Device B advertises SAs to Device A and Device C, but uses only Device A or Device C to accept SA messages. If Device A is first in the configuration file, it will be used if it is up and running. Only when Device A is not running will Device B accept SAs from Device C. This is the behavior without a prefix list.

If you specify a prefix list, the peer will be a default peer only for the prefixes in the list. You can have multiple active default peers when you have a prefix list associated with each. When you do not have any prefix lists, you can configure multiple default peers, but only the first one is the active default peer as long as the device has connectivity to this peer and the peer is alive. If the first configured peer goes down or the connectivity to this peer goes down, the second configured peer becomes the active default, and so on.

The following example shows a partial configuration of Device A and Device C in the figure. Each of these ISPs may have more than one customer using default peering, like the customer in the figure. In that case, they may have similar configurations. That is, they will only accept SAs from a default peer if the SA is permitted by the corresponding prefix list.

### Device A Configuration

```
ip msdp default-peer 10.1.1.1
ip msdp default-peer 10.1.1.1 prefix-list site-b ge 32
ip prefix-list site-b permit 10.0.0.0/8
```

### Device C Configuration

```
ip msdp default-peer 10.1.1.1 prefix-list site-b ge 32
ip prefix-list site-b permit 10.0.0.0/8
```

## Example: Configuring MSDP Mesh Groups

The following example shows how to configure three devices to be fully meshed members of an MSDP mesh group:

### Device A Configuration

```
ip msdp peer 10.2.2.2
ip msdp peer 10.3.3.3
ip msdp mesh-group test-mesh-group 10.2.2.2
ip msdp mesh-group test-mesh-group 10.3.3.3
```

### Device B Configuration

```
ip msdp peer 10.1.1.1
ip msdp peer 10.3.3.3
ip msdp mesh-group test-mesh-group 10.1.1.1
ip msdp mesh-group test-mesh-group 10.3.3.3
```

