. `ap dot11 {5ghz | 24ghz} shutdown`
17. `ap dot11 {5ghz | 24ghz} cac voice sip`
18. `ap dot11 {5ghz | 24ghz} cac voice acm`
19. `ap dot11 {5ghz | 24ghz} cac voice max-bandwidth bandwidth`
20. `ap dot11 {5ghz | 24ghz} cac voice roam-bandwidth bandwidth`
21. `no wlan shutdown`
22. `no ap dot11 {5ghz | 24ghz} shutdown`
23. `end`

</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
</tbody>
</table>
| **Example:**  
Device(config)# wlan wlan1  
Device(config-wlan)# service-policy input policy1 |  
Configures egress SSID policy on a particular WLAN as user-defined policy. |
| **Step 15**  
**wlan wlan_name service-policy output**  
**egress_policy_name** | Disables the radio network.  
**Example:**  
Device(config)# wlan wlan1  
Device(config-wlan)# service-policy output policy2 |
| **Step 16**  
**ap dot11 {5ghz | 24ghz} shutdown** | Enables or disables bandwidth-based voice CAC for the 802.11a or 802.11b/g network.  
**Example:**  
Device(config)# ap dot11 5ghz cac voice sip |
| **Step 17**  
**ap dot11 {5ghz | 24ghz} cac voice sip** | Enables or disables bandwidth-based voice CAC for the 802.11a or 802.11b/g network.  
**Example:**  
Device(config)# ap dot11 5ghz cac voice acm |
| **Step 18**  
**ap dot11 {5ghz | 24ghz} cac voice acm** | Sets the percentage of maximum bandwidth allocated to clients for voice applications on the 802.11a or 802.11b/g network.  
**Example:**  
Device(config)# ap dot11 5ghz cac voice max-bandwidth 85  
The bandwidth range is 5 to 85%, and the default value is 75%. Once the client reaches the value specified, the access point rejects new videos on this network. |
| **Step 19**  
**ap dot11 {5ghz | 24ghz} cac voice roam-bandwidth bandwidth** | Sets the percentage of maximum allocated bandwidth reserved for roaming voice clients.  
**Example:**  
Device(config)# ap dot11 5ghz cac voice roam-bandwidth 10  
The bandwidth range is 0 to 25%, and the default value is 6%. The device reserves this much bandwidth from the maximum allocated bandwidth for roaming voice clients. |
| **Step 20**  
**no wlan shutdown** | Reenables all WLANs with WMM enabled.  
**Example:**  
Device(config-wlan)# no wlan shutdown |
| **Step 21**  
**no ap dot11 {5ghz | 24ghz} shutdown** | Reenables the radio network.  
**Example:**  
Device(config)# no ap dot11 5ghz shutdown |
| **Step 22**  
**end** | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.  
**Example:**  
Device(config)# end |
**Example**

<td><strong>Step 10</strong></td>
<td>`ap dot11 {5ghz</td>
<td>24ghz} cac voice sip`</td>
</tr>
</tbody>
</table>

**Example:**

- **Step 1:**
  ```
  Device# configure terminal
  ```
- **Step 2:**
  ```
  Device(config)# wlan qos-wlan
  Device(config-wlan)#
  ```
- **Step 3:**
  ```
  Device(config-wlan)# call-snoop
  ```
- **Step 4:**
  ```
  Device(config-wlan)# service-policy input platinum-up
  ```
- **Step 5:**
  ```
  Device(config-wlan)# service-policy output platinum
  ```
- **Step 6:**
  ```
  Device(config)# end
  ```
- **Step 7:**
  ```
  Device# show wlan qos-wlan
  ```
- **Step 8:**
  ```
  Device# configure terminal
  ```
- **Step 9:**
  ```
  Device(config)# ap dot11 5ghz cac voice acm
  ```
- **Step 10:**
  ```
  Device(config)# ap dot11 5ghz cac voice sip
  ```
Configuring a Preferred Call Number (CLI)

**Before you begin**

You must set the following parameters before configuring a preferred call number.

- Set WLAN QoS to voice.
- Enable ACM for the radio.
- Enable SIP call snooping on the WLAN.
- Enable SIP-based CAC.

**SUMMARY STEPS**

1. configure terminal
2. wlan wlan-name qos platinum
3. ap dot11 {5ghz|24ghz} cac {voice|video} acm
4. wlan wlan-name
5. wireless sip preferred-call-no call_index call_number
6. no wireless sip preferred-call-no call_index
7. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

Example

**Monitoring Voice and Video Parameters**

This section describes the new commands for the voice and video parameters. The following commands can be used to monitor voice and video parameters.

**Table 185: Monitoring Voice Parameters Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show ap dot11 {5ghz</td>
<td>24ghz} network`</td>
</tr>
<tr>
<td><code>show ap name ap_name dot11 24ghz tsm all</code></td>
<td>Displays the TSM voice metrics and current status of MAC optimization for voice.</td>
</tr>
<tr>
<td><code>show ap name apname cac voice</code></td>
<td>Displays the information about CAC for a particular access point.</td>
</tr>
<tr>
<td><code>show client detail client_mac</code></td>
<td>Displays the U-APSD status for a particular client.</td>
</tr>
<tr>
<td><code>show policy-map interface wireless client</code></td>
<td>Displays the video client policy details.</td>
</tr>
<tr>
<td><code>show access-list</code></td>
<td>Displays the video client dynamic access-list from the device.</td>
</tr>
<tr>
<td><code>show wireless client voice diag status</code></td>
<td>Displays information about whether voice diagnostics are enabled or disabled. If enabled, this also displays information about the clients in the watch list and the time remaining for the diagnostics of the voice call. <strong>Note</strong> To work on voice diagnostics CLIs, you need to enter the following command: <code>debug voice-diagnostic mac-addr client_mac_01 client_mac_02</code></td>
</tr>
<tr>
<td><code>show wireless client voice diag tspec</code></td>
<td>Displays the TSPEC information sent from the clients that are enabled for voice diagnostics.</td>
</tr>
<tr>
<td><code>show wireless client voice diag qos-map</code></td>
<td>Displays information about the QoS/DSCP mapping and packet statistics in each of the four queues: VO, VI, BE, BK. The different DSCP values are also displayed.</td>
</tr>
<tr>
<td><code>show wireless client voice diag rss</code></td>
<td>Display the client’s RSSI values in the last 5 seconds when voice diagnostics is enabled.</td>
</tr>
<tr>
<td><code>show client voice-diag roam-history</code></td>
<td>Displays information about the last three roaming calls. The output contains the timestamp, access point associated with roaming, roaming reason, and if there is a roaming failure, reason for roaming-failure.</td>
</tr>
</tbody>
</table>
### Monitoring Voice and Video Parameters

<td><code>show controllers d1 b queue</code></td>
<td>Displays which queue the packets are going through on an access point based on 2.4- and 5-GHz bands.</td>
</tr>
<tr>
<td><code>show cont d1 b Media</code></td>
<td>Displays the video metric details on the band A or B.</td>
</tr>
<tr>
<td><code>show capwap mcast mgid all</code></td>
<td>Displays information about all of the multicast groups and their corresponding multicast group identifications (MGIDs) associated to the access point.</td>
</tr>
</tbody>
</table>
Configuration Examples for Voice and Video Parameters

Example: Configuring Voice and Video

**Configuring Egress SSID Policy for Voice and Video**

The following example shows how to create and configure an egress SSID policy for voice and video:

```
    table-map egress_ssid_tb
    map from 24 to 24
    map from 34 to 34
    map from 46 to 46
    default copy

    class-map match-any voice
    match dscp ef

    class-map match-any video
    match dscp af41

    policy-map ssid-cac
    class class-default
    shape average 25000000
    set dscp dscp table egress_ssid_tb
    queue-buffers ratio 0
    service-policy ssid-child-cac

    policy-map ssid-child-cac
    class voice
    priority level 1
    police 50000000
    conform-action transmit
    exceed-action drop
    admit cac wmm-tspec
    rate 1000
    wlan-up 6 7

    class video
    priority level 2
    police 10000000
    conform-action transmit
    exceed-action drop
    admit cac wmm-tspec
    rate 3000
    wlan-up 4 5
```

**Configuring Ingress SSID Policy for Voice and Video**

The following example shows how to create and configure an ingress SSID policy for voice and video:

```
    table-map up_to_dscp
    map from 0 to 0
    map from 1 to 8
    map from 2 to 8
    map from 3 to 0
    map from 4 to 34
```
map from 5 to 34
map from 6 to 46
map from 7 to 48
default copy

policy-map ingress_ssid
class class-default
  set dscp wlan user-priority table up_to_dscp

Configuring Egress Port Policy Voice and Video

The following example shows how to create and configure an egress port policy for voice and video:

policy-map port_child_policy
class non-client-nrt-class
  bandwidth remaining ratio 10

class voice
  priority level 1
  police rate 3000000

class video
  priority level 2
  police rate 4000000

Applying Ingress and Egress SSID policies for Voice and Video on a WLAN

The following example shows how to apply ingress and egress SSID policies for voice and video on a WLAN:

wlan voice_video 1 voice_video
  service-policy input ingress_ssid
  service-policy output ssid-cac

</thead>
<tbody>
<tr>
<td>Cisco IOS XE 3.2SE</td>
<td>This feature was introduced.</td>
</tr>
</tbody>
</table>
Configuring RFID Tag Tracking

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring RFID Tag Tracking

The Device enables you to configure radio-frequency identification (RFID) tag tracking. RFID tags are small wireless devices that are affixed to assets for real-time location tracking. They operate by advertising their location using special 802.11 packets, which are processed by access points, the controller, and the location appliance.

How to Configure RFID Tag Tracking

Configuring RFID Tag Tracking (CLI)

SUMMARY STEPS

1. location rfid status
2. (Optional) no location rfid status
3. `location rfid timeout seconds`
4. `location rfid mobility vendor-name name`
5. (Optional) `no location rfid mobility name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>location rfid status</strong></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# location rfid status</code></td>
</tr>
<tr>
<td></td>
<td>Enables RFID tag tracking. By default, RFID tag tracking is enabled.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>(Optional) <code>no location rfid status</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# no location rfid status</code></td>
</tr>
<tr>
<td></td>
<td>Disables RFID tag tracking.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>location rfid timeout seconds</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# location rfid timeout 1500</code></td>
</tr>
<tr>
<td></td>
<td>Specifies a static timeout value (between 60 and 7200 seconds). The static timeout value is the amount of time that the device maintains tags before expiring them. For example, if a tag is configured to beacon every 30 seconds, we recommend that you set the timeout value to 90 seconds (approximately three times the beacon value). The default value is 1200 seconds.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>location rfid mobility vendor-name name</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# location rfid mobility vendor-name Aerosct</code></td>
</tr>
<tr>
<td></td>
<td>Enables RFID tag mobility for specific tags. When you enter the <code>location rfid mobility vendor-name</code> command, tags are unable to obtain a DHCP address for client mode when attempting to select and/or download a configuration. <strong>Note</strong> These commands can be used only for Pango tags. Therefore, the only valid entry for <code>vendor-name</code> is “pango” in all lowercase letters.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>(Optional) <code>no location rfid mobility name</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# no location rfid mobility test</code></td>
</tr>
<tr>
<td></td>
<td>Disables RFID tag mobility for specific tags. When you enter the <code>no location rfid mobility</code> command, tags can obtain a DHCP address. If a tag roams from one subnet to another, it obtains a new address rather than retaining the anchor state.</td>
</tr>
</tbody>
</table>

**Monitoring RFID Tag Tracking Information**

This section describes the new commands for the RFID tag tracking Information.

The following commands can be used to monitor the RFID tag tracking Information on the.

Information About Configuring Location Settings

The device determines the location of client devices by gathering Received Signal Strength Indication (RSSI) measurements from access points all around the client of interest. The device can obtain location reports from up to 16 access points for clients, RFID tags, and rogue access points.

You can configure the path loss measurement (S60) request for normal clients or calibrating clients to improve location accuracy.
How to Configure Location Settings

Configuring Location Settings (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `location plm {calibrating [multiband | uniband] | client burst_interval`
3. `location rssi-half-life {calibrating-client | client | rogue-aps | tags } seconds`
4. `location expiry {calibrating-client | client | rogue-aps | tags } timeout`
5. `location algorithm {rssi-average | simple}`
6. `location admin-tag string`
7. `location civic-location identifier {identifier | host}`
8. `location custom-location identifier {identifier | host}`
9. `location geo-location identifier {identifier | host}`
10. `location prefer {cdp | lldp-med | static} weight priority_value`
11. `location rfid {status | timeout | vendor-name}`
12. `end`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Step 2</strong></th>
<th>Configures the path loss measurement (S60) request for calibrating clients or non-calibrating.</th>
</tr>
</thead>
<tbody>
<tr>
<td>`location plm {calibrating [multiband</td>
<td>uniband]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# location plm client 100</code></td>
<td></td>
</tr>
</tbody>
</table>

The path loss measurement request improves the location accuracy. You can configure the `burst_interval` parameter for the normal, noncalibrating client from zero through 3600 seconds, and the default value is 60 seconds.

You can configure the path loss measurement request for calibrating clients on the associated 802.11a or 802.11b/g radio or on the associated 802.11a/b/g radio.

If a client does not send probes often or sends them only on a few channels, its location cannot be updated or cannot be updated accurately. The `location plm` command forces clients to send more packets on all channels. When a CCXv4 (or higher) client associates, the Device sends it a path loss measurement request, which instructs the client to transmit on the bands and channels that the access points are on (typically, channels 1, 6, and 11 for 2.4-GHz-only.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>access points</strong> at a configurable interval (such as 60 seconds) indefinitely.</td>
</tr>
<tr>
<td>location rssi-half-life {calibrating-client</td>
<td>client</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>You can enter the location rssi-half-life parameter value for the clients, calibrating clients, RFID tags, and rogue access points as 0, 1, 2, 5, 10, 20, 30, 60, 90, 120, 180, or 300 seconds, and the default value is 0 seconds.</td>
</tr>
<tr>
<td>Device(config)# location rssi-half-life calibrating-client 60</td>
<td>Some client devices transmit at reduced power immediately after changing channels, and RF is variable, so RSSI values might vary considerably from packet to packet. The location rssi-half-life command increases accuracy by averaging nonuniformly arriving data using a configurable forget period (or half life).</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>We recommend that you do not use or modify the location rssi-half-life command.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Configure the RSSI timeout value for the clients, calibrating clients, RFID tags, and rogue access points.</strong></td>
</tr>
<tr>
<td>location expiry {calibrating-client</td>
<td>client</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>You can enter the RSSI timeout value for the clients, RFID tags, and rogue access points from 5 through 3600 seconds, and the default value is 5 seconds.</td>
</tr>
<tr>
<td>Device(config)# location expiry calibrating-client 50</td>
<td>For the calibrating clients, you can enter the RSSI timeout value from 0 through 3600 seconds, and the default value is 5 seconds.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Ensuring that recent, strong RSSIs are retained by the CPU is critical to location accuracy. The location expiry command enables you to specify the length of time after which old RSSI averages expire.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>We recommend that you do not use or modify the location expiry command.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Configure the algorithm used to average RSSI and signal-to-noise ratio (SNR) values.</strong></td>
</tr>
<tr>
<td>location algorithm {rssi-average</td>
<td>simple}</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>You can enter the location algorithm rssi-average command to specify a more accurate algorithm but requires more CPU overhead or the location algorithm simple command to specify a faster algorithm that requires low CPU overhead but provides less accuracy.</td>
</tr>
<tr>
<td>Device(config)# location algorithm rssi-average</td>
<td><strong>Note</strong> We recommend that you do not use or modify the location algorithm command.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td></td>
</tr>
<tr>
<td><code>location admin-tag string</code></td>
<td>Sets administrative tag or site information for the location of client devices.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# location admin-tag</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td></td>
</tr>
<tr>
<td>`location civic-location identifier {identifier</td>
<td>host}`</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config)# location civic-location identifier host</td>
<td>You can set the civic location identifier either as a string or host.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td></td>
</tr>

### Example

**Modifying the NMSP Notification Interval for Clients, RFID Tags, and Rogues (CLI)**

The Network Mobility Services Protocol (NMSP) manages communication between the mobility services engine and the controller for incoming and outgoing traffic. If your application requires more frequent location updates, you can modify the NMSP notification interval (to a value between 1 and 180 seconds) for clients, active RFID tags, and rogue access points and clients.
The TCP port (16113) that the controller and mobility services engine communicate over must be open (not blocked) on any firewall that exists between the controller and the mobility services engine for NMSP to function.

**SUMMARY STEPS**

1. configure terminal
2. nmsp notification interval {attachment seconds | location seconds | rssi [clients interval | rfid interval | rogues [ap | client] interval]}
3. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>

</table>

Examples: Location Settings Configuration

This example shows how to configure the path loss measurement (S60) request for calibrating client on the associated 802.11a or 802.11b/g radio:

```
Device# configure terminal
Device(config)# location plm calibrating uniband
Device(config)# end
Device# show location summary
```

This example shows how to configure the RSSI half life for a rogue access point:

```
Device# configure terminal
Device(config)# location rssi-half-life rogue-aps 20
Device(config)# end
Device# show location summary
```

Examples: NMSP Settings Configuration

This example shows how to configure the NMSP notification interval for RFID tags:

```
Device# configure terminal
Device(config)# nmsp notification interval rssi rfid 50
Device(config)# end
Device# show nmsp notification interval
```
This example shows how to configure the NMSP notification threshold for clients:

```
Device# configure terminal
Device(config)# nmsp notify-threshold 5
Device(config)# end
Device# show nmsp statistics summary
```

Monitoring Flow Control

Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Flow Control

Flow control is enabled by default on the device.

Flow control provides shim layers between WCM and Cisco IOS for a reliable IPC. Every component in WCM has a dedicated channel. Few of the components in WCM have leveraged flow control in that. There is no configuration of flow control from CLI. You can monitor the flow control for any channel.

Monitoring Flow Control

This section describes the new commands for flow control.

The following commands can be used to monitor flow control on the device.

<table>
<thead>
<tr>

CHAPTER 114

Configuring SDM Templates

• Finding Feature Information, on page 2237
• Information About Configuring SDM Templates, on page 2237
• How to Configure SDM Templates, on page 2239
• Monitoring and Maintaining SDM Templates, on page 2240
• Configuration Examples for SDM Templates, on page 2240
• Additional References for SDM Templates, on page 2242
• Feature History and Information for Configuring SDM Templates, on page 2243

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring SDM Templates

SDM Templates

You can use SDM templates to configure system resources to optimize support for specific features, depending on how your device is used in the network. You can select a template to provide maximum system usage for some functions.

These templates are supported on your device:

• Advanced—The advanced template is available on all supported images for this release. It maximizes system resources for features like netflow, multicast groups, security ACEs, QoS ACEs, and so on.

• VLAN—The VLAN template is available only on the LAN Base license. The VLAN template disables routing and supports the maximum number of unicast MAC addresses. It would typically be selected for a Layer 2 device.
After you change the template and the system reboots, you can use the `show sdm prefer` privileged EXEC command to verify the new template configuration. If you enter the `show sdm prefer` command before you enter the `reload` privileged EXEC command, the `show sdm prefer` command shows the template currently in use and the template that will become active after a reload.

The default is the advanced template.

**Table 191: Approximate Number of Feature Resources Allowed by Templates**

<table>
<thead>
<tr>

<tr>
<td>Output Netflow flows:</td>
<td>16 K</td>
<td>16 K</td>
</tr>
</tbody>
</table>

When the switch is used as a Wireless Mobility Agent, the only template allowed is the advanced template.

The tables represent approximate hardware boundaries set when a template is selected. If a section of a hardware resource is full, all processing overflow is sent to the CPU, seriously impacting switch performance.
SDM Templates and Switch Stacks

In a switch stack, all stack members must use the same SDM template that is stored on the active switch. When a new switch is added to a stack, the SDM configuration that is stored on the active switch overrides the template configured on an individual switch.

You can use the `show switch` privileged EXEC command to see if any stack members are in SDM mismatch mode.

How to Configure SDM Templates

Configuring SDM Templates

Configuring the Switch SDM Template

Setting the SDM Template

Follow these steps to use the SDM template to maximize feature usage:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `sdm prefer { advanced | vlan }
4. end
5. reload

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>`sdm prefer { advanced</td>
<td>vlan }`</td>
</tr>
<tr>
<td><code>end</code></td>
<td>Specifies the SDM template to be used on the switch. The keywords have these meanings:</td>
</tr>
<tr>
<td><code>reload</code></td>
<td>Specifies the SDM template to be used on the switch. The keywords have these meanings:</td>
</tr>
<tr>
<td><code>advanced</code></td>
<td>• supports advanced features such as Netflow.</td>
</tr>
<tr>
<td><code>vlan</code></td>
<td>• supports advanced features such as Netflow.</td>
</tr>
</tbody>
</table>
Monitoring and Maintaining SDM Templates

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• vlan</td>
<td>Maximizes VLAN configuration on the switch with no routing supported in hardware.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> The no sdm prefer command and a default template is not supported.</td>
</tr>
</tbody>
</table>

**Step 4**

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

**Step 5**

**Example:**

```
Device# reload
```

Reloads the operating system.

Configuration Examples for SDM Templates

Examples: Configuring SDM Templates

This example shows how to configure the VLAN template:

```
Device(config)# sdm prefer vlan
Device(config)# exit
Device# reload
  Proceed with reload? [confirm]
```
Examples: Displaying SDM Templates

This is an example output showing the advanced template information:

Device# show sdm prefer

Showing SDM Template Info

This is the Advanced template.

- Number of VLANs: 4094
- Unicast MAC addresses: 32768
- Overflow Unicast MAC addresses: 512
- IGMP and Multicast groups: 8192
- Overflow IGMP and Multicast groups: 512
- Directly connected routes: 32768
- Indirect routes: 8192
- Security Access Control Entries: 3072
- QoS Access Control Entries: 2816
- Policy Based Routing ACEs: 1024
- Netflow ACEs: 1024
- Input Microflow policer ACEs: 256
- Output Microflow policer ACEs: 256
- Flow SPAN ACEs: 256
- Tunnels: 256
- Control Plane Entries: 512
- Input Netflow flows: 8192
- Output Netflow flows: 16384

These numbers are typical for L2 and IPv4 features. Some features such as IPv6, use up double the entry size; so only half as many entries can be created.

Device#

This is an example output showing the VLAN template information:

Device# show sdm prefer vlan

Showing SDM Template Info

This is the VLAN template for a typical Layer 2 network.

- Number of VLANs: 4094
- Unicast MAC addresses: 32768
- Overflow Unicast MAC addresses: 512
- IGMP and Multicast groups: 8192
- Overflow IGMP and Multicast groups: 512
- Directly connected routes: 32768
- Indirect routes: 8192
- Security Access Control Entries: 3072
- QoS Access Control Entries: 3072
- Policy Based Routing ACEs: 0
- Netflow ACEs: 1024
- Input Microflow policer ACEs: 0
- Output Microflow policer ACEs: 0
- Flow SPAN ACEs: 256
- Tunnels: 0
- Control Plane Entries: 512
- Input Netflow flows: 16384
- Output Netflow flows: 8192

These numbers are typical for L2 and IPv4 features. Some features such as IPv6, use up double the entry size;
so only half as many entries can be created.

Device#

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring System Message Logs

System Message Logging

By default, a switch sends the output from system messages and debug privileged EXEC commands to a logging process. Stack members can trigger system messages. A stack member that generates a system message appends its hostname in the form of hostname-n, where n is a switch range from 1 to 4, and redirects the output to the logging process on the active switch. Though the active switch is a stack member, it does not append its hostname to system messages. The logging process controls the distribution of logging messages to various destinations, such as the logging buffer, terminal lines, or a UNIX syslog server, depending on your configuration. The process also sends messages to the console.

When the logging process is disabled, messages are sent only to the console. The messages are sent as they are generated, so message and debug output are interspersed with prompts or output from other commands. Messages appear on the active consoles after the process that generated them has finished.
You can set the severity level of the messages to control the type of messages displayed on the consoles and each of the destinations. You can time-stamp log messages or set the syslog source address to enhance real-time debugging and management. For information on possible messages, see the system message guide for this release.

You can access logged system messages by using the switch command-line interface (CLI) or by saving them to a properly configured syslog server. The switch software saves syslog messages in an internal buffer on a standalone switch, and in the case of a switch stack, on the active switch. If a standalone switch or the stack master fails, the log is lost unless you had saved it to flash memory.

You can remotely monitor system messages by viewing the logs on a syslog server or by accessing the switch through Telnet, through the console port, or through the Ethernet management port. In a switch stack, all stack member consoles provide the same console output.

---

**Note**

The syslog format is compatible with 4.3 BSD UNIX.

### System Log Message Format

System log messages can contain up to 80 characters and a percent sign (%), which follows the optional sequence number or time-stamp information, if configured. Depending on the switch, messages appear in one of these formats:

- `seq no:timestamp: %facility-severity-MNEMONIC:description (hostname-n)`
- `seq no:timestamp: %facility-severity-MNEMONIC:description`

The part of the message preceding the percent sign depends on the setting of these global configuration commands:

- `service sequence-numbers`
- `service timestamps log datetime`
- `service timestamps log datetime [localtime] [msec] [show-timezone]`
- `service timestamps log uptime`

---

**Table 192: System Log Message Elements**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>seq no:</code></td>
<td>Stamps log messages with a sequence number only if the <code>service sequence-numbers</code> global configuration command is configured.</td>
</tr>
</tbody>
</table>
Date and time of the message or event. This information appears only if the `service timestamps log [datetime | log]` global configuration command is configured.

The facility to which the message refers (for example, SNMP, SYS, and so forth).

Single-digit code from 0 to 7 that is the severity of the message.

Text string that uniquely describes the message.

Text string containing detailed information about the event being reported.

Hostname of a stack member and its switch number in the stack. Though the active switch is a stack member, it does not append its hostname to system messages.

</table>
Syslog Message Limits

If you enabled syslog message traps to be sent to an SNMP network management station by using the `snmp-server enable trap` global configuration command, you can change the level of messages sent and stored in the switch history table. You also can change the number of messages that are stored in the history table.

Messages are stored in the history table because SNMP traps are not guaranteed to reach their destination. By default, one message of the level `warning` and numerically lower levels are stored in the history table even if syslog traps are not enabled.

When the history table is full (it contains the maximum number of message entries specified with the `logging history size` global configuration command), the oldest message entry is deleted from the table to allow the new message entry to be stored.

The history table lists the level keywords and severity level. For SNMP usage, the severity level values increase by 1. For example, `emergencies` equal 1, not 0, and `critical` equals 3, not 2.

How to Configure System Message Logs

Setting the Message Display Destination Device

If message logging is enabled, you can send messages to specific locations in addition to the console. This task is optional.

SUMMARY STEPS

1. `configure terminal`  
2. `logging buffered [size]`  
3. `logging host`  
4. `logging file flash: filename [max-file-size [min-file-size]] [severity-level-number | type]`  
5. `end`  
6. `terminal monitor`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# <code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>logging buffered [size]</code></td>
<td>Logs messages to an internal buffer on the switch or on a standalone switch or, in the case of a switch stack, on the active switch. The range is 4096 to 2147483647 bytes. The default buffer size is 4096 bytes.</td>
</tr>
<tr>
<td>Example: Device(config)# <code>logging buffered 8192</code></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>If a standalone switch or the active switch fails, the log file is lost unless you previously saved it to flash memory. See Step 4.</td>
<td>Do not make the buffer size too large because the switch could run out of memory for other tasks. Use the show memory privileged EXEC command to view the free processor memory on the switch. However, this value is the maximum available, and the buffer size should not be set to this amount.</td>
</tr>
</tbody>
</table>
| **Step 3**  

logging host  
Example:  
Device(config)# logging 125.1.1.100 | Logs messages to a UNIX syslog server host.  
host specifies the name or IP address of the host to be used as the syslog server.  
To build a list of syslog servers that receive logging messages, enter this command more than once. |
| **Step 4**  

logging file flash: filename [max-file-size [min-file-size]] [severity-level-number | type]  
Example:  
Device(config)# logging file flash:log_msg.txt 40960 4096 3 | Stores log messages in a file in flash memory on a standalone switch or, in the case of a switch stack, on the active switch.  
- filename—Enters the log message filename.  
- (Optional) max-file-size—Specifies the maximum logging file size. The range is 4096 to 2147483647. The default is 4096 bytes.  
- (Optional) min-file-size—Specifies the minimum logging file size. The range is 1024 to 2147483647. The default is 2048 bytes.  
- (Optional) severity-level-number | type—Specifies either the logging severity level or the logging type. The severity range is 0 to 7. |
| **Step 5**  

end  
Example:  
Device(config)# end | Returns to privileged EXEC mode. |
| **Step 6**  

terminal monitor  
Example:  
Device# terminal monitor | Logs messages to a nonconsole terminal during the current session.  
Terminal parameter-setting commands are set locally and do not remain in effect after the session has ended. You must perform this step for each session to see the debugging messages. |
Synchronizing Log Messages

You can synchronize unsolicited messages and `debug` privileged EXEC command output with solicited device output and prompts for a specific console port line or virtual terminal line. You can identify the types of messages to be output asynchronously based on the level of severity. You can also configure the maximum number of buffers for storing asynchronous messages for the terminal after which messages are dropped.

When synchronous logging of unsolicited messages and `debug` command output is enabled, unsolicited device output appears on the console or printed after solicited device output appears or is printed. Unsolicited messages and `debug` command output appear on the console after the prompt for user input is returned. Therefore, unsolicited messages and `debug` command output are not interspersed with solicited device output and prompts. After the unsolicited messages appear, the console again displays the user prompt.

This task is optional.

SUMMARY STEPS

1. configure terminal
2. line [console | vty] line-number [ending-line-number]
3. logging synchronous [level [severity-level | all] | limit number-of-buffers]
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** configure terminal  
Device# configure terminal | Enters global configuration mode. |
| **Step 2** line [console | vty] line-number [ending-line-number]  
Device(config)# line console | Specifies the line to be configured for synchronous logging of messages. |

- **console** — Specifies configurations that occur through the switch console port or the Ethernet management port.

- **line vty line-number** — Specifies which vty lines are to have synchronous logging enabled. You use a vty connection for configurations that occur through a Telnet session. The range of line numbers is from 0 to 15.

You can change the setting of all 16 vty lines at once by entering:

```
line vty 0 15
```

You can also change the setting of the single vty line being used for your current connection. For example, to change the setting for vty line 2, enter:

```
line vty 2
```
Disabling Message Logging

Message logging is enabled by default. It must be enabled to send messages to any destination other than the console. When enabled, log messages are sent to a logging process, which logs messages to designated locations asynchronously to the processes that generated the messages.

Disabling the logging process can slow down the switch because a process must wait until the messages are written to the console before continuing. When the logging process is disabled, messages appear on the console as soon as they are produced, often appearing in the middle of command output.

The `logging synchronous` global configuration command also affects the display of messages to the console. When this command is enabled, messages appear only after you press Return.

To reenable message logging after it has been disabled, use the `logging on` global configuration command.

This task is optional.

**SUMMARY STEPS**

1. configure terminal
2. no logging console
3. end

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 3</strong> logging synchronous [level [severity-level</td>
<td>Enables synchronous logging of messages.</td>

</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>
Enabling and Disabling Time Stamps on Log Messages

By default, log messages are not time-stamped.
This task is optional.

SUMMARY STEPS

1. configure terminal
2. Use one of these commands:
   • service timestamps log uptime
   • service timestamps log datetime[msec | localtime | show-timezone]
3. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

<td><code>logging history level</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# logging history 3</code></td>
</tr>
<tr>
<td></td>
<td>Changes the default level of syslog messages stored in the history file and sent to the SNMP server. By default, <strong>warnings</strong>, <strong>errors</strong>, <strong>critical</strong>, <strong>alerts</strong>, and <strong>emergencies</strong> messages are sent.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>logging history size number</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# logging history size 200</code></td>
</tr>
<tr>
<td></td>
<td>Specifies the number of syslog messages that can be stored in the history table. The default is to store one message. The range is 0 to 500 messages.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>end</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config)# end</code></td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

### Logging Messages to a UNIX Syslog Daemon

This task is optional.
Some recent versions of UNIX syslog daemons no longer accept by default syslog packets from the network. If this is the case with your system, use the UNIX `man syslogd` command to decide what options must be added to or removed from the syslog command line to enable logging of remote syslog messages.

**Before you begin**

- Log in as root.
- Before you can send system log messages to a UNIX syslog server, you must configure the syslog daemon on a UNIX server.

**SUMMARY STEPS**

1. Add a line to the file `/etc/syslog.conf`.
2. Enter these commands at the UNIX shell prompt.
3. Make sure the syslog daemon reads the new changes.

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | Add a line to the file `/etc/syslog.conf`.  
**Example:**  
`local7.debug /usr/adm/logs/cisco.log` | • *local7*—Specifies the logging facility.  
• *debug*—Specifies the syslog level. The file must already exist, and the syslog daemon must have permission to write to it. |
| Step 2 | Enter these commands at the UNIX shell prompt.  
**Example:**  
`; touch /var/log/cisco.log  
`; chmod 666 /var/log/cisco.log` | Creates the log file. The syslog daemon sends messages at this level or at a more severe level to this file. |
| Step 3 | Make sure the syslog daemon reads the new changes.  
**Example:**  
`; kill -HUP `cat /etc/syslog.pid` | For more information, see the `man syslog.conf` and `man syslogd` commands on your UNIX system. |
Monitoring and Maintaining System Message Logs

Monitoring Configuration Archive Logs

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show archive log config {all</td>
<td>number [end-number]</td>
</tr>
</tbody>
</table>

Configuration Examples for System Message Logs

Example: Stacking System Message

This example shows a partial switch system message for active switch and a stack member (hostname Switch-2):

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/2, changed state to up
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan1, changed state to down
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet1/0/1, changed state to down
*Mar 1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
18:47:02: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
*Mar 1 18:48:50.483 UTC: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up (Switch-2)
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet2/0/1, changed state to up (Switch-2)
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet2/0/2, changed state to up (Switch-2)
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan1, changed state to down (Switch-2)
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet2/0/1, changed state to down 2 (Switch-2)
```

Example: Switch System Message

This example shows a partial switch system message on a switch:

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet0/1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet0/2, changed state to up
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan1, changed state to down
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet0/1, changed state to down 2
*Mar 1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
18:47:02: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Configuring Online Diagnostics

Online Diagnostics

With online diagnostics, you can test and verify the hardware functionality of the Device while the Device is connected to a live network.

The online diagnostics contain packet switching tests that check different hardware components and verify the data path and the control signals.

The online diagnostics detect problems in these areas:

- Hardware components
- Interfaces (Ethernet ports and so forth)
- Solder joints
Online diagnostics are categorized as on-demand, scheduled, or health-monitoring diagnostics. On-demand diagnostics run from the CLI; scheduled diagnostics run at user-designated intervals or at specified times when the Device is connected to a live network; and health-monitoring runs in the background with user-defined intervals. By default, the health-monitoring test runs for every 30 seconds.

After you configure online diagnostics, you can manually start diagnostic tests or display the test results. You can also see which tests are configured for the Device or switch stack and the diagnostic tests that have already run.

### How to Configure Online Diagnostics

#### Starting Online Diagnostic Tests

After you configure diagnostic tests to run on the Device, use the `diagnostic start` privileged EXEC command to begin diagnostic testing.

After starting the tests, you cannot stop the testing process.

Use this privileged EXEC command to manually start online diagnostic testing:

**SUMMARY STEPS**

1. `diagnostic start switch number test {name | test-id | test-id-range | all | basic | complete | minimal | non-disruptive | per-port}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>`diagnostic start switch number test {name</td>
<td>test-id</td>
</tr>
</tbody>
</table>

The `switch number` keyword is supported only on stacking Device. The range is from 1 to 4.

You can specify the tests by using one of these options:

- `name`—Enters the name of the test.
- `test-id`—Enters the ID number of the test.
- `test-id-range`—Enters the range of test IDs by using integers separated by a comma and a hyphen.
- `all`—Starts all of the tests.
- `basic`—Starts the basic test suite.
- `complete`—Starts the complete test suite.
- `minimal`—Starts the minimal bootup test suite.
- `non-disruptive`—Starts the non-disruptive test suite.
- `per-port`—Starts the per-port test suite.

Example:

```
Device# diagnostic start switch 2 test basic
```
### Configuring Online Diagnostics

You must configure the failure threshold and the interval between tests before enabling diagnostic monitoring.

### Scheduling Online Diagnostics

You can schedule online diagnostics to run at a designated time of day or on a daily, weekly, or monthly basis for a Device. Use the no form of this command to remove the scheduling.

#### SUMMARY STEPS

1. configure terminal
2. diagnostic schedule switch number test \{name | test-id | test-id-range | all | basic | complete | minimal | non-disruptive | per-port\} \{daily | on mm dd yyyy hh:mm | port inter-port-number port-number-list | weekly day-of-week hh:mm\}

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
| Step 2 diagnostic schedule switch number test \{name | test-id | test-id-range | all | basic | complete | minimal | non-disruptive | per-port\} \{daily | on mm dd yyyy hh:mm | port inter-port-number port-number-list | weekly day-of-week hh:mm\} Example:Device(config)# diagnostic schedule switch 3 test 1-5 on July 3 2013 23:10 | Schedules on-demand diagnostic tests for a specific day and time. The switch number keyword is supported only on stacking switches. The range is from 1 to 4. When specifying the tests to be scheduled, use these options:  
  * name—Name of the test that appears in the show diagnostic content command output.  
  * test-id—ID number of the test that appears in the show diagnostic content command output.  
  * test-id-range—ID numbers of the tests that appear in the show diagnostic content command output.  
  * all—All test IDs.  
  * basic—Starts the basic on-demand diagnostic tests.  
  * complete—Starts the complete test suite.  
  * minimal—Starts the minimal bootup test suite.  
  * non-disruptive—Starts the non-disruptive test suite.  
  * per-port—Starts the per-port test suite.
Purpose

Command or Action

You can schedule the tests as follows:

- Daily—Use the daily \( hh:mm \) parameter.
- Specific day and time—Use the on \( mm \ d d \ yyyy \ hh:mm \) parameter.
- Weekly—Use the weekly day-of-week \( hh:mm \) parameter.

Configuring Health-Monitoring Diagnostics

You can configure health-monitoring diagnostic testing on a Device while it is connected to a live network. You can configure the execution interval for each health-monitoring test, enable the Device to generate a syslog message because of a test failure, and enable a specific test.

Use the no form of this command to disable testing.

By default, health monitoring is disabled, but the Device generates a syslog message when a test fails.

Follow these steps to configure and enable the health-monitoring diagnostic tests:

SUMMARY STEPS

1. enable
2. configure terminal
3. diagnostic monitor interval switch number test \{name | test-id | test-id-range | all\} \( hh:mm:ss \) milliseconds day
4. diagnostic monitor syslog
5. diagnostic monitor threshold switch number test \{name | test-id | test-id-range | all\} failure count
6. diagnostic monitor switch number test \{name | test-id | test-id-range | all\}
7. end
8. show running-config
9. copy running-config startup-config

<tr>
<td><strong>Step 4</strong></td>
<td>(Optional) Configures the switch to generate a syslog message when a health-monitoring test fails.</td>
<td></td>
</tr>
<tr>
<td><strong>diagnostic monitor syslog</strong></td>
<td><strong>Step 5</strong></td>
<td>(Optional) Sets the failure threshold for the health-monitoring tests.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>The <code>switch number</code> keyword is supported only on stacking switches. The range is from 1 to 9.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When specifying the tests, use one of these parameters:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>name</code>—Name of the test that appears in the <code>show diagnostic content</code> command output.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>test-id</code>—ID number of the test that appears in the <code>show diagnostic content</code> command output.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>test-id-range</code>—ID numbers of the tests that appear in the <code>show diagnostic content</code> command output.</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>• all — All of the diagnostic tests.</td>
<td></td>
</tr>
<tr>
<td>The range for the failure threshold <code>count</code> is 0 to 99.</td>
<td></td>
</tr>
</tbody>
</table>

#### Step 6

**diagnostic monitor switch number test {name | test-id | test-id-range | all}**

**Example:**