### Device C Configuration

```
ip msdp peer 10.1.1.1
ip msdp peer 10.2.2.2
ip msdp mesh-group test-mesh-group 10.1.1.1
ip msdp mesh-group test-mesh-group 10.2.2.2
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring Wireless Multicast

- The IP multicast routing must be enabled and the PIM version and PIM mode must be configured. The default routes should be available in the device. After performing these tasks, the device can then forward multicast packets and can populate its multicast routing table.
- To participate in IP multicasting, the multicast hosts, routers, and multilayer switches must have IGMP operating.
- When enabling multicast mode on the , a CAPWAP multicast group address should also be configured. Access points listen to the CAPWAP multicast group using IGMP.

## Restrictions for Configuring Wireless Multicast

The following are the restrictions for configuring IP multicast routing:

- Access points in monitor mode, sniffer mode, or rogue detector mode do not join the CAPWAP multicast group address.
- The CAPWAP multicast group configured on the should be different for different devices.
- Multicast routing should not be enabled for the management interface.

## Restrictions for IPv6 Snooping

The IPv6 snooping feature is not supported on Etherchannel ports.

## Restrictions for IPv6 RA Guard

- The IPv6 RA Guard feature does not offer protection in environments where IPv6 traffic is tunneled.
- This feature is supported only in hardware when the ternary content addressable memory (TCAM) is programmed.
- This feature can be configured on a switch port interface in the ingress direction.
- This feature supports host mode and router mode.
- This feature is supported only in the ingress direction; it is not supported in the egress direction.
- This feature is not supported on EtherChannel and EtherChannel port members.
- This feature is not supported on trunk ports with merge mode.
- This feature is supported on auxiliary VLANs and private VLANs (PVLANS). In the case of PVLANS, primary VLAN features are inherited and merged with port features.
- Packets dropped by the IPv6 RA Guard feature can be spanned.
- If the **platform ipv6 acl icmp optimize neighbor-discovery command** is configured, the IPv6 RA Guard feature cannot be configured and an error message will be displayed. This command adds default global Internet Control Message Protocol (ICMP) entries that will override the RA guard ICMP entries.

## Information About Wireless Multicast

If the network supports packet multicasting, the multicast method that the device uses can be configured. The device performs multicasting in two modes:

- Unicast mode—The device unicasts every multicast packet to every access point associated to the device. This mode is inefficient but might be required on networks that do not support multicasting.
- Multicast mode—The device sends multicast packets to a CAPWAP multicast group. This method reduces overhead on the device processor and shifts the work of packet replication to the network, which is much more efficient than the unicast method.

When the multicast mode is enabled and the device receives a multicast packet from the wired LAN, the device encapsulates the packet using CAPWAP and forwards the packet to the CAPWAP multicast group address. The device always uses the management VLAN for sending multicast packets. Access points in the

multicast group receive the packet and forward it to all the BSSIDs mapped to the VLAN on which clients receive multicast traffic.

The device supports all the capabilities of v1 including Multicast Listener Discovery (MLD) v1 snooping but the v2 and v3 capabilities are limited. This feature keeps track of and delivers IPv6 multicast flows to the clients that request them. To support IPv6 multicast, global multicast mode should be enabled.

Internet Group Management Protocol (IGMP) snooping is introduced to better direct multicast packets. When this feature is enabled, the device snooping gathers IGMP reports from the clients, processes them, creates unique multicast group IDs (MGIDs) based on the Layer 3 multicast address and the VLAN number, and sends the IGMP reports to the IGMP querier. The device then updates the access point MGID table on the access point with the client MAC address. When the device receives multicast traffic for a particular multicast group, it forwards it to all the access points, but only those access points that have active clients listening or subscribed to that multicast group send multicast traffic on that particular WLAN. IP packets are forwarded with an MGID that is unique for an ingress VLAN and the destination multicast group. Layer 2 multicast packets are forwarded with an MGID that is unique for the ingress VLAN.

MGID is a 14-bit value filled in the 16-bit reserved field of wireless information in CAPWAP header. The remaining 2 bits should be set to zero.

## Information About Multicast Optimization

Multicast used to be based on the group of the multicast addresses and the VLAN as one entity, MGID. With the VLAN group, duplicate packets might increase. Using the VLAN group feature, every client listens to the multicast stream on a different VLAN. As a result, the device creates different MGIDs for each multicast address and VLAN. Therefore, in a worst case situation, the upstream router sends one copy for each VLAN, which results in as many copies as the number of VLANs in the group. Because the WLAN remains the same for all clients, multiple copies of the multicast packet are sent over the wireless network. To suppress the duplication of a multicast stream on the wireless medium between the device and the access points, the multicast optimization feature can be used.

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the device can be configured as a multicast VLAN where multicast groups are registered. The clients are allowed to listen to a multicast stream on the multicast VLAN. The MGID is generated using the multicast VLAN and multicast IP addresses. If multiple clients on different VLANs of the same WLAN are listening to a single multicast IP address, a single MGID is generated. The device makes sure that all multicast streams from the clients on this VLAN group always go out on the multicast VLAN to ensure that the upstream router has one entry for all the VLANs of the VLAN group. Only one multicast stream hits the VLAN group even if the clients are on different VLANs. Therefore, the multicast packets that are sent out over the network is just one stream.

## IPv6 Global Policies

IPv6 global policies provide storage and access policy database services. IPv6 ND inspection and IPv6 RA guard are IPv6 global policies features. Every time an ND inspection or RA guard is configured globally, the

policy attributes are stored in the software policy database. The policy is then applied to an interface, and the software policy database entry is updated to include this interface to which the policy is applied.

## IPv6 RA Guard

The IPv6 RA Guard feature provides support for allowing the network administrator to block or reject unwanted or rogue RA guard messages that arrive at the network device platform. RAs are used by devices to announce themselves on the link. The IPv6 RA Guard feature analyzes these RAs and filters out RAs that are sent by unauthorized devices. In host mode, all RA and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 (L2) device with the information found in the received RA frame. Once the L2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.

## Information About IPv6 Snooping

### IPv6 Neighbor Discovery Inspection

The IPv6 Neighbor Discovery Inspection, or IPv6 "snooping," feature bundles several Layer 2 IPv6 first-hop security features, including IPv6 Address Glean and IPv6 Device Tracking. IPv6 neighbor discovery (ND) inspection operates at Layer 2, or between Layer 2 and Layer 3, and provides IPv6 features with security and scalability. This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables and analyzes ND messages in order to build a trusted binding table. IPv6 ND messages that do not have valid bindings are dropped. An ND message is considered trustworthy if its IPv6-to-MAC mapping is verifiable.

When IPv6 ND inspection is configured on a target (which varies depending on platform target support and may include device ports, switch ports, Layer 2 interfaces, Layer 3 interfaces, and VLANs), capture instructions are downloaded to the hardware to redirect the ND protocol and Dynamic Host Configuration Protocol (DHCP) for IPv6 traffic up to the switch integrated security features (SISF) infrastructure in the routing device. For ND traffic, messages such as NS, NA, RS, RA, and REDIRECT are directed to SISF. For DHCP, UDP messages sourced from port 546 or 547 are redirected.

IPv6 ND inspection registers its "capture rules" to the classifier, which aggregates all rules from all features on a given target and installs the corresponding ACL down into the platform-dependent modules. Upon receiving redirected traffic, the classifier calls all entry points from any registered feature (for the target on which the traffic is being received), including the IPv6 ND inspection entry point. This entry point is the last to be called, so any decision (such as drop) made by another feature supersedes the IPv6 ND inspection decision.

### IPv6 ND Inspection

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables. IPv6 ND inspection analyzes neighbor discovery messages in order to build a trusted binding table database, and IPv6 neighbor discovery messages that do not have valid bindings are dropped. A neighbor discovery message is considered trustworthy if its IPv6-to-MAC mapping is verifiable.

This feature mitigates some of the inherent vulnerabilities for the neighbor discovery mechanism, such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache.

## IPv6 Device Tracking

IPv6 device tracking provides IPv6 host liveness tracking so that a neighbor table can be immediately updated when an IPv6 host disappears.

### *IPv6 First-Hop Security Binding Table*

The IPv6 First-Hop Security Binding Table recovery mechanism feature enables the binding table to recover in the event of a device reboot. A database table of IPv6 neighbors connected to the device is created from information sources such as ND snooping. This database, or binding, table is used by various IPv6 guard features to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors to prevent spoofing and redirect attacks.

This mechanism enables the binding table to recover in the event of a device reboot. The recovery mechanism will block any data traffic sourced from an unknown source; that is, a source not already specified in the binding table and previously learned through ND or DHCP gleaning. This feature recovers the missing binding table entries when the resolution for a destination address fails in the destination guard. When a failure occurs, a binding table entry is recovered by querying the DHCP server or the destination host, depending on the configuration.

### Recovery Protocols and Prefix Lists

The IPv6 First-Hop Security Binding Table Recovery Mechanism feature introduces the capability to provide a prefix list that is matched before the recovery is attempted for both DHCP and NDP.

If an address does not match the prefix list associated with the protocol, then the recovery of the binding table entry will not be attempted with that protocol. The prefix list should correspond to the prefixes that are valid for address assignment in the Layer 2 domain using the protocol. The default is that there is no prefix list, in which case the recovery is attempted for all addresses. The command to associate a prefix list to a protocol is **protocol {dhcp | ndp} [prefix-list *prefix-list-name*]**.

### *IPv6 Device Tracking*

IPv6 device tracking provides IPv6 host liveness tracking so that a neighbor table can be immediately updated when an IPv6 host disappears.

## IPv6 Address Glean

IPv6 address glean is the foundation for many other IPv6 features that depend on an accurate binding table. It inspects ND and DHCP messages on a link to glean addresses, and then populates the binding table with these addresses. This feature also enforces address ownership and limits the number of addresses any given node is allowed to claim.

The following figure shows how IPv6 address glean works.

Figure 29: IPv6 Address Glean

Binding Table

| IPv6            | MAC               | VLAN | IF |
|-----------------|-------------------|------|----|
| A <sub>1</sub>  | MAC <sub>H1</sub> | 100  | P1 |
| A <sub>21</sub> | MAC <sub>H2</sub> | 100  | P2 |
| A <sub>22</sub> | MAC <sub>H2</sub> | 100  | P2 |
| A <sub>3</sub>  | MAC <sub>H3</sub> | 100  | P3 |

## Configuring IPv6 Snooping (CLI)

### SUMMARY STEPS

- enable
- configure terminal
- ipv6 mld snooping

### DETAILED STEPS

|               | Command or Action                                                                     | Purpose                                                                                                          |
|---------------|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br><br>Device> <b>enable</b>                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters global command mode.                                                                                      |

|        | Command or Action                                                                       | Purpose               |
|--------|-----------------------------------------------------------------------------------------|-----------------------|
| Step 3 | <b>ipv6 mld snooping</b><br><b>Example:</b><br>Device(config)# <b>ipv6 mld snooping</b> | Enables MLD snooping. |

## Configuring IPv6 Snooping Policy (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ipv6 snooping policy** *policy-name*
4. **security-level guard**
5. **device-role node**
6. **protocol** {**dhcp** | **ndp**}

### DETAILED STEPS

|        | Command or Action                                                                                                         | Purpose                                                                                                            |
|--------|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                 | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                         | Enters global command mode.                                                                                        |
| Step 3 | <b>ipv6 snooping policy</b> <i>policy-name</i><br><b>Example:</b><br>Device(config)# <b>ipv6 snooping policy mypolicy</b> | Configures an IPv6 snooping policy with a name.                                                                    |
| Step 4 | <b>security-level guard</b><br><b>Example:</b><br>Device(config-ipv6-snooping)# <b>security-level guard</b>               | Configures security level to inspect and drop any unauthorized messages.                                           |
| Step 5 | <b>device-role node</b><br><b>Example:</b><br>Device(config-ipv6-snooping)# <b>device-role node</b>                       | Configures the role of the device, which is a node, to the attached port.                                          |
| Step 6 | <b>protocol</b> { <b>dhcp</b>   <b>ndp</b> }                                                                              | Sets the protocol to glean addresses in DHCP or NDP packets.                                                       |

## Configuring Layer 2 Port as Multicast Router Port (CLI)

### SUMMARY STEPS

1. enable
2. configure terminal
3. `ipv6 mld snooping vlan vlan-id mrouter interface Port-channel port-channel-interface-number`

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                        | Purpose                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                                                        | Enters global command mode.                                                                                        |
| Step 3 | <b>ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface Port-channel <i>port-channel-interface-number</i></b><br><b>Example:</b><br>Device(config)# <b>ipv6 mld snooping vlan 2 mrouter interface Port-channel 22</b> | Configures a Layer 2 port as a Multicast router port. The VLAN is the client VLAN.                                 |

## Configuring IPv6 RA Guard (CLI)

### SUMMARY STEPS

1. enable
2. configure terminal
3. `ipv6 nd raguard policy policy-name`
4. trusted-port
5. device-role {host | monitor | router | switch}

### DETAILED STEPS

|        | Command or Action                                         | Purpose                                                                                                            |
|--------|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |

|        | Command or Action                                                                                                                          | Purpose                                           |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                    | Enters global command mode.                       |
| Step 3 | <b>ipv6 nd raguard policy <i>policy-name</i></b><br><b>Example:</b><br>Device(config)# <code>ipv6 nd raguard policy myraguardpolicy</code> | Configures a policy for RA Guard.                 |
| Step 4 | <b>trusted-port</b><br><b>Example:</b><br>Device(config-nd-raguard)# <code>trusted-port</code>                                             | Sets up a trusted port.                           |
| Step 5 | <b>device-role {host   monitor   router   switch}</b><br><b>Example:</b><br>Device(config-nd-raguard)# <code>device-role router</code>     | Sets the role of the device attached to the port. |

## Configuring Non-IP Wireless Multicast (CLI)

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `wireless multicast non-ip`
4. `wireless multicast non-ip vlanid`
5. `end`

### DETAILED STEPS

|        | Command or Action                                                                       | Purpose                                                                                                                                                                                                        |
|--------|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code>                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                             |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code> | Enters global command mode.                                                                                                                                                                                    |
| Step 3 | <b>wireless multicast non-ip</b><br><b>Example:</b>                                     | Enables non-IP multicast in all VLANs. Default value is <b>enable</b> . Wireless multicast must be enabled for the traffic to pass. Add <b>no</b> in the command to disable the non-IP multicast in all VLANs. |

|               | Command or Action                                                                                                                                                                  | Purpose                                                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device(config) # <b>wireless multicast non-ip</b><br>Device(config) # <b>no wireless multicast non-ip</b>                                                                          |                                                                                                                                                                                                                                       |
| <b>Step 4</b> | <b>wireless multicast non-ip</b> <i>vlanid</i><br><b>Example:</b><br>Device(config) # <b>wireless multicast non-ip</b> 5<br>Device(config) # <b>no wireless multicast non-ip</b> 5 | Enables non-IP multicast per VLAN. Default value is <b>enable</b> . Both wireless multicast and wireless multicast non-IP must be enabled for traffic to pass. Add <b>no</b> in the command to disable the non-IP multicast per VLAN. |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config) # <b>end</b>                                                                                                                       | Exits the configuration mode. Alternatively, press <b>Ctrl-Z</b> to exit the configuration mode.                                                                                                                                      |

## Configuring Wireless Broadcast (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **wireless broadcast**
4. **wireless broadcast vlan** *vlanid*
5. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                                           | Purpose                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                   | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul>                                                                                                 |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                           | Enters global command mode.                                                                                                                                                                                         |
| <b>Step 3</b> | <b>wireless broadcast</b><br><b>Example:</b><br>Device(config) # <b>wireless broadcast</b><br>Device(config) # <b>no wireless broadcast</b> | Enables broadcast packets for wireless clients. Default value is disable. Enabling <b>wireless broadcast</b> enables broadcast traffic for each VLAN. Add <b>no</b> in the command to disable broadcasting packets. |
| <b>Step 4</b> | <b>wireless broadcast vlan</b> <i>vlanid</i><br><b>Example:</b>                                                                             | Enables broadcast packets for single VLAN. Default value is <b>enable</b> . Wireless broadcast must be enabled for                                                                                                  |

|               | Command or Action                                                                                       | Purpose                                                                                          |
|---------------|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
|               | Device(config)# <b>wireless broadcast vlan 3</b><br>Device(config)# <b>no wireless broadcast vlan 3</b> | broadcasting. Add <b>no</b> in the command to disable the broadcast traffic for each VLAN.       |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                             | Exits the configuration mode. Alternatively, press <b>Ctrl-Z</b> to exit the configuration mode. |

## Configuring IP Multicast VLAN for WLAN (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **wlan *wlan\_name***
4. **shutdown**
5. **ip multicast vlan {*vlan\_name* *vlan\_id*}**
6. **no shutdown**
7. **end**

### DETAILED STEPS

|               | Command or Action                                                                     | Purpose                                                                                                             |
|---------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                             | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>     | Enters global command mode.                                                                                         |
| <b>Step 3</b> | <b>wlan <i>wlan_name</i></b><br><b>Example:</b><br>Device(config)# <b>wlan test 1</b> | Enters the configuration mode to configure various parameters in the WLAN.                                          |
| <b>Step 4</b> | <b>shutdown</b><br><b>Example:</b><br>Device(config-wlan)# <b>shutdown</b>            | Disables WLAN.                                                                                                      |
| <b>Step 5</b> | <b>ip multicast vlan {<i>vlan_name</i> <i>vlan_id</i>}</b><br><b>Example:</b>         | Configures multicast VLAN for WLAN. Add <b>no</b> in the command to disable the multicast VLAN for WLAN.            |

## Monitoring Wireless Multicast

*Table 47: Commands for Monitoring Wireless Multicast*

| Commands                                                               | Description                                                                                                                                    |
|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show wireless multicast</b>                                         | Displays the multicast status and IP multicast mode, each VLAN's broadcast and non-IP multicast status. Also displays the mDNS bridging state. |
| <b>show wireless multicast group summary</b>                           | Displays all (Source, Group and VLAN) lists and the corresponding MGID value.                                                                  |
| <b>show wireless multicast [source source] group group vlan vlanid</b> | Displays details of the given (S,G,V) and shows all of the clients associated with it and their MC2UC status.                                  |
| <b>show ip igmp snooping wireless mcast-spi-count</b>                  | Displays statistics of the number of multicast SPIs per MGID sent between IOS and the Wireless Controller Module.                              |
| <b>show ip igmp snooping wireless mgid</b>                             | Displays the MGID mappings.                                                                                                                    |
| <b>show ip igmp snooping igmpv2-tracking</b>                           | Displays the client-to-SGV mappings and SGV-to-client mappings.                                                                                |
| <b>show ip igmp snooping querier vlan vlanid</b>                       | Displays IGMP querier information for the specified VLAN.                                                                                      |
| <b>show ip igmp snooping querier detail</b>                            | Displays detailed IGMP querier information of all the VLANs.                                                                                   |
| <b>show ipv6 mld snooping querier vlan vlanid</b>                      | Displays MLD querier information for the specified VLAN.                                                                                       |
| <b>show ipv6 mld snooping wireless mgid</b>                            | Displays MGIDs for IPv6 multicast group.                                                                                                       |

## Where to Go Next for Wireless Multicast

You can configure the following:

- IGMP
- PIM
- SSM
- IP Multicast Routing
- Service Discovery Gateway

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring SSM

The following are the prerequisites for configuring source-specific multicast (SSM) and SSM mapping:

- Before you configure SSM mapping, you must perform the following tasks:
  - Enable IP multicast routing.
  - Enable PIM sparse mode.
  - Configure SSM.
- Before you configure static SSM mapping, you must configure access control lists (ACLs) that define the group ranges to be mapped to source addresses.

- Before you can configure and use SSM mapping with DNS lookups, you need to add records to a running DNS server. If you do not already have a DNS server running, you need to install one.

---

**Note** You can use a product such as *Cisco Network Registrar* to add records to a running DNS server.

---

## Restrictions for Configuring SSM

The following are the restrictions for configuring SSM:

- To run SSM with IGMPv3, SSM must be supported in the Cisco IOS router, the host where the application is running, and the application itself.
- Existing applications in a network predating SSM will not work within the SSM range unless they are modified to support (S, G) channel subscriptions. Therefore, enabling SSM in a network may cause problems for existing applications if they use addresses within the designated SSM range.
- IGMP Snooping—IGMPv3 uses new membership report messages that might not be correctly recognized by older IGMP snooping devices.
- Address management is still necessary to some degree when SSM is used with Layer 2 switching mechanisms. Cisco Group Management Protocol (CGMP), IGMP snooping, or Router-Port Group Management Protocol (RGMP) support only group-specific filtering, not (S, G) channel-specific filtering. If different receivers in a switched network request different (S, G) channels sharing the same group, they do not benefit from these existing mechanisms. Instead, both receivers receive all (S, G) channel traffic and filter out the unwanted traffic on input. Because SSM can re-use the group addresses in the SSM range for many independent applications, this situation can lead to decreased traffic filtering in a switched network. For this reason, it is important to use random IP addresses from the SSM range for an application to minimize the chance for re-use of a single address within the SSM range between different applications. For example, an application service providing a set of television channels should, even with SSM, use a different group for each television (S, G) channel. This setup guarantees that multiple receivers to different channels within the same application service never experience traffic aliasing in networks that include Layer 2 devices.
- In PIM-SSM, the last hop router will continue to periodically send (S, G) join messages if appropriate (S, G) subscriptions are on the interfaces. Therefore, as long as receivers send (S, G) subscriptions, the shortest path tree (SPT) state from the receivers to the source will be maintained, even if the source is not sending traffic for longer periods of time (or even never).

The opposite situation occurs with PIM-SM, where (S, G) state is maintained only if the source is sending traffic and receivers are joining the group. If a source stops sending traffic for more than 3 minutes in PIM-SM, the (S, G) state is deleted and only reestablished after packets from the source arrive again through the RPT (rendezvous point tree). Because no mechanism in PIM-SSM notifies a receiver that a source is active, the network must maintain the (S, G) state in PIM-SSM as long as receivers are requesting receipt of that channel.

The following are the restrictions for configuring SSM mapping:

- The SSM Mapping feature does not share the benefit of full SSM. SSM mapping takes a group G join from a host and identifies this group with an application associated with one or more sources, therefore,

it can only support one such application per group G. Nevertheless, full SSM applications may still share the same group also used in SSM mapping.

- Enable IGMPv3 with care on the last hop router when you rely solely on SSM mapping as a transition solution for full SSM. When you enable both SSM mapping and IGMPv3 and the hosts already support IGMPv3 (but not SSM), the hosts send IGMPv3 group reports. SSM mapping does not support these IGMPv3 group reports, and the router does not correctly associate sources with these reports.

## Information About SSM

The source-specific multicast (SSM) feature is an extension of IP multicast in which datagram traffic is forwarded to receivers from only those multicast sources that the receivers have explicitly joined. For multicast groups configured for SSM, only SSM distribution trees (no shared trees) are created.

This section describes how to configure source-specific multicast (SSM). For a complete description of the SSM commands in this section, refer to the *IP Multicast Command Reference*. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

## SSM Components Overview

SSM is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core networking technology for the Cisco implementation of IP multicast solutions targeted for audio and video broadcast application environments. The device supports the following components that support SSM implementation:

- Protocol independent multicast source-specific mode (PIM-SSM)

PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM sparse mode (PIM-SM).

- Internet Group Management Protocol version 3 (IGMPv3)

## SSM and Internet Standard Multicast (ISM)

The current IP multicast infrastructure in the Internet and many enterprise intranets is based on the PIM-SM protocol and Multicast Source Discovery Protocol (MSDP). These protocols have the limitations of the Internet Standard Multicast (ISM) service model. For example, with ISM, the network must maintain knowledge about which hosts in the network are actively sending multicast traffic.

The ISM service consists of the delivery of IP datagrams from any source to a group of receivers called the multicast host group. The datagram traffic for the multicast host group consists of datagrams with an arbitrary IP unicast source address (S) and the multicast group address (G) as the IP destination address. Systems receive this traffic by becoming members of the host group. Membership in a host group simply requires signaling the host group through IGMP version 1, 2, or 3.

In SSM, delivery of datagrams is based on (S, G) channels. In both SSM and ISM, no signaling is required to become a source. However, in SSM, receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources. In other words, receivers can receive traffic only from (S, G) channels to which they are subscribed, whereas in ISM, receivers need not know the IP addresses of sources from which they receive their traffic. The proposed standard approach for channel subscription signaling uses IGMP and includes modes membership reports, which are supported only in IGMP version 3.

## SSM IP Address Range

SSM can coexist with the ISM service by applying the SSM delivery model to a configured subset of the IP multicast group address range. Cisco IOS software allows SSM configuration for the IP multicast address range of 224.0.0.0 through 239.255.255.255. When an SSM range is defined, existing IP multicast receiver applications do not receive any traffic when they try to use an address in the SSM range (unless the application is modified to use an explicit (S, G) channel subscription).

## SSM Operations

An established network, in which IP multicast service is based on PIM-SM, can support SSM services. SSM can also be deployed alone in a network without the full range of protocols required for interdomain PIM-SM (for example, MSDP, Auto-RP, or bootstrap router [BSR]) if only SSM service is needed.

If SSM is deployed in a network already configured for PIM-SM, only the last-hop routers support SSM. Routers that are not directly connected to receivers do not require support for SSM. In general, these not-last-hop routers must only run PIM-SM in the SSM range and might need additional access control configuration to suppress MSDP signalling, registering, or PIM-SM shared tree operations from occurring within the SSM range.

Use the **ip pim ssm** global configuration command to configure the SSM range and to enable SSM. This configuration has the following effects:

- For groups within the SSM range, (S, G) channel subscriptions are accepted through IGMPv3 include-mode membership reports.
- PIM operations within the SSM range of addresses change to PIM-SSM, a mode derived from PIM-SM. In this mode, only PIM (S, G) join and prune messages are generated by the router, and no (S, G) rendezvous point tree (RPT) or (\*, G) RPT messages are generated. Incoming messages related to RPT operations are ignored or rejected, and incoming PIM register messages are immediately answered with register-stop messages. PIM-SSM is backward-compatible with PIM-SM unless a router is a last-hop router. Therefore, routers that are not last-hop routers can run PIM-SM for SSM groups (for example, if they do not yet support SSM).
- No MSDP source-active (SA) messages within the SSM range are accepted, generated, or forwarded.

## SSM Mapping

In a typical set-top box (STB) deployment, each TV channel uses one separate IP multicast group and has one active server host sending the TV channel. A single server can send multiple TV channels, but each to a different group. In this network environment, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the report addresses the well-known TV server for the TV channel associated with the multicast group.

When SSM mapping is configured, if a router receives an IGMPv1 or IGMPv2 membership report for a particular group, the router translates this report into one or more channel memberships for the well-known sources associated with this group.

When the router receives an IGMPv1 or IGMPv2 membership report for a group, the router uses SSM mapping to determine one or more source IP addresses for the group. SSM mapping then translates the membership report as an IGMPv3 report and continues as if it had received an IGMPv3 report. The router then sends PIM joins and continues to be joined to these groups as long as it continues to receive the IGMPv1 or IGMPv2 membership reports, and the SSM mapping for the group remains the same.

SSM mapping enables the last hop router to determine the source addresses either by a statically configured table on the router or through a DNS server. When the statically configured table or the DNS mapping changes, the router leaves the current sources associated with the joined groups.

## Static SSM Mapping

With static SSM mapping, you can configure the last hop router to use a static map to determine the sources that are sending to groups. Static SSM mapping requires that you configure ACLs to define group ranges. After configuring the ACLs to define group ranges, you can then map the groups permitted by those ACLs to sources by using the `ip igmp ssm-map static` global configuration command.

You can configure static SSM mapping in smaller networks when a DNS is not needed or to locally override DNS mappings. When configured, static SSM mappings take precedence over DNS mappings.

## DNS-Based SSM Mapping

You can use DNS-based SSM mapping to configure the last hop router to perform a reverse DNS lookup to determine sources sending to groups. When DNS-based SSM mapping is configured, the router constructs a domain name that includes the group address and performs a reverse lookup into the DNS. The router looks up IP address resource records and uses them as the source addresses associated with this group. SSM mapping supports up to 20 sources for each group. The router joins all sources configured for a group.

**Figure 30: DNS-Based SSM Mapping**

The following figure displays DNS-based SSM

mapping. The SSM mapping mechanism that enables the last hop router to join multiple sources for a group can provide source redundancy for a TV broadcast. In this context, the last hop router provides redundancy using SSM mapping to simultaneously join two video sources for the same TV channel. However, to prevent the last hop

router from duplicating the video traffic, the video sources must use a server-side switchover mechanism. One video source is active, and the other backup video source is passive. The passive source waits until an active source failure is detected before sending the video traffic for the TV channel. Thus, the server-side switchover mechanism ensures that only one of the servers is actively sending video traffic for the TV channel.

To look up one or more source addresses for a group that includes G1, G2, G3, and G4, you must configure these DNS records on the DNS server:

```
G4.G3.G2.G1 [multicast-domain] [timeout] IN A source-address-1
IN A source-address-2
IN A source-address-n
```

See your DNS server documentation for more information about configuring DNS resource records.

## How to Configure SSM

For a complete description of the source-specific multicast (SSM) commands in this section, see the *IP Multicast Command Reference, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*. To locate documentation for other commands that appear in this chapter, use the command reference master index, or search online.

### Configuring SSM (CLI)

Follow these steps to configure SSM:

This procedure is optional.

#### Before you begin

If you want to use an access list to define the Source Specific Multicast (SSM) range, configure the access list before you reference the access list in the **ip pim ssm** command.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip pim ssm** [**default** | **range** *access-list*]
4. **interface** *type number*
5. **ip pim** {**sparse-mode** | **sparse-dense-mode**}
6. **ip igmp version 3**
7. **end**
8. **show running-config**
9. **copy running-config startup-config**

## DETAILED STEPS

|--------|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                        | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>ip pim ssm [default   range <i>access-list</i>]</b><br><b>Example:</b><br>Device(config)# <b>ip pim ssm range 20</b>  | Defines the SSM range of IP multicast addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 4 | <b>interface <i>type number</i></b><br><b>Example:</b><br>Device(config)# <b>interface gigabitethernet 1/0/1</b>         | <p>Selects an interface that is connected to hosts on which IGMPv3 can be enabled, and enters the interface configuration mode.</p> <p>The specified interface must be one of the following:</p> <ul style="list-style-type: none"> <li>• A routed port—A physical port that has been configured as a Layer 3 port by entering the <b>no switchport</b> interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group.</li> <li>• An SVI—A VLAN interface created by using the <b>interface vlan <i>vlan-id</i></b> global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface.</li> </ul> <p>These interfaces must have IP addresses assigned to them.</p> |
| Step 5 | <b>ip pim {sparse-mode   sparse-dense-mode}</b><br><b>Example:</b><br>Device(config-if)# <b>ip pim sparse-dense-mode</b> | Enables PIM on an interface. You must use either sparse mode or sparse-dense mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 6 | <b>ip igmp version 3</b><br><b>Example:</b>                                                                              | Enables IGMPv3 on this interface. The default version of IGMP is set to Version 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|               | Command or Action                                                                                                       | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
|               | Device(config-if)# <code>ip igmp version 3</code>                                                                       |                                                          |
| <b>Step 7</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                       | Returns to privileged EXEC mode.                         |
| <b>Step 8</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                               | Verifies your entries.                                   |
| <b>Step 9</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

## Configuring Source Specific Multicast Mapping

The Source Specific Multicast (SSM) mapping feature supports SSM transition when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. You can use SSM mapping to leverage SSM for video delivery to legacy STBs that do not support IGMPv3 or for applications that do not use the IGMPv3 host stack.

### Configuring Static SSM Mapping (CLI)

Follow these steps to configure static SSM Mapping:

For additional information on SSM mapping, see the IP Multicast CG Library, Cisco IOS XE Release 3SE (Catalyst 3850 Switches).

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip igmp ssm-map enable`
4. `no ip igmp ssm-map query dns`
5. `ip igmp ssm-map static access-list source-address`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

## DETAILED STEPS

|        | Command or Action                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                             | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                     | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 3 | <b>ip igmp ssm-map enable</b><br><b>Example:</b><br>Device(config)# <b>ip igmp ssm-map enable</b>                                                     | Enables SSM mapping for groups in the configured SSM range.<br><b>Note</b> By default, this command enables DNS-based SSM mapping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 4 | <b>no ip igmp ssm-map query dns</b><br><b>Example:</b><br>Device(config)# <b>no ip igmp ssm-map query dns</b>                                         | (Optional) Disables DNS-based SSM mapping.<br><b>Note</b> Disable DNS-based SSM mapping if you only want to rely on static SSM mapping. By default, the <b>ip igmp ssm-map</b> command enables DNS-based SSM mapping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 5 | <b>ip igmp ssm-map static</b> <i>access-list source-address</i><br><b>Example:</b><br>Device(config)# <b>ip igmp ssm-map static</b> 11<br>172.16.8.11 | Configures static SSM mapping.<br><ul style="list-style-type: none"> <li>The ACL supplied for the <i>access-list</i> argument defines the groups to be mapped to the source IP address entered for the <i>source-address</i> argument.</li> </ul> <b>Note</b> You can configure additional static SSM mappings. If additional SSM mappings are configured and the router receives an IGMPv1 or IGMPv2 membership report for a group in the SSM range, the device determines the source addresses associated with the group by walking each configured <b>ip igmp ssm-map static</b> command. The device associates up to 20 sources per group.<br><br>Repeat Step to configure additional static SSM mappings, if required. |
| Step 6 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                           | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|               | Command or Action                                                                                                       | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 7</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                               | Verifies your entries.                                   |
| <b>Step 8</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

**Configuring DNS-Based SSM Mapping (CLI)**

To configure DNS-based SSM mapping, you need to create a DNS server zone or add records to an existing zone. If the routers that are using DNS-based SSM mapping are also using DNS for other purposes, you should use a normally configured DNS server. If DNS-based SSM mapping is the only DNS implementation being used on the router, you can configure a false DNS setup with an empty root zone or a root zone that points back to itself.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip igmp ssm-map enable`
4. `ip igmp ssm-map query dns`
5. `ip domain multicast domain-prefix`
6. `ip name-server server-address1 [server-address2...server-address6]`
7. Repeat Step 6 to configure additional DNS servers for redundancy, if required.
8. `end`
9. `show running-config`
10. `copy running-config startup-config`

**DETAILED STEPS**

|               | Command or Action                                                     | Purpose                                                        |
|---------------|-----------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <code>enable</code><br><b>Example:</b><br>Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                           | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                         |
| <b>Step 3</b> | <b>ip igmp ssm-map enable</b><br><b>Example:</b><br>Device(config)# ip igmp ssm-map enable                                                                  | Enables SSM mapping for groups in a configured SSM range.                                                                                                                                                                                                                                                                                                     |
| <b>Step 4</b> | <b>ip igmp ssm-map query dns</b><br><b>Example:</b><br>Device(config)# ip igmp ssm-map query dns                                                            | (Optional) Enables DNS-based SSM mapping. <ul style="list-style-type: none"> <li>• By default, the <b>ip igmp ssm-map</b> command enables DNS-based SSM mapping. Only the <b>no</b> form of this command is saved to the running configuration.</li> </ul> <b>Note</b> Use this command to reenab DNS-based SSM mapping if DNS-based SSM mapping is disabled. |
| <b>Step 5</b> | <b>ip domain multicast</b> <i>domain-prefix</i><br><b>Example:</b><br>Device(config)# ip domain multicast<br>ssm-map.cisco.com                              | (Optional) Changes the domain prefix used for DNS-based SSM mapping. <ul style="list-style-type: none"> <li>• By default, the software uses the ip-addr.arpa domain prefix.</li> </ul>                                                                                                                                                                        |
| <b>Step 6</b> | <b>ip name-server</b> <i>server-address1</i><br><i>[server-address2...server-address6]</i><br><b>Example:</b><br>Device(config)# ip name-server 10.48.81.21 | Specifies the address of one or more name servers to use for name and address resolution.                                                                                                                                                                                                                                                                     |
| <b>Step 7</b> | Repeat Step 6 to configure additional DNS servers for redundancy, if required.                                                                              |                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 8</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                                 | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                              |
| <b>Step 9</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                                                                         | Verifies your entries.                                                                                                                                                                                                                                                                                                                                        |

|                | Command or Action                                                                                                       | Purpose                                                  |
|----------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

**Configuring Static Traffic Forwarding with SSM Mapping (CLI)**

Follow these steps to configure static traffic forwarding with SSM mapping on the last hop router:

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **ip igmp static-group *group-address* source ssm-map**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

**DETAILED STEPS**

|               | Command or Action                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|-------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code>                                                         | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                 | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 3</b> | <b>interface <i>interface-id</i></b><br><b>Example:</b><br>Device(config)# <code>interface gigabitethernet 1/0/1</code> | Selects an interface on which to statically forward traffic for a multicast group using SSM mapping, and enters interface configuration mode.<br><br>The specified interface must be one of the following: <ul style="list-style-type: none"> <li>• A routed port—A physical port that has been configured as a Layer 3 port by entering the <b>no switchport</b> interface configuration command. You will also need to enable IP PIM sparse-dense-mode on</li> </ul> |

|               | Command or Action                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                                                           | <p>the interface, and join the interface as a statically connected member to an IGMP static group.</p> <ul style="list-style-type: none"> <li>An SVI—A VLAN interface created by using the <b>interface vlan <i>vlan-id</i></b> global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface.</li> </ul> <p>These interfaces must have IP addresses assigned to them.</p> <p><b>Note</b> Static forwarding of traffic with SSM mapping works with either DNS-based SSM mapping or statically configured SSM mapping.</p> |
| <b>Step 4</b> | <p><b>ip igmp static-group <i>group-address</i> source ssm-map</b></p> <p><b>Example:</b></p> <pre>Device(config-if)# ip igmp static-group 239.1.2.1 source ssm-map</pre> | <p>Configures SSM mapping to statically forward a (S, G) channel from the interface.</p> <p>Use this command if you want to statically forward SSM traffic for certain groups. Use DNS-based SSM mapping to determine the source addresses of the channels.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 5</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# end</pre>                                                                                                   | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 6</b> | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Device# show running-config</pre>                                                                           | <p>Verifies your entries.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 7</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Device# copy running-config startup-config</pre>                                             | <p>(Optional) Saves your entries in the configuration file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Monitoring SSM

Use the privileged EXEC commands in the following table to monitor SSM.

*Table 48: Commands for Monitoring SSM*

| Command                           | Purpose                                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>show ip igmp groups detail</b> | Displays the (S, G) channel subscription through IGMPv3.                                                       |
| <b>show ip mroute</b>             | Displays whether a multicast group supports SSM service or whether a source-specific host report was received. |

## Monitoring SSM Mapping

Use the privileged EXEC commands in the following table to monitor SSM mapping.

*Table 49: SSM Mapping Monitoring Commands*

| Command                                                                                                                                    | Purpose                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Device# <b>show ip igmp ssm-mapping</b>                                                                                                    | Displays information about SSM mapping.                                                                                                          |
| Device# <b>show ip igmp ssm-mapping group-address</b>                                                                                      | Displays the sources that SSM mapping uses for a particular group.                                                                               |
| Device# <b>show ip igmp groups</b> [ <i>group-name</i>   <i>group-address</i>   <i>interface-type interface-number</i> ] [ <b>detail</b> ] | Displays the multicast groups with receivers that are directly connected to the router and that were learned through IGMP.                       |
| Device# <b>show host</b>                                                                                                                   | Displays the default domain name, the style of name lookup service, a list of name server hosts, and the cached list of hostnames and addresses. |
| Device# <b>debug ip igmp group-address</b>                                                                                                 | Displays the IGMP packets received and sent and IGMP host-related events.                                                                        |

## Where to Go Next for SSM

You can configure the following:

- IGMP
- Wireless Multicast
- PIM
- IP Multicast Routing

- Service Discovery Gateway

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see [Bug Search Tool](#) and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

## Prerequisites for Basic IP Multicast Routing

The following are the prerequisites for configuring basic IP multicast routing:

- To use this feature, the device or active device must be running the IP services feature set. The IP Services image contains complete multicast routing.
- You must configure the PIM version and the PIM mode in order to perform IP multicast routing. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting. You can configure an interface to be in the PIM dense mode, sparse mode, or sparse-dense mode.
- Enabling PIM on an interface also enables IGMP operation on that interface. (To participate in IP multicasting, the multicast hosts, routers, and multilayer device must have IGMP operating. )

If you enable PIM on multiple interfaces, when most of these interfaces are not on the outgoing interface list, and IGMP snooping is disabled, the outgoing interface might not be able to sustain line rate for multicast traffic because of the extra replication.

## Restrictions for Basic IP Multicast Routing

The following are the restrictions for IP multicast routing:

- IP multicast routing is not supported on switches running the LAN base feature set.
- High-availability support for Layer 3 multicast routing is not supported.
- You cannot have a device stack containing a mix of Catalyst 3850 and Catalyst 3650 devices.

## Information About Basic IP Multicast Routing

IP multicasting is an efficient way to use network resources, especially for bandwidth-intensive services such as audio and video. IP multicast routing enables a host (source) to send packets to a group of hosts (receivers) anywhere within the IP network by using a special form of IP address called the IP multicast group address.

The sending host inserts the multicast group address into the IP destination address field of the packet, and IP multicast routers and multilayer devices forward incoming IP multicast packets out all interfaces that lead to members of the multicast group. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

---

**Note** For complete syntax and usage information for the commands used in this chapter, see the *IP Multicast Command Reference, Cisco IOS XE Release 3SE (Catalyst 3850 Switches)*. For information on configuring the Multicast Source Discovery Protocol (MSDP), see the *Catalyst 3850 Routing Configuration Guide*.

## Multicast Forwarding Information Base Overview

The device uses the Multicast Forwarding Information Base (MFIB) architecture and the Multicast Routing Information Base (MRIB) for IP multicast.

The MFIB architecture provides both modularity and separation between the multicast control plane (Protocol Independent Multicast [PIM] and Internet Group Management Protocol [IGMP]) and the multicast forwarding plane (MFIB). This architecture is used in Cisco IOS IPv6 multicast implementations.

MFIB itself is a multicast routing protocol independent forwarding engine; that is, it does not depend on PIM or any other multicast routing protocol. It is responsible for:

- Forwarding multicast packets
- Registering with the MRIB to learn the entry and interface flags set by the control plane
- Handling data-driven events that must be sent to the control plane
- Maintaining counts, rates, and bytes of received, dropped, and forwarded multicast packets

The MRIB is the communication channel between MRIB clients. Examples of MRIB clients are PIM, IGMP, the multicast routing (mroute) table, and the MFIB.

## Multicast Routing and Device Stacks

For all multicast routing protocols, the entire stack appears as a single router to the network and operates as a single multicast router.

In a device stack, the active device performs these functions:

- It is responsible for completing the IP multicast routing functions of the stack. It fully initializes and runs the IP multicast routing protocols.
- It builds and maintains the multicast routing table for the entire stack.
- It is responsible for distributing the multicast routing table to all stack members.

The stack members perform these functions:

- They act as multicast routing standby devices and are ready to take over if there is a active device failure. If the active device fails, all stack members delete their multicast routing tables. The newly elected active device starts building the routing tables and distributes them to the stack members.
- They do not build multicast routing tables. Instead, they use the multicast routing table that is distributed by the active device.

## Default IP Multicast Routing Configuration

This table displays the default IP multicast routing configuration.

**Table 50: Default IP Multicast Routing Configuration**

| Feature           | Default Setting             |
|-------------------|-----------------------------|
| Multicast routing | Disabled on all interfaces. |
| PIM version       | Version 2.                  |
| PIM mode          | No mode is defined.         |
| PIM stub routing  | None configured.            |

| Feature                           | Default Setting  |
|-----------------------------------|------------------|
| PIM RP address                    | None configured. |
| PIM domain border                 | Disabled.        |
| PIM multicast boundary            | None.            |
| Candidate BSRs                    | Disabled.        |
| Candidate RPs                     | Disabled.        |
| Shortest-path tree threshold rate | 0 kb/s.          |
| PIM router query message interval | 30 seconds.      |

## How to Configure Basic IP Multicast Routing

### Configuring Basic IP Multicast Routing

By default, multicast routing is disabled, and there is no default mode setting.

This procedure is required.

#### Before you begin

You must configure the PIM version and the PIM mode. The switch populates its multicast routing table and forwards multicast packets it receives from its directly connected LANs according to the mode setting.

In populating the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream devices or when there is a directly connected member on the interface. When forwarding from a LAN, sparse-mode operation occurs if there is an RP known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver's first-hop router might send join messages toward the source to build a source-based distribution tree.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip multicast-routing**
4. **interface *interface-id***
5. **ip pim {dense-mode | sparse-mode | sparse-dense-mode}**
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

## DETAILED STEPS

|        | Command or Action                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Configuring IP Multicast Forwarding (CLI)

You can use the following procedure to configure IPv4 Multicast Forwarding Information Base (MFIB) interrupt-level IP multicast forwarding of incoming packets or outgoing packets on the device.

**Note** After you have enabled IP multicast routing by using the **ip multicast-routing** command, IPv4 multicast forwarding is enabled. Because IPv4 multicast forwarding is enabled by default, you can use the **no** form of the **ip mfib** command to disable IPv4 multicast forwarding.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip mfib**
4. **exit**

5. `show running-config`
6. `copy running-config startup-config`

### DETAILED STEPS

|        | Command or Action                                                                                                       | Purpose                                                                                                            |
|--------|-------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code>                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                 | Enters the global configuration mode.                                                                              |
| Step 3 | <b>ip mfib</b><br><b>Example:</b><br>Device(config)# <code>ip mfib</code>                                               | Enables IP multicast forwarding.                                                                                   |
| Step 4 | <b>exit</b><br><b>Example:</b><br>Device(config)# <code>exit</code>                                                     | Returns to privileged EXEC mode.                                                                                   |
| Step 5 | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                               | Verifies your entries.                                                                                             |
| Step 6 | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file.                                                           |

## Configuring a Static Multicast Route (mroute) (CLI)

You can use the following procedure to configure static mroutes. Static mroutes are similar to unicast static routes but differ in the following ways:

- Static mroutes are used to calculate RPF information, not to forward traffic.
- Static mroutes cannot be redistributed.

Static mroutes are strictly local to the device on which they are defined. Because Protocol Independent Multicast (PIM) does not have its own routing protocol, there is no mechanism to distribute static mroutes throughout the network. Consequently, the administration of static mroutes tends to be more complicated than the administration of unicast static routes.

When static mroutes are configured, they are stored on the device in a separate table referred to as the static mroute table. When configured, the **ip mroute** command enters a static mroute into the static mroute table for the source address or source address range specified for the source-address and mask arguments. Sources that match the source address or that fall in the source address range specified for the source-address argument will RPF to either the interface associated with the IP address specified for the *rpf-address* argument or the local interface on the device specified for the *interface-type* and *interface-number* arguments. If an IP address is specified for the *rpf-address* argument, a recursive lookup is done from the unicast routing table on this address to find the directly connected neighbor.

If there are multiple static mroutes configured, the device performs a longest-match lookup of the mroute table. When the mroute with the longest match (of the source-address) is found, the search terminates and the information in the matching static mroute is used. The order in which the static mroutes are configured is not important.

The administrative distance of an mroute may be specified for the optional distance argument. If a value is not specified for the distance argument, the distance of the mroute defaults to zero. If the static mroute has the same distance as another RPF source, the static mroute will take precedence. There are only two exceptions to this rule: directly connected routes and the default unicast route.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip mroute** [*vrf vrf-name*] *source-address mask* { **fallback-lookup** {**global** | **vrf vrf-name** } [*protocol*] {*rpf-address* | *interface-type interface-number*} } [**distance**]
4. **exit**
5. **show running-config**
6. **copy running-config startup-config**

|        | Command or Action                                                                                                                                                                                                                                                                                                                                         | Purpose                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>ip mroute</b> [<i>vrf vrf-name</i>] <i>source-address mask</i> {<br/> <b>fallback-lookup</b> {<i>global</i>   <i>vrf vrf-name</i> } [<i>protocol</i> ]<br/> {i<i>rpf-address</i>   <i>interface-type interface-number</i>} } [<i>distance</i>]</p> <p><b>Example:</b></p> <pre>Device(configure)# ip mroute 10.1.1.1 255.255.255.255 10.2.2.2</pre> | The source IP address 10.1.1.1 is configured to be reachable through the interface associated with IP address 10.2.2.2. |
| Step 4 | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Device(config)# exit</pre>                                                                                                                                                                                                                                                                                 | Returns to privileged EXEC mode.                                                                                        |
| Step 5 | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Device# show running-config</pre>                                                                                                                                                                                                                                                           | (Optional) Verifies your entries.                                                                                       |
| Step 6 | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Device# copy running-config startup-config</pre>                                                                                                                                                                                                                             | (Optional) Saves your entries in the configuration file.                                                                |

## Configuring Optional IP Multicast Routing Features

### Defining the IP Multicast Boundary (CLI)

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.

This procedure is optional.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* **deny** *source* [*source-wildcard*]
4. **interface** *interface-id*
5. **ip multicast boundary** *access-list-number*
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

## DETAILED STEPS

## Configuring sdr Listener Support

### Enabling sdr Listener Support (CLI)

By default, the device does not listen to session directory advertisements.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **ip sap listen**
5. **end**

6. `show running-config`
7. `copy running-config startup-config`

## DETAILED STEPS

|               | Command or Action                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code>                                                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                 | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 3</b> | <b>interface <i>interface-id</i></b><br><b>Example:</b><br>Device(config)# <code>interface gigabitethernet 1/0/1</code> | Specifies the interface to be enabled for sdr, and enters interface configuration mode.<br><br>The specified interface must be one of the following: <ul style="list-style-type: none"> <li>• A routed port—A physical port that has been configured as a Layer 3 port by entering the <b>no switchport</b> interface configuration command. You will also need to enable IP PIM sparse-dense-mode on the interface, and join the interface as a statically connected member to an IGMP static group. For a configuration example, see <a href="#">Example: Interface Configuration as a Routed Port, on page 444</a></li> <li>• An SVI—A VLAN interface created by using the <b>interface vlan <i>vlan-id</i></b> global configuration command. You will also need to enable IP PIM sparse-dense-mode on the VLAN, join the VLAN as a statically connected member to an IGMP static group, and then enable IGMP snooping on the VLAN, the IGMP static group, and physical interface. For a configuration example, see <a href="#">Example: Interface Configuration as an SVI, on page 444</a></li> </ul> These interfaces must have IP addresses assigned to them. |
| <b>Step 4</b> | <b>ip sdr listen</b><br><b>Example:</b><br>Device(config-if)# <code>ip sdr listen</code>                                | Enables the device software to listen to session directory announcements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|        | Command or Action                                                                                                     | Purpose                                                  |
|--------|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 5 | <b>end</b><br><b>Example:</b><br><pre>Device(config-if)# end</pre>                                                    | Returns to privileged EXEC mode.                         |
| Step 6 | <b>show running-config</b><br><b>Example:</b><br><pre>Device# show running-config</pre>                               | Verifies your entries.                                   |
| Step 7 | <b>copy running-config startup-config</b><br><b>Example:</b><br><pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

### Limiting How Long an sdr Cache Entry Exists (CLI)

By default, entries are never deleted from the sdr cache. You can limit how long the entry remains active so that if a source stops advertising SAP information, old advertisements are not unnecessarily kept.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sap cache-timeout *minutes***
4. **end**
5. **show running-config**
6. **show ip sap**
7. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                                | Purpose                                                                                                            |
|--------|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Device&gt; enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b>                     | Enters the global configuration mode.                                                                              |

|               | Command or Action                                                                                                       | Purpose                                                                                                                                                                                                                          |
|---------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device# <code>configure terminal</code>                                                                                 |                                                                                                                                                                                                                                  |
| <b>Step 3</b> | <b>ip sap cache-timeout</b> <i>minutes</i><br><b>Example:</b><br>Device(config)# <code>ip sap cache-timeout 30</code>   | Limits how long a Session Announcement Protocol (SAP) cache entry stays active in the cache.<br><br>By default, entries are never deleted from the cache.<br><br>For <i>minutes</i> , the range is 1 to 1440 minutes (24 hours). |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                 |
| <b>Step 5</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                               | Verifies your entries.                                                                                                                                                                                                           |
| <b>Step 6</b> | <b>show ip sap</b><br><b>Example:</b><br>Device# <code>show ip sap</code>                                               | Displays the SAP cache.                                                                                                                                                                                                          |
| <b>Step 7</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                         |

## Monitoring and Maintaining Basic IP Multicast Routing

### Clearing Caches, Tables, and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure are or suspected to be invalid.

You can use any of the privileged EXEC commands in the following table to clear IP multicast caches, tables, and databases.

**Table 51: Commands for Clearing Caches, Tables, and Databases**

| Command                                                                                                                                                                                                              | Purpose                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <b>clear ip igmp group</b> { <b>group</b> [ <i>hostname</i>   <i>IP address</i> ]   <b>vrf name group</b> [ <i>hostname</i>   <i>IP address</i> ] }                                                                  | Deletes entries from the IGMP cache.                                                  |
| <b>clear ip mfib</b> { <b>counters</b> [ <i>group</i>   <i>source</i> ]   <b>global counters</b> [ <i>group</i>   <i>source</i> ]   <b>vrf *</b> }                                                                   | Clears all active IPv4 Multicast Forwarding Information Base (MFIB) traffic counters. |
| <b>clear ip mrm</b> { <b>status-report</b> [ <i>source</i> ] }                                                                                                                                                       | IP multicast routing clear commands.                                                  |
| <b>clear ip mroute</b> { *   [ <i>hostname</i>   <i>IP address</i> ]   <b>vrf name group</b> [ <i>hostname</i>   <i>IP address</i> ] }                                                                               | Deletes entries from the IP multicast routing table.                                  |
| <b>clear ip msdp</b> { <b>peer</b>   <b>sa-cache</b>   <b>statistics</b>   <b>vrf</b> }                                                                                                                              | Clears the Multicast Source Discovery Protocol (MSDP) cache.                          |
| <b>clear ip multicast</b> { <b>limit</b>   <b>redundancy statistics</b> }                                                                                                                                            | Clears the IP multicast information.                                                  |
| <b>clear ip pim</b> { <b>df</b> [ <i>int</i>   <b>rp</b> <i>rp address</i> ]   <b>interface</b>   <b>rp-mapping</b> [ <i>rp address</i> ]   <b>vrf vpn name</b> { <b>df</b>   <b>interface</b>   <b>rp-mapping</b> } | Clears the PIM cache.                                                                 |
| <b>clear ip sap</b> [ <i>group-address</i>   “ <i>session-name</i> ” ]                                                                                                                                               | Deletes the Session Directory Protocol Version 2 cache or an sdr cache entry.         |

## Displaying System and Network Statistics

You can display specific statistics, such as the contents of IP routing tables, caches, and databases.

**Note** This release does not support per-route statistics.

You can display information to learn resource usage and solve network problems. You can also display information about node reachability and discover the routing path that packets of your device are taking through the network.

You can use any of the privileged EXEC commands in the following table to display various routing statistics.

**Table 52: Commands for Displaying System and Network Statistics**

| Command                                                  | Purpose                                                  |
|----------------------------------------------------------|----------------------------------------------------------|
| <b>ping</b> [ <i>group-name</i>   <i>group-address</i> ] | Sends an ICMP Echo Request to a multicast group address. |
| <b>show ip igmp filter</b>                               | Displays IGMP filter information.                        |

| Command                                                                                                                                                                                      | Purpose                                                                                                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>show ip igmp groups</b><br>[ <i>group-name</i>   <i>group-address</i>   <i>type-number</i> ]                                                                                              | Displays the multicast groups that are directly connected to the device and that were learned through IGMP. |
| <b>show ip igmp interface</b> [ <i>type number</i> ]                                                                                                                                         | Displays multicast-related information about an interface.                                                  |
| <b>show ip igmp profile</b> [ <i>profile_number</i> ]                                                                                                                                        | Displays IGMP profile information.                                                                          |
| <b>show ip igmp ssm-mapping</b> [ <i>hostname/IP address</i> ]                                                                                                                               | Displays IGMP SSM mapping information.                                                                      |
| <b>show ip igmp static-group</b> { <b>class-map</b> [ <b>interface</b> [ <i>type</i> ] ]                                                                                                     | Displays static group information.                                                                          |
| <b>show ip igmp membership</b> [ <i>name/group address</i>   <b>all</b>   <b>tracked</b> ]                                                                                                   | Displays IGMP membership information for forwarding.                                                        |
| <b>show ip igmp vrf</b>                                                                                                                                                                      | Displays the selected VPN Routing/Forwarding instance by name.                                              |
| <b>show ip mfib</b> [ <i>type number</i> ]                                                                                                                                                   | Displays the IP multicast forwarding information base.                                                      |
| <b>show ip mrrib</b> { <b>client</b>   <b>route</b>   <b>vrf</b> }                                                                                                                           | Displays the multicast routing information base.                                                            |
| <b>show ip mrm</b> { <b>interface</b>   <b>manager</b>   <b>status-report</b> }                                                                                                              | Displays the IP multicast routing monitor information.                                                      |
| <b>show ip mroute</b> [ <i>group-name</i>   <i>group-address</i> ]<br>[ <i>source</i> ] [ <b>count</b>   <b>interface</b>   <b>proxy</b>   <b>pruned</b>   <b>summary</b>   <b>verbose</b> ] | Displays the contents of the IP multicast routing table.                                                    |
| <b>show ip msdp</b> { <b>count</b>   <b>peer</b>   <b>rpf-peer</b>   <b>sa-cache</b>   <b>summary</b>   <b>vrf</b> }                                                                         | Displays the Multicast Source Discovery Protocol (MSDP) information.                                        |
| <b>show ip multicast</b> [ <b>interface</b>   <b>limit</b>   <b>mpls</b>   <b>redundancy</b>   <b>vrf</b> ]                                                                                  | Displays global multicast information.                                                                      |
| <b>show ip pim all-vrfs</b> { <b>tunnel</b> }                                                                                                                                                | Display all VRFs.                                                                                           |
| <b>show ip pim autorp</b>                                                                                                                                                                    | Display global auto-RP information.                                                                         |
| <b>show ip pim boundary</b> [ <i>type number</i> ]                                                                                                                                           | Displays boundary information.                                                                              |
| <b>show ip pim bsr-router</b>                                                                                                                                                                | Display bootstrap router information (version 2).                                                           |
| <b>show ip pim interface</b> [ <i>type number</i> ] [ <b>count</b>   <b>detail</b>   <b>df</b>   <b>stats</b> ]                                                                              | Displays information about interfaces configured for PIM. This command is available in all software images. |
| <b>show ip pim neighbor</b> [ <i>type number</i> ]                                                                                                                                           | Lists the PIM neighbors discovered by the device. This command is available in all software images.         |

| Command                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show ip pim mdt [ bgp ]</code>                          | Displays multicast tunnel information.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>show ip pim rp [group-name   group-address]</code>      | Displays the RP routers associated with a sparse-mode multicast group. This command is available in all software images.                                                                                                                                                                                                                                                                                                              |
| <code>show ip pim rp-hash [group-name   group-address]</code> | Displays the RP to be chosen based upon the group selected.                                                                                                                                                                                                                                                                                                                                                                           |
| <code>show ip pim tunnel [ tunnel   verbose ]</code>          | Displays the registered tunnels.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>show ip pim vrf name</code>                             | Displays VPN routing and forwarding instances.                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>show ip rpf {source-address   name}</code>              | <p>Displays how the device is doing Reverse-Path Forwarding (that is, from the unicast routing table, DVMRP routing table, or static mroutes).</p> <p>Command parameters include:</p> <ul style="list-style-type: none"> <li>• <i>Host name</i> or <i>IP address</i>—IP name or group address.</li> <li>• <b>Select</b>—Group-based VRF select information.</li> <li>• <b>vrf</b>—Selects VPN Routing/Forwarding instance.</li> </ul> |
| <code>show ip sap [group   "session-name"   detail]</code>    | <p>Displays the Session Announcement Protocol (SAP) Version 2 cache.</p> <p>Command parameters include:</p> <ul style="list-style-type: none"> <li>• <i>A.B.C.D</i>—IP group address.</li> <li>• <i>WORD</i>—Session name (in double quotes).</li> <li>• <b>detail</b>—Session details.</li> </ul>                                                                                                                                    |

## Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing

You can use the privileged EXEC commands in the following table to monitor IP multicast routers, packets, and paths.

*Table 53: Commands for Displaying Multicast Peers, Packet Rates and Loss Information, and Path Tracing*

| Command                                            | Purpose                                                                                                        |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>mrinfo { [hostname   address]   vrf }</code> | Queries a multicast router or multilayer device about which neighboring multicast devices are peering with it. |
| <code>mstat { [hostname   address]   vrf }</code>  | Displays IP multicast packet rate and information loss.                                                        |

| Command                                            | Purpose                                                                                                    |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>mtrace { [hostname   address]   vrf }</code> | Traces the path from a source to a destination branch for a multicast distribution tree for a given group. |

## Configuration Examples for IP Multicast Routing

### Example: Configuring an IP Multicast Boundary

This example shows how to set up a boundary for all administratively-scoped addresses:

```
Device(config)# access-list 1 deny 239.0.0.0 0.255.255.255
Device(config)# access-list 1 permit 224.0.0.0 15.255.255.255
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip multicast boundary 1
```

#### Related Topics

### Example: Responding to mroute Requests

The software answers mroute requests sent by mrouter systems and Cisco routers and multilayer devices. The software returns information about neighbors through DVMRP tunnels and all the routed interfaces. This information includes the metric (always set to 1), the configured TTL threshold, the status of the interface, and various flags. You can also use the `mroute` privileged EXEC command to query the router or device itself, as in this example:

```
Device# mroute
171.69.214.27 (mm1-7kd.cisco.com) [version cisco 11.1] [flags: PMS]:
171.69.214.27 -> 171.69.214.26 (mm1-r7kb.cisco.com) [1/0/pim/querier]
171.69.214.27 -> 171.69.214.25 (mm1-45a.cisco.com) [1/0/pim/querier]
171.69.214.33 -> 171.69.214.34 (mm1-45c.cisco.com) [1/0/pim]
171.69.214.137 -> 0.0.0.0 [1/0/pim/querier/down/leaf]
171.69.214.203 -> 0.0.0.0 [1/0/pim/querier/down/leaf]
171.69.214.18 -> 171.69.214.20 (mm1-45e.cisco.com) [1/0/pim]
171.69.214.18 -> 171.69.214.19 (mm1-45c.cisco.com) [1/0/pim]
171.69.214.18 -> 171.69.214.17 (mm1-45a.cisco.com) [1/0/pim]
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions for Configuring the Service Discovery Gateway

The following are restrictions for configuring the Service Discovery Gateway:

- The Service Discovery Gateway does not support topologies with multiple hops. All network segments must be connected directly to it. The Service Discovery Gateway can learn services from all connected segments to build its cache and respond to requests acting as a proxy.
- The use of third-party mDNS servers or applications are not supported with this feature.

# Information about the Service Discovery Gateway and mDNS

## mDNS

mDNS was defined to achieve zero configuration, with zero configuration being defined as providing the following features:

- Addressing—Allocating IP addresses to hosts
- Naming—Using names to refer to hosts instead of IP addresses
- Service discovery—Finding services automatically on the network

With mDNS, network users no longer have to assign IP addresses, assign host names, or type in names to access services on the network. Users only need to ask to see what network services are available, and choose from a list.

With mDNS, *addressing* is accomplished through the use of DHCP/DHCPv6 or IPv4 and IPv6 Link Local scoped addresses. The benefit of zero-configuration occurs when no infrastructure services such as DHCP or DNS are present and self-assigned link-local addressing can be used. The client can then select a random IPv4 address in the link-local range (169.254.0.0/24) or use its IPv6 link-local address (FE80::/10) for communication.

With mDNS, *naming* (name-to-address translation on a local network using mDNS) queries are sent over the local network using link-local scoped IP multicast. Because these DNS queries are sent to a multicast address (IPv4 address 224.0.0.251 or IPv6 address FF02::FB), no single DNS server with global knowledge is required to answer the queries. When a service or device sees a query for any service it is aware of, it provides a DNS response with the information from its cache.

With mDNS, *service discovery* is accomplished by browsing. An mDNS query is sent out for a given service type and domain, and any device that is aware of matching services replies with service information. The result is a list of available services for the user to choose from.

The mDNS protocol (mDNS-RFC), together with DNS Service Discovery (DNS-SD-RFC) achieves the zero-configuration addressing, naming, and service discovery.

## mDNS-SD

Multicast DNS Service Discovery (mDNS-SD) uses DNS protocol semantics and multicast over well-known multicast addresses to achieve zero configuration service discovery. DNS packets are sent to and received on port 5353 using a multicast address of 224.0.0.251 and its IPv6 equivalent FF02::FB.

Because mDNS uses a link-local multicast address, its scope is limited to a single physical or logical LAN. If the networking reach needs to be extended to a distributed campus or to a wide-area environment consisting of many different networking technologies, mDNS gateway is implemented. An mDNS gateway provides a transport for mDNS packets across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain to another.

### mDNS-SD Considerations for Wireless Clients

- mDNS packets can be sent out of Layer 3 interfaces that might not have an IP address.
- Packets with mDNS multicast IP and multicast MAC are sent on a multicast CAPWAP tunnel, if multicast-multicast mode is enabled. A multicast CAPWAP tunnel is a special CAPWAP tunnel used

for reducing the number of copies of multicast packet that are required to be generated for each AP CAPWAP tunnel. Sending packets on the multicast CAPWAP tunnel requires the outer IP header to be destined to the multicast CAPWAP tunnel's address, which all APs are subscribed to.

- All mDNS packet handling is done at a foreign switch for roamed clients. A foreign switch is the new switch that a roamed wireless client is actually attached to, which is called the point of attachment.

## Service Discovery Gateway

The Service Discovery Gateway feature enables multicast Domain Name System (mDNS) to operate across Layer 3 boundaries (different subnets). An mDNS gateway provides transport for service discovery across Layer 3 boundaries by filtering, caching, and redistributing services from one Layer 3 domain (subnet) to another. Prior to implementation of this feature, mDNS was limited in scope to within a subnet because of the use of link-local scoped multicast addresses. This feature enhances Bring Your Own Device (BYOD).

## mDNS Gateway and Subnets

You need to enable an mDNS gateway for service discovery to operate across subnets. You can enable mDNS gateway for a device or for an interface.

**Note** You need to configure service routing globally before configuring at the interface level.

After the device or interface is enabled, you can redistribute service discovery information across subnets. You can create service policies and apply filters on either incoming service discovery information (called IN-bound filtering) or outgoing service discovery information (called OUT-bound filtering).

**Note** If redistribution is enabled globally, global configuration is given higher priority than interface configuration.