```plaintext
Device(config)# diagnostic monitor switch 2 test 1
```

Enables the specified health-monitoring tests.

The `switch number` keyword is supported only on stacking switches. The range is from 1 to 9.

When specifying the tests, use one of these parameters:

- **name** — Name of the test that appears in the `show diagnostic content` command output.
- **test-id** — ID number of the test that appears in the `show diagnostic content` command output.
- **test-id-range** — ID numbers of the tests that appear in the `show diagnostic content` command output.
- **all** — All of the diagnostic tests.

#### Step 7

**end**

**Example:**

```plaintext
Device(config)# end
```

Returns to privileged EXEC mode.

#### Step 8

**show running-config**

**Example:**

```plaintext
Device# show running-config
```

Verifies your entries.

#### Step 9

**copy running-config startup-config**

**Example:**

```plaintext
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

---

**What to do next**

Use the `no diagnostic monitor interval test {test-id | test-id-range}` global configuration command to change the interval to the default value or to zero. Use the `no diagnostic monitor syslog` command to disable generation of syslog messages when a health-monitoring test fails. Use the `diagnostic monitor threshold test {test-id | test-id-range} failure count` command to remove the failure threshold.
Monitoring and Maintaining Online Diagnostics

Displaying Online Diagnostic Tests and Test Results

You can display the online diagnostic tests that are configured for the Device or Device stack and check the test results by using the privileged EXEC `show` commands in this table:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`show diagnostic content switch [number</td>
<td>all]`</td>
</tr>
<tr>
<td><code>show diagnostic status</code></td>
<td>Displays the currently running diagnostic tests.</td>
</tr>
<tr>
<td>`show diagnostic result switch [number</td>
<td>all] [detail</td>
</tr>
<tr>
<td>`show diagnostic switch [number</td>
<td>all] [detail]`</td>
</tr>
<tr>
<td>`show diagnostic schedule switch [number</td>
<td>all]`</td>
</tr>
<tr>
<td><code>show diagnostic post</code></td>
<td>Displays the POST results. (The output is the same as the <code>show post</code> command output.)</td>
</tr>
</tbody>
</table>

Configuration Examples for Online Diagnostic Tests

Examples: Start Diagnostic Tests

This example shows how to start a diagnostic test by using the test name:

```
Device# diagnostic start switch 2 test TestInlinePwrCtlr
```

This example shows how to start all of the basic diagnostic tests:

```
Device# diagnostic start switch 1 test all
```
Example: Configure a Health Monitoring Test

This example shows how to configure a health-monitoring test:

```
Device(config)# diagnostic monitor threshold switch 1 test 1 failure count 50
Device(config)# diagnostic monitor interval switch 1 test TestPortAsicStackPortLoopback
```

Examples: Schedule Diagnostic Test

This example shows how to schedule diagnostic testing for a specific day and time on a specific switch:

```
Device(config)# diagnostic schedule test DiagThermalTest on June 3 2013 22:25
```

This example shows how to schedule diagnostic testing to occur weekly at a certain time on a specific switch:

```
Device(config)# diagnostic schedule switch 1 test 1,2,4-6 weekly saturday 10:30
```

Examples: Displaying Online Diagnostics

This example shows how to display on demand diagnostic settings:

```
Device# show diagnostic ondemand settings
Test iterations = 1
Action on test failure = continue
```

This example shows how to display diagnostic events for errors:

```
Device# show diagnostic events event-type error
Diagnostic events (storage for 500 events, 0 events recorded)
Number of events matching above criteria = 0
No diagnostic log entry exists.
```

This example shows how to display the description for a diagnostic test:

```
Device# show diagnostic description switch 1 test all
DiagGoldPktTest :
The GOLD packet Loopback test verifies the MAC level loopback functionality. In this test, a GOLD packet, for which doppler provides the support in hardware, is sent. The packet loops back at MAC level and is matched against the stored packet. It is a non-disruptive test.

DiagThermalTest :
This test verifies the temperature reading from the sensor is below the yellow temperature threshold. It is a non-disruptive test and can be run as a health
monitoring test.

**DiagFanTest**: This test verifies all fan modules have been inserted and working properly on the board. It is a non-disruptive test and can be run as a health monitoring test.

**DiagPhyLoopbackTest**: The PHY Loopback test verifies the PHY level loopback functionality. In this test, a packet is sent which loops back at PHY level and is matched against the stored packet. It is a disruptive test and cannot be run as a health monitoring test.

**DiagScratchRegisterTest**: The Scratch Register test monitors the health of application-specific integrated circuits (ASICs) by writing values into registers and reading back the values from these registers. It is a non-disruptive test and can be run as a health monitoring test.

**DiagPoETest**: This test checks the PoE controller functionality. This is a disruptive test and should not be performed during normal switch operation.

**DiagStackCableTest**: This test verifies the stack ring loopback functionality in the stacking environment. It is a disruptive test and cannot be run as a health monitoring test.

**DiagMemoryTest**: This test runs the exhaustive ASIC memory test during normal switch operation. NG3K utilizes mbist for this test. Memory test is very disruptive in nature and requires switch reboot after the test.

Device#

This example shows how to display the boot up level:

Device# `show diagnostic bootup level`

Current bootup diagnostic level: minimal

Device#

Managing Configuration Files

- Prerequisites for Managing Configuration Files, on page 2271
- Restrictions for Managing Configuration Files, on page 2271
- Information About Managing Configuration Files, on page 2271
- How to Manage Configuration File Information, on page 2278
- Additional References, on page 2307

Prerequisites for Managing Configuration Files

- You should have at least a basic familiarity with the Cisco IOS environment and the command-line interface.
- You should have at least a minimal configuration running on your system. You can create a basic configuration file using the `setup` command.

Restrictions for Managing Configuration Files

- Many of the Cisco IOS commands described in this document are available and function only in certain configuration modes on the device.
- Some of the Cisco IOS configuration commands are only available on certain device platforms, and the command syntax may vary on different platforms.

Information About Managing Configuration Files

Types of Configuration Files

Configuration files contain the Cisco IOS software commands used to customize the functionality of your Cisco device. Commands are parsed (translated and executed) by the Cisco IOS software when the system is booted (from the startup-config file) or when you enter commands at the CLI in a configuration mode.

Startup configuration files (startup-config) are used during system startup to configure the software. Running configuration files (running-config) contain the current configuration of the software. The two configuration
files can be different. For example, you may want to change the configuration for a short time period rather than permanently. In this case, you would change the running configuration using the `configure terminal` EXEC command but not save the configuration using the `copy running-config startup-config` EXEC command.

To change the running configuration, use the `configure terminal` command, as described in the Modifying the Configuration File (CLI) section. As you use the Cisco IOS configuration modes, commands generally are executed immediately and are saved to the running configuration file either immediately after you enter them or when you exit a configuration mode.

To change the startup configuration file, you can either save the running configuration file to the startup configuration using the `copy running-config startup-config` EXEC command or copy a configuration file from a file server to the startup configuration (see the Copying a Configuration File from a TFTP Server to the Device (CLI) section for more information).

### Configuration Mode and Selecting a Configuration Source

To enter configuration mode on the device, enter the `configure` command at the privileged EXEC prompt. The Cisco IOS software responds with the following prompt asking you to specify the terminal, memory, or a file stored on a network server (network) as the source of configuration commands:

```
Configuring from terminal, memory, or network [terminal]?
```

Configuring from the terminal allows you to enter configuration commands at the command line, as described in the following section. See the Re-executing the Configuration Commands in the Startup Configuration File (CLI) section for more information.

Configuring from the network allows you to load and execute configuration commands over the network. See the Copying a Configuration File from a TFTP Server to the Device (CLI) section for more information.

### Configuration File Changes Using the CLI

The Cisco IOS software accepts one configuration command per line. You can enter as many configuration commands as you want. You can add comments to a configuration file describing the commands you have entered. Precede a comment with an exclamation point (!). Because comments are not stored in NVRAM or in the active copy of the configuration file, comments do not appear when you list the active configuration with the `show running-config` or `more system:running-config` EXEC command. Comments are not displayed when you list the startup configuration with the `show startup-config` or `more nvram:startup-config` EXEC mode command. Comments are stripped out of the configuration file when it is loaded onto the device. However, you can list the comments in configuration files stored on a File Transfer Protocol (FTP), Remote Copy Protocol (RCP), or Trivial File Transfer Protocol (TFTP) server. When you configure the software using the CLI, the software executes the commands as you enter them.

### Location of Configuration Files

Configuration files are stored in the following locations:

- The running configuration is stored in RAM.
- On all platforms except the Class A Flash file system platforms, the startup configuration is stored in nonvolatile random-access memory (NVRAM).
On Class A Flash file system platforms, the startup configuration is stored in the location specified by the 
CONFIG_FILE environment variable (see the Specifying the CONFIG_FILE Environment Variable on Class A Flash File Systems (CLI) section). The CONFIG_FILE variable defaults to NVRAM and 
can be a file in the following file systems:

- **nvram**: (NVRAM)
- **bootflash**: (internal flash memory)
- **usbflash0**: (flash file system)

Copy Configuration Files from a Network Server to the Device

You can copy configuration files from a TFTP, rcp, or FTP server to the running configuration or startup 
configuration of the device. You may want to perform this function for one of the following reasons:

- To restore a backed-up configuration file.
- To use the configuration file for another device. For example, you may add another device to your network 
and want it to have a similar configuration to the original device. By copying the file to the new device, 
you can change the relevant parts rather than recreating the whole file.
- To load the same configuration commands on to all of the devicees in your network so that all of the 
devicees have similar configurations.

The `copy {ftp: | rcp: | tftp:system:running-config} EXEC` command loads the configuration files into the 
device as if you were typing the commands on the command line. The device does not erase the existing 
running configuration before adding the commands. If a command in the copied configuration file replaces 
a command in the existing configuration file, the existing command is erased. For example, if the copied 
configuration file contains a different IP address in a particular command than the existing configuration, the 
IP address in the copied configuration is used. However, some commands in the existing configuration may 
not be replaced or negated. In this case, the resulting configuration file is a mixture of the existing configuration 
file and the copied configuration file, with the copied configuration file having precedence.

To restore a configuration file to an exact copy of a file stored on a server, you need to copy the configuration 
file directly to the startup configuration (using the `copy ftp:| rcp:| tftp: nvram:startup-config` command) 
and reload the device.

To copy configuration files from a server to a device, perform the tasks described in the following sections.
The protocol that you use depends on which type of server you are using. The FTP and rcp transport mechanisms 
provide faster performance and more reliable delivery of data than TFTP. These improvements are possible 
because the FTP and rcp transport mechanisms are built on and use the TCP/IP stack, which is 
connection-oriented.

Copying a Configuration File from the Device to a TFTP Server

In some implementations of TFTP, you must create a dummy file on the TFTP server and give it read, write, 
and execute permissions before copying a file over it. Refer to your TFTP documentation for more information.

Copying a Configuration File from the Device to an RCP Server

You can copy a configuration file from the device to an RCP server.
One of the first attempts to use the network as a resource in the UNIX community resulted in the design and implementation of the remote shell protocol, which included the remote shell (rsh) and remote copy (rcp) functions. Rsh and rcp give users the ability to execute commands remotely and copy files to and from a file system residing on a remote host or server on the network. The Cisco implementation of rsh and rcp interoperates with standard implementations.

The rcp copy commands rely on the rsh server (or daemon) on the remote system. To copy files using rcp, you need not create a server for file distribution, as you do with TFTP. You need only to have access to a server that supports the remote shell (rsh). (Most UNIX systems support rsh.) Because you are copying a file from one place to another, you must have read permission on the source file and write permission on the destination file. If the destination file does not exist, rcp creates it for you.

Although the Cisco rcp implementation emulates the functions of the UNIX rcp implementation—copying files among systems on the network—the Cisco command syntax differs from the UNIX rcp command syntax. The Cisco rcp support offers a set of copy commands that use rcp as the transport mechanism. These rcp copy commands are similar in style to the Cisco TFTP copy commands, but they offer an alternative that provides faster performance and reliable delivery of data. These improvements are possible because the rcp transport mechanism is built on and uses the TCP/IP stack, which is connection-oriented. You can use rcp commands to copy system images and configuration files from the device to a network server and vice versa.

You also can enable rcp support to allow users on remote systems to copy files to and from the device.

To configure the Cisco IOS software to allow remote users to copy files to and from the device, use the ip rcmd rcp-enable global configuration command.

### Restrictions

The RCP protocol requires a client to send a remote username on each RCP request to a server. When you copy a configuration file from the device to a server using RCP, the Cisco IOS software sends the first valid username it encounters in the following sequence:

1. The username specified in the copy EXEC command, if a username is specified.

2. The username set by the ip rcmd remote-username global configuration command, if the command is configured.

3. The remote username associated with the current tty (terminal) process. For example, if the user is connected to the device through Telnet and was authenticated through the username command, the device software sends the Telnet username as the remote username.

4. The device host name.

For the RCP copy request to execute successfully, an account must be defined on the network server for the remote username. If the server has a directory structure, the configuration file or image is written to or copied from the directory associated with the remote username on the server. For example, if the system image resides in the home directory of a user on the server, you can specify that user name as the remote username.

Use the ip rcmd remote-username command to specify a username for all copies. (Rcmd is a UNIX routine used at the super-user level to execute commands on a remote machine using an authentication scheme based on reserved port numbers. Rcmd stands for “remote command”). Include the username in the copy command if you want to specify a username for that copy operation only.

If you are writing to the server, the RCP server must be properly configured to accept the RCP write request from the user on the device. For UNIX systems, you must add an entry to the .rhosts file for the remote user on the RCP server. For example, suppose the device contains the following configuration lines:

```bash
# .rhosts file for the remote user on the RCP server
Owner user
```

**Note:**

- **RCP** is an acronym for Remote Copy Protocol.
- **TFTP** stands for Trivial File Transfer Protocol.
- **Rcmd** is a UNIX routine used to execute commands on a remote machine.
hostname Device1
ip rcmd remote-username User0

If the device IP address translates to device1.example.com, then the .rhosts file for User0 on the RCP server should contain the following line:

Device1.example.com Device1

Requirements for the RCP Username

The RCP protocol requires a client to send a remote username on each RCP request to a server. When you copy a configuration file from the device to a server using RCP, the Cisco IOS software sends the first valid username it encounters in the following sequence:

1. The username specified in the copy EXEC command, if a username is specified.
2. The username set by the ip rcmd remote-username global configuration command, if the command is configured.
3. The remote username associated with the current tty (terminal) process. For example, if the user is connected to the device through Telnet and is authenticated through the username command, the device software sends the Telnet username as the remote username.
4. The device host name.

For the RCP copy request to execute, an account must be defined on the network server for the remote username. If the server has a directory structure, the configuration file or image is written to or copied from the directory associated with the remote username on the server. For example, if the system image resides in the home directory of a user on the server, specify that user name as the remote username.

Refer to the documentation for your RCP server for more information.

Copying a Configuration File from the Device to an FTP Server

You can copy a configuration file from the device to an FTP server.

Understanding the FTP Username and Password

The FTP protocol requires a client to send a remote username and password on each FTP request to a server. When you copy a configuration file from the device to a server using FTP, the Cisco IOS software sends the first valid username it encounters in the following sequence:

1. The username specified in the copy EXEC command, if a username is specified.
2. The username set by the ip ftp username global configuration command, if the command is configured.
3. Anonymous.

The device sends the first valid password it encounters in the following sequence:

1. The password specified in the copy command, if a password is specified.
2. The password set by the ip ftp password command, if the command is configured.
3. The device forms a password `username @devicename.domain`. The variable `username` is the username associated with the current session, `devicename` is the configured host name, and `domain` is the domain of the device.

The username and password must be associated with an account on the FTP server. If you are writing to the server, the FTP server must be properly configured to accept the FTP write request from the user on the device. If the server has a directory structure, the configuration file or image is written to or copied from the directory associated with the username on the server. For example, if the system image resides in the home directory of a user on the server, specify that user name as the remote username.

Refer to the documentation for your FTP server for more information.

Use the `ip ftp username` and `ip ftp password` global configuration commands to specify a username and password for all copies. Include the username in the `copy` EXEC command if you want to specify a username for that copy operation only.

### Copy Configuration Files from a Switch to Another Switch

You can copy the configurations from one switch to another. This is a 2-step process - Copy the configurations from the switch to the TFTP server, and then from TFTP to another switch.

To copy your current configurations from the switch, run the command `copy startup-config tftp:` and follow the instructions. The configurations are copied onto the TFTP server.

Then, login to another switch and run the command `copy tftp: startup-config` and follow the instructions. The configurations are now copied onto the other switch.

After the configurations are copied, to save your configurations, use `write memory` command and then either reload the switch or run the `copy startup-config running-config` command.

For more information, see *Cisco IOS Configuration Fundamentals Command Reference, Cisco IOS XE Release 16.1 (Catalyst 3850 Switches)*.

### Configuration Files Larger than NVRAM

To maintain a configuration file that exceeds the size of NVRAM, you should be aware of the information in the following sections.

### Compressing the Configuration File

The `service compress-config` global configuration command specifies that the configuration file be stored compressed in NVRAM. Once the configuration file has been compressed, the device functions normally. When the system is booted, it recognizes that the configuration file is compressed, expands it, and proceeds normally. The `more nvram:startup-config` EXEC command expands the configuration before displaying it.

Before you compress configuration files, refer to the appropriate hardware installation and maintenance publication. Verify that your system’s ROMs support file compression. If not, you can install new ROMs that support file compression.

The size of the configuration must not exceed three times the NVRAM size. For a 128-KB size NVRAM, the largest expanded configuration file size is 384 KB.
The `service compress-config` global configuration command works only if you have Cisco IOS software Release 10.0 or later release boot ROMs. Installing new ROMs is a one-time operation and is necessary only if you do not already have Cisco IOS Release 10.0 in ROM. If the boot ROMs do not recognize a compressed configuration, the following message is displayed:

```
Boot ROMs do not support NVRAM compression Config NOT written to NVRAM
```

### Storing the Configuration in Flash Memory on Class A Flash File Systems

On class A Flash file system devices, you can store the startup configuration in flash memory by setting the `CONFIG_FILE` environment variable to a file in internal flash memory or flash memory in a PCMCIA slot.

See the Specifying the `CONFIG_FILE` Environment Variable on Class A Flash File Systems (CLI) section for more information.

Care must be taken when editing or changing a large configuration. Flash memory space is used every time a `copy system:running-config nvram:startup-config` EXEC command is issued. Because file management for flash memory (such as optimizing free space) is not done automatically, you must pay close attention to available flash memory. Use the `squeeze` command to reclaim used space. We recommend that you use a large-capacity Flash card of at least 20 MB.

### Loading the Configuration Commands from the Network

You can also store large configurations on FTP, RCP, or TFTP servers and download them at system startup. To use a network server to store large configurations, see the Copying a Configuration File from the Device to a TFTP Server (CLI) and Configuring the Device to Download Configuration Files sections for more information on these commands.

### Configuring the Device to Download Configuration Files

You can configure the device to load one or two configuration files at system startup. The configuration files are loaded into memory and read in as if you were typing the commands at the command line. Thus, the configuration for the device is a mixture of the original startup configuration and the one or two downloaded configuration files.

### Network Versus Host Configuration Files

For historical reasons, the first file the device downloads is called the network configuration file. The second file the device downloads is called the host configuration file. Two configuration files can be used when all of the devices on a network use many of the same commands. The network configuration file contains the standard commands used to configure all of the devices. The host configuration files contain the commands specific to one particular host. If you are loading two configuration files, the host configuration file should be the configuration file you want to have precedence over the other file. Both the network and host configuration files must reside on a network server reachable via TFTP, RCP, or FTP, and must be readable.
How to Manage Configuration File Information

Displaying Configuration File Information (CLI)

To display information about configuration files, complete the tasks in this section:

**SUMMARY STEPS**

1. `enable`
2. `show boot`
3. `more file-url`
4. `show running-config`
5. `show startup-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>show boot</code></td>
<td>Lists the contents of the BOOT environment variable (if set), the name of the configuration file pointed to by the CONFIG_FILE environment variable, and the contents of the BOOTLDR environment variable.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show boot</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>more file-url</code></td>
<td>Displays the contents of a specified file.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# more 10.1.1.1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>show running-config</code></td>
<td>Displays the contents of the running configuration file. (Command alias for the <code>more system:running-config</code> command.)</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show running-config</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> <code>show startup-config</code></td>
<td>Displays the contents of the startup configuration file. (Command alias for the <code>more nvram:startup-config</code> command.)</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show startup-config</td>
<td>On all platforms except the Class A Flash file system platforms, the default startup-config file usually is stored in NVRAM. On the Class A Flash file system platforms, the CONFIG_FILE environment variable points to the default startup-config file.</td>
</tr>
</tbody>
</table>
The CONFIG_FILE variable defaults to NVRAM.

Modifying the Configuration File (CLI)

The Cisco IOS software accepts one configuration command per line. You can enter as many configuration commands as you want. You can add comments to a configuration file describing the commands you have entered. Precede a comment with an exclamation point (!). Because comments are not stored in NVRAM or in the active copy of the configuration file, comments do not appear when you list the active configuration with the `show running-config` or `more system:running-config` EXEC commands. Comments do not display when you list the startup configuration with the `show startup-config` or `more nvram:startup-config` EXEC mode commands. Comments are stripped out of the configuration file when it is loaded onto the device. However, you can list the comments in configuration files stored on a File Transfer Protocol (FTP), Remote Copy Protocol (RCP), or Trivial File Transfer Protocol (TFTP) server. When you configure the software using the CLI, the software executes the commands as you enter them. To configure the software using the CLI, use the following commands in privileged EXEC mode:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `configuration command`
4. Do one of the following:
   - `end`
   - `^Z`
5. `copy system:running-config nvram:startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> configuration command</td>
<td>Enter the necessary configuration commands. The Cisco IOS documentation set describes configuration commands organized by technology.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device(config)# configuration command</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> Do one of the following:</td>
<td>Ends the configuration session and exits to EXEC mode.</td>
</tr>
</tbody>
</table>
When you press the Ctrl and Z keys simultaneously, ^Z is displayed to the screen.

**Example:**

Device(config)# end

Saves the running configuration file as the startup configuration file.

**Step 5**

**copy system:running-config nvram:startup-config**

**Example:**

Device# copy system:running-config nvram:startup-config

You may also use the **copy running-config startup-config** command alias, but you should be aware that this command is less precise. On most platforms, this command saves the configuration to NVRAM. On the Class A Flash file system platforms, this step saves the configuration to the location specified by the CONFIG_FILE environment variable (the default CONFIG_FILE variable specifies that the file should be saved to NVRAM).

**Examples**

In the following example, the device prompt name of the device is configured. The comment line, indicated by the exclamation mark (!), does not execute any command. The **hostname** command is used to change the device name from device to new_name. By pressing Ctrl-Z (^Z) or entering the **end** command, the user quits configuration mode. The **copy system:running-config nvram:startup-config** command saves the current configuration to the startup configuration.

Device# configure terminal
Device(config)# !The following command provides the switch host name.
Device(config)# hostname new_name
new_name(config)# end
new_name# copy system:running-config nvram:startup-config

When the startup configuration is NVRAM, it stores the current configuration information in text format as configuration commands, recording only non-default settings. The memory is checksummed to guard against corrupted data.

**Note**

Some specific commands might not get saved to NVRAM. You need to enter these commands again if you reboot the machine. These commands are noted in the documentation. We recommend that you keep a list of these settings so that you can quickly reconfigure your device after rebooting.

**Copying a Configuration File from the Device to a TFTP Server (CLI)**

To copy configuration information on a TFTP network server, complete the tasks in this section:
SUMMARY STEPS

1. **enable**
2. **copy system:running-config tftp: [[[//location ]directory ]/filename ]**
3. **copy nvram:startup-config tftp: [[[//location ]directory ]/filename ]**

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device&gt; enable</td>
</tr>
</tbody>
</table>

**Step 2**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# copy system:running-config tftp: //server1/topdir/file10</td>
</tr>
</tbody>
</table>

**Step 3**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy nvram:startup-config tftp: [[[//location ]directory ]/filename ]</td>
<td>Copies the startup configuration file to a TFTP server.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# copy nvram:startup-config tftp: //server1/1stdir/file10</td>
</tr>
</tbody>
</table>

**Examples**
The following example copies a configuration file from a device to a TFTP server:

```
Device# copy system:running-config tftp://172.16.2.155/tokyo-config
Write file tokyo-config on host 172.16.2.155? [confirm] Y
Writing tokyo-config!!! [OK]
```

**What to Do Next**
After you have issued the **copy** command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

**Copying a Configuration File from the Device to an RCP Server (CLI)**
To copy a startup configuration file or a running configuration file from the device to an RCP server, use the following commands beginning in privileged EXEC mode:
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip rcmd remote-username username`
4. `end`
5. Do one of the following:
   - `copy system:running-config rcp: [[[//username@]location ]/directory ]/filename ]`
   - `copy nvram:startup-config rcp: [[[//username@]location ]/directory ]/filename ]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Device&gt;</code> enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip rcmd remote-username username</code></td>
<td>(Optional) Changes the default remote username.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# ip rcmd remote-username NetAdmin1</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> <code>end</code></td>
<td>(Optional) Exits global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device(config)# end</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> Do one of the following:</td>
<td>• Specifies that the device running configuration file is to be stored on an RCP server</td>
</tr>
<tr>
<td>• <code>copy system:running-config rcp: [[[//username@]location ]/directory ]/filename ]</code></td>
<td>or</td>
</tr>
<tr>
<td>• <code>copy nvram:startup-config rcp: [[[//username@]location ]/directory ]/filename ]</code></td>
<td>• Specifies that the device startup configuration file is to be stored on an RCP server</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# copy system:running-config rcp: //NetAdmin1@example.com/dir-files/file1</code></td>
<td></td>
</tr>
</tbody>
</table>
Examples

Storing a Running Configuration File on an RCP Server

The following example copies the running configuration file named runfile2-config to the netadmin1 directory on the remote host with an IP address of 172.16.101.101:

```
Device# copy system:running-config rcp://netadmin1@172.16.101.101/runfile2-config
Write file runfile2-config on host 172.16.101.101?[confirm]
Building configuration...[OK]
Connected to 172.16.101.101
Device#
```

Storing a Startup Configuration File on an RCP Server

The following example shows how to store a startup configuration file on a server by using RCP to copy the file:

```
Device# configure terminal
Device(config)# ip rcmd remote-username netadmin2
Device(config)# end
Device# copy nvram:startup-config rcp:
Remote host[]? 172.16.101.101
Name of configuration file to write [start-confg]? Write file start-confg on host 172.16.101.101?[confirm] ![OK]
```

What to Do Next

After you have issued the copy EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the copy command and the current setting of the file prompt global configuration command.

Copying a Configuration File from the Device to the FTP Server (CLI)

To copy a startup configuration file or a running configuration file from the device to an FTP server, complete the following tasks:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip ftp username *username*
4. ip ftp password *password*
5. end
6. Do one of the following:
   * copy system:running-config ftp: [[[//[username [:password ]@]location]/directory ]/filename ]
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

**Step 2**

Enters global configuration mode on the device.

**Example:**

Device# configure terminal

**Step 3**

(Optional) Specifies the default remote username.

**Example:**

Device(config)# ip ftp username NetAdmin1

**Step 4**

(Optional) Specifies the default password.

**Example:**

Device(config)# ip ftp password adminpassword

**Step 5**

(Optional) Exits global configuration mode. This step is required only if you override the default remote username or password (see Steps 2 and 3).

**Example:**

Device(config)# end

**Step 6**

Do one of the following:

- **copy system:running-config ftp:** `[[[[username [password ]@[]location]directory ]filename ] or
- **copy nvram:startup-config ftp:** `[[[[username [password ]@]location]directory ]filename ]`

**Example:**

Device# copy system:running-config ftp:

### Examples

**Storing a Running Configuration File on an FTP Server**

The following example copies the running configuration file named runfile-confg to the netadmin1 directory on the remote host with an IP address of 172.16.101.101:

```
Device# copy system:running-config ftp://netadmin1:mypass@172.16.101.101/runfile-confg
Write file runfile-confg on host 172.16.101.101? [confirm]
```
Storing a Startup Configuration File on an FTP Server

The following example shows how to store a startup configuration file on a server by using FTP to copy the file:

Device# configure terminal
Device(config)# ip ftp username netadmin2
Device(config)# ip ftp password mypass
Device(config)# end
Device# copy nvram:startup-config ftp:
Remote host[]? 172.16.101.101
Name of configuration file to write [start-confg]? Write file start-confg on host 172.16.101.101?[confirm] ![OK]

What to Do Next

After you have issued the copy EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the copy command and the current setting of the file prompt global configuration command.

Copying a Configuration File from a TFTP Server to the Device (CLI)

To copy a configuration file from a TFTP server to the device, complete the tasks in this section:

SUMMARY STEPS

1. enable
2. copy tftp: [[/location]/directory]/filename system:running-config
3. copy tftp: [[/location]/directory]/filename nvram:startup-config
4. copy tftp: [[/location]/directory]/filename flash-[n]:/directory/startup-config

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> copy tftp: [[/location]/directory]/filename system:running-config</td>
<td>Copies a configuration file from a TFTP server to the running configuration.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# copy tftp://server1/dir10/datasource system:running-config</td>
<td>Copies a configuration file from a TFTP server to the startup configuration.</td>
</tr>
</tbody>
</table>

**Step 3**

- **copy tftp:** 
  
  ```plaintext
  [[[/location]/directory]/filename] 
  nvram:startup-config
  ```

  **Example:**

  ```plaintext
  Device# copy tftp://server1/dir10/datasource nvram:startup-config
  ```

**Step 4**

- **copy tftp:** 
  
  ```plaintext
  [[[/location]/directory]/filename]flash-[n]:/directory/startup-config
  ```

  **Example:**

  ```plaintext
  Device# copy tftp://server1/dir10/datasource flash:startup-config
  ```

### Examples

In the following example, the software is configured from the file named `tokyo-config` at IP address 172.16.2.155:

```plaintext
Device# copy tftp://172.16.2.155/tokyo-config system:running-config
```

Configure using tokyo-config from 172.16.2.155? [confirm] Y

Booting tokyo-config from 172.16.2.155:!!! [OK - 874/16000 bytes]

### What to Do Next

After you have issued the `copy` EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the `copy` command and the current setting of the `file prompt` global configuration command.

### Copying a Configuration File from the rcp Server to the Device (CLI)

To copy a configuration file from an rcp server to the running configuration or startup configuration, complete the following tasks:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip rcmd remote-username *username*
4. end
5. Do one of the following:
   - `copy rcp: [[[/username@]location]/directory]/filename]system:running-config`
• copy rcp://[[username@]location]/directory/filename nvram:startup-config

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>

<tr>
<td>rcp://user1@example.com/dir10/fileone</td>
<td></td>
</tr>
<tr>
<td>nvram:startup-config</td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

**Copy RCP Running-Config**

The following example copies a configuration file named host1-config from the netadmin1 directory on the remote server with an IP address of 172.16.101.101, and loads and runs the commands on the device:

```
Device# copy rcp://netadmin1@172.16.101.101/host1-config system:running-config
Configure using host1-config from 172.16.101.101? [confirm]
Connected to 172.16.101.101
Loading 1112 byte file host1-config:! [OK]
Device#
%SYS-5-CONFIG: Configured from host1-config by rcp from 172.16.101.101
```
Copy RCP Startup-Config

The following example specifies a remote username of netadmin1. Then it copies the configuration file named host2-config from the netadmin1 directory on the remote server with an IP address of 172.16.101.101 to the startup configuration.

Device# configure terminal
Device(config)# ip rcmd remote-username netadmin1
Device(config)# end
Device# copy rcp: nvram:startup-config
Address of remote host [255.255.255.255]? 172.16.101.101
Name of configuration file[rtr2-config]? host2-config
Configure using host2-config from 172.16.101.101?[confirm]
Connected to 172.16.101.101
Loading 1112 byte file host2-config:[OK]
[OK]
Device#
%SYS-5-CONFIG_NV:Non-volatile store configured from host2-config by rcp from 172.16.101.101

What to Do Next

After you have issued the copy EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the copy command and the current setting of the file prompt global configuration command.

Copying a Configuration File from an FTP Server to the Device (CLI)

To copy a configuration file from an FTP server to the running configuration or startup configuration, complete the tasks in this section:

SUMMARY STEPS

1. enable
2. configure terminal
3. ip ftp username username
4. ip ftp password password
5. end
6. Do one of the following:

DETAILED STEPS

<table>

<tr>
<td><code>Device# copy ftp:nvram:startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

**Copy FTP Running-Config**

The following example copies a host configuration file named host1-config from the netadmin1 directory on the remote server with an IP address of 172.16.101.101, and loads and runs the commands on the device:

```
Device# copy ftp://netadmin1:mypass@172.16.101.101/host1-config system:running-config
Configure using host1-config from 172.16.101.101? [confirm]
Connected to 172.16.101.101
Loading 1112 byte file host1-config: ! Ok
Device# %SYS-5-CONFIG: Configured from host1-config by ftp from 172.16.101.101
```

**Copy FTP Startup-Config**

The following example specifies a remote username of netadmin1. Then it copies the configuration file named host2-config from the netadmin1 directory on the remote server with an IP address of 172.16.101.101 to the startup configuration:

```
Device# copy ftp://netadmin1:myspec@172.16.101.101/host2-config nvram:startup-config
Configure using host2-config from 172.16.101.101? [confirm]
Connected to 172.16.101.101
Loading 201 byte file host2-config: ! Ok
Device# %SYS-5-CONFIG: Configured from host2-config by ftp from 172.16.101.101
```
What to Do Next

After you have issued the \texttt{copy} EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the \texttt{copy} command and the current setting of the \texttt{file} prompt global configuration command.

Maintaining Configuration Files Larger than NVRAM

To maintain a configuration file that exceeds the size of NVRAM, perform the tasks described in the following sections:

Compressing the Configuration File (CLI)

To compress configuration files, complete the tasks in this section:

**SUMMARY STEPS**

1. \texttt{enable}
2. \texttt{configure terminal}
3. \texttt{service compress-config}
4. \texttt{end}
5. Do one of the following:
   - Use FTP, RCP, or TFTP to copy the new configuration.
   - \texttt{configure terminal}
6. \texttt{copy system:running-config nvram:startup-config}

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{enable}</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>\texttt{Example:}</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>--------------------------------------</td>
</tr>
</tbody>
</table>
| 2    | configure terminal  
**Example:**  
Device# configure terminal | Enters global configuration mode.                                       |
| 3    | service compress-config  
**Example:**  
Device(config)# service compress-config | Specifies that the configuration file be compressed.                     |
| 4    | end  
**Example:**  
Device(config)# end | Exits global configuration mode.                                         |
| 5    | Do one of the following:  
• Use FTP, RCP, or TFTP to copy the new configuration.  
• configure terminal  
**Example:**  
Device# configure terminal | Enters the new configuration:  
• If you try to load a configuration that is more than three times larger than the NVRAM size, the following error message is displayed:  
“[buffer overflow - file-size / buffer-size bytes].” |
| 6    | copy system:running-config nvram:startup-config  
**Example:**  
Device(config)# copy system:running-config nvram:startup-config | When you have finished changing the running-configuration, save the new configuration. |

**Examples**

The following example compresses a 129-KB configuration file to 11 KB:

```
Device# configure terminal
Device(config)# service compress-config
Device(config)# end
Device# copy tftp://172.16.2.15/tokyo-config system:running-config
Configure using tokyo-config from 172.16.2.155? [confirm] y
Booting tokyo-config from 172.16.2.155:!!! [OK - 874/16000 bytes]
Device# copy system:running-config nvram:startup-config
Building configuration...  
Compressing configuration from 129648 bytes to 11077 bytes  
[OK]
```
Storing the Configuration in Flash Memory on Class A Flash File Systems (CLI)

To store the startup configuration in flash memory, complete the tasks in this section:

### SUMMARY STEPS

1. `enable`
2. `copy nvram:startup-config flashfilesystem:filename`
3. `configure terminal`
4. `boot config flashfilesystem: filename`
5. `end`
6. Do one of the following:
   - Use FTP, RCP, or TFTP to copy the new configuration. If you try to load a configuration that is more than three times larger than the NVRAM size, the following error message is displayed: “[buffer overflow - file-size /buffer-size bytes].”
   - `configure terminal`
7. `copy system:running-config nvram:startup-config`

### DETAILED STEPS

</tr>
<tr>
<td>• configure terminal</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example:

Device# configure terminal

<table>
<thead>
<tr>
<th>Step 7</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy system:running-config nvram:startup-config</td>
<td>When you have finished changing the running-configuration, save the new configuration.</td>
<td></td>
</tr>
</tbody>
</table>

Example:

Device(config)# copy system:running-config nvram:startup-config

Examples

The following example stores the configuration file in usbflash0:

Device# copy nvram:startup-config usbflash0:switch-config
Device# configure terminal
Device(config)# boot config usbflash0:switch-config
Device(config)# end
Device# copy system:running-config nvram:startup-config

Loading the Configuration Commands from the Network (CLI)

To use a network server to store large configurations, complete the tasks in this section:

SUMMARY STEPS

1. enable
2. copy system:running-config {ftp: | rcp: | tftp:}
3. configure terminal
4. boot network {ftp://[username[:password[@]]location[/directory]/filename ] | rcp://[username@]location[/directory]/filename ] | tftp://[location[/directory]/filename ]
5. service config
6. end
7. copy system:running-config nvram:startup-config
### DETAILED STEPS

</table>

### Copying Configuration Files from Flash Memory to the Startup or Running Configuration (CLI)

To copy a configuration file from flash memory directly to your startup configuration in NVRAM or your running configuration, enter one of the commands in Step 2:
**SUMMARY STEPS**

1. `enable`  
2. Do one of the following:  
   - `copy filesystem:[partition-number:][filename] nvram:startup-config`  
   - `copy filesystem:[partition-number:][filename] system:running-config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        |         |
| Do one of the following: |         |
| - `copy filesystem:[partition-number:][filename] nvram:startup-config` |         |
| - `copy filesystem:[partition-number:][filename] system:running-config` |         |
| **Example:**      |         |
| `Device# copy usbflash0:4:ios-upgrade-1 nvram:startup-config` |         |

**Examples**

The following example copies the file named `ios-upgrade-1` from partition 4 of the flash memory PC Card in `usbflash0` to the device startup configurations:

```
Device# copy usbflash0:4:ios-upgrade-1 nvram:startup-config
Copy 'ios-upgrade-1' from flash device as 'startup-config' ? [yes/no] yes
[OK]
```

**Copying Configuration Files Between Flash Memory File Systems (CLI)**

On platforms with multiple flash memory file systems, you can copy files from one flash memory file system, such as internal flash memory to another flash memory file system. Copying files to different flash memory file systems lets you create backup copies of working configurations and duplicate configurations for other devices. To copy a configuration file between flash memory file systems, use the following commands in EXEC mode:

**SUMMARY STEPS**

1. `enable`
2. `show source-filesystem:
3. `copy source-filesystem: [partition-number:]filename dest-filesystem: [partition-number:]filename`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> show source-filesystem:</td>
<td>Displays the layout and contents of flash memory to verify the filename.</td>
</tr>
<tr>
<td>Example: Device# show flash:</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> copy source-filesystem:</td>
<td>Copies a configuration file between flash memory devices.</td>
</tr>
<tr>
<td>dest-filesystem: [partition-number:]filename</td>
<td>• The source device and the destination device cannot be the same. For example, the `copy usbflash0:usbflash0: command is invalid.</td>
</tr>
<tr>
<td>Example: Device# copy flash: usbflash0:</td>
<td></td>
</tr>
</tbody>
</table>

### Example

The following example copies the file named running-config from partition 1 on internal flash memory to partition 1 of usbflash0 on a device. In this example, the source partition is not specified, so the device prompts for the partition number:

Device# `copy flash: usbflash0:`

```
System flash
Partition  Size  Used  Free  Bank-Size  State  Copy Mode
 1  4096K  3070K  1025K  4096K Read/Write Direct
 2  16384K  1671K  14712K  8192K Read/Write Direct
[Type ?<no> for partition directory; ? for full directory; q to abort]
Which partition? [default = 1]
System flash directory, partition 1:
File  Length  Name/status
 1  3142748  dirt/network/mars-test/c3600-j-mz.latest
 2   850      running-config
[3143728 bytes used, 1050576 available, 4194304 total]
usbflash0 flash directory:
File  Length  Name/status
 1  171088  dirt/gate/c3600-i-mz
 2   850      running-config
[1712068 bytes used, 2482236 available, 4194304 total]
Source file name? running-config
```

Destination file name [running-config]? 
Verifying checksum for 'running-config' (file # 2)... OK
Erase flash device before writing? [confirm]
Flash contains files. Are you sure you want to erase? [confirm]
Copy 'running-config' from flash: device
as 'running-config' into usbflash0: device WITH erase? [yes/no] yes

Erasing device... eeeeeeeeeeeeeeeeeeeeeeeeee...erased!

[OK - 850/4194304 bytes]
Flash device copy took 00:00:30 [hh:mm:ss]
Verifying checksum... OK (0x16)

Copying a Configuration File from an FTP Server to Flash Memory Devices (CLI)

To copy a configuration file from an FTP server to a flash memory device, complete the task in this section:

**SUMMARY STEPS**

1. `enable`  
2. `configure terminal`  
3. `ip ftp username username`  
4. `ip ftp password password`  
5. `end`  
6. `copy ftp: [//location/directory]/bundle_name flash:`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1     | **enable** | Enables privileged EXEC mode.  
|       | **Example:** |  
|       | Device>` enable` | • Enter your password if prompted.  |
| 2     | **configure terminal** | (Optional) Enters global configuration mode. This step is required only if you override the default remote username or password (see Steps 3 and 4).  
|       | **Example:** |  
|       | Device>` configure terminal` | |
| 3     | **ip ftp username username** | (Optional) Specifies the remote username.  
|       | **Example:** |  
|       | Device(config)> ip ftp username Admin01 | |
| 4     | **ip ftp password password** | (Optional) Specifies the remote password.  
|       | **Example:** |  
|       | Device(config)> ip ftp password adminpassword | |
### What to Do Next

After you have issued the `copy` EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the `copy` command and the current setting of the `file prompt` global configuration command.

### Copying a Configuration File from an RCP Server to Flash Memory Devices (CLI)

To copy a configuration file from an RCP server to a flash memory device, complete the tasks in this section:

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip rcmd remote-username username`
4. `end`
5. `copy rcp: [[//location]/directory ]/bundle_name flash:`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enabled</td>
<td></td>

<td></td>
</tr>
</tbody>
</table>
### Copying a Configuration File from a TFTP Server to Flash Memory Devices (CLI)

To copy a configuration file from a TFTP server to a flash memory device, complete the tasks in this section:

**SUMMARY STEPS**

1. **enable**
2. **copy tftp:**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Copies the file from a TFTP server to the flash memory device. Reply to any device prompts for additional information or confirmation. Prompting depends on how much information you provide in the copy command and the current setting of the file prompt command.</td>
</tr>
<tr>
<td>copy tftp:</td>
<td></td>
</tr>
<tr>
<td>[ ][ ] location ]directory ]/bundle_name flash:</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# copy tftp://netadmin@172.16.101.101/bundle1</td>
<td></td>
</tr>
</tbody>
</table>
Examples

The following example shows the copying of the configuration file named switch-config from a TFTP server to the flash memory card inserted in usbflash0. The copied file is renamed new-config.

Device#
copy tftp:switch-config usbflash0:new-config

Re-executing the Configuration Commands in the Startup Configuration File (CLI)

To re-execute the commands located in the startup configuration file, complete the task in this section:

SUMMARY STEPS

1. enable
2. configure memory

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure memory</td>
<td>Re-executes the configuration commands located in the startup configuration file.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure memory</td>
<td></td>
</tr>
</tbody>
</table>

Clearing the Startup Configuration (CLI)

You can clear the configuration information from the startup configuration. If you reboot the device with no startup configuration, the device enters the Setup command facility so that you can configure the device from scratch. To clear the contents of your startup configuration, complete the task in this section:

SUMMARY STEPS

1. enable
2. erase nvram

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
Deleting a Specified Configuration File (CLI)

To delete a specified configuration on a specific flash device, complete the task in this section:

SUMMARY STEPS

1.  enable
2.  delete flashfilesystem:filename

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> delete flash-filesystem:filename</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td>Deletes the specified configuration file on the specified flash device.</td>
</tr>
</tbody>
</table>
Specifying the CONFIG_FILE Environment Variable on Class A Flash File Systems (CLI)

On Class A flash file systems, you can configure the Cisco IOS software to load the startup configuration file specified by the CONFIG_FILE environment variable. The CONFIG_FILE variable defaults to NVRAM.

To change the CONFIG_FILE environment variable, complete the tasks in this section:

**SUMMARY STEPS**

1. enable
3. configure terminal
4. boot config dest-flash-url
5. end
6. copy system:running-config nvram:startup-config
7. show boot

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

<p>| Step 2            | Copies the configuration file to the flash file system from which the device loads the file on restart. |
| <strong>Example:</strong>      | |
| Device# copy system:running-config nvram:startup-config |</p>
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 3</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>boot config dest-flash-url</td>
<td>Sets the CONFIG_FILE environment variable. This step modifies the runtime CONFIG_FILE environment variable.</td>
</tr>
<tr>
<td>Example</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# boot config 172.16.1.1</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Exits global configuration mode.</td>
</tr>
<tr>
<td>Example</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device(config)# end</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td>copy system:running-config nvram:startup-config</td>
<td>Saves the configuration performed in Step 3 to the startup configuration.</td>
</tr>
<tr>
<td>Example</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# copy system:running-config nvram:startup-config</td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>show boot</td>
<td>(Optional) Allows you to verify the contents of the CONFIG_FILE environment variable.</td>
</tr>
<tr>
<td>Example</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Device# show boot</td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

The following example copies the running configuration file to the device. This configuration is then used as the startup configuration when the system is restarted:

```
Device# copy system:running-config usbflash0:config2
Device# configure terminal
Device(config)# boot config usbflash0:config2
Device(config)# end
Device# copy system:running-config nvram:startup-config
[ok]
Device# show boot
BOOT variable  =  usbflash0:rsp-boot-m
CONFIG_FILE variable  =  nvram:
Current CONFIG_FILE variable  =  usbflash0:config2
Configuration register is 0x010F
```

**What to Do Next**

After you specify a location for the startup configuration file, the `nvram:startup-config` command is aliased to the new location of the startup configuration file. The `more nvram:startup-config` EXEC command
displaysthestartupconfiguration,regardlessofitslocation. Theredare erase nvram:startup-config EXECcommand erases the contents of NVRAM and deletes the file pointed to by the CONFIG_FILE environment variable.

When you save the configuration using the copy system:running-config nvram:startup-config command, the device saves a complete version of the configuration file to the location specified by the CONFIG_FILE environment variable and a distilled version to NVRAM. A distilled version is one that does not contain access list information. If NVRAM contains a complete configuration file, the device prompts you to confirm your overwrite of the complete version with the distilled version. If NVRAM contains a distilled configuration, the device does not prompt you for confirmation and proceeds with overwriting the existing distilled configuration file in NVRAM.

---

If you specify a file in a flash device as the CONFIG_FILE environment variable, every time you save your configuration file with the copy system:running-config nvram:startup-config command, the old configuration file is marked as “deleted,” and the new configuration file is saved to that device. Eventually, Flash memory fills up as the old configuration files still take up memory. Use the squeeze EXEC command to permanently delete the old configuration files and reclaim the space.

---

### Configuring the Device to Download Configuration Files

You can specify an ordered list of network configuration and host configuration filenames. The Cisco IOS XE software scans this list until it loads the appropriate network or host configuration file.

To configure the device to download configuration files at system startup, perform at least one of the tasks described in the following sections:

- Configuring the Device to Download the Network Configuration File (CLI)
- Configuring the Device to Download the Host Configuration File (CLI)

If the device fails to load a configuration file during startup, it tries again every 10 minutes (the default setting) until a host provides the requested files. With each failed attempt, the device displays the following message on the console terminal:

```
Booting host-config... [timed out]
```

If there are any problems with the startup configuration file, or if the configuration register is set to ignore NVRAM, the device enters the Setup command facility.

### Configuring the Device to Download the Network Configuration File (CLI)

To configure the Cisco IOS software to download a network configuration file from a server at startup, complete the tasks in this section:

#### SUMMARY STEPS

1. enable
2. configure terminal
3. boot network ftp://[//username [password ]@]location ]/directory ]/filename ]
   
   rcp://[//username@]location ]/directory ]/filename ]
   
   tftp://[//location ]/directory ]/filename ]
4. service config
### DETAILED STEPS

</tbody>
</table>

### Configuring the Device to Download the Host Configuration File (CLI)

To configure the Cisco IOS software to download a host configuration file from a server at startup, complete the tasks in this section:
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
4. `service config`
5. `end`
6. `copy system:running-config nvram:startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable  
Example:  
Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Step 2** | configure terminal  
Example:  
Device# configure terminal | Enters global configuration mode. |
Example:  
Device(config)# boot host tftp:hostfile1 | Specifies the host configuration file to download at startup, and the protocol to be used (FTP, RCP, or TFTP):  
• If you do not specify a host configuration filename, the device uses its own name to form a host configuration filename by converting the name to all lowercase letters, removing all domain information, and appending “-confg.” If no host name information is available, the software uses the default host configuration filename device-confg. If you omit the address, the device uses the broadcast address.  
• You can specify more than one host configuration file. The Cisco IOS software tries them in order entered until it loads one. This procedure can be useful for keeping files with different configuration information loaded on a network server. |
| **Step 4** | service config  
Example:  
Device(config)# service config | Enables the system to automatically load the host file upon restart. |
| **Step 5** | end  
Example:  
Device(config)# end | Exits global configuration mode. |
### Purpose

**Step 6**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy system:running-config nvram:startup-config</td>
<td>Saves the running configuration to the startup configuration file.</td>
</tr>
</tbody>
</table>

**Example:**

Device# copy system:running-config nvram:startup-config

---

### Example

In the following example, a device is configured to download the host configuration file named `hostfile1` and the network configuration file named `networkfile1`. The device uses TFTP and the broadcast address to obtain the file:

Device# configure terminal
Device(config)# boot host tftp:hostfile1
Device(config)# boot network tftp:networkfile1
Device(config)# service config
Device(config)# end
Device# copy system:running-config nvram:startup-config

---

Prerequisites for Configuration Replace and Configuration Rollback

The format of the configuration files used as input by the Configuration Replace and Configuration Rollback feature must comply with standard Cisco software configuration file indentation rules as follows:

- Start all commands on a new line with no indentation, unless the command is within a configuration submode.
- Indent commands within a first-level configuration submode one space.
- Indent commands within a second-level configuration submode two spaces.
- Indent commands within subsequent submodes accordingly.

These indentation rules describe how the software creates configuration files for such commands as `show running-config` or `copy running-config destination-url`. Any configuration file generated on a Cisco device complies with these rules.

Free memory larger than the combined size of the two configuration files (the current running configuration and the saved replacement configuration) is required.
Restrictions for Configuration Replace and Configuration Rollback

If the device does not have free memory larger than the combined size of the two configuration files (the current running configuration and the saved replacement configuration), the configuration replace operation is not performed.

Certain Cisco configuration commands such as those pertaining to physical components of a networking device (for example, physical interfaces) cannot be added or removed from the running configuration. For example, a configuration replace operation cannot remove the `interface ethernet 0` command line from the current running configuration if that interface is physically present on the device. Similarly, the `interface ethernet 1` command line cannot be added to the running configuration if no such interface is physically present on the device. A configuration replace operation that attempts to perform these types of changes results in error messages indicating that these specific command lines failed.

In very rare cases, certain Cisco configuration commands cannot be removed from the running configuration without reloading the device. A configuration replace operation that attempts to remove this type of command results in error messages indicating that these specific command lines failed.

Information About Configuration Replace and Configuration Rollback

Configuration Archive

The Cisco IOS configuration archive is intended to provide a mechanism to store, organize, and manage an archive of Cisco IOS configuration files to enhance the configuration rollback capability provided by the `configure replace` command. Before this feature was introduced, you could save copies of the running configuration using the `copy running-config destination-url` command, storing the replacement file either locally or remotely. However, this method lacked any automated file management. On the other hand, the Configuration Replace and Configuration Rollback feature provides the capability to automatically save copies of the running configuration to the Cisco IOS configuration archive. These archived files serve as checkpoint configuration references and can be used by the `configure replace` command to revert to previous configuration states.

The `archive config` command allows you to save Cisco IOS configurations in the configuration archive using a standard location and filename prefix that is automatically appended with an incremental version number (and optional timestamp) as each consecutive file is saved. This functionality provides a means for consistent identification of saved Cisco IOS configuration files. You can specify how many versions of the running configuration are kept in the archive. After the maximum number of files are saved in the archive, the oldest file is automatically deleted when the next, most recent file is saved. The `show archive` command displays information for all configuration files saved in the Cisco IOS configuration archive.

The Cisco IOS configuration archive, in which the configuration files are stored and available for use with the `configure replace` command, can be located on the following file systems: FTP, HTTP, RCP, TFTP.
Configuration Replace

The `configure replace` privileged EXEC command provides the capability to replace the current running configuration with any saved Cisco IOS configuration file. This functionality can be used to revert to a previous configuration state, effectively rolling back any configuration changes that were made since the previous configuration state was saved.

When using the `configure replace` command, you must specify a saved Cisco IOS configuration as the replacement configuration file for the current running configuration. The replacement file must be a complete configuration generated by a Cisco IOS device (for example, a configuration generated by the `copy running-config destination-url` command), or, if generated externally, the replacement file must comply with the format of files generated by Cisco IOS devices. When the `configure replace` command is entered, the current running configuration is compared with the specified replacement configuration and a set of diffs is generated. The algorithm used to compare the two files is the same as that employed by the `show archive config differences` command. The resulting diffs are then applied by the Cisco IOS parser to achieve the replacement configuration state. Only the diffs are applied, avoiding potential service disruption from reapplying configuration commands that already exist in the current running configuration. This algorithm effectively handles configuration changes to order-dependent commands (such as access lists) through a multiple pass process. Under normal circumstances, no more than three passes are needed to complete a configuration replace operation, and a limit of five passes is performed to preclude any looping behavior.

The Cisco IOS `copy source-url running-config` privileged EXEC command is often used to copy a stored Cisco IOS configuration file to the running configuration. When using the `copy source-url running-config` command as an alternative to the `configure replace target-url` privileged EXEC command, the following major differences should be noted:

- The `copy source-url running-config` command is a merge operation and preserves all of the commands from both the source file and the current running configuration. This command does not remove commands from the current running configuration that are not present in the source file. In contrast, the `configure replace target-url` command removes commands from the current running configuration that are not present in the replacement file and adds commands to the current running configuration that need to be added.

- The `copy source-url running-config` command applies every command in the source file, whether or not the command is already present in the current running configuration. This algorithm is inefficient and, in some cases, can result in service outages. In contrast, the `configure replace target-url` command only applies the commands that need to be applied—no existing commands in the current running configuration are reapplied.

- A partial configuration file may be used as the source file for the `copy source-url running-config` command, whereas a complete Cisco IOS configuration file must be used as the replacement file for the `configure replace target-url` command.

A locking feature for the configuration replace operation was introduced. When the `configure replace` command is used, the running configuration file is locked by default for the duration of the configuration replace operation. This locking mechanism prevents other users from changing the running configuration while the replacement operation is taking place, which might otherwise cause the replacement operation to terminate unsuccessfully. You can disable the locking of the running configuration by using the `no lock` keyword when issuing the `configure replace` command.

The running configuration lock is automatically cleared at the end of the configuration replace operation. You can display any locks that may be currently applied to the running configuration using the `show configuration lock` command.
Configuration Rollback

The concept of rollback comes from the transactional processing model common to database operations. In a database transaction, you might make a set of changes to a given database table. You then must choose whether to commit the changes (apply the changes permanently) or to roll back the changes (discard the changes and revert to the previous state of the table). In this context, rollback means that a journal file containing a log of the changes is discarded, and no changes are applied. The result of the rollback operation is to revert to the previous state, before any changes were applied.

The configure replace command allows you to revert to a previous configuration state, effectively rolling back changes that were made since the previous configuration state was saved. Instead of basing the rollback operation on a specific set of changes that were applied, the Cisco IOS configuration rollback capability uses the concept of reverting to a specific configuration state based on a saved Cisco IOS configuration file. This concept is similar to the database idea of saving a checkpoint (a saved version of the database) to preserve a specific state.

If the configuration rollback capability is desired, you must save the Cisco IOS running configuration before making any configuration changes. Then, after entering configuration changes, you can use that saved configuration file to roll back the changes (using the configure replace target-url command). Furthermore, because you can specify any saved Cisco IOS configuration file as the replacement configuration, you are not limited to a fixed number of rollbacks, as is the case in some rollback models.

Configuration Rollback Confirmed Change

The Configuration Rollback Confirmed Change feature allows configuration changes to be performed with an optional requirement that they be confirmed. If this confirmation is not received, the configuration is returned to the state prior to the changes being applied. The mechanism provides a safeguard against inadvertent loss of connectivity between a network device and the user or management application due to configuration changes.

Benefits of Configuration Replace and Configuration Rollback

- Allows you to revert to a previous configuration state, effectively rolling back configuration changes.
- Allows you to replace the current running configuration file with the startup configuration file without having to reload the device or manually undo CLI changes to the running configuration file, therefore reducing system downtime.
- Allows you to revert to any saved Cisco IOS configuration state.
- Simplifies configuration changes by allowing you to apply a complete configuration file to the device, where only the commands that need to be added or removed are affected.
- When using the configure replace command as an alternative to the copy source-url running-config command, increases efficiency and prevents risk of service outages by not reapplying existing commands in the current running configuration.
How to Use Configuration Replace and Configuration Rollback

Creating a Configuration Archive (CLI)

No prerequisite configuration is needed to use the `configure replace` command. Using the `configure replace` command in conjunction with the Cisco IOS configuration archive and the `archive config` command is optional but offers significant benefit for configuration rollback scenarios. Before using the `archive config` command, the configuration archive must be configured. Perform this task to configure the characteristics of the configuration archive.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `archive`
4. `path url`
5. `maximum number`
6. `time-period minutes`
7. `end`
8. `archive config`

DETAILED STEPS

<table>

</tr>
<tr>
<td>Device(config-archive)# path flash:myconfiguration</td>
<td>If a directory is specified in the path instead of file, the directory name must be followed by a forward slash as follows: path flash:/directory/. The forward slash is not necessary after a filename; it is only necessary when specifying a directory.</td>
</tr>
</tbody>
</table>

**Step 5**  
**maximum number**  
**Example:**  
Device(config-archive)# maximum 14  
(Optional) Sets the maximum number of archive files of the running configuration to be saved in the Cisco IOS configuration archive.  
- The *number* argument is the maximum number of archive files of the running configuration to be saved in the Cisco IOS configuration archive. Valid values are from 1 to 14. The default is 10.  
**Note**  
Before using this command, you must configure the *path* command to specify the location and filename prefix for the files in the Cisco IOS configuration archive.

**Step 6**  
**time-period minutes**  
**Example:**  
Device(config-archive)# time-period 1440  
(Optional) Sets the time increment for automatically saving an archive file of the current running configuration in the Cisco IOS configuration archive.  
- The *minutes* argument specifies how often, in minutes, to automatically save an archive file of the current running configuration in the Cisco IOS configuration archive.  
**Note**  
Before using this command, you must configure the *path* command to specify the location and filename prefix for the files in the Cisco IOS configuration archive.

**Step 7**  
**end**  
**Example:**  
Device(config-archive)# end  
Exits to privileged EXEC mode.

**Step 8**  
**archive config**  
**Example:**  
Device# archive config  
Saves the current running configuration file to the configuration archive.  
**Note**  
The *path* command must be configured before using this command.
Performing a Configuration Replace or Configuration Rollback Operation (CLI)

Perform this task to replace the current running configuration file with a saved Cisco IOS configuration file.

**Note**

You must create a configuration archive before performing this procedure. See Creating a Configuration Archive (CLI) for detailed steps. The following procedure details how to return to that archived configuration in the event of a problem with the current running configuration.

**SUMMARY STEPS**

1. **enable**
2. **configure replace target-url [nolock] [list] [force] [ignore case] [revert trigger [error] [timer minutes] | time minutes]**
3. **configure revert { now | timer {minutes | idle minutes} }**
4. **configure confirm**
5. **exit**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| Device> enable | *

| **Step 2** | Replaces the current running configuration file with a saved Cisco IOS configuration file. |
| configure replace target-url [nolock] [list] [force] [ignore case] [revert trigger [error] [timer minutes] | time minutes] | |
| **Example:** | |
| Device# configure replace flash: startup-config time 120 | *

- The `target-url` argument is a URL (accessible by the Cisco IOS file system) of the saved Cisco IOS configuration file that is to replace the current running configuration, such as the configuration file created using the `archive config` command.

- The `list` keyword displays a list of the command lines applied by the Cisco IOS software parser during each pass of the configuration replace operation. The total number of passes performed is also displayed.

- The `force` keyword replaces the current running configuration file with the specified saved Cisco IOS configuration file without prompting you for confirmation.

- The `time` keyword and argument specify the time (in minutes) within which you must enter the `configure confirm` command to confirm replacement of the current running configuration file. If the `configure confirm` command is not entered within the
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Specified time limit, the configuration replace operation is automatically reversed (in other words, the current running configuration file is restored to the configuration state that existed prior to entering the <code>configure replace</code> command).</td>
</tr>
<tr>
<td></td>
<td>- The <code>nolock</code> keyword disables the locking of the running configuration file that prevents other users from changing the running configuration during a configuration replace operation.</td>
</tr>
<tr>
<td></td>
<td>- The <code>revert trigger</code> keywords set the following triggers for reverting to the original configuration:</td>
</tr>
<tr>
<td></td>
<td>- <code>error</code> — Reverts to the original configuration upon error.</td>
</tr>
<tr>
<td></td>
<td>- <code>timer minutes</code> — Reverts to the original configuration if specified time elapses.</td>
</tr>
<tr>
<td></td>
<td>- The <code>ignore case</code> keyword allows the configuration to ignore the case of the confirmation command.</td>
</tr>
</tbody>
</table>

**Step 3**

configure revert { now | timer (minutes | idle minutes) }

Example:

Device# configure revert now

(Optional) To cancel the timed rollback and trigger the rollback immediately, or to reset parameters for the timed rollback, use the `configure revert` command in privileged EXEC mode.

- `now` — Triggers the rollback immediately.
- `timer` — Resets the configuration revert timer.
  - Use the `minutes` argument with the `timer` keyword to specify a new revert time in minutes.
  - Use the `idle` keyword along with a time in minutes to set the maximum allowable time period of no activity before reverting to the saved configuration.

**Step 4**

configure confirm

Example:

Device# configure confirm

(Optional) Confirms replacement of the current running configuration file with a saved Cisco IOS configuration file.

**Note**

Use this command only if the `time seconds` keyword and argument of the `configure replace` command are specified.

**Step 5**

exit

Example:

Device# exit

Exits to user EXEC mode.
Monitoring and Troubleshooting the Feature (CLI)

Perform this task to monitor and troubleshoot the Configuration Replace and Configuration Rollback feature.

SUMMARY STEPS

1. enable
2. show archive
3. debug archive versioning
4. debug archive config timestamp
5. exit

DETAILED STEPS

Step 1  
**enable**

Use this command to enable privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2  
**show archive**

Use this command to display information about the files saved in the Cisco IOS configuration archive.

Example:

```
Device# show archive
There are currently 1 archive configurations saved.
The next archive file will be named flash:myconfiguration-2
Archive  Name
0
1       flash:myconfiguration-1 <- Most Recent
2
3
4
5
6
7
8
9
10
11
12
13
14
```

The following is sample output from the `show archive` command after several archive files of the running configuration have been saved. In this example, the maximum number of archive files to be saved is set to three.

Example:

```
Device# show archive
There are currently 3 archive configurations saved.
The next archive file will be named flash:myconfiguration-8
```
Step 3  debug archive versioning

Use this command to enable debugging of the Cisco IOS configuration archive activities to help monitor and troubleshoot configuration replace and rollback.

Example:

Device# debug archive versioning
Jan 9 06:46:28.419:backup_running_config
Jan 9 06:46:28.419:Current = 7
Jan 9 06:46:28.443:Writing backup file flash:myconfiguration-7
Jan 9 06:46:29.547: backup worked

Step 4  debug archive config timestamp

Use this command to enable debugging of the processing time for each integral step of a configuration replace operation and the size of the configuration files being handled.

Example:

Device# debug archive config timestamp
Device# configure replace flash:myconfiguration force
Timing Debug Statistics for IOS Config Replace operation:
  Time to read file usbflash0:sample_2.cfg = 0 msec (0 sec)
  Number of lines read:55
  Size of file :1054
Starting Pass 1
  Time to read file system:running-config = 0 msec (0 sec)
  Number of lines read:93
  Size of file :2539
  Time taken for positive rollback pass = 320 msec (0 sec)
  Time taken for negative rollback pass = 0 msec (0 sec)
  Time taken for negative incremental diffs pass = 59 msec (0 sec)
  Time taken by PI to apply changes = 0 msec (0 sec)
  Time taken for Pass 1 = 380 msec (0 sec)
Starting Pass 2
  Time to read file system:running-config = 0 msec (0 sec)
  Number of lines read:55
  Size of file :1054
  Time taken for positive rollback pass = 0 msec (0 sec)
  Time taken for negative rollback pass = 0 msec (0 sec)
  Time taken for Pass 2 = 0 msec (0 sec)
Total number of passes:1
Rollback Done

Step 5  exit
Configuration Examples for Configuration Replace and Configuration Rollback

Creating a Configuration Archive

The following example shows how to perform the initial configuration of the Cisco IOS configuration archive. In this example, flash:myconfiguration is specified as the location and filename prefix for the files in the configuration archive and a value of 10 is set as the maximum number of archive files to be saved.

```plaintext
configure terminal
!
archive
    path flash:myconfiguration
    maximum 10
end
```

Replacing the Current Running Configuration with a Saved Cisco IOS Configuration File

The following example shows how to replace the current running configuration with a saved Cisco IOS configuration file named flash:myconfiguration. The `configure replace` command interactively prompts you to confirm the operation.

```
Device# configure replace flash:myconfiguration
This will apply all necessary additions and deletions to replace the current running configuration with the contents of the specified configuration file, which is assumed to be a complete configuration, not a partial configuration. Enter Y if you are sure you want to proceed. ? [no]: Y
Total number of passes: 1
Rollback Done
```

In the following example, the `list` keyword is specified in order to display the command lines that were applied during the configuration replace operation:

```
Device# configure replace flash:myconfiguration list
This will apply all necessary additions and deletions to replace the current running configuration with the contents of the specified configuration file, which is assumed to be a complete configuration, not a partial configuration. Enter Y if you are sure you want to proceed. ? [no]: Y
```
Reverting to the Startup Configuration File

The following example shows how to revert to the Cisco IOS startup configuration file using the `configure replace` command. This example also shows the use of the optional `force` keyword to override the interactive user prompt:

Device# configure replace flash:startup-config force
Total number of passes: 1
Rollback Done

Performing a Configuration Replace Operation with the `configure confirm` Command

The following example shows the use of the `configure replace` command with the `time minutes` keyword and argument. You must enter the `configure confirm` command within the specified time limit to confirm replacement of the current running configuration file. If the `configure confirm` command is not entered within the specified time limit, the configuration replace operation is automatically reversed (in other words, the current running configuration file is restored to the configuration state that existed prior to entering the `configure replace` command).

Device# configure replace flash:startup-config time 120
This will apply all necessary additions and deletions to replace the current running configuration with the contents of the specified configuration file, which is assumed to be a complete configuration, not a partial configuration. Enter Y if you are sure you want to proceed. ? [no]: Y
Total number of passes: 1
Rollback Done
Device# configure confirm

The following example shows the use of the `configure revert` command with the `timer` keyword. You must enter the `configure revert` command to cancel the timed rollback and trigger the rollback immediately, or to reset parameters for the timed rollback.

Device# configure revert timer 100

Performing a Configuration Rollback Operation

The following example shows how to make changes to the current running configuration and then roll back the changes. As part of the configuration rollback operation, you must save the current running configuration before making changes to the file. In this example, the `archive config` command is used to save the current running configuration. The generated output of the `configure replace` command indicates that only one pass was performed to complete the rollback operation.
Before using the `archive config` command, you must configure the `path` command to specify the location and filename prefix for the files in the Cisco IOS configuration archive.

You first save the current running configuration in the configuration archive as follows:

```bash
archive config
```

You then enter configuration changes as shown in the following example:

```bash
configure terminal
!
user netops2 password rain
user netops3 password snow
exit
```

After having made changes to the running configuration file, assume you now want to roll back these changes and revert to the configuration that existed before the changes were made. The `show archive` command is used to verify the version of the configuration to be used as a replacement file. The `configure replace` command is then used to revert to the replacement configuration file as shown in the following example:

```bash
Device# show archive
There are currently 1 archive configurations saved.
The next archive file will be named flash:myconfiguration-2
Archive # Name
 0
 1 flash:myconfiguration-1 <- Most Recent
 2
 3
 4
 5
 6
 7
 8
 9
 10
Device# configure replace flash:myconfiguration-1
Total number of passes: 1
Rollback Done
```

Information About the Flash File System

The flash file system is a single flash device on which you can store files. It also provides several commands to help you manage software bundles and configuration files. The default flash file system on the device is named flash:

As viewed from the active device, or any stack member, flash: refers to the local flash device, which is the device attached to the same device on which the file system is being viewed. In a device stack, each of the flash devices from the various stack members can be viewed from the active device. The names of these flash file systems include the corresponding device member numbers. For example, flash-3:, as viewed from the active device, refers to the same file system as does flash: on stack member 3. Use the show file systems privileged EXEC command to list all file systems, including the flash file systems in the device stack.

Only one user at a time can manage the software bundles and configuration files for a device stack.

Displaying Available File Systems

To display the available file systems on your device, use the show file systems privileged EXEC command as shown in this example for a standalone device:

```
Device# show file systems
File Systems:
   Size(b)   Free(b)   Type   Flags   Prefixes
   * 15998976  5135872 flash   rw    flash:
       -       -   opaque   rw    bs:
       -       -   opaque   rw    vb:
```
This example shows a device stack. In this example, the active device is stack member 1; the file system on stack member 2 is displayed as flash-2; the file system on stack member 3 is displayed as flash-3; and so on up to stack member 9, displayed as flash-9: for a 9-member stack. The example also shows the crashinfo directories and a USB flash drive plugged into the active device:

```plaintext
Device# show file systems
File Systems:

</table>

### Setting the Default File System

You can specify the file system or directory that the system uses as the default file system by using the `cd filesystem` privileged EXEC command. You can set the default file system to omit the `filesystem:` argument from related commands. For example, for all privileged EXEC commands that have the optional `filesystem:` argument, the system uses the file system specified by the `cd` command.

By default, the default file system is `flash:`.

You can display the current default file system as specified by the `cd` command by using the `pwd` privileged EXEC command.

### Displaying Information About Files on a File System

You can view a list of the contents of a file system before manipulating its contents. For example, before copying a new configuration file to flash memory, you might want to verify that the file system does not already contain a configuration file with the same name. Similarly, before copying a flash configuration file to another location, you might want to verify its filename for use in another command. To display information about files on a file system, use one of the privileged EXEC commands listed in the following table.
Table 196: Commands for Displaying Information About Files

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dir [/all] [filesystem:filename]</td>
<td>Displays a list of files on a file system.</td>
</tr>
<tr>
<td>show file systems</td>
<td>Displays more information about each of the files on a file system.</td>
</tr>
<tr>
<td>show file information file-url</td>
<td>Displays information about a specific file.</td>
</tr>
<tr>
<td>show file descriptors</td>
<td>Displays a list of open file descriptors. File descriptors are the internal representations of open files. You can use this command to see if another user has a file open.</td>
</tr>
</tbody>
</table>

For example, to display a list of all files in a file system, use the dir privileged EXEC command:

device# dir flash:
Directory of flash:/
7386 -rwx 2097152 Jan 23 2013 14:06:49 +00:00 nvram_config
7378 drwx 4096 Jan 23 2013 09:35:11 +00:00 mnt
7385 -rw- 221775876 Jan 23 2013 14:15:13 +00:00 cat3k_caa-universalk9.SSA.03.12.02.EZP.150-12.02.EZP.150-12.02.EZP.bin
7389 -rwx 556 Jan 21 2013 20:47:30 +00:00 vlan.dat
712413184 bytes total (445063168 bytes free)
device#

Changing Directories and Displaying the Working Directory (CLI)

Follow these steps to change directories and to display the working directory:

**SUMMARY STEPS**

1. enable
2. dir filesystem:
3. cd directory_name
4. pwd
5. cd

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
## Creating Directories (CLI)

Beginning in privileged EXEC mode, follow these steps to create a directory:

### SUMMARY STEPS

1. `dir filesystem:
2. mkdir directory_name
3. dir filesystem:

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>dir filesystem:</code></td>
<td>Displays the directories on the specified file system.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# dir flash:</code></td>
<td>For <code>filesystem::</code>, use <code>flash:</code> for the system board flash device.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>mkdir directory_name</code></td>
<td>Creates a new directory. Directory names are case sensitive and are</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>limited to 45 characters between the slashes (<code>/</code>); the name cannot</td>
</tr>
<tr>
<td><code>Device# mkdir new_configs</code></td>
<td>contain control characters, spaces, slashes, quotes, semicolons, or</td>
</tr>
<tr>
<td></td>
<td>colons.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td><code>cd directory_name</code></td>
<td>Navigates to the specified directory.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# cd new_configs</code></td>
<td>The command example shows how to navigate to the directory named</td>
</tr>
<tr>
<td></td>
<td><code>new_configs</code>.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td><code>pwd</code></td>
<td>Displays the working directory.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# pwd</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td><code>cd</code></td>
<td>Navigates to the default directory.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device# cd</code></td>
<td></td>
</tr>
</tbody>
</table>
Purpose

Command or Action

Step 3  
dir filesystem:
Example:
Device# dir flash:

Verifies your entry.

Removing Directories

To remove a directory with all its files and subdirectories, use the `delete /force /recursive filesystem:/file-url` privileged EXEC command.

Use the `/recursive` keyword to delete the named directory and all subdirectories and the files contained in it. Use the `/force` keyword to suppress the prompting that confirms a deletion of each file in the directory. You are prompted only once at the beginning of this deletion process.

For `filesystem`, use `flash:` for the system board flash device. For `file-url`, enter the name of the directory to be deleted. All of the files in the directory and the directory are removed.

Caution

When directories are deleted, their contents cannot be recovered.

Copying Files

To copy a file from a source to a destination, use the `copy source-url destination-url` privileged EXEC command. For the source and destination URLs, you can use `running-config` and `startup-config` keyword shortcuts. For example, the `copy running-config startup-config` command saves the currently running configuration file to the NVRAM section of flash memory to be used as the configuration during system initialization.

You can also copy from special filesystems (`xmodem:`, `ymodem:`) as the source for the file from a network machine that uses the Xmodem or Ymodem protocol.

Network file system URLs include ftp:, rcp:, and tftp: and have these syntaxes:

- FTP—ftp://[username[:password]@location]/directory[/filename]
- RCP—rcp://[username@location]/directory[/filename]
- TFTP—tftp://[location]/directory[/filename]

Local writable filesystems include flash:.

Some invalid combinations of source and destination exist. Specifically, you cannot copy these combinations:

- From a running configuration to a running configuration
- From a startup configuration to a startup configuration
- From a device to the same device (for example, the `copy flash: flash:` command is invalid)
Copying Files from One Device in a Stack to Another Device in the Same Stack

To copy a file from one device in a stack to another device in the same stack, use the `flash-X` notation, where X is the device number.

To view all devices in a stack, use the `show switch` command in privileged EXEC mode, as in the following example of a 9-member device stack:

```
Device# show switch
Switch/Stack Mac Address : 0006.f6b9.b580 - Local Mac Address Mac persistency wait time: Indefinite
Switch# Role Mac Address Priority Version State
-----------------------------------------------
*1 Active 0006.f6b9.b580 15 P3B Ready
2 Standby 0006.f6ba.0c80 14 P3B Ready
3 Member 0006.f6ba.3300 7 P3B Ready
4 Member 0006.f6b9.df80 6 P3B Ready
5 Member 0006.f6ba.3880 13 P1A Ready
6 Member 1ce6.c7b6.ef00 4 PF Ready
7 Member 2037.06ce.2580 3 P2A Ready
8 Member 2037.0653.7e00 2 P5A Ready
9 Member 2037.0653.9280 1 P5B Ready
```

To view all file systems available to copy on a specific device, use the `copy` command as in the following example of a 5-member stack:

```
Device# copy flash: ?
  crashinfo-1: Copy to crashinfo-1: file system
  crashinfo-2: Copy to crashinfo-2: file system
  crashinfo-3: Copy to crashinfo-3: file system
  crashinfo-4: Copy to crashinfo-4: file system
  crashinfo-5: Copy to crashinfo-5: file system
  crashinfo: Copy to crashinfo: file system
  flash-1: Copy to flash-1: file system
  flash-2: Copy to flash-2: file system
  flash-3: Copy to flash-3: file system
  flash-4: Copy to flash-4: file system
  flash-5: Copy to flash-5: file system
  flash: Copy to flash: file system
  ftp: Copy to ftp: file system
  http: Copy to http: file system
  https: Copy to https: file system
  null: Copy to null: file system
  nvram: Copy to nvram: file system
  rcp: Copy to rcp: file system
  revrcsf: Copy to revrcsf: file system
  running-config Update (merge with) current system configuration
  scp: Copy to scp: file system
  startup-config Copy to startup configuration
  stby-crashinfo: Copy to stby-crashinfo: file system
  stby-flash: Copy to stby-flash: file system
  stby-nvram: Copy to stby-nvram: file system
  stby-rcsf: Copy to stby-rcsf: file system
  stby-usbflash0: Copy to stby-usbflash0: file system
  syslog: Copy to syslog: file system
  system: Copy to system: file system
  tftp: Copy to tftp: file system
  tmpsys: Copy to tmpsys: file system
  usbflash0-1: Copy to usbflash0-1: file system
```
This example shows how to copy a config file stored in the flash partition of device 2 to the flash partition of device 4. It assumes that device 2 and device 4 are in the same stack.

```
Device# copy flash-2:config.txt flash-4:config.txt
```

### Deleting Files

When you no longer need a file on a flash memory device, you can permanently delete it. To delete a file or directory from a specified flash device, use the `delete [force] [recursive] [filesystem:]file-url` privileged EXEC command.

Use the `/recursive` keyword for deleting a directory and all subdirectories and the files contained in it. Use the `/force` keyword to suppress the prompting that confirms a deletion of each file in the directory. You are prompted only once at the beginning of this deletion process. Use the `/force` and `/recursive` keywords for deleting old software images that were installed by using the `archive download-sw` command but are no longer needed.

If you omit the `filesystem:` option, the device uses the default device specified by the `cd` command. For `file-url`, you specify the path (directory) and the name of the file to be deleted.

When you attempt to delete any files, the system prompts you to confirm the deletion.

---

**Caution**

When files are deleted, their contents cannot be recovered.

This example shows how to delete the file `myconfig` from the default flash memory device:

```
Device# delete myconfig
```

### Creating, Displaying and Extracting Files (CLI)

You can create a file and write files into it, list the files in a file, and extract the files from a file as described in the next sections.

Beginning in privileged EXEC mode, follow these steps to create a file, display the contents, and extract it:

**SUMMARY STEPS**

1. `archive tar /create destination-url flash: /file-url`
2. `archive tar /table source-url`
3. `archive tar /xtract source-url flash:/file-url [dir/file...]`
4. `more [/ascii | /binary | /ebcdic] /file-url`
## Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>archive tar /create destination-url flash: /file-url</code> <strong>Example:</strong> <code>device# archive tar /create tftp:172.20.10.30/saved. flash:/new-configs</code></td>
<td>Creates a file and adds files to it. For <code>destination-url</code>, specify the destination URL alias for the local or network file system and the name of the file to create:</td>
</tr>
<tr>
<td>• Local flash file system syntax: <code>flash:</code></td>
<td></td>
</tr>
<tr>
<td>• FTP syntax: <code>ftp://username:password@location/directory/-filename</code></td>
<td></td>
</tr>
<tr>
<td>• RCP syntax: <code>rcp://username@location/directory/-filename</code></td>
<td></td>
</tr>
<tr>
<td>• TFTP syntax: <code>tftp://location/directory/-filename</code></td>
<td></td>
</tr>
<tr>
<td>For <code>flash: /file-url</code>, specify the location on the local flash file system in which the new file is created. You can also specify an optional list of files or directories within the source directory to add to the new file. If none are specified, all files and directories at this level are written to the newly created file.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>archive tar /table source-url</code> <strong>Example:</strong> <code>device# archive tar /table flash: /new_configs</code></td>
<td>Displays the contents of a file. For <code>source-url</code>, specify the source URL alias for the local or network file system. The <code>-filename</code> is the file to display. These options are supported:</td>
</tr>
<tr>
<td>• Local flash file system syntax: <code>flash:</code></td>
<td></td>
</tr>
<tr>
<td>• FTP syntax: <code>ftp://username:password@location/directory/-filename</code></td>
<td></td>
</tr>
<tr>
<td>• RCP syntax: <code>rcp://username@location/directory/-filename</code></td>
<td></td>
</tr>
<tr>
<td>• TFTP syntax: <code>tftp://location/directory/-filename</code></td>
<td></td>
</tr>
<tr>
<td>You can also limit the file displays by specifying a list of files or directories after the file. Only those files appear. If none are specified, all files and directories appear.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>archive tar /xtract source-url flash:/file-url [dir/file...]</code> <strong>Example:</strong> <code>device# archive tar /xtract tftp://172.20.10.30/saved. flash:/new-configs</code></td>
<td>Extracts a file into a directory on the flash file system. For <code>source-url</code>, specify the source URL alias for the local file system. The <code>-filename</code> is the file from which to extract files. These options are supported:</td>
</tr>
<tr>
<td>• Local flash file system syntax:</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| flash:            | FTP syntax:  
|                   | • ftp://username:password@location/directory/-filename.  
|                   | RCP syntax:  
|                   | • rcp://username@location/directory/-filename.  
|                   | TFTP syntax:  
|                   | • tftp://location/directory/-filename.  

For `flash://file-url [dir/file...]`, specify the location on
the local flash file system from which the file is extracted. Use
the `dir/file...` option to specify a list of files or directories
within the file to be extracted. If none are specified, all files
and directories are extracted.

### Step 4

more [ascii | binary | ebcidc] /file-url

**Example:**

```
device# more
flash:/new-configs
```

 Displays the contents of any readable file, including a file
on a remote file system.

---

Upgrading the Switch Software

For information about upgrading the switch software from Cisco IOS XE Release 3.x.x to Cisco IOS XE Denali 16.1.x, see Release Notes for Cisco Catalyst 3850 Series Switch, Cisco IOS XE Denali 16.1.x.
Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Introduction to Conditional Debugging

The Conditional Debugging feature allows you to selectively enable debugging and logging for the specific features based on the set of conditions you define. This feature is useful in systems where a large number of features are supported.

Note

On Cisco IOS 16.1, only Control Plane Tracing is supported.

The Conditional debug allows you to debug in a very granular fashion in a network that is operating at scale even with a large number of features deployed. It allows you to observe detailed debugs for granular instances...
within the system. This is very useful when we need to debug only a particular session among thousands of sessions. It is also possible to specify multiple conditions.

A condition refers to a feature or identity, where identity could be an interface, IP Address, or a MAC address and so on.

---

**Note**

In Cisco IOS Release 16.1 the only condition that is supported is MAC address. The support for other features will be introduced in the releases that follow.

This is in contrast to the general debug command, that produces its output without discriminating on the feature objects that are being processed, which consumes lot of system resources and impacts the system performance.

---

### Introduction to Radioactive Tracing

Radioactive tracing provides the ability to stitch together a chain of execution for operations of interest across the system at an increased verbosity level. It provides a way to conditionally print debug information (upto DEBUG Level or upto a specified debug level) across threads, processes and function calls.

---

**Note**

In Cisco IOS Release 16.1 the default level is DEBUG. The users cannot change this to another level. The support for other levels will be introduced in the releases that follow.

---

### Conditional Debugging and Radioactive Tracing

Radioactive Tracing when coupled with Conditional Debugging, enable us to have a single debug CLI to debug all executions contexts related to the condition without having to be aware of the various processes within the box that were part of a the control flow for a feature and without having to issue debugs at these processes individually.

---

### Location of Tracefiles

By default the tracefile logs will be generated for each process and saved into either the /tmp/rp/trace or /tmp/fp/trace directory. In this temp directory, the trace logs are written to files, which are of 1 MB size each. The directory can hold upto a maximum of 25 such files for a given process. When a tracefile in the /tmp directory reaches its 1MB limit or whatever size was configured for it at boot time, it is rotated out to an archive location under the /crashinfo partition under a tracelogs directory.

The /tmp directory only holds a single tracefile for a given process. Once the file reaches its filesize limit it is rotated out to /crashinfo/tracelogs. In the archive directory, upto 25 files are accumulated, after which the oldest one is replaced by the newly rotated file from /tmp.

The tracefiles are located in the crashinfo directory in the following formats:

1. Process-name_Process-ID_running-counter.timestamp.gz
Example: IOSRP_R0-0.bin_0.14239.20151101234827.gz

2. Process-name_pmanlog_Process-ID_running-counter.timestamp.bin.gz
   Example: wcm_pmanlog_R0-0.30360_0.20151028233007.bin.gz

## Configuring Conditional Debugging

To configure conditional debugging, follow the steps given below:

### SUMMARY STEPS

1. **enable**
2. **debug platform condition mac** `{mac-address}`
3. **debug platform condition start**
4. **show platform condition** OR **show debug**
5. **debug platform condition stop**
6. **request platform software trace archive** [last `{number}` days] [target `{crashinfo: | flashinfo:}`]
7. **request platform software trace filter-binary** `{wire | wireless}` [context `{mac-address | level | module}`]
8. **show platform software trace** [filter-binary | level | message]
9. **clear platform condition all**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> debug platform condition mac <code>{mac-address}</code></td>
<td>Configures conditional debugging for the MAC Address specified.</td>
</tr>
<tr>
<td>Example: Device# debug platform condition mac bc16.6509.3314</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> debug platform condition start</td>
<td>Starts conditional debugging (this will start radioactive tracing if there is a match on one of the conditions above).</td>
</tr>
<tr>
<td>Example: Device# debug platform condition start</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> show platform condition OR show debug</td>
<td>Displays the current conditions set.</td>
</tr>
<tr>
<td>Example: Device# show platform condition</td>
<td></td>

| **Step 6**                                        |                                                 |
| request platform software trace archive [last \{number\} days] [target \{crashinfo: | Displays historical logs of merged tracefiles on the system. Filter on any combination of number of days or location. |
| \flashinfo:\}]] |                                                 |
| **Example:**                                       |                                                 |
| Device# request platform software trace archive  |                                                 |
| last 2 days                                       |                                                 |

| **Step 7**                                        |                                                 |
| request platform software trace filter-binary \{wire | Filter the modules to collate the information (wire or wireless) and then on the context of Mac address specified. These logs can be viewed off-line. |
| wireless\} [context \{mac-address\} | level | module] |
| **Example:**                                       |                                                 |
| Device# request platform software trace filter-binary wireless context bc16.6509.3314 |                                                 |

| **Step 8**                                        |                                                 |
| show platform software trace \{filter-binary | Filter on any combination of application condition, trace module name, and trace level. |
| \level \| \message\} |                                                 |
| **Example:**                                       |                                                 |
| Device# show platform software trace message |                                                 |

| **Step 9**                                        |                                                 |
| clear platform condition all                      | Clear all conditions.                           |
| **Example:**                                       |                                                 |
| Device# clear platform condition all              |                                                 |
What to do next

The commands `request platform software trace filter-binary` and `show platform software trace filter-binary` work in a similar way. The only difference is:

- `request platform software trace filter-binary` - Sources the data from historical logs.
- `show platform software trace filter-binary` – Sources the data from the flash Temp directory.

The command `request platform software trace filter-binary wireless {mac-address}` generates 3 flash files:

- `collated_log_<.date..>`
- `mac_log<..date..>`
- `mac_database .. file`

Of these, `mac_log<..date..>` is the most important file, as it gives the messages for the MAC we are debugging. The command `show platform software trace filter-binary` also generates the same flash files, and also prints the `mac_log` on the screen.

Recommended Workflow for Trace files

The Recommended Workflow for Trace files is listed below:

1. Request the tracelogs for a specific time period – Example 1 day
   Use the command:
   ```
   Device# request platform software trace archive last 1 day
   ```

2. The system generates a tar ball (.gz file) of the tracelogs in the location /flash:

3. Copy the file off the box. By copying the file, the tracelogs can be used to work offline. For more details on copying files, refer section below.

4. Delete the tracelog file (.gz) file from /flash: location. This ensures that there is enough space on the box for other operations.

Copying tracefiles off the box

An example of the tracefile is shown below:

```bash
Device# dir crashinfo:/tracelogs
Directory of crashinfo:/tracelogs/
50664 -rwx 760 Sep 22 2015 11:12:21 +00:00 plogd_F0-0.bin_0.gz
50603 -rwx 991 Sep 22 2015 11:12:08 +00:00 fed_pmanlog_F0-0.bin_0.9558.20150922111208.gz
```
The trace files can be copied using one of the various options shown below:

Device# copy crashinfo:/tracelogs ?
  crashinfo: Copy to crashinfo: file system
  flash: Copy to flash: file system
  ftp: Copy to ftp: file system
  http: Copy to http: file system
  https: Copy to https: file system
  null: Copy to null: file system
  nvram: Copy to nvram: file system
  rcp: Copy to rcp: file system
  running-config Update (merge with) current system configuration
  scp: Copy to scp: file system
  startup-config Copy to startup configuration
  syslog: Copy to syslog: file system
  system: Copy to system: file system
  tftp: Copy to tftp: file system
  tmpsys: Copy to tmpsys: file system

The general syntax for copying onto TFTP server is as follows:

Device# copy source: tftp:
Device# copy crashinfo:/tracelogs/IOSRP_R0-0.bin_0.14239.20151101234827.gz tftp:
Address or name of remote host []? 2.2.2.2
Destination filename [IOSRP_R0-0.bin_0.14239.20151101234827.gz]?

Note
It is important to clear the switch of these generated report/archive files in order to have flash space available for tracelogs and other purposes.

Configuration Examples for Conditional Debugging

The following is an output example of the show platform condition command.

Device# show platform condition
Conditional Debug Global State: Stop
Conditions Direction

MAC Address 0024.D7C7.0054 N/A
Feature Condition Type Value

Device#

The following is an output example of the show debug command.

Device# show debug
IOSXE Conditional Debug Configs:
Conditional Debug Global State: Start
Conditions Direction
MAC Address 0024.D7C7.0054 N/A
Feature Condition Type Value
---------------------------------------|-----------------------|--------------------------------
Packet Infra debugs:
Ip Address Port
---------------------------------------|-----------------------|---------
Device#

The following is a sample of the `debug platform condition stop` command.

Device# debug platform condition stop
Conditional Debug Global State: Stop

## Monitoring Conditional Debugging

The table shown below lists the various commands that can be used to monitor conditional debugging.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show platform condition</code></td>
<td>Displays the current conditions set.</td>
</tr>
<tr>
<td><code>show debug</code></td>
<td>Displays the current debug conditions set.</td>
</tr>
<tr>
<td><code>show platform software trace filter-binary</code></td>
<td>Displays logs merged from the latest tracefile.</td>
</tr>
<tr>
<td><code>request platform software trace filter-binary</code></td>
<td>Displays historical logs of merged tracefiles on the system.</td>
</tr>
</tbody>
</table>
Troubleshooting the Software Configuration

This chapter describes how to identify and resolve software problems related to the Cisco IOS software on the switch. Depending on the nature of the problem, you can use the command-line interface (CLI), Device Manager, or Network Assistant to identify and solve problems.

Additional troubleshooting information, such as LED descriptions, is provided in the hardware installation guide.

- Information About Troubleshooting the Software Configuration, on page 2347
- How to Troubleshoot the Software Configuration, on page 2356
- Verifying Troubleshooting of the Software Configuration, on page 2367
- Scenarios for Troubleshooting the Software Configuration, on page 2370
- Configuration Examples for Troubleshooting Software, on page 2372
- Additional References for Troubleshooting Software Configuration, on page 2374
- Feature History and Information for Troubleshooting Software Configuration, on page 2375

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Troubleshooting the Software Configuration

Software Failure on a Switch

Switch software can be corrupted during an upgrade by downloading the incorrect file to the switch, and by deleting the image file. In all of these cases, the switch does not pass the power-on self-test (POST), and there is no connectivity.
Lost or Forgotten Password on a Device

The default configuration for the device allows an end user with physical access to the device to recover from a lost password by interrupting the boot process during power-on and by entering a new password. These recovery procedures require that you have physical access to the device.

Note
On these devices, a system administrator can disable some of the functionality of this feature by allowing an end user to reset a password only by agreeing to return to the default configuration. If you are an end user trying to reset a password when password recovery has been disabled, a status message reminds you to return to the default configuration during the recovery process.

Power over Ethernet Ports

A Power over Ethernet (PoE) switch port automatically supplies power to one of these connected devices if the switch detects that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device
- an IEEE 802.3at-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

After the switch detects a powered device, the switch determines the device power requirements and then grants or denies power to the device. The switch can also detect the real-time power consumption of the device by monitoring and policing the power usage.

For more information, see the "Configuring PoE" chapter in the Interface and Hardware Component Configuration Guide (Catalyst 3850 Switches).

Disabled Port Caused by Power Loss

If a powered device (such as a Cisco IP Phone 7910) that is connected to a PoE Device port and powered by an AC power source loses power from the AC power source, the device might enter an error-disabled state. To recover from an error-disabled state, enter the shutdown interface configuration command, and then enter the no shutdown interface command. You can also configure automatic recovery on the Device to recover from the error-disabled state.
On a Device, the `errdisable recovery cause loopback` and the `errdisable recovery interval seconds` global configuration commands automatically take the interface out of the error-disabled state after the specified period of time.

**Disabled Port Caused by False Link-Up**

If a Cisco powered device is connected to a port and you configure the port by using the `power inline never` interface configuration command, a false link-up can occur, placing the port into an error-disabled state. To take the port out of the error-disabled state, enter the `shutdown` and the `no shutdown` interface configuration commands.

You should not connect a Cisco powered device to a port that has been configured with the `power inline never` command.

**Ping**

The Device supports IP ping, which you can use to test connectivity to remote hosts. Ping sends an echo request packet to an address and waits for a reply. Ping returns one of these responses:

- Normal response—The normal response (hostname is alive) occurs in 1 to 10 seconds, depending on network traffic.
- Destination does not respond—If the host does not respond, a `no-answer` message is returned.
- Unknown host—If the host does not exist, an `unknown host` message is returned.
- Destination unreachable—If the default gateway cannot reach the specified network, a `destination-unreachable` message is returned.
- Network or host unreachable—If there is no entry in the route table for the host or network, a `network or host unreachable` message is returned.

**Related Topics**

- Example: Pinging an IP Host, on page 2372

**Layer 2 Traceroute**

The Layer 2 traceroute feature allows the switch to identify the physical path that a packet takes from a source device to a destination device. Layer 2 traceroute supports only unicast source and destination MAC addresses. Traceroute finds the path by using the MAC address tables of the Device in the path. When the Device detects a device in the path that does not support Layer 2 traceroute, the Device continues to send Layer 2 trace queries and lets them time out.

The Device can only identify the path from the source device to the destination device. It cannot identify the path that a packet takes from source host to the source device or from the destination device to the destination host.

**Layer 2 Traceroute Guidelines**

- Cisco Discovery Protocol (CDP) must be enabled on all the devices in the network. For Layer 2 traceroute to function properly, do not disable CDP.
If any devices in the physical path are transparent to CDP, the switch cannot identify the path through these devices.

- A Device is reachable from another Device when you can test connectivity by using the ping privileged EXEC command. All Device in the physical path must be reachable from each other.

- The maximum number of hops identified in the path is ten.

- You can enter the traceroute mac or the traceroute mac ip privileged EXEC command on a Device that is not in the physical path from the source device to the destination device. All Device in the path must be reachable from this switch.

- The traceroute mac command output shows the Layer 2 path only when the specified source and destination MAC addresses belong to the same VLAN. If you specify source and destination MAC addresses that belong to different VLANs, the Layer 2 path is not identified, and an error message appears.

- If you specify a multicast source or destination MAC address, the path is not identified, and an error message appears.

- If the source or destination MAC address belongs to multiple VLANs, you must specify the VLAN to which both the source and destination MAC addresses belong. If the VLAN is not specified, the path is not identified, and an error message appears.

- The traceroute mac ip command output shows the Layer 2 path when the specified source and destination IP addresses belong to the same subnet. When you specify the IP addresses, the Device uses the Address Resolution Protocol (ARP) to associate the IP addresses with the corresponding MAC addresses and the VLAN IDs.
  
  - If an ARP entry exists for the specified IP address, the Device uses the associated MAC address and identifies the physical path.
  
  - If an ARP entry does not exist, the Device sends an ARP query and tries to resolve the IP address. If the IP address is not resolved, the path is not identified, and an error message appears.

- When multiple devices are attached to one port through hubs (for example, multiple CDP neighbors are detected on a port), the Layer 2 traceroute feature is not supported. When more than one CDP neighbor is detected on a port, the Layer 2 path is not identified, and an error message appears.

- This feature is not supported in Token Ring VLANs.

### IP Traceroute

You can use IP traceroute to identify the path that packets take through the network on a hop-by-hop basis. The command output displays all network layer (Layer 3) devices, such as routers, that the traffic passes through on the way to the destination.

Your Device can participate as the source or destination of the traceroute privileged EXEC command and might or might not appear as a hop in the traceroute command output. If the Device is the destination of the traceroute, it is displayed as the final destination in the traceroute output. Intermediate Device do not show up in the traceroute output if they are only bridging the packet from one port to another within the same VLAN. However, if the intermediate Device is a multilayer Device that is routing a particular packet, this Device shows up as a hop in the traceroute output.

The traceroute privileged EXEC command uses the Time To Live (TTL) field in the IP header to cause routers and servers to generate specific return messages. Traceroute starts by sending a User Datagram Protocol
(UDP) datagram to the destination host with the TTL field set to 1. If a router finds a TTL value of 1 or 0, it drops the datagram and sends an Internet Control Message Protocol (ICMP) time-to-live-exceeded message to the sender. Traceroute finds the address of the first hop by examining the source address field of the ICMP time-to-live-exceeded message.

To identify the next hop, traceroute sends a UDP packet with a TTL value of 2. The first router decrements the TTL field by 1 and sends the datagram to the next router. The second router sees a TTL value of 1, discards the datagram, and returns the time-to-live-exceeded message to the source. This process continues until the TTL is incremented to a value large enough for the datagram to reach the destination host (or until the maximum TTL is reached).

To learn when a datagram reaches its destination, traceroute sets the UDP destination port number in the datagram to a very large value that the destination host is unlikely to be using. When a host receives a datagram destined to itself containing a destination port number that is unused locally, it sends an ICMP port-unreachable error to the source. Because all errors except port-unreachable errors come from intermediate hops, the receipt of a port-unreachable error means that this message was sent by the destination port.

- Example: Performing a Traceroute to an IP Host, on page 2373

---

**Time Domain Reflector Guidelines**

You can use the Time Domain Reflector (TDR) feature to diagnose and resolve cabling problems. When running TDR, a local device sends a signal through a cable and compares the reflected signal to the initial signal.

TDR is supported on 10/100/1000 copper Ethernet ports and on Multigigabit Ethernet (100Mbps/1/2.5/5/10 Gbps) ports. It is not supported on SFP module ports.

TDR can detect these cabling problems:

- Open, broken, or cut twisted-pair wires—The wires are not connected to the wires from the remote device.
- Shorted twisted-pair wires—The wires are touching each other or the wires from the remote device. For example, a shorted twisted pair can occur if one wire of the twisted pair is soldered to the other wire.

If one of the twisted-pair wires is open, TDR can find the length at which the wire is open.

---

**Note**

When using the feature with Multigigabit Ethernet ports, the cable length is displayed only when an open or short condition is detected.

Use TDR to diagnose and resolve cabling problems in these situations:

- Replacing a Device
- Setting up a wiring closet
- Troubleshooting a connection between two devices when a link cannot be established or when it is not operating properly

When you run TDR, the Device reports accurate information in these situations:
• The cable for the gigabit link is a solid-core cable.
• The open-ended cable is not terminated.

When you run TDR, the Device does not report accurate information in these situations:
• The cable for the gigabit link is a twisted-pair cable or is in series with a solid-core cable.
• The link is a 10-megabit or a 100-megabit link.
• The cable is a stranded cable.
• The link partner is a Cisco IP Phone.
• The link partner is not IEEE 802.3 compliant.

### Debug Commands

⚠️ **Caution**

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use `debug` commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. It is best to use `debug` commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased `debug` command processing overhead will affect system use.

All `debug` commands are entered in privileged EXEC mode, and most `debug` commands take no arguments.

**Related Topics**

- Redirecting Debug and Error Message Output, on page 2366
- Example: Enabling All System Diagnostics, on page 2374

### System Report

System reports or crashinfo files save information that helps Cisco technical support representatives to debug problems that caused the Cisco IOS image to fail (crash). It is necessary to quickly and reliably collect critical crash information with high fidelity and integrity. Further, it is necessary to collect this information and bundle it in a way that it can be associated or identified with a specific crash occurrence.

System reports are generated in these situations:

• In case of a switch failure—A system report is generated on the member that failed; reports are not generated on other members in the stack.
• In case of a switchover—System reports are generated only on high availability (HA) member switches. reports are not generated for non-HA members.

The system does not generate reports in case of a reload.

During a process crash, the following is collected locally from the switch:

1. Full process core
2. Tracelogs
3. IOS syslogs (not guaranteed in case of non-active crashes)

4. System process information

5. Bootup logs

6. Reload logs

7. Certain types of /proc information

This information is stored in separate files which are then archived and compressed into one bundle. This makes it convenient to get a crash snapshot in one place, and can be then moved off the box for analysis. This report is generated before the switch goes down to rommon/bootloader.

Except for the full core and trace logs, everything else is a text file.

**Crashinfo Files**

By default the system report file will be generated and saved into the /crashinfo directory. If it cannot be saved to the crashinfo partition for lack of space, then it will be saved to the /flash directory.

To display the files, enter the `dir crashinfo:` command. The following is sample output of a crashinfo directory:

```
Switch#dir crashinfo:
Directory of crashinfo:/

50601 drwx 10240 Oct 28 2015 22:42:50 +00:00 tracelogs

248354816 bytes total (204800000 bytes free)
```

System reports are located in the crashinfo directory in the following format:

```
system-report_[switch number]_[date]-[timestamp]-UTC.gz
```

After a switch crashes, check for a system report file. The name of the most recently generated system report file is stored in the last_systemreport file under the crashinfo directory. The system report and crashinfo files assist TAC while troubleshooting the issue.

The system report generated can be further copied using TFTP, HTTP and few other options.

```
Switch#copy crashinfo: ?
crashinfo: Copy to crashinfo: file system
flash: Copy to flash: file system
ftp: Copy to ftp: file system
http: Copy to http: file system
https: Copy to https: file system
```
null: Copy to null: file system
nvram: Copy to nvram: file system
rcp: Copy to rcp: file system
running-config Update (merge with) current system configuration
scp: Copy to scp: file system
startup-config Copy to startup configuration
syslog: Copy to syslog: file system
system: Copy to system: file system
tftp: Copy to tftp: file system
tmpsys: Copy to tmpsys: file system

The general syntax for copying onto TFTP server is as follows:

Switch#copy crashinfo: tftp:
Source filename [system-report_1_20150909-092728-UTC.gz]?
Address or name of remote host []? 1.1.1.1
Destination filename [system-report_1_20150909-092728-UTC.gz]?

The trace logs from all members in the stack can be collected by issuing a trace archive command. This command provides time period options. The command syntax is as follows:

Switch#request platform software trace archive ?
last Archive trace files of last x days
target Location and name for the archive file

The trace logs stored in crashinfo: or flash: directory from within the last 3650 days can be collected.

Switch# request platform software trace archive last ?
<1-3650> Number of days (1-3650)
Switch#request platform software trace archive last 3650 days target ?
crashinfo: Archive file name and location
flash: Archive file name and location

---

**Note**

It is important to clear the system reports or trace archives from flash or crashinfo directory once they are copied out, in order to have space available for trace logs and other purposes.

---

**Onboard Failure Logging on the Switch**

You can use the onboard failure logging (OBFL) feature to collect information about the Device. The information includes uptime, temperature, and voltage information and helps Cisco technical support representatives to troubleshoot Device problems. We recommend that you keep OBFL enabled and do not erase the data stored in the flash memory.

By default, OBFL is enabled. It collects information about the Device and small form-factor pluggable (SFP) modules. The Device stores this information in the flash memory:

- **CLI commands**—Record of the OBFL CLI commands that are entered on a standalone Device or a switch stack member.
- **Environment data**—Unique device identifier (UDI) information for a standalone Device or a switch stack member and for all the connected FRU devices: the product identification (PID), the version identification (VID), and the serial number.
- **Message**—Record of the hardware-related system messages generated by a standalone Device or a switch stack member.
- **Power over Ethernet (PoE)**—Record of the power consumption of PoE ports on a standalone Device or a switch stack member.
• Temperature—Temperature of a standalone Device or a switch stack member.

• Uptime data—Time when a standalone Device or a switch stack member starts, the reason the Device restarts, and the length of time the Device has been running since it last restarted.

• Voltage—System voltages of a standalone Device or a switch stack member.

You should manually set the system clock or configure it by using Network Time Protocol (NTP).

When the Device is running, you can retrieve the OBFL data by using the `show logging onboard` privileged EXEC commands. If the Device fails, contact your Cisco technical support representative to find out how to retrieve the data.

When an OBFL-enabled Device is restarted, there is a 10-minute delay before logging of new data begins.

  - Displaying OBFL Information, on page 2367

**Fan Failures**

By default, the feature is disabled. When more than one of the fans fails in a field-replaceable unit (FRU) or in a power supply, the Device does not shut down, and this error message appears:

```
Multiple fan(FRU/PS) failure detected. System may get overheated. Change fan quickly.
```

The Device might overheat and shut down.

To enable the fan failures feature, enter the `system env fan-fail-action shut` privileged EXEC command. If more than one fan in the Device fails, the Device automatically shuts down, and this error message appears:

```
Faulty (FRU/PS) fans detected, shutting down system!
```

After the first fan shuts down, if the Device detects a second fan failure, the Device waits for 20 seconds before it shuts down.

To restart the Device, it must be power cycled.

**Possible Symptoms of High CPU Utilization**

Excessive CPU utilization might result in these symptoms, but the symptoms might also result from other causes:

• Spanning tree topology changes

• EtherChannel links brought down due to loss of communication

• Failure to respond to management requests (ICMP ping, SNMP timeouts, slow Telnet or SSH sessions)

• UDLD flapping

• IP SLAs failures because of SLAs responses beyond an acceptable threshold

• DHCP or IEEE 802.1x failures if the switch does not forward or respond to requests
# How to Troubleshoot the Software Configuration

## Recovering from a Software Failure

### Before you begin

This recovery procedure requires that you have physical access to the switch.

This procedure uses boot loader commands and TFTP to recover from a corrupted or incorrect image file.

### Step 1
From your PC, download the software image file (*image.bin*) from Cisco.com.

### Step 2
Load the software image to your TFTP server.

### Step 3
Connect your PC to the switch Ethernet management port.

### Step 4
Unplug the switch power cord.

### Step 5
Press the **Mode** button, and at the same time, reconnect the power cord to the switch.

### Step 6
From the boot loader (ROMMON) prompt, ensure that you can ping your TFTP server.

   a) Set the IP address `switch: set IP_ADDR ip_address subnet_mask`

   **Example:**
   ```
   switch: set IP_ADDR 192.0.2.123/255.255.255.0
   ```

   b) Set the default router IP address `switch: set DEFAULT_ROUTER ip_address`

   **Example:**
   ```
   switch: set DEFAULT_ROUTER 192.0.2.1
   ```

   c) Verify that you can ping the TFTP server `switch: ping ip_address_of_TFTP_server`

   **Example:**
   ```
   switch: ping 192.0.2.15
   ping 192.0.2.1 with 32 bytes of data...
   Host 192.0.2.1 is alive.
   switch:
   ```

### Step 7
Verify that you have a recovery image in your recovery partition (sda9:).

This recovery image is required for recovery using the emergency-install feature.

**Example:**
```
switch: dir sda9:
Directory of sda9:/
   2 drwx 1024 .
   2 drwx 1024 ..
   11 -rw- 18923068 c3850-recovery.bin
36939776 bytes available (20830208 bytes used)
```
Step 8

From the bootloader (ROMMON) prompt, initiate the emergency-install feature that assists you in recovering the software image on your switch.

WARNING: The emergency install command will erase your entire boot flash!

Example:

```
Switch# emergency-install
tftp://192.0.2.47/cat3k_caa-universalk9.SSA.03.12.02.EZP.150-12.02.EZP.150-12.02.EZP.bin
```

The bootflash will be erased during install operation, continue (y/n)?
y
Starting emergency recovery
(tftp://192.0.2.47/cat3k/cat3k_caa-universalk9.SPA.03.02.00.SE.150-1.EX.bin)...

Recovering from a Lost or Forgotten Password

The default configuration for the switch allows an end user with physical access to the switch to recover from a lost password by interrupting the boot process during power-on and by entering a new password. These recovery procedures require that you have physical access to the switch.

Note
On these switches, a system administrator can disable some of the functionality of this feature by allowing an end user to reset a password only by agreeing to return to the default configuration. If you are an end user trying to reset a password when password recovery has been disabled, a status message shows this during the recovery process.

SUMMARY STEPS

1. Connect a terminal or PC to the switch.
2. Set the line speed on the emulation software to 9600 baud.
3. Power off the standalone switch or the entire switch stack.
4. Reconnect the power cord to the or the active switch. Within 15 seconds, press the Mode button while the System LED is still flashing green. Continue pressing the Mode button until all the system LEDs turn on and remain solid; then release the Mode button.
5. After recovering the password, reload the switch or the active switch.
6. Power on the remaining switches in the stack.

DETAILED STEPS

Step 1
Connect a terminal or PC to the switch.

- Connect a terminal or a PC with terminal-emulation software to the switch console port. If you are recovering the password for a switch stack, connect to the console port of the active switch or
- Connect a PC to the Ethernet management port. If you are recovering the password for a switch stack, connect to the Ethernet management port of a stack member.

Step 2
Set the line speed on the emulation software to 9600 baud.

Step 3
Power off the standalone switch or the entire switch stack.

Step 4
Reconnect the power cord to the or the active switch. Within 15 seconds, press the Mode button while the System LED is still flashing green. Continue pressing the Mode button until all the system LEDs turn on and remain solid; then release the Mode button.

Switch:
Xmodem file system is available.
Base ethernet MAC Address: 20:37:06:4d:e9:80
Verifying bootloader digital signature.

The system has been interrupted prior to loading the operating system software, console will be reset to 9600 baud rate.

proceed to the *Procedure with Password Recovery Enabled* section, and follow the steps.

**Step 5** After recovering the password, reload the switch or the active switch.

On a switch:
```
Switch> reload
Proceed with reload? [confirm] y
```

On the active switch:
```
Switch> reload slot <stack-active-member-number>
Proceed with reload? [confirm] y
```

**Step 6** Power on the remaining switches in the stack.

---

**Related Topics**

*Lost or Forgotten Password on a Device*, on page 2348

**Procedure with Password Recovery Enabled**

If the password-recovery operation is enabled, this message appears:

---

**Step 1** Initialize the flash file system.

Device: `flash_init`

**Step 2** Ignore the startup configuration with the following command:

Device: `SWITCH_IGNORE_STARTUP_CFG=1`

**Step 3** Boot the switch with the `packages.conf` file from flash.

Device: `boot flash:packages.conf`

**Step 4** Terminate the initial configuration dialog by answering No.

Would you like to enter the initial configuration dialog? [yes/no]: No

**Step 5** At the switch prompt, enter privileged EXEC mode.
Step 6
Copy the startup configuration to running configuration.

Device# copy startup-config running-config Destination filename [running-config]?

Press Return in response to the confirmation prompts. The configuration file is now reloaded, and you can change the password.

Step 7
Enter global configuration mode and change the enable password.

Device# configure terminal
Device(config)#

Step 8
Write the running configuration to the startup configuration file.

Device# copy running-config startup-config

Step 9
Confirm that manual boot mode is enabled.

Device# show boot

BOOT variable = flash:packages.conf;
Manual Boot = yes
Enable Break = yes

Step 10
Reload the device.

Device# reload

Step 11
Return the Bootloader parameters (previously changed in Steps 2 and 3) to their original values.

Device: switch: SWITCH_IGNORE_STARTUP_CFG=0

Step 12
Boot the device with the packages.conf file from flash.

Device: boot flash:packages.conf

Step 13
After the device boots up, disable manual boot on the device.

Device(config)# no boot manual
Procedure with Password Recovery Disabled

If the password-recovery mechanism is disabled, this message appears:

The password-recovery mechanism has been triggered, but is currently disabled. Access to the boot loader prompt through the password-recovery mechanism is disallowed at this point. However, if you agree to let the system be reset back to the default system configuration, access to the boot loader prompt can still be allowed.

Would you like to reset the system back to the default configuration (y/n)?

Caution

Returning the Device to the default configuration results in the loss of all existing configurations. We recommend that you contact your system administrator to verify if there are backup Device and VLAN configuration files.

• If you enter n (no), the normal boot process continues as if the Mode button had not been pressed; you cannot access the boot loader prompt, and you cannot enter a new password. You see the message:

Press Enter to continue........

• If you enter y (yes), the configuration file in flash memory and the VLAN database file are deleted. When the default configuration loads, you can reset the password.

Step 1

Choose to continue with password recovery and delete the existing configuration:

Would you like to reset the system back to the default configuration (y/n)? Y

Step 2

Display the contents of flash memory:

Device: dir flash:

The Device file system appears.

Directory of flash:/
.
.
.i.
15494 drwx 4096 Jan 1 2000 00:20:20 +00:00 kirch
15508 -rw- 258065648 Sep 4 2013 14:19:03 +00:00 cat3k_caa-universalk9.SSA.03.12.02.EZP.150-12.02.EZP.150-12.02.EZP.bin
162196684

Step 3

Boot up the system:

Device: boot
You are prompted to start the setup program. To continue with password recovery, enter N at the prompt:

```
Continue with the configuration dialog? [yes/no]: N
```

**Step 4**  
At the Device prompt, enter privileged EXEC mode:

```
Device> enable
```

**Step 5**  
Enter global configuration mode:

```
Device# configure terminal
```

**Step 6**  
Change the password:

```
Device(config)# enable secret password
```

The secret password can be from 1 to 25 alphanumeric characters, can start with a number, is case sensitive, and allows spaces but ignores leading spaces.