### *Figure 31: Sample Networking Scenario*

For example, if the mDNS gateway functionality is enabled on the router in this figure, then service information can be sent from one subnet to another and vice-versa. For example, the printer and fax service information being advertised in the network with IP address 192.0.2.6 are redistributed to the network with IP address 198.51.100.4. The printer and fax service information in the network with IP address 192.0.2.6 is learned by

mDNS-enabled hosts and devices in the other network.

## Filtering

After configuring the mDNS gateway and subnets, you can filter services that you want to redistribute. While creating a service list, the **permit** or **deny** command options are used:

- The **permit** command option allows you to permit or transport specific service list information.
- The **deny** option allows you to deny service list information that is available to be transported to other subnets.

You need to include a sequence number when using the **permit** or **deny** command option. The same service list name can be associated with multiple sequence numbers and each sequence number will be mapped to a rule.

**Note** If no filters are configured, then the default action is to deny service list information to be transported through the device or interface.

Query is another option provided when creating service lists. You can create queries using a service list. If you want to browse for a service, then active queries can be used. This function is helpful to keep the records refreshed in the cache.

**Note** Active queries can only be used globally and cannot be used at the interface level.

A service end-point (such as a printer or fax) sends unsolicited announcements when a service starts up. After that, it sends unsolicited announcements whenever a network change event occurs (such as an interface coming up or going down). The device always respond to queries.

After creating a service list and using the **permit** or **deny** command options, you can filter using match statements (commands) based on *service-instance*, *service-type*, or *message-type* (announcement or query).

# How to Configure the Service Discovery Gateway

## Configuring the Service List (CLI)

This procedure describes how to create a service list, apply a filter for the service list, and configure parameters for the service list name.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **service-list mdns-sd** *service-list-name* {**deny** *sequence-number* | **permit** *sequence-number* | **query**}
4. **match message-type** {**announcement** | **any** | **query**}
5. **match service-instance** { *LINE* }
6. **match service-type** {*LINE* }
7. **end**

### DETAILED STEPS

|        | Command or Action                                                                 | Purpose                                                                                                               |

| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                         | Enables privileged EXEC mode.<br><ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters the global configuration mode.                                                                                 |

|               | Command or Action                                                                                                                                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>service-list mdns-sd</b> <i>service-list-name</i> {<b>deny</b> <i>sequence-number</i>   <b>permit</b> <i>sequence-number</i>   <b>query</b>}</p> <p><b>Example:</b></p> <pre>Device(config)# <b>service-list mdns-sd s11 permit 3</b></pre> <pre>Device(config)# <b>service-list mdns-sd s14 query</b></pre> | <p>Enters mDNS service discovery service list mode. In this mode, you can:</p> <ul style="list-style-type: none"> <li>• Create a service list and apply a filter on the service list according to the <b>permit</b> or <b>deny</b> option applied to the sequence number.</li> <li>• Create a service list and associate a query for the service list name if the <b>query</b> option is used.</li> </ul> <p><b>Note</b> The sequence number sets the priority of the rule. A rule with a lower sequence number is selected first and the service announcement or query is allowed or denied accordingly. You define the sequence number as per your network requirements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 4</b> | <p><b>match message-type</b> {<b>announcement</b>   <b>any</b>   <b>query</b>}</p> <p><b>Example:</b></p> <pre>Device(config-mdns-sd-sl)# <b>match message-type announcement</b></pre>                                                                                                                             | <p>(Optional) Sets the message type to match. You can match the following message types:</p> <ul style="list-style-type: none"> <li>• announcement</li> <li>• any</li> <li>• query</li> </ul> <p>These commands configure the parameters for the service list name that is created in step 2.</p> <p>If the <b>match message-type</b> is an announcement, then the service list rule only allows service advertisements or announcements for the device. If the <b>match message-type</b> is a query, then only a query from the client for a certain service in the network is allowed.</p> <p>Multiple service maps of the same name with different sequence numbers can be created and the evaluation of the filters will be ordered on the sequence number. Service lists are an ordered sequence of individual statements, each one has a permit or deny result. Evaluation of service list consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is stopped once the first statement match is found and an action permit/deny associated with the statement match is performed. The default action after scanning through the entire list is to deny.</p> <p><b>Note</b> You cannot use the <b>match</b> command if you have used the <b>query</b> option in the previous step. The <b>match</b> command can be used only for the <b>permit</b> or <b>deny</b> option.</p> |

|        | Command or Action                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <p><b>match service-instance</b> { <i>LINE</i> }</p> <p><b>Example:</b></p> <pre>Device(config-mdns-sd-sl)## match service-instance servInst 1</pre> | <p>(Optional) Sets the service instance to match.</p> <p>This command configures the parameters for the service list name that is created in step 2.</p> <p><b>Note</b> You cannot use the <b>match</b> command if you have used the <b>query</b> option in the previous step. The <b>match</b> command can be used only for the <b>permit</b> or <b>deny</b> option.</p>                      |
| Step 6 | <p><b>match service-type</b> { <i>LINE</i> }</p> <p><b>Example:</b></p> <pre>Device(config-mdns-sd-sl)# match service-type _ipp._tcp</pre>           | <p>(Optional) Sets the value of the mDNS service type string to match.</p> <p>This command configures the parameters for the service list name that is created in step 2.</p> <p><b>Note</b> You cannot use the <b>match</b> command if you have used the <b>query</b> option in the previous step. The <b>match</b> command can be used only for the <b>permit</b> or <b>deny</b> option.</p> |
| Step 7 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config-mdns-sd-sl)# end</pre>                                                                   | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                        |

**What to do next**

Proceed to enable the mDNS gateway and redistribution of services.

## Enabling mDNS Gateway and Redistributing Services (CLI)

After enabling mDNS gateway for a device, you can apply filters (apply IN-bound filtering or OUT-bound filtering) and active queries by using **service-policy** and **service-policy-query** commands, respectively. You can redistribute services and service announcements using the **redistribute mdns-sd** command, and set some part of the system memory for cache using the **cache-memory-max** command.

**Note** By default, mDNS gateway is disabled on all interfaces.

**SUMMARY STEPS**

1. **enable**

2. **configure terminal**
3. **service-routing mdns-sd**
4. **service-policy *service-policy-name* {IN | OUT}**
5. **redistribute mdns-sd**
6. **cache-memory-max *cache-config-percentage***
7. **service-policy-query *service-list-query-name* *service-list-query-periodicity***
8. **exit**
9. **wireless multicast**
10. **no wireless mdns-bridging**
11. **end**

|               | Command or Action                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                  | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                          | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 3</b> | <b>service-routing mdns-sd</b><br><b>Example:</b><br>Device (config)# <b>service-routing mdns-sd</b>                                       | Enables mDNS gateway functionality for a device and enters multicast DNS configuration (config-mdns) mode. <p><b>Note</b> This command enables the mDNS function globally.</p> <p><b>Note</b> Enter the <b>service-routing mdns-sd source-interface <i>if-name</i></b> command in either global-config or interface-config mode, to specify an alternate source interface for outgoing mDNS packets, so its IP address can be used when there is none configured on the outgoing interface.</p> |
| <b>Step 4</b> | <b>service-policy <i>service-policy-name</i> {IN   OUT}</b><br><b>Example:</b><br>Device (config-mdns)# <b>service-policy serv-poll IN</b> | (Optional) For a service list, applies a filter on incoming service discovery information (IN-bound filtering) or outgoing service discovery information (OUT-bound filtering).                                                                                                                                                                                                                                                                                                                 |
| <b>Step 5</b> | <b>redistribute mdns-sd</b><br><b>Example:</b>                                                                                             | (Optional) Redistributes services or service announcements across subnets.                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                | Command or Action                                                                                                                                                                         | Purpose                                                                                                                                                                                                                |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Device (config-mdns)# <b>redistribute mdns-sd</b>                                                                                                                                         | <b>Note</b> If redistribution is enabled globally, global configuration is given higher priority than interface configuration.                                                                                         |
| <b>Step 6</b>  | <b>cache-memory-max</b> <i>cache-config-percentage</i><br><b>Example:</b><br>Device (config-mdns)# <b>cache-memory-max 20</b>                                                             | (Optional) Sets some part of the system memory (in percentage) for cache.<br><b>Note</b> By default, 10 percent of the system memory is set aside for cache. You can override the default value by using this command. |
| <b>Step 7</b>  | <b>service-policy-query</b> <i>service-list-query-name</i><br><i>service-list-query-periodicity</i><br><b>Example:</b><br>Device (config-mdns)# <b>service-policy-query s1-query1 100</b> | (Optional) Configures service list-query periodicity.                                                                                                                                                                  |
| <b>Step 8</b>  | <b>exit</b><br><b>Example:</b><br>Device (config-mdns)# <b>exit</b>                                                                                                                       | (Optional) Returns to global configuration mode.                                                                                                                                                                       |
| <b>Step 9</b>  | <b>wireless multicast</b><br><b>Example:</b><br>Device (config)# <b>wireless multicast</b>                                                                                                | (Optional) Enables wireless Ethernet multicast support.                                                                                                                                                                |
| <b>Step 10</b> | <b>no wireless mdns-bridging</b><br><b>Example:</b><br>Device (config)# <b>no wireless mdns-bridging</b>                                                                                  | (Optional) Disables bridging of mDNS packets to wireless clients.                                                                                                                                                      |
| <b>Step 11</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                                                               | Returns to privileged EXEC mode.                                                                                                                                                                                       |

## Monitoring Service Discovery Gateway

Table 54: Monitoring Service Discovery Gateway

| Command                                                                                                          | Purpose                                                                                                             |
|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>show mdns requests [detail   name record-name  type record-type [ name record-name]]</code>                | This command displays information for outstanding mDNS requests, including record name and record type information. |
| <code>show mdns cache [interface type number   name record-name [type record-type]  type record-type]</code>     | This command displays mDNS cache information.                                                                       |
| <code>show mdns statistics {all   service-list list-name   service-policy {all   interface type number }}</code> | This command displays mDNS statistics.                                                                              |

## Configuration Examples

### Example: Specify Alternative Source Interface for Outgoing mDNS Packets

The following example displays how to specify an alternate source interface for outgoing mDNS packets, so its IP address can be used when there is none configured on the outgoing interface.

```
Device(config)# service-routing mdns-sd
Device(config-mdns)# source-interface if-name
```

### Example: Redistribute Service Announcements

The following example displays how to redistribute service announcements received on one interface over all the interfaces or over a specific interface.

```
Device(config)# service-routing mdns-sd
Device(config-mdns)# Redistribute mdns-sd if-name
```

## Example: Disable Bridging of mDNS Packets to Wireless Clients

The following example displays how to disable bridging of mDNS packets to wireless clients.

```
Device(config)# wireless multicast
Device(config)# no wireless mdns-bridging
```

## Example: Creating a Service-List, Applying a Filter and Configuring Parameters

The following example shows the creation of a service-list s11. The **permit** command option is being applied on sequence number 3 and all services with message-type announcement are filtered and available for transport across various subnets associated with the device.

```
Device# configure terminal
Device(config)# service-list mdns-sd s11 permit 3
Device(config-mdns-sd-s1) #match message-type announcement
Device(config-mdns) # exit
```

## Example: Enabling mDNS Gateway and Redistributing Services

The following example shows how to enable an mDNS gateway for a device and enable redistribution of services across subnets. IN-bound filtering is applied on the service-list serv-poll. Twenty percent of system memory is made available for cache and service-list-query periodicity is configured at 100 seconds.

```
Device# configure terminal
Device# service-routing mdns-sd
Device(config-mdns) # service-policy serv-poll IN
Device(config-mdns) # redistribute mdns-sd
Device(config-mdns) # cache-memory-max 20
Device(config-mdns) # service-policy-query s1-query1 100
Device(config-mdns) # exit
```

## Example: Global mDNS Configuration

The following example displays how to globally configure mDNS.

```
Device# configure terminal
Device(config)# service-list mdns-sd mypermit-all permit 10
Device(config-mdns-sd-s1)# exit
Device(config)# service-list mdns-sd querier query
Device(config-mdns-sd-s1)# service-type _dns._udp
Device(config-mdns-sd-s1)# end
Device# configure terminal
Device(config)# service-routing mdns-sd
Device(config-mdns)# service-policy mypermit-all IN
Device(config-mdns)# service-policy mypermit-all OUT
```

## Example: Interface mDNS Configuration

The following example displays how to configure mDNS for an interface.

```
Device(config)#interface Vlan136
Device(config-if)# description *** Mgmt VLAN ***
Device(config-if)# ip address 9.7.136.10 255.255.255.0
Device(config-if)# ip helper-address 9.1.0.100
Device(config-if)# service-routing mdns-sd
Device(config-if-mdns-sd)# service-policy mypermit-all IN
Device(config-if-mdns-sd)# service-policy mypermit-all OUT
Device(config-if-mdns-sd)# service-policy-query querier 60
```

## Where to Go Next for Configuring Services Discovery Gateway

You can configure the following:

- IGMP

- Wireless Multicast
- PIM
- SSM
- IP Multicast Routing

## Prerequisites for Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

- You must have PIM sparse mode running in your network.
- If you plan to use a group list to control to which groups the shortest-path tree (SPT) threshold applies, you must have configured your access list before performing the task.

## Information About Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

### PIM Registering Process

IP multicast sources do not use a signaling mechanism to announce their presence. Sources just send their data into the attached network, as opposed to receivers that use Internet Group Management Protocol (IGMP) to announce their presence. If a source sends traffic to a multicast group configured in PIM sparse mode (PIM-SM), the Designated Router (DR) leading toward the source must inform the rendezvous point (RP) about the presence of this source. If the RP has downstream receivers that want to receive the multicast traffic (natively) from this source and has not joined the shortest path leading toward the source, then the DR must

send the traffic from the source to the RP. The PIM registering process, which is individually run for each (S, G) entry, accomplishes these tasks between the DR and RP.

The registering process begins when a DR creates a new (S, G) state. The DR encapsulates all the data packets that match the (S, G) state into PIM register messages and unicasts those register messages to the RP.