**Step 7**  
Return to privileged EXEC mode:

```
Device(config)# exit
Device#
```

**Note**  
Before continuing to Step 9, power on any connected stack members and wait until they have completely initialized.

**Step 8**  
Write the running configuration to the startup configuration file:

```
Device# copy running-config startup-config
```

The new password is now in the startup configuration.

**Step 9**  
You must now reconfigure the Device. If the system administrator has the backup Device and VLAN configuration files available, you should use those.

---

**Preventing Switch Stack Problems**

To prevent switch stack problems, you should do the following:

- Make sure that the Device that you add to or remove from the switch stack are powered off. For all powering considerations in switch stacks, see the “Switch Installation” chapter in the hardware installation guide.
- Press the **Mode** button on a stack member until the Stack mode LED is on. The last two port LEDs on the Device should be green. Depending on the Device model, the last two ports are either 10/100/1000 ports or small form-factor pluggable (SFP) module. If one or both of the last two port LEDs are not green, the stack is not operating at full bandwidth.
- We recommend using only one CLI session when managing the switch stack. Be careful when using multiple CLI sessions to the active switch. Commands that you enter in one session are not displayed
in the other sessions. Therefore, it is possible that you might not be able to identify the session from which you entered a command.

- Manually assigning stack member numbers according to the placement of the Device in the stack can make it easier to remotely troubleshoot the switch stack. However, you need to remember that the Device have manually assigned numbers if you add, remove, or rearrange Device later. Use the `switch current-stack-member-number renumber new-stack-member-number` global configuration command to manually assign a stack member number.

If you replace a stack member with an identical model, the new Device functions with the exact same configuration as the replaced Device. This is also assuming the new Device is using the same member number as the replaced Device.

Removing powered-on stack members causes the switch stack to divide (partition) into two or more switch stacks, each with the same configuration. If you want the switch stacks to remain separate, change the IP address or addresses of the newly created switch stacks. To recover from a partitioned switch stack, follow these steps:

1. Power off the newly created switch stacks.
2. Reconnect them to the original switch stack through their StackWise Plus ports.

For the commands that you can use to monitor the switch stack and its members, see the Displaying Switch Stack Information section.

### Preventing Autonegotiation Mismatches

The IEEE 802.3ab autonegotiation protocol manages the Device settings for speed (10 Mb/s, 100 Mb/s, and 1000 Mb/s, excluding SFP module ports) and duplex (half or full). There are situations when this protocol can incorrectly align these settings, reducing performance. A mismatch occurs under these circumstances:

- A manually set speed or duplex parameter is different from the manually set speed or duplex parameter on the connected port.
- A port is set to autonegotiate, and the connected port is set to full duplex with no autonegotiation.

To maximize Device performance and ensure a link, follow one of these guidelines when changing the settings for duplex and speed:

- Let both ports autonegotiate both speed and duplex.
- Manually set the speed and duplex parameters for the ports on both ends of the connection.

**Note**

If a remote device does not autonegotiate, configure the duplex settings on the two ports to match. The speed parameter can adjust itself even if the connected port does not autonegotiate.

### Troubleshooting SFP Module Security and Identification

Cisco small form-factor pluggable (SFP) modules have a serial EEPROM that contains the module serial number, the vendor name and ID, a unique security code, and cyclic redundancy check (CRC). When an SFP
Module is inserted in the Device, the Device software reads the EEPROM to verify the serial number, vendor name and vendor ID, and recompute the security code and CRC. If the serial number, the vendor name or vendor ID, the security code, or CRC is invalid, the software generates a security error message and places the interface in an error-disabled state.

**Note**
The security error message references the GBIC_SECURITY facility. The Device supports SFP modules and does not support GBIC modules. Although the error message text refers to GBIC interfaces and modules, the security messages actually refer to the SFP modules and module interfaces.

If you are using a non-Cisco SFP module, remove the SFP module from the Device, and replace it with a Cisco module. After inserting a Cisco SFP module, use the `errdisablerecovery cause gbic-invalid` global configuration command to verify the port status, and enter a time interval for recovering from the error-disabled state. After the elapsed interval, the Device brings the interface out of the error-disabled state and retries the operation. For more information about the `errdisablerecovery` command, see the command reference for this release.

If the module is identified as a Cisco SFP module, but the system is unable to read vendor-data information to verify its accuracy, an SFP module error message is generated. In this case, you should remove and reinsert the SFP module. If it continues to fail, the SFP module might be defective.

**Monitoring SFP Module Status**

You can check the physical or operational status of an SFP module by using the `show interfaces transceiver` privileged EXEC command. This command shows the operational status, such as the temperature and the current for an SFP module on a specific interface and the alarm status. You can also use the command to check the speed and the duplex settings on an SFP module. For more information, see the `show interfaces transceiver` command in the command reference for this release.

**Executing Ping**

If you attempt to ping a host in a different IP subnetwork, you must define a static route to the network or have IP routing configured to route between those subnets.

IP routing is disabled by default on all Device.

**Note**
Though other protocol keywords are available with the `ping` command, they are not supported in this release.

Use this command to ping another device on the network from the Device:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`ping ip host</td>
<td>address`</td>
</tr>
</tbody>
</table>

Device# ping 172.20.52.3

**Related Topics**

[Ping](#), on page 2349
Monitoring Temperature

The Device monitors the temperature conditions and uses the temperature information to control the fans. Use the `show env temperature status` privileged EXEC command to display the temperature value, state, and thresholds. The temperature value is the temperature in the Device (not the external temperature). You can configure only the yellow threshold level (in Celsius) by using the `system env temperature threshold yellow value` global configuration command to set the difference between the yellow and red thresholds. You cannot configure the green or red thresholds. For more information, see the command reference for this release.

Monitoring the Physical Path

You can monitor the physical path that a packet takes from a source device to a destination device by using one of these privileged EXEC commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`tracetrace mac [interface interface-id]</td>
<td></td>
</tr>
<tr>
<td>{source-mac-address} {interface interface-id}</td>
<td></td>
</tr>
<tr>
<td>{destination-mac-address} {vlan vlan-id} [detail]</td>
<td>Displays the Layer 2 path taken by the packets from the specified source MAC address to the specified destination MAC address.</td>
</tr>
<tr>
<td>`tracetrace mac ip {source-ip-address</td>
<td>source-hostname} {destination-ip-address</td>
</tr>
</tbody>
</table>

Executing IP Traceroute

Though other protocol keywords are available with the `traceroute` privileged EXEC command, they are not supported in this release.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>traceroute ip host</code></td>
<td>Traces the path that packets take through the network.</td>
</tr>
<tr>
<td>Device# traceroute ip 192.51.100.1</td>
<td>Traces the path that packets take through the network.</td>
</tr>
</tbody>
</table>

Running TDR and Displaying the Results

To run TDR, enter the `test cable-diagnostics tdr interface interface-id` privileged EXEC command.
To display the results, enter the `show cable-diagnostics tdr interface interface-id` privileged EXEC command.

### Redirecting Debug and Error Message Output

By default, the network server sends the output from `debug` commands and system error messages to the console. If you use this default, you can use a virtual terminal connection to monitor debug output instead of connecting to the console port or the Ethernet management port.

Possible destinations include the console, virtual terminals, internal buffer, and UNIX hosts running a syslog server. The syslog format is compatible with 4.3 Berkeley Standard Distribution (BSD) UNIX and its derivatives.

---

**Note**

Be aware that the debugging destination you use affects system overhead. When you log messages to the console, very high overhead occurs. When you log messages to a virtual terminal, less overhead occurs. Logging messages to a syslog server produces even less, and logging to an internal buffer produces the least overhead of any method.

For more information about system message logging, see *Configuring System Message Logging*.

---

**Related Topics**

- [Debug Commands](#)

### Using the show platform forward Command

The output from the `show platform forward` privileged EXEC command provides some useful information about the forwarding results if a packet entering an interface is sent through the system. Depending upon the parameters entered about the packet, the output provides lookup table results and port maps used to calculate forwarding destinations, bitmaps, and egress information.

Most of the information in the output from the command is useful mainly for technical support personnel, who have access to detailed information about the Device application-specific integrated circuits (ASICs). However, packet forwarding information can also be helpful in troubleshooting.

### Using the show debug command

The `show debug` command is entered in privileged EXEC mode. This command displays all debug options available on the switch.

To view all conditional debug options run the command `show debug condition`. The commands can be listed by selecting either a condition identifier `<1-1000>` or `all` conditions.

To disable debugging, use the `no debug all` command.

---

**Caution**

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use `debug` commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use `debug` commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased `debug` command processing overhead will affect system use.
Configuring OBFL

We recommend that you do not disable OBFL and that you do not remove the data stored in the flash memory.

- To enable OBFL, use the `hw-switch switch [switch-number] logging onboard [message level level]` global configuration command. On switches, the range for `switch-number` is from 1 to 9. Use the `message level level` parameter to specify the severity of the hardware-related messages that the switch generates and stores in the flash memory.

- To copy the OBFL data to the local network or a specific file system, use the `copy onboard switch switch-number url url-destination` privileged EXEC command.

- To disable OBFL, use the `no hw-switch switch [switch-number] logging onboard [message level level]` global configuration command.

- To clear all the OBFL data in the flash memory except for the uptime and CLI command information, use the `clear onboard switch switch-number` privileged EXEC command.

- In a switch stack, you can enable OBFL on a standalone switch or on all stack members by using the `hw-switch switch [switch-number] logging onboard [message level level]` global configuration command.

- You can enable or disable OBFL on a member switch from the active switch.

For more information about the commands in this section, see the command reference for this release.

### Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **show onboard switch switch-number message**  
Device# show onboard switch 1 message | Displays the hardware-related messages generated by a standalone switch or the specified stack members. |
| **show onboard switch switch-number counter**  
Device# show onboard switch 1 counter | Displays the counter information on a standalone switch or the specified stack members. |
| **show onboard switch switch-number temperature**  
Device# show onboard switch 1 temperature | Displays the temperature of a standalone switch or the specified switch stack members. |
| **show onboard switch switch-number uptime**  
Device# show onboard switch 1 uptime | Displays the time when a standalone switch or the specified stack members start, the reason the standalone switch or specified stack members restart, and the length of time that the standalone switch or specified stack members have been running since they last restarted. |
| **show onboard switch switch-number voltage**  
Device# show onboard switch 1 voltage | Displays the system voltages of a standalone switch or the specified stack members. |
| **show onboard switch switch-number status**  
Device# show onboard switch 1 status | Displays the status of a standalone switch or the specified stack members. |

### Example: Verifying the Problem and Cause for High CPU Utilization

To determine if high CPU utilization is a problem, enter the **show processes cpu sorted** privileged EXEC command. Note the underlined information in the first line of the output example.

```
Device# show processes cpu sorted
CPU utilization for five seconds: 8%/0%; one minute: 7%; five minutes: 8%
PID Runtime(ms) Invoked uSecs 5Sec 1Min 5Min TTY Process
309 42289103 752750 56180 1.75% 1.20% 1.22% 0 RIP Timers
140 8820183 4942081 1784 0.63% 0.37% 0.30% 0 HRPC qos request
100 3427318 16150534 212 0.47% 0.14% 0.11% 0 HRPC pm-counters
192 3093252 14081112 219 0.31% 0.14% 0.11% 0 Spanning Tree
143 8 37 216 0.15% 0.01% 0.00% 0 Exec
...<output truncated>
```

This example shows normal CPU utilization. The output shows that utilization for the last 5 seconds is 8%/0%, which has this meaning:
• The total CPU utilization is 8 percent, including both time running Cisco IOS processes and time spent handling interrupts.

• The time spent handling interrupts is zero percent.

Table 199: Troubleshooting CPU Utilization Problems

<table>
<thead>
<tr>
<th>Type of Problem</th>
<th>Cause</th>
<th>Corrective Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interrupt percentage value is almost as high as total CPU utilization value.</td>
<td>The CPU is receiving too many packets from the network.</td>
<td>Determine the source of the network packet. Stop the flow, or change the switch configuration. See the section on “Analyzing Network Traffic.”</td>
</tr>
<tr>
<td>Total CPU utilization is greater than 50% with minimal time spent on interrupts.</td>
<td>One or more Cisco IOS process is consuming too much CPU time. This is usually triggered by an event that activated the process.</td>
<td>Identify the unusual event, and troubleshoot the root cause. See the section on “Debugging Active Processes.”</td>
</tr>
</tbody>
</table>
### Scenarios for Troubleshooting Power over Ethernet (PoE)

<table>
<thead>
<tr>
<th>Symptom or Problem</th>
<th>Possible Cause and Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only one port does not have PoE. Trouble is on only one switch port. PoE and non-PoE devices do not work on this port, but do on other ports.</td>
<td>Verify that the powered device works on another PoE port. Use the <code>show run</code>, or <code>show interface status</code> user EXEC commands to verify that the port is not shut down or error-disabled. <strong>Note</strong> Most switches turn off port power when the port is shut down, even though the IEEE specifications make this optional. Verify that the Ethernet cable from the powered device to the switch port is good: Connect a known good non-PoE Ethernet device to the Ethernet cable, and make sure that the powered device establishes a link and exchanges traffic with another host. Verify that the total cable length from the switch front panel to the powered device is not more than 100 meters. Disconnect the Ethernet cable from the switch port. Use a short Ethernet cable to connect a known good Ethernet device directly to this port on the switch front panel (not on a patch panel). Verify that it can establish an Ethernet link and exchange traffic with another host, or ping the port VLAN SVI. Next, connect a powered device to this port, and verify that it powers on. If a powered device does not power on when connected with a patch cord to the switch port, compare the total number of connected powered devices to the switch power budget (available PoE). Use the <code>show inline power</code> command to verify the amount of available power.</td>
</tr>
<tr>
<td>Symptom or Problem</td>
<td>Possible Cause and Solution</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>No PoE on all ports or a group of ports. Trouble is on all switch ports. Nonpowered Ethernet devices cannot establish an Ethernet link on any port, and PoE devices do not power on.</td>
<td>If there is a continuous, intermittent, or reoccurring alarm related to power, replace the power supply if possible it is a field-replaceable unit. Otherwise, replace the switch. If the problem is on a consecutive group of ports but not all ports, the power supply is probably not defective, and the problem could be related to PoE regulators in the switch. Use the <code>show log</code> privileged EXEC command to review alarms or system messages that previously reported PoE conditions or status changes. If there are no alarms, use the <code>show interface status</code> command to verify that the ports are not shut down or error-disabled. If ports are error-disabled, use the <code>shut</code> and <code>no shut</code> interface configuration commands to reenable the ports. Use the <code>show env power</code> and <code>show power inline</code> privileged EXEC commands to review the PoE status and power budget (available PoE). Review the running configuration to verify that <code>power inline never</code> is not configured on the ports. Connect a nonpowered Ethernet device directly to a switch port. Use only a short patch cord. Do not use the existing distribution cables. Enter the <code>shut</code> and <code>no shut</code> interface configuration commands, and verify that an Ethernet link is established. If this connection is good, use a short patch cord to connect a powered device to this port and verify that it powers on. If the device powers on, verify that all intermediate patch panels are correctly connected. Disconnect all but one of the Ethernet cables from switch ports. Using a short patch cord, connect a powered device to only one PoE port. Verify the powered device does not require more power than can be delivered by the switch port. Use the <code>show power inline</code> privileged EXEC command to verify that the powered device can receive power when the port is not shut down. Alternatively, watch the powered device to verify that it powers on. If a powered device can power on when only one powered device is connected to the switch, enter the <code>shut</code> and <code>no shut</code> interface configuration commands on the remaining ports, and then reconnect the Ethernet cables one at a time to the switch PoE ports. Use the <code>show interface status</code> and <code>show power inline</code> privileged EXEC commands to monitor inline power statistics and port status. If there is still no PoE at any port, a fuse might be open in the PoE section of the power supply. This normally produces an alarm. Check the log again for alarms reported earlier by system messages.</td>
</tr>
</tbody>
</table>
### Symptom or Problem

| Cisco IP Phone disconnects or resets. After working normally, a Cisco phone or wireless access point intermittently reloads or disconnects from PoE. | Verify all electrical connections from the switch to the powered device. Any unreliable connection results in power interruptions and irregular powered device functioning such as erratic powered device disconnects and reloads. Verify that the cable length is not more than 100 meters from the switch port to the powered device. Notice what changes in the electrical environment at the switch location or what happens at the powered device when the disconnect occurs. Notice whether any error messages appear at the same time a disconnect occurs. Use the `show log` privileged EXEC command to review error messages. Verify that an IP phone is not losing access to the Call Manager immediately before the reload occurs. (It might be a network problem and not a PoE problem.) Replace the powered device with a non-PoE device, and verify that the device works correctly. If a non-PoE device has link problems or a high error rate, the problem might be an unreliable cable connection between the switch port and the powered device. |
| Non-Cisco powered device does not work on Cisco PoE switch. A non-Cisco powered device is connected to a Cisco PoE switch, but never powers on or powers on and then quickly powers off. Non-PoE devices work normally. | Use the `show power inline` command to verify that the switch power budget (available PoE) is not depleted before or after the powered device is connected. Verify that sufficient power is available for the powered device type before you connect it. Use the `show interface status` command to verify that the switch detects the connected powered device. Use the `show log` command to review system messages that reported an overcurrent condition on the port. Identify the symptom precisely: Does the powered device initially power on, but then disconnect? If so, the problem might be an initial surge-in (or `inrush`) current that exceeds a current-limit threshold for the port. |

### Configuration Examples for Troubleshooting Software

#### Example: Pinging an IP Host

This example shows how to ping an IP host:

```
Device# ping 172.20.52.3
```
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echoes to 172.20.52.3, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms

Device# Table 201: Ping Output Display Characters

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>Each exclamation point means receipt of a reply.</td>
</tr>
<tr>
<td>.</td>
<td>Each period means the network server timed out while waiting for a reply.</td>
</tr>
<tr>
<td>U</td>
<td>A destination unreachable error PDU was received.</td>
</tr>
<tr>
<td>C</td>
<td>A congestion experienced packet was received.</td>
</tr>
<tr>
<td>I</td>
<td>User interrupted test.</td>
</tr>
<tr>
<td>?</td>
<td>Unknown packet type.</td>
</tr>
<tr>
<td>&amp;</td>
<td>Packet lifetime exceeded.</td>
</tr>
</tbody>
</table>

To end a ping session, enter the escape sequence (\texttt{Ctrl-^X} by default). Simultaneously press and release the \texttt{Ctrl}, \texttt{Shift}, and \texttt{6} keys and then press the \texttt{X} key.

Related Topics
- \texttt{Ping}, on page 2349
- \texttt{Executing Ping}, on page 2364

**Example: Performing a Traceroute to an IP Host**

This example shows how to perform a \texttt{traceroute} to an IP host:

Device# \texttt{traceroute ip 192.0.2.10}

Type escape sequence to abort.
Tracing the route to 192.0.2.10

```
1 192.0.2.1 0 msec 0 msec 4 msec
2 192.0.2.203 12 msec 8 msec 0 msec
3 192.0.2.100 4 msec 0 msec 0 msec
4 192.0.2.10 0 msec 4 msec 0 msec
```

The display shows the hop count, the IP address of the router, and the round-trip time in milliseconds for each of the three probes that are sent.

**Table 202: Traceroute Output Display Characters**

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>The probe timed out.</td>
</tr>
<tr>
<td>?</td>
<td>Unknown packet type.</td>
</tr>
<tr>
<td>Character</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>A</td>
<td>Administratively unreachable. Usually, this output means that an access list is blocking traffic.</td>
</tr>
<tr>
<td>H</td>
<td>Host unreachable.</td>
</tr>
<tr>
<td>N</td>
<td>Network unreachable.</td>
</tr>
<tr>
<td>P</td>
<td>Protocol unreachable.</td>
</tr>
<tr>
<td>Q</td>
<td>Source quench.</td>
</tr>
<tr>
<td>U</td>
<td>Port unreachable.</td>
</tr>
</tbody>
</table>

To end a trace in progress, enter the escape sequence (\texttt{Ctrl-^X} by default). Simultaneously press and release the \texttt{Ctrl}, \texttt{Shift}, and \texttt{6} keys and then press the \texttt{X} key.

**Example: Enabling All System Diagnostics**

⚠️ **Caution**

Because debugging output takes priority over other network traffic, and because the \texttt{debug all} privileged EXEC command generates more output than any other \texttt{debug} command, it can severely diminish switch performance or even render it unusable. In virtually all cases, it is best to use more specific \texttt{debug} commands.

This command disables all-system diagnostics:

```
Device# debug all
```

The \texttt{no debug all} privileged EXEC command disables all diagnostic output. Using the \texttt{no debug all} command is a convenient way to ensure that you have not accidentally left any \texttt{debug} commands enabled.

• Prerequisites for VideoStream, on page 2379
• Restrictions for Configuring VideoStream, on page 2379
• Information about VideoStream, on page 2380
• How to Configure VideoStream, on page 2380
• Monitoring Media Streams, on page 2384

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for VideoStream

Make sure that the multicast feature is enabled. We recommend configuring IP multicast on the controller with multicast-multicast mode.

Check for the IP address on the client machine. The machine should have an IP address from the respective VLAN.

Verify that the access points have joined the controllers.

Restrictions for Configuring VideoStream

IGMP snooping is required to switch ON for this MC2UC feature to be functional.
Information about VideoStream

The IEEE 802.11 wireless multicast delivery mechanism does not provide a reliable way to acknowledge lost or corrupted packets. The multicast frame packets are sent at a predetermined rate irrespective of the wireless client optimal data rate. As a result, if any multicast packet is lost in the air, it is not sent again which may cause an IP multicast stream unviewable. Also if the packets are delivered faster, the packets get congested.

The VideoStream feature makes the IP multicast stream delivery reliable over the air, by converting the multicast frame to a unicast frame over the air. Each VideoStream client acknowledges receiving a video IP multicast stream.

How to Configure VideoStream

Configuring Multicast-Direct Globally for Media-Stream

SUMMARY STEPS

1. configure terminal
2. wireless multicast
3. IP igmp snooping
4. IP igmp snooping querier
5. wireless media-stream multicast-direct
6. wireless media-stream message
7. wireless media-stream group <name><startIp><endIp>
8. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2 wireless multicast</td>
<td>Enables multicast for wireless forwarding.</td>
</tr>
<tr>
<td>Step 3 IP igmp snooping</td>
<td>Enables IGMP snooping on a per-VLAN basis. If the global setting is disabled, then all VLANs are treated as disabled, whether they are enabled or not.</td>
</tr>
<tr>
<td>Step 4 IP igmp snooping querier</td>
<td>Configures a snooping querier on an interface when there is no multicast router in the VLAN to generate queries.</td>
</tr>
<tr>

<td>Configures the global multicast-direct feature for the controller.</td>
</tr>
<tr>
<td>Example: (config)#wireless media-stream multicast-direct</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

Command or Action | Purpose |
--- | --- |
**Step 6** | Configures various message configuration parameters like phone, URL, email and notes. That is, when a media stream is refused (due to bandwidth constraints), a message can be sent to the user. These parameters configure the messages to send IT support email address, notes (message to display explaining why the stream was refused), URL to which the user can be redirected and the phone number that the user can call about the refused stream. |
**wireless media-stream message** | Example: (config)#wireless media-stream message?
| Email Configure Session Announcement Email
| Notes Configure Session Announcement notes
| URL Configure Session Announcement URL
| phone Configure Session Announcement Phone number |

**Step 7** | Configures each media stream and its parameters like expected multicast destination addresses, stream bandwidth consumption and stream priority parameters. |
**wireless media-stream group <name><startIp><endIp>** | Example: (config)#wireless media-stream group grp1 231.1.1.1 239.1.1.3
| avg-packet-size Configures average packet size
| default Set a command to its defaults
| exit Exit sub-mode
| max-bandwidth Configures maximum Expected Stream Bandwidth in Kbps
| no Negate a command or set its defaults
| policy Configure media stream admission policy
| qos Configure Over the AIR QoS class, '<video>' ONLY |

**Step 8** | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |
**end** | Example: Device(config)# end |

---

### Summary Steps

1. `configure terminal`
2. `wlan wlan_name`
3. `shutdown`
4. `media-stream multicast-direct`
5. `no shutdown`
6. `end`

### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  `configure terminal`
  **Example:**
  `Device# configure terminal`
| Enters global configuration mode. |
| **Step 2**
  `wlan wlan_name`
  **Example:**
  `(config)# wlan wlan50`
| Enters the WLAN configuration mode. |
| **Step 3**
  `shutdown`
  **Example:**
  `(config-wlan)# shutdown`
| Disables the WLAN for configuring its parameters. |
| **Step 4**
  `media-stream multicast-direct`
  **Example:**
  `(config)# media-stream multicast-direct`
| Configures the multicast-direct feature on media-stream for the WLAN. |
### Deleting a Media-Stream

**Before you begin**

The media-stream should be enabled and configured for it to be deleted.

**SUMMARY STEPS**

1. `configure terminal`
2. `no wireless media-stream group media_stream_name`
3. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
configure terminal
Example:
Device# configure terminal | Enters global configuration mode. |
| **Step 2**
no wireless media-stream group media_stream_name
Example:
Device(config)# no wireless media-stream grp1 | Deletes the media-stream which bears the name mentioned in the command. |
| **Step 3**
end
Example:
Device(config)# end | Returns to privileged EXEC mode. Alternatively, you can also press \texttt{Ctrl-Z} to exit global configuration mode. |

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for VTP

Before you create VLANs, you must decide whether to use the VLAN Trunking Protocol (VTP) in your network. Using VTP, you can make configuration changes centrally on one or more devices and have those changes automatically communicated to all the other devices in the network. Without VTP, you cannot send information about VLANs to other devices.

VTP is designed to work in an environment where updates are made on a single device and are sent through VTP to other devices in the domain. It does not work well in a situation where multiple updates to the VLAN database occur simultaneously on devices in the same domain, which would result in an inconsistency in the VLAN database.
The device supports a total of 4094 VLANs. However, the number of configured features affects the usage of the device hardware. If the device is notified by VTP of a new VLAN and the device is already using the maximum available hardware resources, it sends a message that there are not enough hardware resources available and shuts down the VLAN. The output of the `show vlan` user EXEC command shows the VLAN in a suspended state.

You can enable or disable VTP per port by entering the `[no] vtp` interface configuration command. When you disable VTP on trunking ports, all VTP instances for that port are disabled. You cannot set VTP to `off` for the MST database and `on` for the VLAN database on the same port.

When you globally set VTP mode to `off`, it applies to all the trunking ports in the system. However, you can specify on or off on a per-VTP instance basis. For example, you can configure the device as a VTP server for the VLAN database but with VTP `off` for the MST database.

Because trunk ports send and receive VTP advertisements, you must ensure that at least one trunk port is configured on the device or device stack and that this trunk port is connected to the trunk port of another device. Otherwise, the device cannot receive any VTP advertisements.

### Related Topics
- VTP Advertisements, on page 2393
- Adding a VTP Client to a VTP Domain (CLI), on page 2407
- VTP Domain, on page 2391
- VTP Modes, on page 2392

### Restrictions for VTP

The following are restrictions for a VTP:

- You cannot have a device stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

---

**Caution**

Before adding a VTP client device to a VTP domain, always verify that its VTP configuration revision number is lower than the configuration revision number of the other devices in the VTP domain. Devices in a VTP domain always use the VLAN configuration of the device with the highest VTP configuration revision number. If you add a device that has a revision number higher than the revision number in the VTP domain, it can erase all VLAN information from the VTP server and VTP domain.

---

### Information About VTP

**VTP**

VTP is a Layer 2 messaging protocol that maintains VLAN configuration consistency by managing the addition, deletion, and renaming of VLANs on a network-wide basis. VTP minimizes misconfigurations and configuration inconsistencies that can cause several problems, such as duplicate VLAN names, incorrect VLAN-type specifications, and security violations.

VTP functionality is supported across the stack, and all devices in the stack maintain the same VLAN and VTP configuration inherited from the active device. When a device learns of a new VLAN through VTP...
When a VLAN is configured by the user, the new VLAN information is communicated to all devices in the stack.

When a device joins the stack or when stacks merge, the new devices get VTP information from the active device.

**VTP Domain**

A VTP domain (also called a VLAN management domain) consists of one device or several interconnected devices or device stacks under the same administrative responsibility sharing the same VTP domain name. A device can be in only one VTP domain. You make global VLAN configuration changes for the domain.

By default, the device is in the VTP no-management-domain state until it receives an advertisement for a domain over a trunk link (a link that carries the traffic of multiple VLANs) or until you configure a domain name. Until the management domain name is specified or learned, you cannot create or modify VLANs on a VTP server, and VLAN information is not propagated over the network.

If the device receives a VTP advertisement over a trunk link, it inherits the management domain name and the VTP configuration revision number. The device then ignores advertisements with a different domain name or an earlier configuration revision number.

When you make a change to the VLAN configuration on a VTP server, the change is propagated to all devices in the VTP domain. VTP advertisements are sent over all IEEE trunk connections, including IEEE 802.1Q. VTP dynamically maps VLANs with unique names and internal index associates across multiple LAN types. Mapping eliminates excessive device administration required from network administrators.

If you configure a device for VTP transparent mode, you can create and modify VLANs, but the changes are not sent to other devices in the domain, and they affect only the individual device. However, configuration changes made when the device is in this mode are saved in the device running configuration and can be saved to the device startup configuration file.

## VTP Modes

### Table 204: VTP Modes

<table>
<thead>
<tr>
<th>VTP Mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| **VTP server** | In VTP server mode, you can create, modify, and delete VLANs, and specify other configuration parameters (such as the VTP version) for the entire VTP domain. VTP servers advertise their VLAN configurations to other devices in the same VTP domain and synchronize their VLAN configurations with other devices based on advertisements received over trunk links.  
VTP server is the default mode.  
In VTP server mode, VLAN configurations are saved in NVRAM. If the device detects a failure while writing a configuration to NVRAM, VTP mode automatically changes from server mode to client mode. If this happens, the device cannot be returned to VTP server mode until the NVRAM is functioning. |
| **VTP client** | A VTP client functions like a VTP server and transmits and receives VTP updates on its trunks, but you cannot create, change, or delete VLANs on a VTP client. VLANs are configured on another device in the domain that is in server mode.  
In VTP versions 1 and 2 in VTP client mode, VLAN configurations are not saved in NVRAM. In VTP version 3, VLAN configurations are saved in NVRAM in client mode. |
### VTP Mode

<table>
<thead>
<tr>
<th>VTP Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTP transparent</td>
<td>VTP transparent devices do not participate in VTP. A VTP transparent device does not advertise its VLAN configuration and does not synchronize its VLAN configuration based on received advertisements. However, in VTP version 2 or version 3, transparent devices do forward VTP advertisements that they receive from other devices through their trunk interfaces. You can create, modify, and delete VLANs on a device in VTP transparent mode. When the device is in VTP transparent mode, the VTP and VLAN configurations are saved in NVRAM, but they are not advertised to other devices. In this mode, VTP mode and domain name are saved in the device running configuration, and you can save this information in the device startup configuration file by using the <code>copy running-config startup-config</code> privileged EXEC command. In a device stack, the running configuration and the saved configuration are the same for all devices in a stack.</td>
</tr>
<tr>
<td>VTP off</td>
<td>A device in VTP off mode functions in the same manner as a VTP transparent device, except that it does not forward VTP advertisements on trunks.</td>
</tr>
</tbody>
</table>

### Related Topics
- Prerequisites for VTP, on page 2389
- Configuring VTP Mode (CLI), on page 2399

### VTP Advertisements

Each device in the VTP domain sends periodic global configuration advertisements from each trunk port to a reserved multicast address. Neighboring devices receive these advertisements and update their VTP and VLAN configurations as necessary.

VTP advertisements distribute this global domain information:

- VTP domain name
- VTP configuration revision number
- Update identity and update timestamp
- MD5 digest VLAN configuration, including maximum transmission unit (MTU) size for each VLAN
- Frame format

VTP advertisements distribute this VLAN information for each configured VLAN:

- VLAN IDs (including IEEE 802.1Q)
In VTP version 3, VTP advertisements also include the primary server ID, an instance number, and a start index.

**Related Topics**
- [Prerequisites for VTP](#), on page 2389

## VTP Version 2

If you use VTP in your network, you must decide which version of VTP to use. By default, VTP operates in version 1.

VTP version 2 supports these features that are not supported in version 1:

- Token Ring support—VTP version 2 supports Token Ring Bridge Relay Function (TrBRF) and Token Ring Concentrator Relay Function (TrCRF) VLANs.
- Unrecognized Type-Length-Value (TLV) support—A VTP server or client propagates configuration changes to its other trunks, even for TLVs it is not able to parse. The unrecognized TLV is saved in NVRAM when the device is operating in VTP server mode.
- Version-Dependent Transparent Mode—In VTP version 1, a VTP transparent device inspects VTP messages for the domain name and version and forwards a message only if the version and domain name match. Although VTP version 2 supports only one domain, a VTP version 2 transparent device forwards a message only when the domain name matches.
- Consistency Checks—In VTP version 2, VLAN consistency checks (such as VLAN names and values) are performed only when you enter new information through the CLI or SNMP. Consistency checks are not performed when new information is obtained from a VTP message or when information is read from NVRAM. If the MD5 digest on a received VTP message is correct, its information is accepted.

**Related Topics**
- [Enabling the VTP Version (CLI)](#), on page 2403

## VTP Version 3

VTP version 3 supports these features that are not supported in version 1 or version 2:

- Enhanced authentication—You can configure the authentication as **hidden** or **secret**. When **hidden**, the secret key from the password string is saved in the VLAN database file, but it does not appear in plain text in the configuration. Instead, the key associated with the password is saved in hexadecimal format in the running configuration. You must reenter the password if you enter a takeover command in the domain. When you enter the **secret** keyword, you can directly configure the password secret key.
- Support for extended range VLAN (VLANs 1006 to 4094) database propagation—VTP versions 1 and 2 propagate only VLANs 1 to 1005.
VTP pruning still applies only to VLANs 1 to 1005, and VLANs 1002 to 1005 are still reserved and cannot be modified.

**Note**

- Support for any database in a domain—In addition to propagating VTP information, version 3 can propagate Multiple Spanning Tree (MST) protocol database information. A separate instance of the VTP protocol runs for each application that uses VTP.

- VTP primary server and VTP secondary servers—A VTP primary server updates the database information and sends updates that are honored by all devices in the system. A VTP secondary server can only back up the updated VTP configurations received from the primary server to its NVRAM.

By default, all devices come up as secondary servers. You can enter the `vtp primary` privileged EXEC command to specify a primary server. Primary server status is only needed for database updates when the administrator issues a takeover message in the domain. You can have a working VTP domain without any primary servers. Primary server status is lost if the device reloads or domain parameters change, even when a password is configured on the device.

**Related Topics**

- Enabling the VTP Version (CLI), on page 2403

---

**VTP Pruning**

VTP pruning increases network available bandwidth by restricting flooded traffic to those trunk links that the traffic must use to reach the destination devices. Without VTP pruning, a device floods broadcast, multicast, and unknown unicast traffic across all trunk links within a VTP domain even though receiving devices might discard them. VTP pruning is disabled by default.

VTP pruning blocks unneeded flooded traffic to VLANs on trunk ports that are included in the pruning-eligible list. Only VLANs included in the pruning-eligible list can be pruned. By default, VLANs 2 through 1001 are pruning eligible device trunk ports. If the VLANs are configured as pruning-ineligible, the flooding continues. VTP pruning is supported in all VTP versions.

**Figure 122: Flooding Traffic without VTP Pruning**

VTP pruning is disabled in the switched network. Port 1 on Device A and Port 2 on Device D are assigned to the Red VLAN. If a broadcast is sent from the host connected to Device A, Device A floods the broadcast and every device in the network receives it, even though Devices C, E, and F have no ports in the Red VLAN.
VTP pruning is enabled in the switched network. The broadcast traffic from Device A is not forwarded to Devices C, E, and F because traffic for the Red VLAN has been pruned on the links shown (Port 5 on Device B and Port 4 on Device D).

With VTP versions 1 and 2, when you enable pruning on the VTP server, it is enabled for the entire VTP domain. In VTP version 3, you must manually enable pruning on each device in the domain. Making VLANs pruning-eligible or pruning-ineligible affects pruning eligibility for those VLANs on that trunk only (not on all devices in the VTP domain).

VTP pruning takes effect several seconds after you enable it. VTP pruning does not prune traffic from VLANs that are pruning-ineligible. VLAN 1 and VLANs 1002 to 1005 are always pruning-ineligible; traffic from these VLANs cannot be pruned. Extended-range VLANs (VLAN IDs higher than 1005) are also pruning-ineligible.

   Enabling VTP Pruning (CLI), on page 2405

VTP and Device Stacks

VTP configuration is the same in all members of a device stack. When the device stack is in VTP server, client, or transparent mode, all devices in the stack carry the same VTP configuration.
   • When a device joins the stack, it inherits the VTP and VLAN properties of the active switch.
   • All VTP updates are carried across the stack.
   • When VTP mode is changed in a device in the stack, the other devices in the stack also change VTP mode, and the device VLAN database remains consistent.

VTP version 3 functions the same on a standalone device or a stack except when the device stack is the primary server for the VTP database. In this case, the MAC address of the active switch is used as the primary server ID. If the active device reloads or is powered off, a new active switch is elected.

   • If you do not configure the persistent MAC address feature, when the new active device is elected, it sends a takeover message using the current stack MAC address.

   Note  By default the persistent MAC address is on.
VTP Configuration Guidelines

VTP Configuration Requirements

When you configure VTP, you must configure a trunk port so that the device can send and receive VTP advertisements to and from other devices in the domain.

VTP Settings

The VTP information is saved in the VTP VLAN database. When VTP mode is transparent, the VTP domain name and mode are also saved in the device running configuration file, and you can save it in the device startup configuration file by entering the copy running-config startup-config privileged EXEC command. You must use this command if you want to save VTP mode as transparent, even if the device resets.

When you save VTP information in the device startup configuration file and reboot the device, the device configuration is selected as follows:

- If the VTP mode is transparent in the startup configuration and the VLAN database and the VTP domain name from the VLAN database matches that in the startup configuration file, the VLAN database is ignored (cleared), and the VTP and VLAN configurations in the startup configuration file are used. The VLAN database revision number remains unchanged in the VLAN database.

- If the VTP mode or domain name in the startup configuration do not match the VLAN database, the domain name and VTP mode and configuration for VLAN IDs 1 to 1005 use the VLAN database information.

Domain Names for Configuring VTP

When configuring VTP for the first time, you must always assign a domain name. You must configure all devices in the VTP domain with the same domain name. Devices in VTP transparent mode do not exchange VTP messages with other devices, and you do not need to configure a VTP domain name for them.

Note

If the NVRAM and DRAM storage is sufficient, all devices in a VTP domain should be in VTP server mode.

Caution

Do not configure a VTP domain if all devices are operating in VTP client mode. If you configure the domain, it is impossible to make changes to the VLAN configuration of that domain. Make sure that you configure at least one device in the VTP domain for VTP server mode.

Related Topics

Adding a VTP Client to a VTP Domain (CLI), on page 2407
Passwords for the VTP Domain

You can configure a password for the VTP domain, but it is not required. If you do configure a domain password, all domain devices must share the same password and you must configure the password on each device in the management domain. Devices without a password or with the wrong password reject VTP advertisements.

If you configure a VTP password for a domain, a device that is booted without a VTP configuration does not accept VTP advertisements until you configure it with the correct password. After the configuration, the device accepts the next VTP advertisement that uses the same password and domain name in the advertisement.

If you are adding a new device to an existing network with VTP capability, the new device learns the domain name only after the applicable password has been configured on it.

Caution

When you configure a VTP domain password, the management domain does not function properly if you do not assign a management domain password to each device in the domain.

Example: Configuring a Switch as the Primary Server, on page 2410

VTP Version

Follow these guidelines when deciding which VTP version to implement:

• All devices in a VTP domain must have the same domain name, but they do not need to run the same VTP version.

• A VTP version 2-capable device can operate in the same VTP domain as a device running VTP version 1 if version 2 is disabled on the version 2-capable device (version 2 is disabled by default).

• If a device running VTP version 1, but capable of running VTP version 2, receives VTP version 3 advertisements, it automatically moves to VTP version 2.

• If a device running VTP version 3 is connected to a device running VTP version 1, the VTP version 1 device moves to VTP version 2, and the VTP version 3 device sends scaled-down versions of the VTP packets so that the VTP version 2 device can update its database.

• A device running VTP version 3 cannot move to version 1 or 2 if it has extended VLANs.

• Do not enable VTP version 2 on a device unless all of the devices in the same VTP domain are version-2-capable. When you enable version 2 on a device, all of the version-2-capable devices in the domain enable version 2. If there is a version 1-only device, it does not exchange VTP information with devices that have version 2 enabled.

• Cisco recommends placing VTP version 1 and 2 devices at the edge of the network because they do not forward VTP version 3 advertisements.

• If there are TrBRF and TrCRF Token Ring networks in your environment, you must enable VTP version 2 or version 3 for Token Ring VLAN switching to function properly. To run Token Ring and Token Ring-Net, disable VTP version 2.
- VTP version 1 and version 2 do not propagate configuration information for extended range VLANs (VLANs 1006 to 4094). You must configure these VLANs manually on each device. VTP version 3 supports extended-range VLANs and support for extended range VLAN database propagation.

- When a VTP version 3 device trunk port receives messages from a VTP version 2 device, it sends a scaled-down version of the VLAN database on that particular trunk in VTP version 2 format. A VTP version 3 device does not send VTP version 2-formatted packets on a trunk unless it first receives VTP version 2 packets on that trunk port.

- When a VTP version 3 device detects a VTP version 2 device on a trunk port, it continues to send VTP version 3 packets, in addition to VTP version 2 packets, to allow both kinds of neighbors to coexist on the same trunk.

- A VTP version 3 device does not accept configuration information from a VTP version 2 or version 1 device.

- Two VTP version 3 regions can only communicate in transparent mode over a VTP version 1 or version 2 region.

- Devices that are only VTP version 1 capable cannot interoperate with VTP version 3 devices.

- VTP version 1 and version 2 do not propagate configuration information for extended range VLANs (VLANs 1006 to 4094). You must manually configure these VLANs on each device.

**How to Configure VTP**

**Configuring VTP Mode (CLI)**

You can configure VTP mode as one of these:

- **VTP server mode**—In VTP server mode, you can change the VLAN configuration and have it propagated throughout the network.

- **VTP client mode**—In VTP client mode, you cannot change its VLAN configuration. The client device receives VTP updates from a VTP server in the VTP domain and then modifies its configuration accordingly.

- **VTP transparent mode**—In VTP transparent mode, VTP is disabled on the device. The device does not send VTP updates and does not act on VTP updates received from other device. However, a VTP transparent device running VTP version 2 does forward received VTP advertisements on its trunk links.

- **VTP off mode**—VTP off mode is the same as VTP transparent mode except that VTP advertisements are not forwarded.

When you configure a domain name, it cannot be removed; you can only reassign a device to a different domain.

**SUMMARY STEPS**

1. **enable**
2. configure terminal
3. vtp domain domain-name
4. vtp mode {client | server | transparent | off} {vlan | mst | unknown}
5. vtp password password
6. end
7. show vtp status
8. copy running-config startup-config

<table>

</tbody>
</table>
## Configuring a VTP Version 3 Password (CLI)

You can configure a VTP version 3 password on the device.

### SUMMARY STEPS

1. enable
2. configure terminal
3. vtp password password [hidden | secret]
4. end
5. show vtp password
6. copy running-config startup-config

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
Purpose

Command or Action

Device# configure terminal

Step 3

vtp password password [hidden | secret]

Example:

Device(config)# vtp password mypassword hidden

(Optional) Sets the password for the VTP domain. The password can be 8 to 64 characters.

• (Optional) hidden—Saves the secret key generated from the password string in the nvram:vlan.dat file. If you configure a takeover by configuring a VTP primary server, you are prompted to reenter the password.

• (Optional) secret—Directly configures the password. The secret password must contain 32 hexadecimal characters.

Step 4

end

Example:

Device(config)# end

Returns to privileged EXEC mode.

Step 5

show vtp password

Example:

Device# show vtp password

Verifies your entries. The output appears like this:

VTP password: 89914640C8D90868B6A0D8103847A733

Step 6

copy running-config startup-config

Example:

Device# copy running-config startup-config

(Optional) Saves your entries in the configuration file.

### Enabling the VTP Version (CLI)

VTP version 2 and version 3 are disabled by default.

- When you enable VTP version 2 on a device, every VTP version 2-capable device in the VTP domain enables version 2. To enable VTP version 3, you must manually configure it on each device.

- With VTP versions 1 and 2, you can configure the version only on devices in VTP server or transparent mode. If a device is running VTP version 3, you can change to version 2 when the device is in client mode if no extended VLANs exist, and no hidden password was configured.

**Caution**

VTP version 1 and VTP version 2 are not interoperable on devices in the same VTP domain. Do not enable VTP version 2 unless every device in the VTP domain supports version 2.

- In TrCRF and TrBRF Token Ring environments, you must enable VTP version 2 or VTP version 3 for Token Ring VLAN switching to function properly. For Token Ring and Token Ring-Net media, disable VTP version 2.

**Caution**

In VTP version 3, both the primary and secondary servers can exist on an instance in the domain.

Enabling VTP Pruning (CLI)

Before you begin

VTP pruning is not designed to function in VTP transparent mode. If one or more devices in the network are in VTP transparent mode, you should do one of these actions:

- Turn off VTP pruning in the entire network.
- Turn off VTP pruning by making all VLANs on the trunk of the device upstream to the VTP transparent device pruning ineligible.

To configure VTP pruning on an interface, use the switchport trunk pruning vlan interface configuration command. VTP pruning operates when an interface is trunking. You can set VLAN pruning-eligibility, whether or not VTP pruning is enabled for the VTP domain, whether or not any given VLAN exists, and whether or not the interface is currently trunking.

SUMMARY STEPS

1. enable
2. configure terminal
3. vtp pruning
4. end
5. show vtp status

**Adding a VTP Client to a VTP Domain (CLI)**

Follow these steps to verify and reset the VTP configuration revision number on a device *before* adding it to a VTP domain.

**Before you begin**

Before adding a VTP client to a VTP domain, always verify that its VTP configuration revision number is *lower* than the configuration revision number of the other devices in the VTP domain. Devices in a VTP domain always use the VLAN configuration of the device with the highest VTP configuration revision number. With VTP versions 1 and 2, adding a device that has a revision number higher than the revision number in the VTP domain can erase all VLAN information from the VTP server and VTP domain. With VTP version 3, the VLAN information is not erased.

You can use the `vtp mode transparent` global configuration command to disable VTP on the device and then to change its VLAN information without affecting the other devices in the VTP domain.
SUMMARY STEPS

1. enable
2. show vtp status
3. configure terminal
4. vtp domain domain-name
5. end
6. show vtp status
7. configure terminal
8. vtp domain domain-name
9. end
10. show vtp status

## Monitoring VTP

This section describes commands used to display and monitor the VTP configuration.
You monitor VTP by displaying VTP configuration information: the domain name, the current VTP revision, and the number of VLANs. You can also display statistics about the advertisements sent and received by the device.

Table 205: VTP Monitoring Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show vtp counters</td>
<td>Displays counters about VTP messages that have been sent and received.</td>
</tr>
<tr>
<td>show vtp devices [conflict]</td>
<td>Displays information about all VTP version 3 devices in the domain. Conflicts are VTP version 3 devices with conflicting primary servers. The show vtp devices command does not display information when the device is in transparent or off mode.</td>
</tr>
<tr>
<td>show vtp interface [interface-id]</td>
<td>Displays VTP status and configuration for all interfaces or the specified interface.</td>
</tr>
<tr>
<td>show vtp password</td>
<td>Displays the VTP password. The form of the password displayed depends on whether or not the hidden keyword was entered and if encryption is enabled on the device.</td>
</tr>
<tr>
<td>show vtp status</td>
<td>Displays the VTP device configuration information.</td>
</tr>
</tbody>
</table>

Configuration Examples for VTP

Example: Configuring a Switch as the Primary Server

This example shows how to configure a device as the primary server for the VLAN database (the default) when a hidden or secret password was configured:

```
Device# vtp primary vlan
Enter VTP password: mypassword
This switch is becoming Primary server for vlan feature in the VTP domain

VTP Database Conf Switch ID Primary Server Revision System Name
-------------- ---- ------------------------------ -------------- -------- -------------------------------
VLANDB       Yes 00d0.00b8.1400-00d0.00b8.1400 1 stp7

Do you want to continue {y/n} [n]? y
```

Configuring VLANs

- Finding Feature Information, on page 2413
- Prerequisites for VLANs, on page 2413
- Restrictions for VLANs, on page 2414
- Information About VLANs, on page 2414
- How to Configure VLANs, on page 2418
- Monitoring VLANs, on page 2427
- Where to Go Next, on page 2428
- Additional References, on page 2429
- Feature History and Information for VLANs, on page 2430

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for VLANs

The following are prerequisites and considerations for configuring VLANs:

- Before you create VLANs, you must decide whether to use VLAN Trunking Protocol (VTP) to maintain global VLAN configuration for your network.

- If you plan to configure many VLANs on the device and to not enable routing, you can set the Switch Database Management (SDM) feature to the VLAN template, which configures system resources to support the maximum number of unicast MAC addresses.

- Devices running the LAN Base feature set support only static routing on SVIs.

- A VLAN should be present in the device to be able to add it to the VLAN group.
Restrictions for VLANs

The following are restrictions for VLANs:

- The device supports per-VLAN spanning-tree plus (PVST+) or rapid PVST+ with a maximum of 128 spanning-tree instances. One spanning-tree instance is allowed per VLAN.
- The device supports IEEE 802.1Q trunking methods for sending VLAN traffic over Ethernet ports.
- Configuring an interface VLAN router's MAC address is not supported. The interface VLAN already has an MAC address assigned by default.
- Private VLANs are not supported on the device.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

Information About VLANs

Logical Networks

A VLAN is a switched network that is logically segmented by function, project team, or application, without regard to the physical locations of the users. VLANs have the same attributes as physical LANs, but you can group end stations even if they are not physically located on the same LAN segment. Any device port can belong to a VLAN, and unicast, broadcast, and multicast packets are forwarded and flooded only to end stations in the VLAN. Each VLAN is considered a logical network, and packets destined for stations that do not belong to the VLAN must be forwarded through a router or a device supporting fallback bridging. In a device stack, VLANs can be formed with ports across the stack. Because a VLAN is considered a separate logical network, it contains its own bridge Management Information Base (MIB) information and can support its own implementation of spanning tree.

Figure 124: VLANs as Logically Defined Networks
VLANs are often associated with IP subnetworks. For example, all the end stations in a particular IP subnet belong to the same VLAN. Interface VLAN membership on the device is assigned manually on an interface-by-interface basis. When you assign device interfaces to VLANs by using this method, it is known as interface-based, or static, VLAN membership.

Traffic between VLANs must be routed.

The device can route traffic between VLANs by using device virtual interfaces (SVIs). An SVI must be explicitly configured and assigned an IP address to route traffic between VLANs.

**Supported VLANs**

The device supports VLANs in VTP client, server, and transparent modes. VLANs are identified by a number from 1 to 4094. VLAN 1 is the default VLAN and is created during system initialization. VLAN IDs 1002 through 1005 are reserved for Token Ring and FDDI VLANs. All of the VLANs except 1002 to 1005 are available for user configuration.

There are 3 VTP versions: VTP version 1, version 2, and version 3. All VTP versions support both normal and extended range VLANs, but only with VTP version 3, does the device propagate extended range VLAN configuration information. When extended range VLANs are created in VTP versions 1 and 2, their configuration information is not propagated. Even the local VTP database entries on the device are not updated, but the extended range VLANs configuration information is created and stored in the running configuration file.

You can configure up to 4094 VLANs on the device.

- Creating an Extended-Range VLAN with an Internal VLAN ID

**VLAN Port Membership Modes**

You configure a port to belong to a VLAN by assigning a membership mode that specifies the kind of traffic the port carries and the number of VLANs to which it can belong.

When a port belongs to a VLAN, the device learns and manages the addresses associated with the port on a per-VLAN basis.
### Table 206: Port Membership Modes and Characteristics

<table>
<thead>
<tr>
<th>Membership Mode</th>
<th>VLAN Membership Characteristics</th>
<th>VTP Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static-access</td>
<td>A static-access port can belong to one VLAN and is manually assigned to that VLAN.</td>
<td>VTP is not required. If you do not want VTP to globally propagate information, set the VTP mode to transparent. To participate in VTP, there must be at least one trunk port on the device or the device stack connected to a trunk port of a second device or device stack.</td>
</tr>
<tr>
<td>Trunk (IEEE 802.1Q)</td>
<td>A trunk port is a member of all VLANs by default, including extended-range VLANs, but membership can be limited by configuring the allowed-VLAN list. You can also modify the pruning-eligible list to block flooded traffic to VLANs on trunk ports that are included in the list.</td>
<td>VTP is recommended but not required. VTP maintains VLAN configuration consistency by managing the addition, deletion, and renaming of VLANs on a network-wide basis. VTP exchanges VLAN configuration messages with other devices over trunk links.</td>
</tr>
<tr>
<td>Voice VLAN</td>
<td>A voice VLAN port is an access port attached to a Cisco IP Phone, configured to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.</td>
<td>VTP is not required; it has no effect on a voice VLAN.</td>
</tr>
</tbody>
</table>

### VLAN Configuration Files

Configurations for VLAN IDs 1 to 1005 are written to the vlan.dat file (VLAN database), and you can display them by entering the `show vlan` privileged EXEC command. The vlan.dat file is stored in flash memory. If the VTP mode is transparent, they are also saved in the device running configuration file.

In a device stack, the whole stack uses the same vlan.dat file and running configuration. On some devices, the vlan.dat file is stored in flash memory on the active device.

You use the interface configuration mode to define the port membership mode and to add and remove ports from VLANs. The results of these commands are written to the running-configuration file, and you can display the file by entering the `show running-config` privileged EXEC command.

When you save VLAN and VTP information (including extended-range VLAN configuration information) in the startup configuration file and reboot the device, the device configuration is selected as follows:

- If the VTP mode is transparent in the startup configuration, and the VLAN database and the VTP domain name from the VLAN database matches that in the startup configuration file, the VLAN database is...
ignored (cleared), and the VTP and VLAN configurations in the startup configuration file are used. The VLAN database revision number remains unchanged in the VLAN database.

- If the VTP mode or domain name in the startup configuration does not match the VLAN database, the domain name and VTP mode and configuration for the VLAN IDs 1 to 1005 use the VLAN database information.

- In VTP versions 1 and 2, if VTP mode is server, the domain name and VLAN configuration for VLAN IDs 1 to 1005 use the VLAN database information. VTP version 3 also supports VLANs 1006 to 4094.

Ensure that you delete the vlan.dat file along with the configuration files before you reset the switch configuration using `write erase` command. This ensures that the switch reboots correctly on a reset.

### Normal-Range VLAN Configuration Guidelines

Normal-range VLANs are VLANs with IDs from 1 to 1005.

Follow these guidelines when creating and modifying normal-range VLANs in your network:

- Normal-range VLANs are identified with a number between 1 and 1001. VLAN numbers 1002 through 1005 are reserved for Token Ring and FDDI VLANs.

- VLAN configurations for VLANs 1 to 1005 are always saved in the VLAN database. If the VTP mode is transparent, VTP and VLAN configurations are also saved in the device running configuration file.

- If the device is in VTP server or VTP transparent mode, you can add, modify or remove configurations for VLANs 2 to 1001 in the VLAN database. (VLAN IDs 1 and 1002 to 1005 are automatically created and cannot be removed.)

- Extended-range VLANs created in VTP transparent mode are not saved in the VLAN database and are not propagated. VTP version 3 supports extended range VLAN (VLANs 1006 to 4094) database propagation in VTP server mode.

- Before you can create a VLAN, the device must be in VTP server mode or VTP transparent mode. If the device is a VTP server, you must define a VTP domain or VTP will not function.

- The device does not support Token Ring or FDDI media. The device does not forward FDDI, FDDI-Net, TrCRF, or TrBFR traffic, but it does propagate the VLAN configuration through VTP.

- The device supports 128 spanning tree instances. If a device has more active VLANs than supported spanning-tree instances, spanning tree can be enabled on 128 VLANs and is disabled on the remaining VLANs. If you have already used all available spanning-tree instances on a device, adding another VLAN anywhere in the VTP domain creates a VLAN on that device that is not running spanning-tree. If you have the default allowed list on the trunk ports of that device (which is to allow all VLANs), the new VLAN is carried on all trunk ports. Depending on the topology of the network, this could create a loop in the new VLAN that would not be broken, particularly if there are several adjacent devices that all have run out of spanning-tree instances. You can prevent this possibility by setting allowed lists on the trunk ports of devices that have used up their allocation of spanning-tree instances.

If the number of VLANs on the device exceeds the number of supported spanning-tree instances, we recommend that you configure the IEEE 802.1s Multiple STP (MSTP) on your device to map multiple VLANs to a single spanning-tree instance.
• When a device in a stack learns a new VLAN or deletes or modifies an existing VLAN (either through VTP over network ports or through the CLI), the VLAN information is communicated to all stack members.

• When a device joins a stack or when stacks merge, VTP information (the vlan.dat file) on the new devices will be consistent with the active device.

**Extended-Range VLAN Configuration Guidelines**

Extended-range VLANs are VLANs with IDs from 1006 to 4094.

Follow these guidelines when creating extended-range VLANs:

• VLAN IDs in the extended range are not saved in the VLAN database and are not recognized by VTP unless the device is running VTP version 3.

• You cannot include extended-range VLANs in the pruning eligible range.

• For VTP version 1 or 2, you can set the VTP mode to transparent in global configuration mode. You should save this configuration to the startup configuration so that the device boots up in VTP transparent mode. Otherwise, you lose the extended-range VLAN configuration if the device resets. If you create extended-range VLANs in VTP version 3, you cannot convert to VTP version 1 or 2.

• In a device stack, the whole stack uses the same running configuration and saved configuration, and extended-range VLAN information is shared across the stack.

**Related Topics**

**How to Configure VLANs**

**How to Configure Normal-Range VLANs**

You can set these parameters when you create a new normal-range VLAN or modify an existing VLAN in the VLAN database:

• VLAN ID

• VLAN name

• VLAN type
  • Ethernet
Creating or Modifying an Ethernet VLAN (CLI)

Before you begin

With VTP version 1 and 2, if the device is in VTP transparent mode, you can assign VLAN IDs greater than 1006, but they are not added to the VLAN database.

The device supports only Ethernet interfaces. Because FDDI and Token Ring VLANs are not locally supported, you only configure FDDI and Token Ring media-specific characteristics for VTP global advertisements to other devices.

Although the device does not support Token Ring connections, a remote device with Token Ring connections could be managed from one of the supported devices. Devices running VTP Version 2 advertise information about these Token Ring VLANs:

- Token Ring TrBRF VLANs
- Token Ring TrCRF VLANs

SUMMARY STEPS

1. configure terminal
2. vlan vlan-id
3. name vlan-name
4. media { ethernet | fd-net | fddi | tokenring | trn-net }
5. remote-span
6. end
7. `show vlan {name vlan-name | id vlan-id}`

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `configure terminal` | Enters the global configuration mode.  
**Example:**  
Device# configure terminal |
| **Step 2** | `vlan vlan-id` | Enters a VLAN ID, and enters VLAN configuration mode. Enter a new VLAN ID to create a VLAN, or enter an existing VLAN ID to modify that VLAN.  
**Note** The available VLAN ID range for this command is 1 to 4094.  
**Additional vlan command options include:**  
- **access-map**—Creates VLAN access-maps or enters the vlan access map command mode.  
- **configuration**—Enters the vlan feature configuration mode.  
- **dot1q**—Configures VLAN dot1q tag native parameters.  
- **filter**—Applies a VLAN filter map to a VLAN list.  
- **group**—Creates a VLAN group.  
**Example:**  
Device(config)# vlan 20 |
| **Step 3** | `name vlan-name` | (Optional) Enters a name for the VLAN. If no name is entered for the VLAN, the default is to append the `vlan-id` value with leading zeros to the word VLAN. For example, `VLAN0004` is a default VLAN name for VLAN 4.  
**The following additional VLAN configuration command options are available:**  
- **are**—Sets the maximum number of All Router Explorer (ARE) hops for the VLAN.  
- **backupcrf**—Enables or disables the backup concentrator relay function (CRF) mode for the VLAN.  
- **bridge**—Sets the value of the bridge number for the FDDI net or Token Ring net type VLANs.  
- **exit**—Applies changes, bumps the revision number, and exits.  
- **media**—Sets the media type of the VLAN.  
- **no**—Negates the command or default.  
**Example:**  
Device(config-vlan)# name test20 |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent</td>
<td>Sets the value of the ID for the parent VLAN for FDDI or Token Ring type VLANs.</td>
</tr>
<tr>
<td>remote-span</td>
<td>Configures a remote SPAN VLAN.</td>
</tr>
<tr>
<td>ring</td>
<td>Sets the ring number value for FDDI or Token Ring type VLANs.</td>
</tr>
<tr>
<td>said</td>
<td>Sets the IEEE 802.10 SAID value.</td>
</tr>
<tr>
<td>shutdown</td>
<td>Shuts down the VLAN switching.</td>
</tr>
<tr>
<td>state</td>
<td>Sets the operational VLAN state to active or suspended.</td>
</tr>
<tr>
<td>ste</td>
<td>Sets the maximum number of Spanning Tree Explorer (STE) hops for the VLAN.</td>
</tr>
<tr>
<td>stp</td>
<td>Sets the Spanning Tree characteristics of the VLAN.</td>
</tr>
</tbody>
</table>

**Step 4**

Configure the VLAN media type. Command options include:

- ethernet—Sets the VLAN media type as Ethernet.
- fd-net—Sets the VLAN media type as FDDI net.
- fddi—Sets the VLAN media type as FDDI.
- tokenring—Sets the VLAN media type as Token Ring.
- trn-net—Sets the VLAN media type as Token Ring net.

**Example:**

```
Device(config-vlan)# media ethernet
```

**Step 5**

(Optional) Configure the VLAN as the RSPAN VLAN for a remote SPAN session. For more information on remote SPAN, see the Catalyst 3850 Network Management Configuration Guide.

**Example:**

```
Device(config-vlan)# remote-span
```

**Step 6**

Returns to privileged EXEC mode.

**Example:**

```
Device(config)# end
```

**Step 7**

Verifies your entries.

**Example:**

```
Device# show vlan name test20 id 20
```
Deleting a VLAN (CLI)

When you delete a VLAN from a device that is in VTP server mode, the VLAN is removed from the VLAN database for all devices in the VTP domain. When you delete a VLAN from a device that is in VTP transparent mode, the VLAN is deleted only on that specific device or a device stack.

You cannot delete the default VLANs for the different media types: Ethernet VLAN 1 and FDDI or Token Ring VLANs 1002 to 1005.

⚠️ Caution

When you delete a VLAN, any ports assigned to that VLAN become inactive. They remain associated with the VLAN (and thus inactive) until you assign them to a new VLAN.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no vlan vlan-id`
4. `end`
5. `show vlan brief`
6. `copy running-config startup-config`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 <code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 <code>no vlan vlan-id</code></td>
<td>Removes the VLAN by entering the VLAN ID.</td>
</tr>
<tr>
<td>Example: Device(config)# no vlan 4</td>
<td></td>
</tr>
</tbody>
</table>
### Assigning Static-Access Ports to a VLAN (CLI)

You can assign a static-access port to a VLAN without having VTP globally propagate VLAN configuration information by disabling VTP (VTP transparent mode).

If you are assigning a port on a cluster member device to a VLAN, first use the `rcommand` privileged EXEC command to log in to the cluster member switch.

If you assign an interface to a VLAN that does not exist, the new VLAN is created.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport mode access`
5. `switchport access vlan vlan-id`
6. `end`
7. `show running-config interface interface-id`
8. `show interfaces interface-id switchport`
9. `copy running-config startup-config`

### How to Configure Extended-Range VLANs

Extended-range VLANs enable service providers to extend their infrastructure to a greater number of customers. The extended-range VLAN IDs are allowed for any `switchport` commands that allow VLAN IDs.

With VTP version 1 or 2, extended-range VLAN configurations are not stored in the VLAN database, but because VTP mode is transparent, they are stored in the device running configuration file, and you can save the configuration in the startup configuration file. Extended-range VLANs created in VTP version 3 are stored in the VLAN database.

You can change only the MTU size and the remote SPAN configuration state on extended-range VLANs; all other characteristics must remain at the default state.

### Creating an Extended-Range VLAN (CLI)

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `vlan vlan-id`
4. `remote-span`
5. `exit`
6. `interface vlan`
7. `ip mtu mtu-size`
8. `end`
9. `show vlan id vlan-id`
10. `copy running-config startup-config`

Table 207: Privileged EXEC show Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show interfaces [vlan vlan-id]</td>
<td>Displays characteristics for all interfaces or for the specified VLAN configured on the device.</td>
</tr>
</tbody>
</table>
### Command

```
show vlan [ access-map name ] brief | dot1q { tag native } | filter [ access-map | vlan ] | group [ group-name name ] | id vlan-id | ifindex | mtu | name name | remote-span | summary ]
```

### Purpose

Displays parameters for all VLANs or the specified VLAN on the device. The following command options are available:

- **access-map**—Displays the VLAN access-maps.
- **brief**—Displays VTP VLAN status in brief.
- **dot1q**—Displays the dot1q parameters.
- **filter**—Displays VLAN filter information.
- **group**—Displays the VLAN group with its name and the connected VLANs that are available.
- **id**—Displays VTP VLAN status by identification number.
- **ifindex**—Displays SNMP ifIndex.
- **mtu**—Displays VLAN MTU information.
- **name**—Displays the VTP VLAN information by specified name.
- **remote-span**—Displays the remote SPAN VLANs.
- **summary**—Displays a summary of VLAN information.

• Feature History and Information for VLAN Groups, on page 2436

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for VLAN Groups

• A VLAN should be present in the device to be able to add it to the VLAN group.

• For VLAN group to function properly, in addition to enabling DHCP snooping globally, you must ensure that DHCP snooping is enabled in all the VLANs.

Restrictions for VLAN Groups

The number of VLANs mapped to a VLAN group is not limited by Cisco IOS Software Release. But if the number of VLANs in a VLAN group exceed the recommended value of 32, the mobility behavior is unexpected and in the VLAN group, L2 multicast breaks for some VLANs. So it is the responsibility of the administrator to configure feasible number of VLANs in a VLAN group. When a VLAN is added to a VLAN group mapped
to a WLAN which already has 32 VLANs, a warning is generated. But when a new VLAN group is mapped to a WLAN with more than 32 VLANs, an error is generated.

For expected behavior of the VLAN group, the VLANs mapped in the group must be present in the device. The static IP client behavior is not supported.

**Information About VLAN Groups**

Whenever a client connects to a wireless network (WLAN), the client is placed in a VLAN that is associated with the WLAN. In a large venue such as an auditorium, a stadium, or a conference room where there are numerous wireless clients, having only a single WLAN to accommodate many clients might be a challenge.

The VLAN group feature uses a single WLAN that can support multiple VLANs. The clients can get assigned to one of the configured VLANs. This feature maps a WLAN to a single VLAN or multiple VLANs using the VLAN groups. When a wireless client associates to the WLAN, the VLAN is derived by an algorithm based on the MAC address of the wireless client. A VLAN is assigned to the client and the client gets the IP address from the assigned VLAN. This feature also extends the current AP group architecture and AAA override architecture, where the AP groups and AAA override can override a VLAN or a VLAN group to which the WLAN is mapped.

Behavior change introduced in Cisco IOS XE Release 3.7.0E: When a client associates with a WLAN and the WLAN is applied to a VLAN group, an index is calculated based on the MAC address of the client and the number of VLANs in the VLAN group using a hash algorithm. Based on this index, a VLAN is assigned to the client. If the index is "dirty," another index is generated in a round-robin manner and the VLAN is assigned to the client based on the newly generated index.

The system marks VLAN as "dirty" for 30 minutes when the clients are unable to receive IP address using DHCP. The system might not clear the "dirty" flag from the VLAN even after 30 minutes for a VLAN group. This is expected behavior because the timestamp of each interface has to be checked to see if it is greater than 30 minutes, due to which there is a lag of 5 minutes for the global timer to expire.

Configuring VLAN Trunks

• Finding Feature Information, on page 2437
• Prerequisites for VLAN Trunks, on page 2437
• Restrictions for VLAN Trunks, on page 2438
• Information About VLAN Trunks, on page 2439
• How to Configure VLAN Trunks, on page 2441
• Where to Go Next, on page 2455
• Additional References, on page 2455
• Feature History and Information for VLAN Trunks, on page 2456

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for VLAN Trunks

The IEEE 802.1Q trunks impose these limitations on the trunking strategy for a network:

• In a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for each VLAN allowed on the trunks. Non-Cisco devices might support one spanning-tree instance for all VLANs.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device combines the spanning-tree instance of the VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device. However, spanning-tree information for each VLAN is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.
• Make sure the native VLAN for an IEEE 802.1Q trunk is the same on both ends of the trunk link. If the native VLAN on one end of the trunk is different from the native VLAN on the other end, spanning-tree loops might result.

• Disabling spanning tree on the native VLAN of an IEEE 802.1Q trunk without disabling spanning tree on every VLAN in the network can potentially cause spanning-tree loops. We recommend that you leave spanning tree enabled on the native VLAN of an IEEE 802.1Q trunk or disable spanning tree on every VLAN in the network. Make sure your network is loop-free before disabling spanning tree.

Restrictions for VLAN Trunks

The following are restrictions for VLAN trunks:

• A trunk port cannot be a secure port.

• Trunk ports can be grouped into EtherChannel port groups, but all trunks in the group must have the same configuration. When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, the device propagates the setting that you entered to all ports in the group:
  • Allowed-VLAN list.
  • STP port priority for each VLAN.
  • STP Port Fast setting.
  • Trunk status:
    If one port in a port group ceases to be a trunk, all ports cease to be trunks.

• We recommend that you configure no more than 24 trunk ports in Per VLAN Spanning Tree (PVST) mode and no more than 40 trunk ports in Multiple Spanning Tree (MST) mode.

• If you try to enable IEEE 802.1x on a trunk port, an error message appears, and IEEE 802.1x is not enabled. If you try to change the mode of an IEEE 802.1x-enabled port to trunk, the port mode is not changed.

• A port in dynamic mode can negotiate with its neighbor to become a trunk port. If you try to enable IEEE 802.1x on a dynamic port, an error message appears, and IEEE 802.1x is not enabled. If you try to change the mode of an IEEE 802.1x-enabled port to dynamic, the port mode is not changed.

• Dynamic Trunking Protocol (DTP) is not supported on tunnel ports.

• The device does not support Layer 3 trunks; you cannot configure subinterfaces or use the encapsulation keyword on Layer 3 interfaces. The device does support Layer 2 trunks and Layer 3 VLAN interfaces, which provide equivalent capabilities.

• You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
Information About VLAN Trunks

Trunking Overview

A trunk is a point-to-point link between one or more Ethernet device interfaces and another networking device such as a router or a device. Ethernet trunks carry the traffic of multiple VLANs over a single link, and you can extend the VLANs across an entire network.

The following trunking encapsulations are available on all Ethernet interfaces:

• IEEE 802.1Q—Industry-standard trunking encapsulation.

Trunking Modes

Ethernet trunk interfaces support different trunking modes. You can set an interface as trunking or nontrunking or to negotiate trunking with the neighboring interface. To autonegotiate trunking, the interfaces must be in the same VTP domain.

Trunk negotiation is managed by the Dynamic Trunking Protocol (DTP), which is a Point-to-Point Protocol (PPP). However, some internetworking devices might forward DTP frames improperly, which could cause misconfigurations.

Layer 2 Interface Modes

Table 208: Layer 2 Interface Modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>switchport mode access</td>
<td>Puts the interface (access port) into permanent nontrunking mode and negotiates to convert the link into a nontrunk link. The interface becomes a nontrunk interface regardless of whether or not the neighboring interface is a trunk interface.</td>
</tr>
<tr>
<td>switchport mode dynamic auto</td>
<td>Makes the interface able to convert the link to a trunk link. The interface becomes a trunk interface if the neighboring interface is set to trunk or desirable mode. The default switchport mode for all Ethernet interfaces is dynamic auto.</td>
</tr>
<tr>
<td>switchport mode dynamic desirable</td>
<td>Makes the interface actively attempt to convert the link to a trunk link. The interface becomes a trunk interface if the neighboring interface is set to trunk, desirable, or auto mode.</td>
</tr>
<tr>
<td>switchport mode trunk</td>
<td>Puts the interface into permanent trunking mode and negotiates to convert the neighboring link into a trunk link. The interface becomes a trunk interface even if the neighboring interface is not a trunk interface.</td>
</tr>
</tbody>
</table>
**Function Mode**

Prevent the interface from generating DTP frames. You can use this command only when the interface switchport mode is access or trunk. You must manually configure the neighboring interface as a trunk interface to establish a trunk link.

### Allowed VLANs on a Trunk

By default, a trunk port sends traffic to and receives traffic from all VLANs. All VLAN IDs, 1 to 4094, are allowed on each trunk. However, you can remove VLANs from the allowed list, preventing traffic from those VLANs from passing over the trunk.

To reduce the risk of spanning-tree loops or storms, you can disable VLAN 1 on any individual VLAN trunk port by removing VLAN 1 from the allowed list. When you remove VLAN 1 from a trunk port, the interface continues to send and receive management traffic, for example, Cisco Discovery Protocol (CDP), Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), DTP, and VTP in VLAN 1.

If a trunk port with VLAN 1 disabled is converted to a nontrunk port, it is added to the access VLAN. If the access VLAN is set to 1, the port will be added to VLAN 1, regardless of the switchport trunk allowed setting. The same is true for any VLAN that has been disabled on the port.

A trunk port can become a member of a VLAN if the VLAN is enabled, if VTP knows of the VLAN, and if the VLAN is in the allowed list for the port. When VTP detects a newly enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of the enabled VLAN. When VTP detects a new VLAN and the VLAN is not in the allowed list for a trunk port, the trunk port does not become a member of the new VLAN.

### Load Sharing on Trunk Ports

Load sharing divides the bandwidth supplied by parallel trunks connecting devices. To avoid loops, STP normally blocks all but one parallel link between devices. Using load sharing, you divide the traffic between the links according to which VLAN the traffic belongs.

You configure load sharing on trunk ports by using STP port priorities or STP path costs. For load sharing using STP port priorities, both load-sharing links must be connected to the same device. For load sharing using STP path costs, each load-sharing link can be connected to the same device or to two different devices.

### Network Load Sharing Using STP Priorities

When two ports on the same device form a loop, the device uses the STP port priority to decide which port is enabled and which port is in a blocking state. You can set the priorities on a parallel trunk port so that the port carries all the traffic for a given VLAN. The trunk port with the higher priority (lower values) for a VLAN is forwarding traffic for that VLAN. The trunk port with the lower priority (higher values) for the same VLAN remains in a blocking state for that VLAN. One trunk port sends or receives all traffic for the VLAN.
Network Load Sharing Using STP Path Cost

You can configure parallel trunks to share VLAN traffic by setting different path costs on a trunk and associating the path costs with different sets of VLANs, blocking different ports for different VLANs. The VLANs keep the traffic separate and maintain redundancy in the event of a lost link.

Feature Interactions

Trunking interacts with other features in these ways:

- A trunk port cannot be a secure port.

- Trunk ports can be grouped into EtherChannel port groups, but all trunks in the group must have the same configuration. When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, the device propagates the setting that you entered to all ports in the group:
  - Allowed-VLAN list.
  - STP port priority for each VLAN.
  - STP Port Fast setting.
  - Trunk status:
    - If one port in a port group ceases to be a trunk, all ports cease to be trunks.

- We recommend that you configure no more than 24 trunk ports in Per VLAN Spanning Tree (PVST) mode and no more than 40 trunk ports in Multiple Spanning Tree (MST) mode.

- If you try to enable IEEE 802.1x on a trunk port, an error message appears, and IEEE 802.1x is not enabled. If you try to change the mode of an IEEE 802.1x-enabled port to trunk, the port mode is not changed.

- A port in dynamic mode can negotiate with its neighbor to become a trunk port. If you try to enable IEEE 802.1x on a dynamic port, an error message appears, and IEEE 802.1x is not enabled. If you try to change the mode of an IEEE 802.1x-enabled port to dynamic, the port mode is not changed.

How to Configure VLAN Trunks

To avoid trunking misconfigurations, configure interfaces connected to devices that do not support DTP to not forward DTP frames, that is, to turn off DTP.

- If you do not intend to trunk across those links, use the `switchport mode access` interface configuration command to disable trunking.
To enable trunking to a device that does not support DTP, use the `switchport mode trunk` and `switchport nonegotiate` interface configuration commands to cause the interface to become a trunk but to not generate DTP frames.

### Configuring an Ethernet Interface as a Trunk Port

#### Configuring a Trunk Port (CLI)

Because trunk ports send and receive VTP advertisements, to use VTP you must ensure that at least one trunk port is configured on the device and that this trunk port is connected to the trunk port of a second device. Otherwise, the device cannot receive any VTP advertisements.