If an RP has downstream receivers that want to receive register messages from a new source, the RP can either continue to receive the register messages through the DR or join the shortest path leading toward the source. By default, the RP will join the shortest path, because delivery of native multicast traffic provides the highest throughput. Upon receipt of the first packet that arrives natively through the shortest path, the RP will send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

If an RP has no downstream receivers that want to receive register messages from a new source, the RP will not join the shortest path. Instead, the RP will immediately send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

Once a routing entry is established for a source, a periodic reregistering takes place between the DR and RP. One minute before the multicast routing table state times out, the DR will send one dataless register message to the RP each second that the source is active until the DR receives a register-stop message from the RP.

This action restarts the timeout time of the multicast routing table entry, typically resulting in one reregistering exchange every 2 minutes. Reregistering is necessary to maintain state, to recover from lost state, and to keep track of sources on the RP. It will take place independently of the RP joining the shortest path.

## PIM Version 1 Compatibility

If an RP is running PIM Version 1, it will not understand dataless register messages. In this case, the DR will not send dataless register messages to the RP. Instead, approximately every 3 minutes after receipt of a register-stop message from the RP, the DR encapsulates the incoming data packets from the source into register messages and sends them to the RP. The DR continues to send register messages until it receives another register-stop message from the RP. The same behavior occurs if the DR is running PIM Version 1.

When a DR running PIM Version 1 encapsulates data packets into register messages for a specific (S, G) entry, the entry is process-switched, not fast-switched or hardware-switched. On platforms that support these faster paths, the PIM registering process for an RP or DR running PIM Version 1 may lead to periodic out-of-order packet delivery. For this reason, we recommend upgrading your network from PIM Version 1 to PIM Version 2.

## PIM Designated Router

Devices configured for IP multicast send PIM hello messages to determine which device will be the designated router (DR) for each LAN segment (subnet). The hello messages contain the device's IP address, and the device with the highest IP address becomes the DR.

The DR sends Internet Group Management Protocol (IGMP) host query messages to all hosts on the directly connected LAN. When operating in sparse mode, the DR sends source registration messages to the rendezvous point (RP).

By default, multicast devices send PIM router query messages every 30 seconds. By enabling a device to send PIM hello messages more often, the device can discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently. It is appropriate to make this change only on redundant devices on the edge of the network.

## PIM Sparse-Mode Register Messages

Dataless register messages are sent at a rate of one message per second. Continuous high rates of register messages might occur if a DR is registering bursty sources (sources with high data rates) and if the RP is not running PIM Version 2.

By default, PIM sparse-mode register messages are sent without limiting their rate. Limiting the rate of register messages will limit the load on the DR and RP, at the expense of dropping those register messages that exceed the set limit. Receivers may experience data packet loss within the first second in which packets are sent from bursty sources.

## Preventing Use of Shortest-Path Tree to Reduce Memory Requirement

Understanding PIM shared tree and source tree will help you understand how preventing the use of the shortest-path tree can reduce memory requirements.

### PIM Shared Tree and Source Tree

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

**Figure 32: Shared Tree and Source Tree (Shortest-Path Tree)**

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software devices to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.

3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.
4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.
5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.
6. By default, reception of the first data packet prompts Router C to send a join message toward the source.
7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.
8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the **ip pim spt-threshold** global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

#### Related Topics

[Delaying the Use of PIM Shortest-Path Tree \(CLI\)](#), on page 511

## Benefit of Preventing or Delaying the Use of the Shortest-Path Tree

The switch from shared to source tree happens upon the arrival of the first data packet at the last hop device (Router C in [PIM Shared Tree and Source Tree](#), on page 482). This switch occurs because the **ip pim spt-threshold** command controls that timing, and its default setting is 0 kbps.

The shortest-path tree requires more memory than the shared tree, but reduces delay. You might want to prevent or delay its use to reduce memory requirements. Instead of allowing the leaf device to move to the shortest-path tree immediately, you can prevent use of the SPT or specify that the traffic must first reach a threshold.

You can configure when a PIM leaf device should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified *kbps* rate, the device triggers a PIM Join message toward the source to construct a source tree (shortest-path tree). If the **infinity** keyword is specified, all sources for the specified group use the shared tree, never switching to the source tree.

# How to Optimize PIM Sparse Mode in a Large IP Multicast Deployment

## Optimizing PIM Sparse Mode in a Large Deployment

Consider performing this task if your deployment of IP multicast is large.

Steps 3, 5, and 6 in this task are independent of each other and are therefore considered optional. Any one of these steps will help optimize PIM sparse mode. If you are going to perform Step 5 or 6, you must perform Step 4. Step 6 applies only to a designated router; changing the PIM query interval is only appropriate on redundant routers on the edge of the PIM domain.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip pim register-rate-limit** *rate*
4. **ip pim spt-threshold** *{kbps| infinity}***[group-list** *access-list***]**
5. **interface** *type number*
6. **ip pim query-interval** *period* **[msec]**

### DETAILED STEPS

|        | Command or Action                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                             | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 3 | <b>ip pim register-rate-limit</b> <i>rate</i><br><b>Example:</b><br><pre>Router(config)# ip pim register-rate-limit 10</pre> | (Optional) Sets a limit on the maximum number of PIM sparse mode register messages sent per second for each (S, G) routing entry. <ul style="list-style-type: none"> <li>• Use this command to limit the number of register messages that the designated router (DR) will allow for each (S, G) entry.</li> <li>• By default, there is no maximum rate set.</li> <li>• Configuring this command will limit the load on the DR and RP at the expense of dropping those register messages that exceed the set limit.</li> </ul> |

|               | Command or Action                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|               |                                                                                                                                                                                               | <ul style="list-style-type: none"> <li>Receivers may experience data packet loss within the first second in which register messages are sent from bursty sources.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 4</b> | <p><b>ip pim spt-threshold</b> <i>{kpbs  infinity}</i>[<b>group-list</b> <i>access-list</i>]</p> <p><b>Example:</b></p> <pre>Router(config)# ip pim spt-threshold infinity group-list 5</pre> | <p>(Optional) Specifies the threshold that must be reached before moving to the shortest-path tree.</p> <ul style="list-style-type: none"> <li>The default value is <b>0</b>, which causes the router to join the SPT immediately upon the first data packet it receives.</li> <li>Specifying the <b>infinity</b> keyword causes the router never to move to the shortest-path tree; it remains on the shared tree. This keyword applies to a multicast environment of “many-to-many” communication.</li> <li>The group list is a standard access list that controls which groups the SPT threshold applies to. If a value of 0 is specified or the group list is not used, the threshold applies to all groups.</li> <li>In the example, group-list 5 is already configured to permit the multicast groups 239.254.2.0 and 239.254.3.0:           <pre>access-list 5 permit 239.254.2.0 0.0.0.255 access-list 5 permit 239.254.3.0 0.0.0.255</pre> </li> </ul> |
| <b>Step 5</b> | <p><b>interface</b> <i>type number</i></p> <p><b>Example:</b></p> <pre>Router(config)# interface ethernet 0</pre>                                                                             | <p>Configures an interface.</p> <ul style="list-style-type: none"> <li>If you do not want to change the default values of the PIM SPT threshold or the PIM query interval, do not perform this step; you are done with this task.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 6</b> | <p><b>ip pim query-interval</b> <i>period</i> [msec]</p> <p><b>Example:</b></p> <pre>Router(config-if)# ip pim query-interval 1</pre>                                                         | <p>(Optional) Configures the frequency at which multicast routers send PIM router query messages.</p> <ul style="list-style-type: none"> <li>Perform this step only on redundant routers on the edge of a PIM domain.</li> <li>The default query interval is 30 seconds.</li> <li>The <i>period</i> argument is in seconds unless the <b>msec</b> keyword is specified.</li> <li>Set the query interval to a smaller number of seconds for faster convergence, but keep in mind the trade-off between faster convergence and higher CPU and bandwidth usage.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                         |

# Configuration Examples for Optimizing PIM Sparse Mode in a Large Multicast Deployment

## Optimizing PIM Sparse Mode in a Large IP Multicast Deployment Example

The following example shows how to:

- Set the query interval to 1 second for faster convergence.
- Configure the router to never move to the SPT but to remain on the shared tree.
- Set a limit of 10 PIM sparse mode register messages sent per second for each (S, G) routing entry.

```
interface ethernet 0
 ip pim query-interval 1
 .
 .
 .
 !
 ip pim spt-threshold infinity
 ip pim register-rate-limit 10
 !
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Multicast Subsecond Convergence

Service providers must have a multicast-enabled core in order to use the Cisco Multicast Subsecond Convergence feature.

## Restrictions for Multicast Subsecond Convergence

Devices that use the subsecond designated router (DR) failover enhancement must be able to process hello interval information arriving in milliseconds. Devices that are congested or do not have enough CPU cycles to process the hello interval can assume that the Protocol Independent Multicast (PIM) neighbor is disconnected, although this may not be the case.

# Information About Multicast Subsecond Convergence

## Benefits of Multicast Subsecond Convergence

- The scalability components improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content).
- New algorithms and processes (such as aggregated join messages, which deliver up to 1000 individual messages in a single packet) reduce the time to reach convergence by a factor of 10.
- Multicast subsecond convergence improves service availability for large multicast networks.
- Multicast users such as financial services firms and brokerages receive better quality of service (QoS), because multicast functionality is restored in a fraction of the time previously required.

## Multicast Subsecond Convergence Scalability Enhancements

The Multicast Subsecond Convergence feature provides scalability enhancements that improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content). Scalability enhancements in this release include the following:

- Improved Internet Group Management Protocol (IGMP) and PIM state maintenance through new timer management techniques
- Improved scaling of the Multicast Source Discovery Protocol (MSDP) Source-Active (SA) cache

The scalability enhancements provide the following benefits:

- Increased potential PIM multicast route (mroute), IGMP, and MSDP SA cache state capacity
- Decreased CPU usage

## PIM Router Query Messages

Multicast subsecond convergence allows you to send PIM router query messages (PIM hellos) every few milliseconds. The PIM hello message is used to locate neighboring PIM devices. Before the introduction of this feature, the device could send the PIM hellos only every few seconds. By enabling a device to send PIM hello messages more often, this feature allows the device to discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently.

### Related Topics

[Modifying the PIM Router Query Message Interval](#), on page 657

[Modifying the PIM Router Query Message Interval Example](#), on page 660

## Reverse Path Forwarding

Unicast Reverse Path Forwarding (RPF) helps to mitigate problems caused by the introduction of malformed or forged IP source addresses into a network by discarding IP packets that lack a verifiable IP source address.

Malformed or forged source addresses can indicate denial-of-service (DoS) attacks based on source IP address spoofing.

RPF uses access control lists (ACLs) in determining whether to drop or forward data packets that have malformed or forged IP source addresses. An option in the ACL commands allows system administrators to log information about dropped or forwarded packets. Logging information about forged packets can help in uncovering information about possible network attacks.

Per-interface statistics can help system administrators quickly discover the interface serving as the entry point for an attack on the network.

## RPF Checks

PIM is designed to forward IP multicast traffic using the standard unicast routing table. PIM uses the unicast routing table to decide if the source of the IP multicast packet has arrived on the optimal path from the source. This process, the RPF check, is protocol-independent because it is based on the contents of the unicast routing table and not on any particular routing protocol.

### Related Topics

[Modifying the Periodic RPF Check Interval](#), on page 656

[Example Modifying the Periodic RPF Check Interval](#), on page 659

## Triggered RPF Checks

Multicast subsecond convergence provides the ability to trigger a check of RPF changes for mroute states. This check is triggered by unicast routing changes. By performing a triggered RPF check, users can set the periodic RPF check to a relatively high value (for example, 10 seconds) and still fail over quickly.

The triggered RPF check enhancement reduces the time needed for service to be restored after disruption, such as for single service events (for example, in a situation with one source and one receiver) or as the service scales along any parameter (for example, many sources, many receivers, and many interfaces). This enhancement decreases in time-to-converge PIM (mroute), IGMP, and MSDP (SA cache) states.

## RPF Failover

In an unstable unicast routing environment that uses triggered RPF checks, the environment could be constantly triggering RPF checks, which places a burden on the resources of the device. To avoid this problem, use the **ip multicast rpf backoff** command to prevent a second triggered RPF check from occurring for the length of time configured. That is, the PIM “backs off” from another triggered RPF check for a minimum amount of milliseconds as configured by the user.

If the backoff period expires without further routing table changes, PIM then scans for routing changes and accordingly establishes multicast RPF changes. However, if more routing changes occur during the backoff period, PIM doubles the backoff period to avoid overloading the device with PIM RPF changes while the routing table is still converging.

[Example Configuring PIM RPF Failover Intervals](#), on page 660

## Topology Changes and Multicast Routing Recovery

The Multicast Subsecond Convergence feature set enhances both enterprise and service provider network backbones by providing almost instantaneous recovery of multicast paths after unicast routing recovery.

Because PIM relies on the unicast routing table to calculate its RPF when a change in the network topology occurs, unicast protocols first need to calculate options for the best paths for traffic, and then multicast can determine the best path.

Multicast subsecond convergence allows multicast protocol calculations to finish almost immediately after the unicast calculations are completed. As a result, multicast traffic forwarding is restored substantially faster after a topology change.

## How to Configure Multicast Subsecond Convergence

### Modifying the Periodic RPF Check Interval

Perform this optional task to modify the intervals at which periodic RPF checks occur.

#### Note

Cisco recommends that you do *not* change the default values for the **ip rpf interval** command. The default values allow subsecond RPF failover. The default interval at which periodic RPF checks occur is 10 seconds.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip multicast rpf interval** *seconds* [**list** *access-list* | **route-map** *route-map*]

#### DETAILED STEPS

|        | Command or Action                                                                                                                                                                         | Purpose                                                                                                            |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> enable                                                                                                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                                                                                                | Enters global configuration mode.                                                                                  |
| Step 3 | <b>ip multicast rpf interval</b> <i>seconds</i> [ <b>list</b> <i>access-list</i>   <b>route-map</b> <i>route-map</i> ]<br><b>Example:</b><br>Device(config)# ip multicast rpf interval 10 | Configures the periodic RPF check intervals to occur at a specified interval, in seconds.                          |

**Verifying Multicast Subsecond Convergence Configurations**

Perform this task to display detailed information about and to verify information regarding the Multicast Subsecond Convergence feature.

**SUMMARY STEPS**

1. **enable**
2. **show ip pim interface** *type number*
3. **show ip pim neighbor**

## DETAILED STEPS

### Step 1 enable

#### Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

### Step 2 show ip pim interface *type number*

Use this command to display information about interfaces configured for PIM.

The following is sample output from the **show ip pim interface** command:

#### Example:

```
Device# show ip pim interface GigabitEthernet 1/0/0
Address      Interface          Ver/   Nbr   Query  DR    DR
              Mode              Count  Intvl Prior
172.16.1.4   GigabitEthernet1/0/0 v2/S   1     100 ms 1     172.16.1.4
```

### Step 3 show ip pim neighbor

Use this command to display the PIM neighbors discovered by the Cisco IOS XE software.

The following is sample output from the **show ip pim neighbor** command:

#### Example:

```
Device# show ip pim neighbor
PIM Neighbor Table
Neighbor      Interface          Uptime/Expires  Ver  DR
Address      Prio/Mode
172.16.1.3   GigabitEthernet1/0/0 00:03:41/250 msec v2   1 / S
```

# Configuration Examples for Multicast Subsecond Convergence

## Example Modifying the Periodic RPF Check Interval

In the following example, the **ip multicast rpf interval** has been set to 10 seconds. This command does not show up in **show running-config** output unless the interval value has been configured to be the nondefault value.