**Before you begin**

By default, an interface is in Layer 2 mode. The default mode for Layer 2 interfaces is `switchport mode dynamic auto`. If the neighboring interface supports trunking and is configured to allow trunking, the link is a Layer 2 trunk or, if the interface is in Layer 3 mode, it becomes a Layer 2 trunk when you enter the `switchport` interface configuration command.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport mode {dynamic {auto | desirable} | trunk}`
5. `switchport access vlan vlan-id`
6. `switchport trunk native vlan vlan-id`
7. `end`
8. `show interfaces interface-id switchport`
9. `show interfaces interface-id trunk`
10. `copy running-config startup-config`

#### DETAILED STEPS

### Defining the Allowed VLANs on a Trunk (CLI)

VLAN 1 is the default VLAN on all trunk ports in all Cisco devices, and it has previously been a requirement that VLAN 1 always be enabled on every trunk link. You can use the VLAN 1 minimization feature to disable VLAN 1 on any individual VLAN trunk link so that no user traffic (including spanning-tree advertisements) is sent or received on VLAN 1.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport mode trunk`
5. `switchport trunk allowed vlan { word | add | all | except | none | remove} vlan-list`
6. `end`
7. `show interfaces interface-id switchport`
8. `copy running-config startup-config`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters the global configuration mode.</td>
</tr>
<tr>
<td><code>interface interface-id</code></td>
<td></td>
</tr>
<tr>
<td><code>switchport mode trunk</code></td>
<td></td>
</tr>
<tr>
<td>`switchport trunk allowed vlan { word</td>
<td>add</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
<tr>
<td><code>show interfaces interface-id switchport</code></td>
<td></td>
</tr>
<tr>
<td><code>copy running-config startup-config</code></td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

| Step 3 | `interface interface-id`  
Example:  
Device(config)# interface gigabitethernet1/0/1 | Specifies the port to be configured, and enters interface configuration mode. |
| Step 4 | `switchport mode trunk`  
Example:  
Device(config-if)# switchport mode trunk | Configures the interface as a VLAN trunk port. |
| Step 5 | `switchport trunk allowed vlan { word | add | all | except | none | remove } vlan-list`  
Example:  
Device(config-if)# switchport trunk allowed vlan remove 2 | (Optional) Configures the list of VLANs allowed on the trunk.  
The `vlan-list` parameter is either a single VLAN number from 1 to 4094 or a range of VLANs described by two VLAN numbers, the lower one first, separated by a hyphen. Do not enter any spaces between comma-separated VLAN parameters or in hyphen-specified ranges.  
All VLANs are allowed by default. |
| Step 6 | `end`  
Example:  
Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | `show interfaces interface-id switchport`  
Example:  
Device# show interfaces gigabitethernet1/0/1 switchport | Verifies your entries in the `Trunking VLANs Enabled` field of the display. |
| Step 8 | `copy running-config startup-config`  
Example:  
Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface interface-id</td>
<td>Selects the trunk port for which VLANs should be pruned, and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet2/0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> switchport trunk pruning vlan {add</td>
<td>except</td>
</tr>
<tr>
<td></td>
<td>For explanations about using the <strong>add</strong>, <strong>except</strong>, <strong>none</strong>, and <strong>remove</strong> keywords, see the command reference for this release.</td>
</tr>
<tr>
<td></td>
<td>Separate non-consecutive VLAN IDs with a comma and no spaces; use a hyphen to designate a range of IDs. Valid IDs are 2 to 1001. Extended-range VLANs (VLAN IDs 1006 to 4094) cannot be pruned.</td>
</tr>
<tr>
<td></td>
<td>VLANs that are pruning-eligible receive flooded traffic.</td>
</tr>
<tr>
<td></td>
<td>The default list of VLANs allowed to be pruned contains VLANs 2 to 1001.</td>
</tr>
</tbody>
</table>
### Configuring the Native VLAN for Untagged Traffic (CLI)

A trunk port configured with IEEE 802.1Q tagging can receive both tagged and untagged traffic. By default, the device forwards untagged traffic in the native VLAN configured for the port. The native VLAN is VLAN 1 by default.

The native VLAN can be assigned any VLAN ID.

If a packet has a VLAN ID that is the same as the outgoing port native VLAN ID, the packet is sent untagged; otherwise, the device sends the packet with a tag.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport trunk native vlan vlan-id`
5. `end`
6. `show interfaces interface-id switchport`
7. `copy running-config startup-config`

#### DETAILED STEPS

<table>

### Configuring Trunk Ports for Load Sharing

#### Configuring Load Sharing Using STP Port Priorities (CLI)

If your device is a member of a device stack, you must use the `spanning-tree [vlan vlan-id] cost cost` interface configuration command instead of the `spanning-tree [vlan vlan-id] port-priority priority` interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

These steps describe how to configure a network with load sharing using STP port priorities.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>interface interface-id</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# interface gigabitethernet1/0/2</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>switchport trunk native vlan vlan-id</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# switchport trunk native vlan 12</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>end</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>show interfaces interface-id switchport</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# show interfaces gigabitethernet1/0/2 switchport</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>copy running-config startup-config</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# copy running-config startup-config</td>
</tr>
</tbody>
</table>
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `vtp domain domain-name`
4. `vtp mode server`
5. `end`
6. `show vtp status`
7. `show vlan`
8. `configure terminal`
9. `interface interface-id`
10. `switchport mode trunk`
11. `end`
12. `show interfaces interface-id switchport`
13. Repeat the above steps on Device A for a second port in the device or device stack.
14. Repeat the above steps on Device B to configure the trunk ports that connect to the trunk ports configured on Device A.
15. `show vlan`
16. `configure terminal`
17. `interface interface-id`
18. `spanning-tree vlan vlan-range port-priority priority-value`
19. `exit`
20. `interface interface-id`
21. `spanning-tree vlan vlan-range port-priority priority-value`
22. `end`
23. `show running-config`
24. `copy running-config startup-config`

**Configuring Load Sharing Using STP Path Cost (CLI)**

These steps describe how to configure a network with load sharing using STP path costs.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface interface-id
4. switchport mode trunk
5. exit
6. Repeat Steps 2 through 4 on a second interface in Device A or in Device A stack.
7. end
8. show running-config
9. show vlan
10. configure terminal
11. `interface interface-id`
12. `spanning-tree vlan vlan-range cost cost-value`
13. `end`
14. Repeat Steps 9 through 13 on the other configured trunk interface on Device A, and set the spanning-tree path cost to 30 for VLANs 8, 9, and 10.
15. `exit`
16. `show running-config`
17. `copy running-config startup-config`

</table>
| **Step 8** | show running-config  
  Example:  
  Device# show running-config | Verifies your entries. In the display, make sure that the interfaces are configured as trunk ports. |
| **Step 9** | show vlan  
  Example:  
  Device# show vlan | When the trunk links come up, Device A receives the VTP information from the other devices. This command verifies that Device A has learned the VLAN configuration. |
| **Step 10** | configure terminal  
  Example:  
  Device# configure terminal | Enters global configuration mode. |
| **Step 11** | interface interface-id  
  Example:  
  Device(config)# interface gigabitethernet1/0/1 | Defines the interface on which to set the STP cost, and enters interface configuration mode. |
| **Step 12** | spanning-tree vlan vlan-range cost cost-value  
  Example:  
  Device(config-if)# spanning-tree vlan 2-4 cost 30 | Sets the spanning-tree path cost to 30 for VLANs 2 through 4. |
| **Step 13** | end  
  Example:  
  Device(config-if)# end | Returns to global configuration mode. |
| **Step 14** | Repeat Steps 9 through 13 on the other configured trunk interface on Device A, and set the spanning-tree path cost to 30 for VLANs 8, 9, and 10. | |
| **Step 15** | exit  
  Example:  
  Device(config)# exit | Returns to privileged EXEC mode. |
| **Step 16** | show running-config  
  Example: | Verifies your entries. In the display, verify that the path costs are set correctly for both trunk interfaces. |

- Feature History and Information for Voice VLAN, on page 2465

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Voice VLANs

The following are the prerequisites for voice VLANs:

- Voice VLAN configuration is only supported on device access ports; voice VLAN configuration is not supported on trunk ports.

**Note**

Trunk ports can carry any number of voice VLANs, similar to regular VLANs. The configuration of voice VLANs is not supported on trunk ports.
• Before you enable voice VLAN, enable QoS on the device by entering the `trust device cisco-phone`
  interface configuration command. If you use the auto QoS feature, these settings are automatically
  configured.

• You must enable CDP on the device port connected to the Cisco IP Phone to send the configuration to
  the phone. (CDP is globally enabled by default on all device interfaces.)

Restrictions for Voice VLANs

You cannot configure static secure MAC addresses in the voice VLAN.

Information About Voice VLAN

Voice VLANs

The voice VLAN feature enables access ports to carry IP voice traffic from an IP phone. When the device is
connected to a Cisco 7960 IP Phone, the phone sends voice traffic with Layer 3 IP precedence and Layer 2
class of service (CoS) values, which are both set to 5 by default. Because the sound quality of an IP phone
call can deteriorate if the data is unevenly sent, the device supports quality of service (QoS) based on IEEE
802.1p CoS. QoS uses classification and scheduling to send network traffic from the device in a predictable
manner.

By default, the voice VLAN feature is disabled. When the feature is enabled, all untagged traffic is sent
according to the default, CoS priority of the port. The CoS value is not trusted for IEEE 802.1Q or for IEEE
802.1p tagged traffic.

The Cisco 7960 IP Phone is a configurable device, and you can configure it to forward traffic with an IEEE
802.1p priority. You can configure the device to trust or override the traffic priority assigned by a Cisco
IP Phone.

Cisco IP Phone Voice Traffic

You can configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and
another VLAN for data traffic from a device attached to the phone. You can configure access ports on the
device to send Cisco Discovery Protocol (CDP) packets that instruct an attached phone to send voice traffic
to the device in any of these ways:

• In the voice VLAN tagged with a Layer 2 CoS priority value
• In the access VLAN tagged with a Layer 2 CoS priority value
• In the access VLAN, untagged (no Layer 2 CoS priority value)

Note

In all configurations, the voice traffic carries a Layer 3 IP precedence value (the default is 5 for voice traffic
and 3 for voice control traffic).
Cisco IP Phone Data Traffic

The device can also process tagged data traffic (traffic in IEEE 802.1Q or IEEE 802.1p frame types) from the device attached to the access port on the Cisco IP Phone. You can configure Layer 2 access ports on the device to send CDP packets that instruct the attached phone to configure the phone access port in one of these modes:

- In trusted mode, all traffic received through the access port on the Cisco IP Phone passes through the phone unchanged.
- In untrusted mode, all traffic in IEEE 802.1Q or IEEE 802.1p frames received through the access port on the Cisco IP Phone receive a configured Layer 2 CoS value. The default Layer 2 CoS value is 0. Untrusted mode is the default.

Untagged traffic from the device attached to the Cisco IP Phone passes through the phone unchanged, regardless of the trust state of the access port on the phone.

Voice VLAN Configuration Guidelines

- Because a Cisco 7960 IP Phone also supports a connection to a PC or other device, a port connecting the device to a Cisco IP Phone can carry mixed traffic. You can configure a port to decide how the Cisco IP Phone carries voice traffic and data traffic.

- The voice VLAN should be present and active on the device for the IP phone to correctly communicate on the voice VLAN. Use the `show vlan` privileged EXEC command to see if the VLAN is present (listed in the display). If the VLAN is not listed, create the voice VLAN.

- The Power over Ethernet (PoE) devices are capable of automatically providing power to Cisco pre-standard and IEEE 802.3af-compliant powered devices if they are not being powered by an AC power source.

- The Port Fast feature is automatically enabled when voice VLAN is configured. When you disable voice VLAN, the Port Fast feature is not automatically disabled.

- If the Cisco IP Phone and a device attached to the phone are in the same VLAN, they must be in the same IP subnet. These conditions indicate that they are in the same VLAN:
  - They both use IEEE 802.1p or untagged frames.
  - The Cisco IP Phone uses IEEE 802.1p frames, and the device uses untagged frames.
  - The Cisco IP Phone uses untagged frames, and the device uses IEEE 802.1p frames.
  - The Cisco IP Phone uses IEEE 802.1Q frames, and the voice VLAN is the same as the access VLAN.
• The Cisco IP Phone and a device attached to the phone cannot communicate if they are in the same VLAN and subnet but use different frame types because traffic in the same subnet is not routed (routing would eliminate the frame type difference).

• Voice VLAN ports can also be these port types:
  • Dynamic access port.
  • IEEE 802.1x authenticated port.

  **Note**
  If you enable IEEE 802.1x on an access port on which a voice VLAN is configured and to which a Cisco IP Phone is connected, the phone loses connectivity to the device for up to 30 seconds.

• Protected port.

• A source or destination port for a SPAN or RSPAN session.

• Secure port.

  **Note**
  When you enable port security on an interface that is also configured with a voice VLAN, you must set the maximum allowed secure addresses on the port to two plus the maximum number of secure addresses allowed on the access VLAN. When the port is connected to a Cisco IP Phone, the phone requires up to two MAC addresses. The phone address is learned on the voice VLAN and might also be learned on the access VLAN. Connecting a PC to the phone requires additional MAC addresses.

---

**How to Configure Voice VLAN**

**Configuring Cisco IP Phone Voice Traffic (CLI)**

You can configure a port connected to the Cisco IP Phone to send CDP packets to the phone to configure the way in which the phone sends voice traffic. The phone can carry voice traffic in IEEE 802.1Q frames for a specified voice VLAN with a Layer 2 CoS value. It can use IEEE 802.1p priority tagging to give voice traffic a higher priority and forward all voice traffic through the native (access) VLAN. The Cisco IP Phone can also send untagged voice traffic or use its own configuration to send voice traffic in the access VLAN. In all configurations, the voice traffic carries a Layer 3 IP precedence value (the default is 5).

**SUMMARY STEPS**

1. `configure terminal`
2. `interface interface-id`
3. `trust device cisco-phone`
4. `switchport voice vlan {vlan-id | dot1p | none | untagged}`
5. end
6. Use one of the following:
   - `show interfaces interface-id switchport`
   - `show running-config interface interface-id`
7. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

### Step 6

Use one of the following:
- `show interfaces interface-id switchport`
- `show running-config interface interface-id`

**Example:**

```
Device# show interfaces gigabitethernet1/0/1 switchport
```

or

```
Device# show running-config interface gigabitethernet1/0/1
```

### Step 7

**copy running-config startup-config**

**Example:**

```
Device# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

### Configuring the Priority of Incoming Data Frames (CLI)

You can connect a PC or other data device to a Cisco IP Phone port. To process tagged data traffic (in IEEE 802.1Q or IEEE 802.1p frames), you can configure the device to send CDP packets to instruct the phone how to send data packets from the device attached to the access port on the Cisco IP Phone. The PC can generate packets with an assigned CoS value. You can configure the phone to not change (trust) or to override (not trust) the priority of frames arriving on the phone port from connected devices.

Follow these steps to set the priority of data traffic received from the non-voice port on the Cisco IP Phone:

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport priority extend {cos value | trust}`
5. `end`
6. `show interfaces interface-id switchport`
7. `copy running-config startup-config`

Software Configuration Guide, Cisco IOS XE Denali 16.1.x (Catalyst 3850 Switches)
Monitoring Voice VLAN

To display voice VLAN configuration for an interface, use the `show interfaces interface-id switchport` privileged EXEC command.

Where to Go Next

After configuring voice VLANs, you can configure the following:

- VLANs
- VLAN groups
- VLAN Trunking
- VTP

- Prerequisites for Private VLANs, on page 2467
- Restrictions for Private VLANs, on page 2468
- Information About Private VLANs, on page 2469
- How to Configure Private VLANs, on page 2477
- Monitoring Private VLANs, on page 2487
- Configuration Examples for Private VLANs, on page 2487
- Where to Go Next, on page 2490
- Additional References, on page 2490

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Private VLANs

Private vlans are supported in transparent mode for VTP 1, 2 and 3. Private VLANS are also supported on server mode with VTP 3.

When configuring private VLANs on the device, always use the default Switch Database Management (SDM) template to balance system resources between unicast routes and Layer 2 entries. If another SDM template is configured, use the sdm prefer default global configuration command to set the default template.
Restrictions for Private VLANs

Note
In some cases, the configuration is accepted with no error messages, but the commands have no effect.

- Do not configure fallback bridging on devices with private VLANs.
- Do not configure a remote SPAN (RSPAN) VLAN as a private-VLAN primary or secondary VLAN.
- Do not configure private-VLAN ports on interfaces configured for these other features:
  - Dynamic-access port VLAN membership
  - Dynamic Trunking Protocol (DTP)
  - IPv6 Security Group (SG)
  - Port Aggregation Protocol (PAgP)
  - Link Aggregation Control Protocol (LACP)
  - Multicast VLAN Registration (MVR)
  - Voice VLAN
  - Web Cache Communication Protocol (WCCP)

- You can configure IEEE 802.1x port-based authentication on a private-VLAN port, but do not configure 802.1x with port security, voice VLAN, or per-user ACL on private-VLAN ports.

- A private-VLAN host or promiscuous port cannot be a SPAN destination port. If you configure a SPAN destination port as a private-VLAN port, the port becomes inactive.

- If you configure a static MAC address on a promiscuous port in the primary VLAN, you need not add the same static address to all associated secondary VLANs. Similarly, if you configure a static MAC address on a host port in a secondary VLAN, you need not add the same static MAC address to the associated primary VLAN. Also, when you delete a static MAC address from a private-VLAN port, you do not have to remove all instances of the configured MAC address from the private VLAN.

Note
Dynamic MAC addresses learned in Secondary VLAN of a private VLAN are replicated to the Primary VLANs. All mac entries are learnt on secondary VLANs, even if the traffic ingresses from primary VLAN. If a mac-address is dynamically learnt in the primary VLAN it will not get replicated in the associated secondary VLANS.

- Configure Layer 3 VLAN interfaces (SVIs) only for primary VLANs.
Information About Private VLANs

Private VLAN Domains

The private VLAN feature addresses two problems that service providers face when using VLANs:

- When running the IP Base or IP Services image, the device supports up to 4094 active VLANs. If a service provider assigns one VLAN per customer, this limits the numbers of customers the service provider can support.

- To enable IP routing, each VLAN is assigned a subnet address space or a block of addresses, which can result in wasting the unused IP addresses, and cause IP address management problems.

**Figure 125: Private VLAN Domain**

Using private VLANs addresses the scalability problem and provides IP address management benefits for service providers and Layer 2 security for customers. Private VLANs partition a regular VLAN domain into subdomains. A subdomain is represented by a pair of VLANs: a primary VLAN and a secondary VLAN. A private VLAN can have multiple VLAN pairs, one pair for each subdomain. All VLAN pairs in a private VLAN share the same primary VLAN. The secondary VLAN ID differentiates one subdomain from another.

Secondary VLANs

There are two types of secondary VLANs:

- Isolated VLANs—Ports within an isolated VLAN cannot communicate with each other at the Layer 2 level.

- Community VLANs—Ports within a community VLAN can communicate with each other but cannot communicate with ports in other communities at the Layer 2 level.
Private VLANs Ports

Private VLANs provide Layer 2 isolation between ports within the same private VLAN. Private VLAN ports are access ports that are one of these types:

- Promiscuous—A promiscuous port belongs to the primary VLAN and can communicate with all interfaces, including the community and isolated host ports that belong to the secondary VLANs associated with the primary VLAN.

- Isolated—An isolated port is a host port that belongs to an isolated secondary VLAN. It has complete Layer 2 separation from other ports within the same private VLAN, except for the promiscuous ports. Private VLANs block all traffic to isolated ports except traffic from promiscuous ports. Traffic received from an isolated port is forwarded only to promiscuous ports.

- Community—A community port is a host port that belongs to a community secondary VLAN. Community ports communicate with other ports in the same community VLAN and with promiscuous ports. These interfaces are isolated at Layer 2 from all other interfaces in other communities and from isolated ports within their private VLAN.

Trunk ports carry traffic from regular VLANs and also from primary, isolated, and community VLANs.

Primary and secondary VLANs have these characteristics:

- Primary VLAN—A private VLAN has only one primary VLAN. Every port in a private VLAN is a member of the primary VLAN. The primary VLAN carries unidirectional traffic downstream from the promiscuous ports to the (isolated and community) host ports and to other promiscuous ports.

- Isolated VLAN —A private VLAN has only one isolated VLAN. An isolated VLAN is a secondary VLAN that carries unidirectional traffic upstream from the hosts toward the promiscuous ports and the gateway.

- Community VLAN—A community VLAN is a secondary VLAN that carries upstream traffic from the community ports to the promiscuous port gateways and to other host ports in the same community. You can configure multiple community VLANs in a private VLAN.

A promiscuous port can serve only one primary VLAN, one isolated VLAN, and multiple community VLANs. Layer 3 gateways are typically connected to the device through a promiscuous port. With a promiscuous port, you can connect a wide range of devices as access points to a private VLAN. For example, you can use a promiscuous port to monitor or back up all the private VLAN servers from an administration workstation.

Private VLANs in Networks

In a switched environment, you can assign an individual private VLAN and associated IP subnet to each individual or common group of end stations. The end stations need to communicate only with a default gateway to communicate outside the private VLAN.

You can use private VLANs to control access to end stations in these ways:

- Configure selected interfaces connected to end stations as isolated ports to prevent any communication at Layer 2. For example, if the end stations are servers, this configuration prevents Layer 2 communication between the servers.

- Configure interfaces connected to default gateways and selected end stations (for example, backup servers) as promiscuous ports to allow all end stations access to a default gateway.

You can extend private VLANs across multiple devices by trunking the primary, isolated, and community VLANs to other devices that support private VLANs. To maintain the security of your private VLAN configuration and to avoid other use of the VLANs configured as private VLANs, configure private VLANs on all intermediate devices, including devices that have no private VLAN ports.

IP Addressing Scheme with Private VLANs

Assigning a separate VLAN to each customer creates an inefficient IP addressing scheme:

- Assigning a block of addresses to a customer VLAN can result in unused IP addresses.

- If the number of devices in the VLAN increases, the number of assigned address might not be large enough to accommodate them.

These problems are reduced by using private VLANs, where all members in the private VLAN share a common address space, which is allocated to the primary VLAN. Hosts are connected to secondary VLANs, and the DHCP server assigns them IP addresses from the block of addresses allocated to the primary VLAN. Subsequent IP addresses can be assigned to customer devices in different secondary VLANs, but in the same primary VLAN. When new devices are added, the DHCP server assigns them the next available address from a large pool of subnet addresses.

Private VLANs Across Multiple Devices

As with regular VLANs, private VLANs can span multiple devices. A trunk port carries the primary VLAN and secondary VLANs to a neighboring device. The trunk port treats the private VLAN as any other VLAN. A feature of private VLANs across multiple devices is that traffic from an isolated port in Device A does not reach an isolated port on Device B.
Private VLANs are supported in transparent mode for VTP 1, 2 and 3. Private vlan is also supported on server mode for VTP 3. If we have a server client setup using VTP 3, private vlans configured on the server should be reflected on the client.

Private-VLAN Interaction with Other Features

Private VLANs and Unicast, Broadcast, and Multicast Traffic

In regular VLANs, devices in the same VLAN can communicate with each other at the Layer 2 level, but devices connected to interfaces in different VLANs must communicate at the Layer 3 level. In private VLANs, the promiscuous ports are members of the primary VLAN, while the host ports belong to secondary VLANs. Because the secondary VLAN is associated to the primary VLAN, members of these VLANs can communicate with each other at the Layer 2 level.

In a regular VLAN, broadcasts are forwarded to all ports in that VLAN. Private VLAN broadcast forwarding depends on the port sending the broadcast:

- An isolated port sends a broadcast only to the promiscuous ports or trunk ports.
- A community port sends a broadcast to all promiscuous ports, trunk ports, and ports in the same community VLAN.
- A promiscuous port sends a broadcast to all ports in the private VLAN (other promiscuous ports, trunk ports, isolated ports, and community ports).

Multicast traffic is routed or bridged across private VLAN boundaries and within a single community VLAN. Multicast traffic is not forwarded between ports in the same isolated VLAN or between ports in different secondary VLANs.

Private VLAN multicast forwarding supports the following:

- Sender can be outside the VLAN and the Receivers can be inside the VLAN domain.
- Sender can be inside the VLAN and the Receivers can be outside the VLAN domain.
- Sender and Receiver can both be in the same community vlan.
**Private VLANs and SVIs**

In a Layer 3 device, a device virtual interface (SVI) represents the Layer 3 interface of a VLAN. Layer 3 devices communicate with a private VLAN only through the primary VLAN and not through secondary VLANs. Configure Layer 3 VLAN interfaces (SVIs) only for primary VLANs. You cannot configure Layer 3 VLAN interfaces for secondary VLANs. SVIs for secondary VLANs are inactive while the VLAN is configured as a secondary VLAN.

- If you try to configure a VLAN with an active SVI as a secondary VLAN, the configuration is not allowed until you disable the SVI.

- If you try to create an SVI on a VLAN that is configured as a secondary VLAN and the secondary VLAN is already mapped at Layer 3, the SVI is not created, and an error is returned. If the SVI is not mapped at Layer 3, the SVI is created, but it is automatically shut down.

When the primary VLAN is associated with and mapped to the secondary VLAN, any configuration on the primary VLAN is propagated to the secondary VLAN SVIs. For example, if you assign an IP subnet to the primary VLAN SVI, this subnet is the IP subnet address of the entire private VLAN.

**Private VLANs and Device Stacks**

Private VLANs can operate within the device stack, and private-VLAN ports can reside on different stack members. However, the following changes to the stack can impact private-VLAN operation:

- If a stack contains only one private-VLAN promiscuous port and the stack member that contains that port is removed from the stack, host ports in that private VLAN lose connectivity outside the private VLAN.

- If a stack master stack that contains the only private-VLAN promiscuous port in the stack fails or leaves the stack and a new stack master is elected, host ports in a private VLAN that had its promiscuous port on the old stack master lose connectivity outside of the private VLAN.

- If two stacks merge, private VLANs on the winning stack are not affected, but private-VLAN configuration on the losing device is lost when that device reboots.

**Private VLAN with Dynamic Mac Address**

The Mac addresses learnt in the secondary VLAN are replicated to the primary VLAN and not vice-versa. This saves the hardware L2 cam space. The primary VLAN is always used for forwarding lookups in both directions.

Dynamic MAC addresses learned in Primary VLAN of a private VLAN are then, if required, replicated in the secondary VLANs. For example, if a mac-address is dynamically received on the secondary VLAN, it will be learnt as part of primary VLAN. In case of isolated VLANs, a blocked entry for the same mac will be added to secondary VLAN in the mac address table. So, mac learnt on host ports in secondary domain are installed as blocked type entries. All mac entries are learnt on secondary VLANs, even if the traffic ingress from primary VLAN.

However, if a mac-address is dynamically learnt in the primary VLAN it will not get replicated in the associated secondary VLANs.

**Private VLAN with Static Mac Address**

Users are not required to replicate the Static Mac Address CLI for private VLAN hosts as compare to legacy model.
Example:

- In the legacy model, if the user configures a static mac address, they need to add same mac static mac-address in the associated VLAN too. For example, if mac-address A is user configured on port 1/0/1 in VLAN 101, where VLAN 101 is a secondary VLAN and VLAN 100 is a primary VLAN, then the user has to configure
  
  ```
  mac-address static A vlan 101 interface G1/0/1
  mac-address static A vlan 100 interface G1/0/1
  ```

- In this device, the user does not need to replicate the mac address to the associated VLAN. For the above example, user has to configure only

  ```
  mac-address static A vlan 101 interface G1/0/1
  ```

**Private VLAN Interaction with VACL/QOS**

Private VLANs are bidirectional in case of this device, as compared to “Unidirectional” in other platforms.

After layer-2 forward lookup, proper egress VLAN mapping happens and all the egress VLAN based feature processing happens in the egress VLAN context.

When a frame in Layer-2 is forwarded within a private VLAN, the VLAN map is applied at the ingress side and at the egress side. When a frame is routed from inside a private VLAN to an external port, the private-VLAN map is applied at the ingress side. Similarly, when the frame is routed from an external port to a Private VLAN, the private-VLAN is applied at the egress side. This is applicable to both bridged and routed traffic.

**Bridging:**

- For upstream traffic from secondary VLAN to primary VLAN, the MAP of the secondary VLAN is applied on the ingress side and the MAP of the primary VLAN is applied on the egress side.

- For downstream traffic from primary VLAN to secondary VLAN, the MAP of the primary VLAN is applied in the ingress direction and the MAP of the secondary VLAN is applied in the egress direction.

**Routing**

If we have two private VLAN domains - PV1 (sec1, prim1) and PV2 (sec2, prim2). For frames routed from PV1 to PV2:

- The MAP of sec1 and L3 ACL of prim1 is applied in the ingress port.
- The MAP of sec2 and L3 ACL of prim2 is applied in the egress port.

For packets going upstream or downstream from isolated host port to promiscuous port, the isolated VLAN’s VACL is applied in the ingress direction and primary VLAN’s VACL is applied in the egress direction. This allows user to configure different VACL for different secondary VLAN in a same primary VLAN domain.

---

**Note**

2-way community VLAN is now not required as the private VLANS on this device are always bi-directional.

**Private VLANs and HA Support**

PVLAN will work seamlessly with High Availability (HA) feature. The Private VLAN existing on the master before switchover should be the same after switchover (new master should have similar PVLAN configuration both on IOS side and FED side as that of the old master).
Private-VLAN Configuration Guidelines

Default Private-VLAN Configurations

No private VLANs are configured.

Secondary and Primary VLAN Configuration

Follow these guidelines when configuring private VLANs:

- Private VLANs are supported in transparent mode for VTP 1, 2 and 3. If the device is running VTP version 1 or 2, you must set VTP to transparent mode. After you configure a private VLAN, you should not change the VTP mode to client or server. VTP version 3 supports private VLANs in all modes.

- With VTP version 1 or 2, after you have configured private VLANs, use the `copy running-config startup config` privileged EXEC command to save the VTP transparent mode configuration and private-VLAN configuration in the device startup configuration file. Otherwise, if the device resets, it defaults to VTP server mode, which does not support private VLANs. VTP version 3 does support private VLANs.

- VTP version 1 and 2 do not propagate private-VLAN configuration. You must configure private VLANs on each device where you want private-VLAN ports unless the devices are running VTP version 3, as VTP3 propagate private vlans.

- You cannot configure VLAN 1 or VLANs 1002 to 1005 as primary or secondary VLANs. Extended VLANs (VLAN IDs 1006 to 4094) can belong to private VLANs.

- A primary VLAN can have one isolated VLAN and multiple community VLANs associated with it. An isolated or community VLAN can have only one primary VLAN associated with it.

- Although a private VLAN contains more than one VLAN, only one Spanning Tree Protocol (STP) instance runs for the entire private VLAN. When a secondary VLAN is associated with the primary VLAN, the STP parameters of the primary VLAN are propagated to the secondary VLAN.

- When copying a PVLAN configuration from a tftp server and applying it on a running-config, the PVLAN association will not be formed. You will need to check and ensure that the primary VLAN is associated to all the secondary VLANs.

You can also use `configure replace flash:config_file force` instead of `copy flash:config_file running-config`.

- You can enable DHCP snooping on private VLANs. When you enable DHCP snooping on the primary VLAN, it is propagated to the secondary VLANs. If you configure DHCP on a secondary VLAN, the configuration does not take effect if the primary VLAN is already configured.

- When you enable IP source guard on private-VLAN ports, you must enable DHCP snooping on the primary VLAN.

- We recommend that you prune the private VLANs from the trunks on devices that carry no traffic in the private VLANs.

- You can apply different quality of service (QoS) configurations to primary, isolated, and community VLANs.

- Note the following considerations for sticky ARP:
  - Sticky ARP entries are those learned on SVIs and Layer 3 interfaces. These entries do not age out.
• The **ip sticky-arp** global configuration command is supported only on SVIs belonging to private VLANs.

• The **ip sticky-arp** interface configuration command is only supported on:
  
  • Layer 3 interfaces
  
  • SVIs belonging to normal VLANs
  
  • SVIs belonging to private VLANs

For more information about using the **ip sticky-arp global** configuration and the **ip sticky-arp interface** configuration commands, see the command reference for this release.

• You can configure VLAN maps on primary and secondary VLANs. However, we recommend that you configure the same VLAN maps on private-VLAN primary and secondary VLANs.

• PVLANs are bidirectional. They can be applied at both the ingress and egress sides.

When a frame in Layer-2 is forwarded within a private VLAN, the VLAN map is applied at the ingress side and at the egress side. When a frame is routed from inside a private VLAN to an external port, the private-VLAN map is applied at the ingress side. Similarly, when the frame is routed from an external port to a Private VLAN, the private-VLAN is applied at the egress side.

**Bridging**

• For upstream traffic from secondary VLAN to primary VLAN, the MAP of the secondary VLAN is applied on the ingress side and the MAP of the primary VLAN is applied on the egress side.

• For downstream traffic from primary VLAN to secondary VLAN, the MAP of the primary VLAN is applied in the ingress direction and the MAP of the secondary VLAN is applied in the egress direction.

**Routing**

If we have two private VLAN domains - PV1 (sec1, prim1) and PV2 (sec2, prim2). For frames routed from PV1 to PV2:

- The MAP of sec1 and L3 ACL of prim1 is applied in the ingress port.
- The MAP of sec1 and L3 ACL of prim2 is applied in the egress port.
- For packets going upstream or downstream from isolated host port to promiscuous port, the isolated VLAN’s VACL is applied in the ingress direction and primary VLAN’S VACL is applied in the egress direction. This allows user to configure different VACL for different secondary VLAN in a same primary VLAN domain.

To filter out specific IP traffic for a private VLAN, you should apply the VLAN map to both the primary and secondary VLANs.

• You can apply router ACLs only on the primary-VLAN SVIs. The ACL is applied to both primary and secondary VLAN Layer 3 traffic.

• Although private VLANs provide host isolation at Layer 2, hosts can communicate with each other at Layer 3.

• Private VLANs support these Switched Port Analyzer (SPAN) features:
Private VLAN Port Configuration

Follow these guidelines when configuring private VLAN ports:

• Use only the private VLAN configuration commands to assign ports to primary, isolated, or community VLANs. Layer 2 access ports assigned to the VLANs that you configure as primary, isolated, or community VLANs are inactive while the VLAN is part of the private VLAN configuration. Layer 2 trunk interfaces remain in the STP forwarding state.

• Do not configure ports that belong to a PAgP or LACP EtherChannel as private VLAN ports. While a port is part of the private VLAN configuration, any EtherChannel configuration for it is inactive.

• Enable Port Fast and BPDU guard on isolated and community host ports to prevent STP loops due to misconfigurations and to speed up STP convergence. When enabled, STP applies the BPDU guard feature to all Port Fast-configured Layer 2 LAN ports. Do not enable Port Fast and BPDU guard on promiscuous ports.

• If you delete a VLAN used in the private VLAN configuration, the private VLAN ports associated with the VLAN become inactive.

• Private VLAN ports can be on different network devices if the devices are trunk-connected and the primary and secondary VLANs have not been removed from the trunk.

How to Configure Private VLANs

Configuring Private VLANs

To configure a private VLAN, perform these steps:

1. Set VTP mode to **transparent**.
2. Create the primary and secondary VLANs and associate them.
3. Configure interfaces to be isolated or community host ports, and assign VLAN membership to the host port.
4. Configure interfaces as promiscuous ports, and map the promiscuous ports to the primary-secondary VLAN pair.
5. If inter-VLAN routing will be used, configure the primary SVI, and map secondary VLANs to the primary.
6. Verify private-VLAN configuration.
DETAILED STEPS

Step 1  Set VTP mode to transparent.

Note  Note: For VTP3, you can set mode to either server or transparent mode.

Step 2  Create the primary and secondary VLANs and associate them.

See the Configuring and Associating VLANs in a Private VLAN, on page 2478

Note  If the VLAN is not created already, the private-VLAN configuration process creates it.

Step 3  Configure interfaces to be isolated or community host ports, and assign VLAN membership to the host port.

See the Configuring a Layer 2 Interface as a Private VLAN Host Port, on page 2482

Step 4  Configure interfaces as promiscuous ports, and map the promiscuous ports to the primary-secondary VLAN pair.

See the Configuring a Layer 2 Interface as a Private VLAN Promiscuous Port, on page 2483

Step 5  If inter-VLAN routing will be used, configure the primary SVI, and map secondary VLANs to the primary.

See the Mapping Secondary VLANs to a Primary VLAN Layer 3 VLAN Interface, on page 2485

Step 6  Verify private-VLAN configuration.

Configuring and Associating VLANs in a Private VLAN

The private-vlan commands do not take effect until you exit VLAN configuration mode.

To configure and associate VLANs in a Private VLAN, perform these steps:

SUMMARY STEPS

1.  enable
2.  configure terminal
3.  vtp mode transparent
4.  vlan vlan-id
5.  private-vlan primary
6.  exit
7.  vlan vlan-id
8.  private-vlan isolated
9.  exit
10.  vlan vlan-id
11.  private-vlan community
12.  exit
13.  vlan vlan-id
14.  private-vlan community
15.  exit
16.  vlan vlan-id
17.  private-vlan association [add | remove] secondary_vlan_list

</tbody>
</table>
| **Step 16** | **vlan vlan-id**  
**Example:**  
Device(config)# vlan 20  |
| Enters VLAN configuration mode for the primary VLAN designated in Step 4. |
| **Step 17** | **private-vlan association [add | remove]**  
**secondary_vlan_list**  
**Example:**  
Device(config-vlan)# private-vlan association 501-503  |
| Associates the secondary VLANs with the primary VLAN. It can be a single private-VLAN ID or a hyphenated range of private-VLAN IDs.  
- The *secondary_vlan_list* parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single private-VLAN ID or a hyphenated range of private-VLAN IDs.  
- The *secondary_vlan_list* parameter can contain multiple community VLAN IDs but only one isolated VLAN ID.  
- Enter a *secondary_vlan_list*, or use the **add** keyword with a *secondary_vlan_list* to associate secondary VLANs with a primary VLAN.  
- Use the **remove** keyword with a *secondary_vlan_list* to clear the association between secondary VLANs and a primary VLAN.  
- The command does not take effect until you exit VLAN configuration mode. |
| **Step 18** | **end**  
**Example:**  
Device(config)# end  |
| Returns to privileged EXEC mode. |
| **Step 19** | **show vlan private-vlan [type] or show interfaces status**  
**Example:**  
Device# show vlan private-vlan  |
| Verifies the configuration. |
| **Step 20** | **copy running-config startup config**  
**Example:**  
Device# copy running-config startup-config  |
| Saves your entries in the device startup configuration file. |
Configuring a Layer 2 Interface as a Private VLAN Host Port

Follow these steps to configure a Layer 2 interface as a private-VLAN host port and to associate it with primary and secondary VLANs:

---

**Note**

Isolated and community VLANs are both secondary VLANs.

---

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface interface-id`
4. `switchport mode private-vlan host`
5. `switchport private-vlan host-association primary_vlan_id secondary_vlan_id`
6. `end`
7. `show interfaces [interface-id] switchport`
8. `copy running-config startup-config`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** `configure terminal` | Enters the global configuration mode. |
| **Example:** Device# configure terminal |

| **Step 3** `interface interface-id` | Enters interface configuration mode for the Layer 2 interface to be configured. |
| **Example:** Device(config)# interface gigabitethernet1/0/22 |

| **Step 4** `switchport mode private-vlan host` | Configures the Layer 2 port as a private-VLAN host port. |
| **Example:** Device(config-if)# switchport mode private-vlan host |
### Purpose

**Step 5**

```
switchport private-vlan host-association primary_vlan_id secondary_vlan_id
```

**Example:**

```
Device(config-if)# switchport private-vlan host-association 20 501
```

**Purpose:**

Associates the Layer 2 port with a private VLAN.

**Note:** This is a required step to associate the P VLAN to a Layer 2 interface.

---

**Step 6**

```
end
```

**Example:**

```
Device(config)# end
```

**Purpose:**

Returns to privileged EXEC mode.

---

**Step 7**

```
show interfaces [interface-id] switchport
```

**Example:**

```
Device# show interfaces gigabitethernet1/0/22 switchport
```

**Purpose:**

Verifies the configuration.

---

**Step 8**

```
copy running-config startup-config
```

**Example:**

```
Device# copy running-config startup-config
```

**Purpose:**

(Optional) Saves your entries in the configuration file.

**Mapping Secondary VLANs to a Primary VLAN Layer 3 VLAN Interface**

If the private VLAN will be used for inter-VLAN routing, you configure an SVI for the primary VLAN and map secondary VLANs to the SVI.

---

**Note**
Isolated and community VLANs are both secondary VLANs.

Follow these steps to map secondary VLANs to the SVI of a primary VLAN to allow Layer 3 switching of private VLAN traffic:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface vlan primary_vlan_id`
4. `private-vlan mapping [add | remove] secondary_vlan_list`
5. `end`
6. `show interface private-vlan mapping`
7. `copy running-config startup config`

Configuration Examples for Private VLANs

Example: Configuring and Associating VLANs in a Private VLAN

This example shows how to configure VLAN 20 as a primary VLAN, VLAN 501 as an isolated VLAN, and VLANs 502 and 503 as community VLANs, to associate them in a private VLAN, and to verify the configuration:
Example: Configuring an Interface as a Host Port

This example shows how to configure an interface as a private VLAN host port, associate it with a private VLAN pair, and verify the configuration:

Device# configure terminal
Device(config)# interface gigabitethernet1/0/22
Device(config-if)# switchport mode private-vlan host
Device(config-if)# switchport private-vlan host-association 20 501
Device(config-if)# end

Device# show interfaces gigabitethernet1/0/22 switchport
Name: Gi1/0/22
Switchport: Enabled
Administrative Mode: private-vlan host
Operational Mode: private-vlan host
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: native
Negotiation of Trunking: Off
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: enabled
Voice VLAN: none
Administrative private-vlan host-association: 20 501
Administrative private-vlan mapping: none
Administrative private-vlan trunk native VLAN: none
Administrative private-vlan trunk Native VLAN tagging: enabled
Administrative private-vlan trunk encapsulation: dot1q
Administrative private-vlan trunk normal VLANs: none
Administrative private-vlan trunk private VLANs: none
Operational private-vlan:
20 501

<output truncated>
Example: Configuring an Interface as a Private VLAN Promiscuous Port

This example shows how to configure an interface as a private VLAN promiscuous port and map it to a private VLAN. The interface is a member of primary VLAN 20 and secondary VLANs 501 to 503 are mapped to it.

```
Device# configure terminal
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# switchport mode private-vlan promiscous
Device(config-if)# switchport private-vlan mapping 20 add 501-503
Device(config-if)# end
```

Use the `show vlan private-vlan` or the `show interface status` privileged EXEC command to display primary and secondary VLANs and private-VLAN ports on the Device.

Example: Mapping Secondary VLANs to a Primary VLAN Interface

This example shows how to map the interfaces for VLANs 501 and 502 to primary VLAN 10, which permits routing of secondary VLAN ingress traffic from private VLANs 501 and 502:

```
Device# configure terminal
Device(config)# interface vlan 20
Device(config-if)# private-vlan mapping 501-503
Device(config-if)# end
Device# show interfaces private-vlan mapping
Interface Secondary VLAN Type
---------- ------------------ -----------------
vl20 501 isolated
vl20 502 community
vl20 503 community
```

- Secondary VLANs, on page 2469
- Mapping Secondary VLANs to a Primary VLAN Layer 3 VLAN Interface, on page 2485

Example: Monitoring Private VLANs

This example shows output from the `show vlan private-vlan` command:

```
Device# show vlan private-vlan
```
Where to Go Next

You can configure the following:

- VTP
- VLANs
- VLAN trunking
- Voice VLANs

Configuring DHCP for WLANs

• Finding Feature Information, on page 2495
• Prerequisites for Configuring DHCP for WLANs, on page 2495
• Restrictions for Configuring DHCP for WLANs, on page 2497
• Information About the Dynamic Host Configuration Protocol, on page 2497
• How to Configure DHCP for WLANs, on page 2500
• Additional References, on page 2503
• Feature Information for DHCP for WLANs, on page 2504

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring DHCP for WLANs

• To be able to use the DHCP option 82, you must configure DHCP on Cisco IOS software. By default, DHCP option 82 is enabled for all clients. You can control the wireless client behavior using the WLAN suboptions.

• The Cisco converged access platforms support internal DHCP server functionality. However, as a general deployment guideline to build large enterprise-class networks, we recommend that you use external DHCP server to provide dynamic IP addressing to wireless clients. Such distributed function reduces processing and configuration load on network devices and allows them to operate efficiently in large scale deployments.

• DHCP Snooping Configuration—DHCP snooping configuration is the required best practices configuration on for rapid client join function. DHCP snooping needs to be enabled on each client VLAN including the override VLAN if override is applied on the WLAN.

Example of DHCP snooping configuration
1. Global DHCP snooping configuration:

1. Device(config)#ip dhcp snooping
   Device(config)#ip dhcp snooping vlan 100

2. Enable bootp-broadcast command. This is required for clients that send DHCP messages with broadcast addresses and broadcast bit is set in the DHCP message:
   Device(config)#ip dhcp snooping wireless bootp-broadcast enable

3. To not append DHCP Option information, enter this command:
   Device(config)#no ip dhcp snooping information option

2. On the interface:

   **Note**  
   IP DHCP snooping trust is required on Port-Channel interface in addition to member link of the Port-Channel interface.

   Device(config)#interface range TenGigabitEthernet 1/0/1 – 2
   Device(config-if)#switchport mode trunk
   Device(config-if)#switchport trunk allowed vlan 100
   Device(config-if)#ip dhcp snooping trust

   Device(config)#interface port-channel 1
   Device(config-if)#switchport mode trunk
   Device(config-if)#switchport trunk allowed vlan 100
   Device(config-if)#ip dhcp snooping trust

   **Note**  
   DHCP snooping must be configured on the Guest Anchor for guest access similar to the Config above.

Restrictions for Configuring DHCP for WLANs

• If you override the DHCP server in a WLAN, you must ensure that you configure the underlying Cisco IOS configuration to make sure that the DHCP server is reachable.

• WLAN DHCP override works only if DHCP service is enabled on the device.

You can configure DHCP service in the following ways:

• Configuring the DHCP pool on the device.

• Configuring a DHCP relay agent on the SVI. Note: the VLAN of the SVI must be mapped to the WLAN where DHCP override is configured.

Information About the Dynamic Host Configuration Protocol

You can configure WLANs to use the same or different Dynamic Host Configuration Protocol (DHCP) servers or no DHCP server. Two types of DHCP servers are available: internal and external.

Related Topics

Configuring DHCP for WLANs (CLI), on page 2500
Prerequisites for Configuring DHCP for WLANs, on page 2495
Restrictions for Configuring DHCP for WLANs, on page 2497

Internal DHCP Servers

The devices contain an internal DHCP server. This server is typically used in branch offices that do not already have a DHCP server. The wireless network generally contains a maximum of 10 access points or fewer, with the access points on the same IP subnet as the device. The internal server provides DHCP addresses to wireless clients, direct-connect access points, and DHCP requests that are relayed from access points. Only lightweight access points are supported. When you want to use the internal DHCP server, you must set the management interface IP address of the device as the DHCP server IP address.

DHCP option 43 is not supported on the internal server. Therefore, the access point must use an alternative method to locate the management interface IP address of the device, such as local subnet broadcast, Domain Name System (DNS), or priming.

An internal DHCP server pool only serves the wireless clients of that device, not clients of other devices. Also, an internal DHCP server can serve only wireless clients, not wired clients.
When clients use the internal DHCP server of the device, IP addresses are not preserved across reboots. As a result, multiple clients can be assigned with the same IP address. To resolve any IP address conflicts, clients must release their existing IP address and request a new one. Wired guest clients are always on a Layer 2 network connected to a local or foreign device.

Note

DHCPv6 is not supported in the internal DHCP servers.

- Prerequisites for Configuring DHCP for WLANs, on page 2495
- Restrictions for Configuring DHCP for WLANs, on page 2497

External DHCP Servers

The operating system is designed to appear as a DHCP Relay to the network and as a DHCP server to clients with industry-standard external DHCP servers that support DHCP Relay, which means that each device appears as a DHCP Relay agent to the DHCP server and as a DHCP server at the virtual IP address to wireless clients. Because the device captures the client IP address that is obtained from a DHCP server, it maintains the same IP address for that client during intra device, inter device, and inter-subnet client roaming.

Note

External DHCP servers can support DHCPv6.

Related Topics

- Configuring DHCP for WLANs (CLI), on page 2500
- Prerequisites for Configuring DHCP for WLANs, on page 2495
- Restrictions for Configuring DHCP for WLANs, on page 2497

DHCP Assignments

You can configure DHCP on a per-interface or per-WLAN basis. We recommend that you use the primary DHCP server address that is assigned to a particular interface.

You can assign DHCP servers for individual interfaces. You can configure the management interface, AP-manager interface, and dynamic interface for a primary and secondary DHCP server, and you can configure the service-port interface to enable or disable DHCP servers. You can also define a DHCP server on a WLAN. In this case, the server overrides the DHCP server address on the interface assigned to the WLAN.

Security Considerations

For enhanced security, we recommend that you require all clients to obtain their IP addresses from a DHCP server. To enforce this requirement, you can configure all WLANs with a DHCP Addr. Assignment Required setting, which disallows client static IP addresses. If DHCP Addr. Assignment Required is selected, clients must obtain an IP address via DHCP. Any client with a static IP address is not allowed on the network. The device monitors DHCP traffic because it acts as a DHCP proxy for the clients.
WLANs that support management over wireless must allow management (device-servicing) clients to obtain an IP address from a DHCP server.

If slightly less security is tolerable, you can create WLANs with DHCP Addr. Assignment Required disabled. Clients then have the option of using a static IP address or obtaining an IP address from a designated DHCP server.

DHCP Addr. Assignment Required is not supported for wired guest LANs.

You can create separate WLANs with DHCP Addr. Assignment Required configured as disabled. This is applicable only if DHCP proxy is enabled for the device. You must not define the primary/secondary configuration DHCP server you should disable the DHCP proxy. These WLANs drop all DHCP requests and force clients to use a static IP address. These WLANs do not support management over wireless connections.

**Related Topics**
- Configuring DHCP for WLANs (CLI), on page 2500
- Prerequisites for Configuring DHCP for WLANs, on page 2495
- Restrictions for Configuring DHCP for WLANs, on page 2497

**Information About DHCP Option 82**

DHCP option 82 provides additional security when DHCP is used to allocate network addresses. It enables the device to act as a DHCP relay agent to prevent DHCP client requests from untrusted sources. You can configure the device to add option 82 information to DHCP requests from clients before forwarding the requests to the DHCP server.

*Figure 127: DHCP Option 82*

The access point forwards all DHCP requests from a client to the device. The device adds the DHCP option 82 payload and forwards the request to the DHCP server. The payload can contain the MAC address or the MAC address and SSID of the access point, depending on how you configure this option.

Any DHCP packets that already include a relay agent option are dropped at the device.
For DHCP option 82 to operate correctly, DHCP proxy must be enabled.

- Restrictions for Configuring DHCP for WLANs, on page 2497

Information About DHCP Scopes

Devices have built-in DHCP relay agents. However, when you desire network segments that do not have a separate DHCP server, the devices can have built-in DHCP scopes that assign IP addresses and subnet masks to wireless clients. Typically, one device can have one or more DHCP scopes that each provide a range of IP addresses.

DHCP scopes are needed for internal DHCP to work. Once DHCP is defined on the device, you can then point the primary DHCP server IP address on the management, AP-manager, and dynamic interfaces to the device’s management interface.

How to Configure DHCP for WLANs

Configuring DHCP for WLANs (CLI)

Use this procedure to configure the following DHCP parameters on a WLAN:

- DHCP Option 82 Payload
- DHCP Required
- DHCP Override

Before you begin

- You must have admin privileges for configuring the WLAN.
- To configure the DHCP override, you must have the IP address of the DHCP server.
### SUMMARY STEPS

1. `configure terminal`
2. `shutdown`
3. `wlan profile-name`
4. `ip dhcp opt82 {ascii | format {add-ssid | ap-ethmac} | rid}`
5. `ip dhcp required`
6. `ip dhcp server ip-address`
7. `no shutdown`
8. `end`
9. `show wlan wlan-name`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>shutdown</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device(config)# <code>shutdown</code></td>
<td>Shut down the WLAN.</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>wlan profile-name</code>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Device# <code>wlan test4</code></td>
<td>Enters the WLAN configuration submode. The <code>profile-name</code> is the profile name of the configured WLAN.</td>
</tr>
</tbody>
</table>
| Step 4 | `ip dhcp opt82 {ascii | format {add-ssid | ap-ethmac} | rid}`<br>**Example:**<br>Device(config)# `ip dhcp opt82 format add-ssid` | Specifies the DHCP82 payload on the WLAN. The keyword and arguments are as follows:  
  • `ascii`—Configures ASCII for DHCP Option 82. If this is not configured, the option 82 format is set to ASCII format.  
  • `format`—Specifies the DHCP option 82 format. The following options are available:  
    • `add-ssid`—Set RemoteID format that is the AP radio MAC address and SSID.  
    • `ap-ethmac`—Set RemoteID format that is the AP Ethernet MAC address.  
  
  **Note** If the format option is not configured, only the AP radio MAC address is used.  
  • `rid`—Adds the Cisco 2 byte RID for DHCP option 82. |
## Configuring DHCP Scopes (CLI)

### SUMMARY STEPS

1. configure terminal
2. ip dhcp pool pool-name
3. network network-name mask-address
4. dns-server hostname
5. end

### Command or Action | Purpose
--- | ---
Step 5 ip dhcp required | Makes it mandatory for clients to get their IP address from the DHCP server. Static clients are not allowed.

**Example:**
```
Device(config-wlan)# ip dhcp required
```

Step 6 ip dhcp server ip-address | Defines a DHCP server on the WLAN that overrides the DHCP server address on the interface assigned to the WLAN.

**Example:**
```
Device(config-wlan)# ip dhcp server 200.1.1.2
```

Step 7 no shutdown | Restarts the WLAN.

**Example:**
```
Device(config-wlan)# no shutdown
```

Step 8 end | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

**Example:**
```
Device(config)# end
```

Step 9 show wlan wlan-name | Verifies the DHCP configuration.

**Example:**
```
Device(config-wlan)# show wlan test-wlan
```

CHAPTER 131

Configuring WLAN Security

- Finding Feature Information, on page 2505
- Prerequisites for Layer 2 Security, on page 2505
- Information About AAA Override, on page 2506
- How to Configure WLAN Security, on page 2506
- Additional References, on page 2511
- Feature Information about WLAN Layer 2 Security, on page 2512

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Layer 2 Security

WLANs with the same SSID must have unique Layer 2 security policies so that clients can make a WLAN selection based on information advertised in beacon and probe responses. The available Layer 2 security policies are as follows:

- None (open WLAN)
- Static WEP or 802.1X

Note

Because static WEP and 802.1X are both advertised by the same bit in beacon and probe responses, they cannot be differentiated by clients. Therefore, they cannot both be used by multiple WLANs with the same SSID.

- WPA/WPA2
Although WPA and WPA2 cannot be used by multiple WLANs with the same SSID, you can configure two WLANs with the same SSID with WPA/TKIP with PSK and Wi-Fi Protected Access (WPA) Temporal Key Integrity Protocol (TKIP) with 802.1X, or with WPA/TKIP with 802.1X or WPA/AES with 802.1X.

A WLAN that is configured with TKIP support will not be enabled on an RM3000AC module.

Related Topics
- Configuring Static WEP + 802.1X Layer 2 Security Parameters (CLI), on page 2506
- Configuring Static WEP Layer 2 Security Parameters (CLI), on page 2507

- Configuring 802.1X Layer 2 Security Parameters (CLI), on page 2510
- Configuring Advanced WLAN Properties (CLI)
- Information About AAA Override, on page 2506

Information About AAA Override

The AAA Override option of a WLAN enables you to configure the WLAN for identity networking. It enables you to apply VLAN tagging, Quality of Service (QoS), and Access Control Lists (ACLs) to individual clients based on the returned RADIUS attributes from the AAA server.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Setting Client Count for WLANs

- When a WLAN has reached the limit on the maximum number of clients connected to it or an AP radio and a new client tries to join the WLAN, the client cannot connect to the WLAN until an existing client gets disconnected.

- Roaming clients are considered as new clients. The new client can connect to a WLAN, which has reached the maximum limit on the number of connected clients, only when an existing client gets disconnected.

Note

For more information about the number of clients that are supported, see the product data sheet of your device.

Related Topics

Configuring Client Count per WLAN (CLI), on page 2514
Information About Setting the Client Count per WLAN

You can set a limit to the number of clients that can connect to a WLAN, which is useful in scenarios where you have a limited number of clients that can connect to a device. For example, consider a scenario where the device can serve up to 256 clients on a WLAN and these clients can be shared between enterprise users (employees) and guest users. You can set a limit on the number of guest clients that can access a given WLAN. The number of clients that you can configure for each WLAN depends on the platform that you are using.

Prerequisites for 802.11w

• To configure 802.11w feature for optional and mandatory, you must have WPA and AKM configured.
  
  **Note**  The RNS (Robust Secure Network) IE must be enabled with an AES Cipher.
  
  • To configure 802.11w as mandatory, you must enable PMF AKM in addition to WPA AKM.

Related Topics

- Configuring 802.11w (CLI), on page 2521
- Disabling 802.11w (CLI), on page 2522
Restrictions for 802.11w

- 802.11w cannot be applied on an open WLAN, WEP-encrypted WLAN, or a TKIP-encrypted WLAN.
- The WLAN on which 802.11w is configured must have either WPA2-PSK or WPA2-802.1x security configured.

Related Topics
- Configuring 802.11w (CLI), on page 2521
- Disabling 802.11w (CLI), on page 2522
- Information About 802.11w, on page 2520

Information About 802.11w

Wi-Fi is a broadcast medium that enables any device to eavesdrop and participate either as a legitimate or rogue device. Control and management frames such as authentication/deauthentication, association/dissociation, beacons, and probes are used by wireless clients to select an AP and to initiate a session for network services.

Unlike data traffic which can be encrypted to provide a level of confidentiality, these frames must be heard and understood by all clients and therefore must be transmitted as open or unencrypted. While these frames cannot be encrypted, they must be protected from forgery to protect the wireless medium from attacks. For example, an attacker could spoof management frames from an AP to tear down a session between a client and AP.

The 802.11w protocol applies only to a set of robust management frames that are protected by the Management Frame Protection (PMF) service. These include Disassociation, Deauthentication, and Robust Action frames. Management frames that are considered as robust action and therefore protected are the following:

- Spectrum Management
- QoS
- Block Ack
- SA Query
- Vendor-specific Protected

When 802.11w is implemented in the wireless medium, the following occur:

- Client protection is added by the AP adding cryptographic protection (by including the MIC information element) to deauthentication and disassociation frames preventing them from being spoofed in a DOS attack.
- Infrastructure protection is added by adding a Security Association (SA) teardown protection mechanism consisting of an Association Comeback Time and an SA-Query procedure preventing spoofed association request from disconnecting an already connected client.

<tr>
<th>Command</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>no security pmf [association-comeback association-check-comeback-interval-seconds</td>
<td>mandatory</td>
</tr>
<tr>
<td></td>
<td>optional</td>
</tr>
</tbody>
</table>

Example:

```
Device(config-wlan)# no security pmf
```

Disables PMF on the WLAN. The following attributes are available:

- **association-comeback** — Disables the 802.11w association comeback time.
- **mandatory** — Disables clients to negotiate 802.11w PMF protection on a WLAN.
- **optional** — Disables 802.11w PMF protection on a WLAN.
- **saquery** — Time interval identified in the association response to an already associated client before the association can be tried again. This time interval checks if the client is a real client and not a rogue client during the association comeback time. If the client does not respond within this time, the client association is deleted from the device.

The range is from 100 to 500 ms. The value must be specified in multiples of 100 milliseconds.

**Step 5**

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>no shutdown</td>
<td>Device no shutdown</td>
</tr>
</tbody>
</table>

Example:

```
Device(config-wlan)# no shutdown
```

**Step 6**

<table>
<thead>
<tr>
<th>Command</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Device(config-wlan)# end</td>
</tr>
</tbody>
</table>

Example:

```
Device(config-wlan)# end
```

Returns to privileged EXEC mode. Alternatively, you can also press `Ctrl-z` to exit global configuration mode.

CHAPTER 134

Configuring Wi-Fi Direct Client Policy

• Finding Feature Information, on page 2527
• Restrictions for the Wi-Fi Direct Client Policy, on page 2527
• Information About the Wi-Fi Direct Client Policy, on page 2527
• How to Configure Wi-Fi Direct Client Policy, on page 2528
• Additional References for Wi-Fi Direct Client Policy, on page 2530
• Feature Information about Wi-Fi Direct Client Policy, on page 2531

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for the Wi-Fi Direct Client Policy

• Wi-Fi Direct Client Policy is applicable to WLANs that have APs in local mode only.

• If WLAN applied client policy is invalid, the client is excluded with the exclusion reason being 'Client QoS Policy failure'.

Information About the Wi-Fi Direct Client Policy

Devices that are Wi-Fi Direct capable can connect directly to each other quickly and conveniently to do tasks such as printing, synchronization, and sharing of data. Wi-Fi Direct devices may associate with multiple peer-to-peer (P2P) devices and with infrastructure wireless LANs (WLANs) concurrently. You can use the device to configure the Wi-Fi Direct Client Policy, on a per WLAN basis, where you can allow or disallow association of Wi-Fi devices with infrastructure WLANs, or disable Wi-Fi Direct Client Policy altogether for WLANs.
**How to Configure Wi-Fi Direct Client Policy**

### Configuring the Wi-Fi Direct Client Policy (CLI)

**SUMMARY STEPS**

1. `configure terminal`  
2. `wlan profile-name`  
3. `wifidirect policy {permit | deny}`  
4. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code>&lt;br&gt;<code>Example:&lt;br&gt;Device# configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>wlan profile-name</code>&lt;br&gt;<code>Example:&lt;br&gt;Device# wlan test4</code></td>
<td>Enters the WLAN configuration submode. The <code>profile-name</code> is the profile name of the configured WLAN.</td>
</tr>
</tbody>
</table>
| Step 3 | `wifidirect policy {permit | deny}`<br>`Example:<br>Device(config-wlan)# wifidirect policy permit` | Configures the Wi-Fi Direct client policy on the WLAN using one of the following:  
- **permit**—Enables Wi-Fi Direct clients to associate with the WLAN.  
- **deny**—When the Wi-Fi Direct policy is configured as "deny," the device permits or denies Wi-Fi Direct devices based on the device capabilities. A Wi-Fi Direct device reports these capabilities in its association request to the device and these are based on the Wi-Fi capabilities of the device. These include:  
  - Concurrent operation  
  - Cross connection |
Disabling Wi-Fi Direct Client Policy (CLI)

SUMMARY STEPS

1. configure terminal
2. wlan profile-name
3. no wifidirect policy
4. end

- Information About 802.11r Fast Transition, on page 2534
- How to Configure 802.11r Fast Transition, on page 2536
- Additional References for 802.11r Fast Transition, on page 2543
- Feature Information for 802.11r Fast Transition, on page 2544

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for 802.11r Fast Transition

- 802.11r client association is not supported on access points in standalone mode.
- 802.11r fast roaming is not supported on access points in standalone mode.
- 802.11r fast roaming between local authentication and central authentication WLAN is not supported.
- For APs in FlexConnect mode, 802.11r fast roaming works only if the APs are in the same FlexConnect group.
- EAP LEAP method is not supported.
- TSpec is not supported for 802.11r fast roaming. Therefore, RIC IE handling is not supported.
- If WAN link latency exists, fast roaming is also delayed. Voice or data maximum latency should be verified. The device handles 802.11r Fast Transition authentication request during roaming for both Over-the-Air and Over-the-DS methods.
• This feature is supported only on open and WPA2 configured WLANs.

• Legacy clients cannot associate with a WLAN that has 802.11r enabled if the driver of the supplicant that is responsible for parsing the Robust Security Network Information Exchange (RSN IE) is old and not aware of the additional AKM suites in the IE. Due to this limitation, clients cannot send association requests to WLANs. These clients, however, can still associate with non-802.11r WLANs. Clients that are 802.11r capable can associate as 802.11i clients on WLANs that have both 802.11i and 802.11r Authentication Key Management Suites enabled.

The workaround is to enable or upgrade the driver of the legacy clients to work with the new 802.11r AKMs, after which the legacy clients can successfully associate with 802.11r enabled WLANs.

Another workaround is to have two SSIDs with the same name but with different security settings (FT and non-FT).

• Fast Transition resource request protocol is not supported because clients do not support this protocol. Also, the resource request protocol is an optional protocol.

• To avoid any Denial of Service (DoS) attack, each device allows a maximum of three Fast Transition handshakes with different APs.

  Information About 802.11r Fast Transition, on page 2534

Information About 802.11r Fast Transition

802.11r, which is the IEEE standard for fast roaming, introduces a new concept of roaming where the initial handshake with the new AP is done even before the client roams to the target AP, which is called Fast Transition (FT). The initial handshake allows the client and APs to do the Pairwise Transient Key (PTK) calculation in advance. These PTK keys are applied to the client and AP after the client does the reassociation request or response exchange with new target AP.

802.11r provides two methods of roaming:

  • Over-the-Air
  • Over-the-DS (Distribution System)

The FT key hierarchy is designed to allow clients to make fast BSS transitions between APs without requiring reauthentication at every AP. WLAN configuration contains a new Authenticated Key Management (AKM) type called FT (Fast Transition).

From Release 3E, you can create an 802.11r WLAN that is also an WPAv2 WLAN. In earlier releases, you had to create separate WLANs for 802.11r and for normal security. Non-802.11r clients can now join 802.11r-enabled WLANs as the 802.11r WLANs can accept non-802.11r associations. If clients do not support mixed mode or 802.11r join, they can join non-802.11r WLANS. When you configure FT PSK and later define PSK, clients that can join only PSK can now join the WLAN in mixed mode.
How a Client Roams

For a client to move from its current AP to a target AP using the FT protocols, the message exchanges are performed using one of the following two methods:

- Over-the-Air—The client communicates directly with the target AP using IEEE 802.11 authentication with the FT authentication algorithm.
- Over-the-DS—The client communicates with the target AP through the current AP. The communication between the client and the target AP is carried in FT action frames between the client and the current AP and is then sent through the device.

**Figure 128: Message Exchanges when Over the Air client roaming is configured**

This figure shows the sequence of message exchanges that occur when Over the Air client roaming is configured.
How to Configure 802.11r Fast Transition

Configuring 802.11r Fast Transition in an Open WLAN (CLI)

SUMMARY STEPS

1. configure terminal
2. wlan profile-name
3. client vlan vlan-id
4. no security wpa
5. no security wpa akm dot1x
6. no security wpa wpa2
7. no wpa wpa2 ciphers aes
8. security ft
9. **no shutdown**  
10. **end**

**DETAILED STEPS**

### Monitoring 802.11r Fast Transition (CLI)

The following command can be used to monitor 802.11r Fast Transition:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show wlan name wlan-name</code></td>
<td>Displays a summary of the configured parameters on the WLAN.</td>
</tr>
</tbody>
</table>
### Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show wireless client mac-address mac-address</code></td>
<td>Displays the summary of the 802.11r authentication key management configuration on a client.</td>
</tr>
</tbody>
</table>

- Client Capabilities
  - CF Pollable: Not implemented
  - CF Poll Request: Not implemented
  - Short Preamble: Not implemented
  - PBCC: Not implemented
  - Channel Agility: Not implemented
  - Listen Interval: 15
  - Fast BSS Transition: Implemented

**Fast BSS Transition Details**

**Client Statistics:**
- Number of Bytes Received: 9019
- Number of Bytes Sent: 3765
- Number of Packets Received: 130
- Number of Packets Sent: 36
- Number of EAP Id Request Msg Timeouts: 0
- Number of EAP Request Msg Timeouts: 0
- Number of EAP Key Msg Timeouts: 0
- Number of Data Retries: 1
- Number of RTS Retries: 0
- Number of Duplicate Received Packets: 1
- Number of Decrypt Failed Packets: 0
- Number of Mic Failed Packets: 0
- Number of Mic Missing Packets: 0
- Number of Policy Errors: 0
- Radio Signal Strength Indicator: -48 dBm
- Signal to Noise Ratio: 40 dB

- If the AKM for the client is 802.11r mixed mode, the following information appears in the output:

  - Authentication Key Management: FT-PSK

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Assisted Roaming

- The assisted roaming feature is supported across multiple devices.
- This feature is supported only on 802.11n capable indoor access points. For a single band configuration, a maximum of 6 neighbors are visible in a neighbor list. For dual band configuration, a maximum of 12 neighbors are visible.
- You can configure assisted roaming only using the device CLI.

Related Topics

Information About Assisted Roaming

The 802.11k standard allows clients to request neighbor reports containing information about known neighbor access points that are candidates for a service set transition. The use of the 802.11k neighbor list can limit the need for active and passive scanning.

The assisted roaming feature is based on an intelligent and client optimized neighbor list. Unlike the Cisco Client Extension (CCX) neighbor list, the 802.11k neighbor list is generated dynamically on-demand and is not maintained on the device. The 802.11k neighbor list is based on the location of the clients without requiring the mobility services engine (MSE). Two clients on the same device but different APs can have different neighbor lists delivered depending on their individual relationship with the surrounding APs.

By default, the neighbor list contains only neighbors in the same band with which the client is associated. However, a switch exists that allows 802.11k to return neighbors in both bands.

Clients send requests for neighbor lists only after associating with the APs that advertise the RRM (Radio Resource Management) capability information element (IE) in the beacon. The neighbor list includes information about BSSID, channel, and operation details of the neighboring radios.

Assembling and Optimizing the Neighbor List

When the device receives a request for an 802.11k neighbor list, the following occurs:

1. The device searches the RRM neighbor table for a list of neighbors on the same band as the AP with which the client is currently associated with.

2. The device checks the neighbors according to the RSSI (Received Signal Strength Indication) between the APs, the current location of the present AP, the floor information of the neighboring AP from Cisco Prime Infrastructure, and roaming history information on the device to reduce the list of neighbors to six per band. The list is optimized for APs on the same floor.

Assisted Roaming for Non-802.11k Clients

It is also possible to optimize roaming for non-802.11k clients. You can generate a prediction neighbor list for each client without the client requiring to send an 802.11k neighbor list request. When this is enabled on a WLAN, after each successful client association/reassociation, the same neighbor list optimization is applied on the non-802.11k client to generate the neighbor list and store the list in the mobile station software data structure. Clients at different locations have different lists because the client probes are seen with different RSSI values by different neighbors. Because clients usually probe before any association or reassociation, this list is constructed with the most updated probe data and predicts the next AP that the client is likely to roam to.

We discourage clients from roaming to those less desirable neighbors by denying association if the association request to an AP does not match the entries on the stored prediction neighbor list.

Similar to aggressive load balancing, there is a switch to turn on the assisted roaming feature both on a per-WLAN basis and globally. The following options are available:

- Denial count—Maximum number of times a client is refused association.
- Prediction threshold—Minimum number of entries required in the prediction list for the assisted roaming feature to be activated.
Because both load balancing and assisted roaming are designed to influence the AP that a client associates with, it is not possible to enable both the options at the same time on a WLAN.

## How to Configure Assisted Roaming

### Configuring Assisted Roaming (CLI)

**SUMMARY STEPS**

1. configure terminal
2. wireless assisted-roaming floor-bias dBm
3. wlan wlan-id
4. assisted-roaming neighbor-list
5. assisted-roaming dual-list
6. assisted-roaming prediction
7. wireless assisted-roaming prediction-minimum count
8. wireless assisted-roaming denial-maximum count
9. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**         | Configures neighbor floor label bias. The valid range is from 5 to 25 dBm, and the default value is 15 dBm. |
| wireless assisted-roaming floor-bias dBm |         |
| Example:            |         |
| Device(config)# wireless assisted-roaming floor-bias 20 |         |

| **Step 3**         | Enters the WLAN configuration submode. The wlan-name is the profile name of the configured WLAN. |
| wlan wlan-id       |         |
| Example:            |         |
| Device(config)# wlan wlan1 |         |

| **Step 4**         | Configures an 802.11k neighbor list for a WLAN. By default, assisted roaming is enabled on the neighbor list when you create a WLAN. The no form of the command disables assisted roaming neighbor list. |
| assisted-roaming neighbor-list |         |
| Example:              |         |
| Device(wlan)# assisted-roaming neighbor-list |         |
### Monitoring Assisted Roaming

The following command can be used to monitor assisted roaming configured on a WLAN.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show wlan id wlan-id</td>
<td>Displays the WLAN parameters on the WLAN.</td>
</tr>
</tbody>
</table>

**Related Topics**

Configuration Examples for Assisted Roaming

This example shows how to configure the neighbor floor label bias:

Device# configure terminal
Device(config)# wireless assisted-roaming floor-bias 10
Device(config)# end
Device# show wlan id 23

This example shows how to disable neighbor list on a specific WLAN:

Device# configure terminal
Device(config)# wlan test1
Device(config (wlan)# no assisted-roaming neighbor-list
Device(config) (wlan)# end
Device# show wlan id 23

This example shows how to configure the prediction list on a specific WLAN:

Device# configure terminal
Device(config)# wlan test1
Device(config) (wlan)# assisted-roaming prediction
Device(config) (wlan)# end
Device# show wlan id 23

This example shows how to configure the prediction list based on assisted roaming prediction threshold and maximum denial count on a specific WLAN:

Device# configure terminal
Device(config)# wireless assisted-roaming prediction-minimum 4
Device(config)# wireless assisted-roaming denial-maximum 4
Device(config) (wlan)# end
Device# show wlan id 23

• How to Configure Access Point Groups, on page 2553
• Additional References, on page 2555
• Feature History and Information for Access Point Groups, on page 2556

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the Feature Information Table at the end of this document.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring AP Groups

The following are the prerequisites for creating access point groups on a device:

• The required access control list (ACL) must be defined on the router that serves the VLAN or subnet.
• Multicast traffic is supported with access point group VLANs. However, if the client roams from one access point to another, the client might stop receiving multicast traffic, unless IGMP snooping is enabled.

Related Topics

Information About Access Point Groups, on page 2552
Restrictions for Configuring Access Point Groups, on page 2552
Restrictions for Configuring Access Point Groups

- Suppose that the interface mapping for a WLAN in the AP group table is the same as the WLAN interface. If the WLAN interface is changed, the interface mapping for the WLAN in the AP group table also changes to the new WLAN interface.

Suppose that the interface mapping for a WLAN in the AP group table is different from the one defined for the WLAN. If the WLAN interface is changed, then the interface mapping for the WLAN in the AP group table does not change to the new WLAN interface.

- If you clear the configuration on the device, all of the access point groups disappear except for the default access point group “default-group,” which is created automatically.

- The default access point group can have up to 16 WLANs associated with it. The WLAN IDs for the default access point group must be less than or equal to 16. If a WLAN with an ID greater than 16 is created in the default access point group, the WLAN SSID will not be broadcasted. All WLAN IDs in the default access point group must have an ID that is less than or equal to 16. WLANs with IDs greater than 16 can be assigned to custom access point groups.

- We recommend that you configure all Flex+Bridge APs in a mesh tree (in the same sector) in the same AP group and the same FlexConnect group, to inherit the WLAN-VLAN mappings properly.

Information About Access Point Groups

After you create up to 512 WLANs on the device, you can selectively publish them (using access point groups) to different access points to better manage your wireless network. In a typical deployment, all users on a WLAN are mapped to a single interface on the device. Therefore, all users that are associated with that WLAN are on the same subnet or VLAN. However, you can choose to distribute the load among several interfaces or to a group of users based on specific criteria such as individual departments (such as Marketing) by creating access point groups. Additionally, these access point groups can be configured in separate VLANs to simplify network administration.

How to Configure Access Point Groups

Creating Access Point Groups

Before you begin
You must have administrator privileges to perform this operation.

SUMMARY STEPS

1. configure terminal
2. ap group ap-group-name
3. wlan wlan-name
4. (Optional) vlan vlan-name
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>ap group ap-group-name</td>
<td>Creates an access point group.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# ap group my-ap-group</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>wlan wlan-name</td>
<td>Associates the AP group to a WLAN.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-apgroup)# wlan wlan-name</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>(Optional) vlan vlan-name</td>
<td>Assigns the access point group to a VLAN.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config-apgroup)# vlan test-vlan</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>end</td>
<td>Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Device(config)# end</td>
<td></td>
</tr>
</tbody>
</table>

Example
This example shows how to create an AP group:
Assigning an Access Point to an AP Group

Before you begin
You must have administrator privileges to perform this operation.

SUMMARY STEPS

1. ap name ap-name ap-group-name ap-group

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ap name ap-name ap-group-name ap-group</td>
<td>Assigns the access point to the access point group. The keywords and arguments are as follows:</td>
</tr>
</tbody>
</table>

- **name**—Specifies that the argument following this keyword is the name of an AP that is associated to the device.
- **ap-name**—AP that you want to associate to the AP group.
- **ap-group-name**—Specifies that the argument following this keyword is the name of the AP group that is configured on the device.
- **ap-group**—Name of the access point group that is configured on the device.

Example:
Device# ap name 1240-101 ap-groupname apgroup_16