```
!
ip multicast-routing
ip multicast rpf interval 10
.
.
.
interface Ethernet0/0
 ip address 172.16.2.1 255.255.255.0
```

```

.
.
.
ip pim sparse-mode
!

```

## Example Configuring PIM RPF Failover Intervals

In the following example, the **ip multicast rpf backoff** command has been configured with a minimum backoff interval value of 100 and a maximum backoff interval value of 2500. This command does not show up in **show running-config** command output unless the interval value has been configured to be the nondefault value.

```

!
ip multicast-routing
.
.
.
ip multicast rpf backoff 100 2500
!
!
interface Ethernet0/0
 ip address 172.16.2.1 255.255.255.0
.
.
.
ip pim sparse-mode
!

```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for IP Multicast Load Splitting across Equal-Cost Paths

IP multicast is enabled on the device using the tasks described in the “Configuring Basic IP Multicast” module of the *IP Multicast: PIM Configuration Guide*.

# Information About IP Multicast Load Splitting across Equal-Cost Paths

## Load Splitting Versus Load Balancing

Load splitting and load balancing are not the same. Load splitting provides a means to randomly distribute (\*, G) and (S, G) traffic streams across multiple equal-cost reverse path forwarding (RPF) paths, which does not necessarily result in a balanced IP multicast traffic load on those equal-cost RPF paths. By randomly distributing (\*, G) and (S, G) traffic streams, the methods used for load splitting IP multicast traffic attempt to distribute an equal amount of traffic flows on each of the available RPF paths not by counting the flows, but, rather, by making a pseudorandom decision. These methods are collectively referred to as equal-cost multipath (ECMP) multicast load splitting methods and result in better load-sharing in networks where there are many traffic streams that utilize approximately the same amount of bandwidth.

If there are just a few (S, G) or (\*, G) states flowing across a set of equal-cost links, the chance that they are well balanced is quite low. To overcome this limitation, precalculated source addresses--for (S, G) states or rendezvous point (RP) addresses for (\*, G) states, can be used to achieve a reasonable form of load balancing. This limitation applies equally to the per-flow load splitting in Cisco Express Forwarding (CEF) or with EtherChannels: As long as there are only a few flows, those methods of load splitting will not result in good load distribution without some form of manual engineering.

## Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist

By default, for Protocol Independent Multicast sparse mode (PIM-SM), Source Specific Multicast (PIM-SSM), bidirectional PIM (bidir-PIM), and PIM dense mode (PIM-DM) groups, if multiple equal-cost paths are available, Reverse Path Forwarding (RPF) for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address. This method is referred to as the highest PIM neighbor behavior. This behavior is in accordance with RFC 2362 for PIM-SM, but also applies to PIM-SSM, PIM-DM, and bidir-PIM.

The figure illustrates a sample topology that is used in this section to explain the default behavior for IP multicast when multiple equal-cost paths exist.

---

**Note** Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

---

Figure 33: Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist

In the figure, two sources, S1 and S2, are sending traffic to IPv4 multicast groups, G1 and G2. Either PIM-SM, PIM-SSM, or PIM-DM can be used in this topology. If PIM-SM is used, assume that the default of 0 for the `ip pim spt-threshold` command is being used on Device 2, that an Interior Gateway Protocol (IGP) is being run, and that the output of the `show ip route` command for S1 and for S2 (when entered on Device 2) displays serial interface 0 and serial interface 1 on Device 1 as equal-cost next-hop PIM neighbors of Device 2.

Without further configuration, IPv4 multicast traffic in the topology illustrated in the figure would always flow across one serial interface (either serial interface 0 or serial interface 1), depending on which interface has the higher IP address. For example, suppose that the IP addresses configured on serial interface 0 and serial interface 1 on Device 1 are 10.1.1.1 and 10.1.2.1, respectively. Given that scenario, in the case of PIM-SM and PIM-SSM, Device 2 would always send PIM join messages towards 10.1.2.1 and would always receive IPv4 multicast traffic on serial interface 1 for all sources and groups shown in the figure. In the case of PIM-DM, Device 2 would always receive IP multicast traffic on serial interface 1, only that in this case, PIM join messages are not used in PIM-DM; instead Device 2 would prune the IP multicast traffic across serial interface 0 and would receive it through serial interface 1 because that interface has the higher IP address on Device 1.

IPv4 RPF lookups are performed by intermediate multicast device to determine the RPF interface and RPF neighbor for IPv4 (\*,G) and (S, G) multicast routes (trees). An RPF lookup consists of RPF route-selection and route-path-selection. RPF route-selection operates solely on the IP unicast address to identify the root of the multicast tree. For (\*, G) routes (PIM-SM and Bidir-PIM), the root of the multicast tree is the RP address for the group G; for (S, G) trees (PIM-SM, PIM-SSM and PIM-DM), the root of the multicast tree is the source S. RPF route-selection finds the best route towards the RP or source in the routing information base (RIB), and, if configured (or available), the Distance Vector Multicast Routing Protocol (DVMRP) routing table, the Multiprotocol Border Gateway Protocol (MBGP) routing table or configured static mroutes. If the resulting route has only one available path, then the RPF lookup is complete, and the next-hop device and interface of the route become the RPF neighbor and RPF interface of this multicast tree. If the route has more than one path available, then route-path-selection is used to determine which path to choose.

For IP multicast, the following route-path-selection methods are available:

**Note** All methods but the default method of route-path-selection available in IP multicast enable some form of ECMP multicast load splitting.

- Highest PIM neighbor--This is the default method; thus, no configuration is required. If multiple equal-cost paths are available, RPF for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address; as a result, without configuration, ECMP multicast load splitting is disabled by default.

- ECMP multicast load splitting method based on source address--You can configure ECMP multicast load splitting using the **ip multicast multipath** command. Entering this form of the **ip multicast multipath** command enables ECMP multicast load splitting based on source address using the S-hash algorithm. For more information, see the [ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm, on page 666](#) section.
- ECMP multicast load splitting method based on source and group address--You can configure ECMP multicast load splitting using the **ip multicast multipath** command with the **s-g-hash** and **basic** keywords. Entering this form of the **ip multicast multipath** command enables ECMP multicast load splitting based on source and group address using the basic S-G-hash algorithm. For more information, see the [ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm, on page 667](#) section.
- ECMP multicast load splitting method based on source, group, and next-hop address--You can configure ECMP multicast load splitting using the **ip multicast multipath** command with the **s-g-hash** and **next-hop-based** keywords. Entering this form of the command enables ECMP multicast load splitting based on source, group, and next-hop address using the next-hop-based S-G-hash algorithm. For more information, see the [ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address, on page 668](#) section.

The default behavior (the highest PIM neighbor behavior) does not result in any form of ECMP load-splitting in IP multicast, but instead selects the PIM neighbor that has the highest IP address among the next-hop PIM neighbors for the available paths. A next hop is considered to be a PIM neighbor when it displays in the output of the **show ip pim neighbor** command, which is the case when PIM hello messages have been received from it and have not timed out. If none of the available next hops are PIM neighbors, then simply the next hop with the highest IP address is chosen.

## Methods to Load Split IP Multicast Traffic

In general, the following methods are available to load split IP multicast traffic:

- You can enable ECMP multicast load splitting based on source address, based on source and group address, or based on source, group, and next-hop address. After the equal-cost paths are recognized, ECMP multicast load splitting operates on a per (S, G) basis, rather than a per packet basis as in unicast traffic.
- Alternative methods to load split IP multicast are to consolidate two or more equal-cost paths into a generic routing encapsulation (GRE) tunnel and allow the unicast routing protocol to perform the load splitting, or to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, Multilink PPP (MLPPP) link bundles, or Multilink Frame Relay (FR.16) link bundles.

## Overview of ECMP Multicast Load Splitting

By default, ECMP multicast load splitting of IPv4 multicast traffic is disabled. ECMP multicast load splitting can be enabled using the **ip multicast multipath** command.

### ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm

ECMP multicast load splitting traffic based on source address uses the S-hash algorithm, enabling the RPF interface for each (\*, G) or (S, G) state to be selected among the available equal-cost paths, depending on the

RPF address to which the state resolves. For an (S, G) state, the RPF address is the source address of the state; for a (\*, G) state, the RPF address is the address of the RP associated with the group address of the state.

When ECMP multicast load splitting based on source address is configured, multicast traffic for different states can be received across more than just one of the equal-cost interfaces. The method applied by IPv4 multicast is quite similar in principle to the default per-flow load splitting in IPv4 CEF or the load splitting used with Fast and Gigabit EtherChannels. This method of ECMP multicast load splitting, however, is subject to polarization.

#### Related Topics

[Enabling ECMP Multicast Load Splitting Based on Source Address](#), on page 674

[Example Enabling ECMP Multicast Load Splitting Based on Source Address](#), on page 680

## ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm

ECMP multicast load splitting based on source and group address uses a simple hash, referred to as the basic S-G-hash algorithm, which is based on source and group address. The basic S-G-hash algorithm is predictable because no randomization is used in coming up with the hash value. The S-G-hash mechanism, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device this hash is being calculated on.

---

**Note** The basic S-G-hash algorithm ignores bidir-PIM groups.

---

#### Related Topics

[Enabling ECMP Multicast Load Splitting Based on Source and Group Address](#), on page 676

[Example Enabling ECMP Multicast Load Splitting Based on Source and Group Address](#), on page 680

## Predictability As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The method used by ECMP multicast load splitting in IPv4 multicast allows for consistent load splitting in a network where the same number of equal-cost paths are present in multiple places in a topology. If an RP address or source addresses are calculated once to have flows split across N paths, then they will be split across those N paths in the same way in all places in the topology. Consistent load splitting allows for predictability, which, in turn, enables load splitting of IPv4 multicast traffic to be manually engineered.

## Polarization As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The hash mechanism used in IPv4 multicast to load split multicast traffic by source address or by source and group address is subject to a problem usually referred to as polarization. A by-product of ECMP multicast load splitting based on source address or on source and group address, polarization is a problem that prevents routers in some topologies from effectively utilizing all available paths for load splitting.

The figure illustrates a sample topology that is used in this section to explain the problem of polarization when configuring ECMP multicast load splitting based on source address or on source and group address.

---

**Note** Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

---

Figure 34: Polarization Topology

In the topology illustrated in the figure, notice that Router 7 has two equal-cost paths towards the sources, S1 to S10, through Router 5 and Router 6. For this topology, suppose that ECMP multicast load splitting is enabled with the **ip multicast multipath** command on all routers in the topology. In that scenario, Router 7 would apply equal-cost load splitting to the 10 (S, G) states. The problem of polarization in this scenario would affect Router 7 because that router would end up choosing serial interface 0 on Router 5 for sources S1 to S5 and serial interface 1 on Router 6 for sources S6 to S10. The problem of polarization, furthermore, would also affect Router 5 and Router 6 in this topology. Router 5 has two equal-cost paths for S1 to S5 through serial interface 0 on Router 1 and serial interface 1 on Router 2. Because Router 5 would apply the same hash algorithm to select which of the two paths to use, it would end up using just one of these two upstream paths for sources S1 to S5; that is, either all the traffic would flow across Router 1 and Router 5 or across Router 2 and Router 5. It would be impossible in this topology to utilize Router 1 and Router 5 and Router 2 and Router 5 for load splitting. Likewise, the polarization problem would apply to Router 3 and Router 6 and Router 4 and Router 6; that is, it would be impossible in this topology to utilize both Router 3 and Router 6 and Router 4 and Router 6 for load splitting.

## ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address

Configuring ECMP multicast load splitting based on source, group, and next-hop address enables a more complex hash, the next-hop-based S-G-hash algorithm, which is based on source, group, and next-hop address. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

**Note** The next-hop-based S-G-hash algorithm in IPv4 multicast is the same algorithm used in IPv6 ECMP multicast load splitting, which, in turn, utilizes the same hash function used for PIM-SM bootstrap device (BSR).

The next-hop-based hash mechanism does not produce polarization and also maintains better RPF stability when paths fail. These benefits come at the cost that the source or RP IP addresses cannot be used to reliably predict and engineer the outcome of load splitting when the next-hop-based S-G-hash algorithm is used. Because many customer networks have implemented equal-cost multipath topologies, the manual engineering of load splitting, thus, is not a requirement in many cases. Rather, it is more of a requirement that the default behavior of IP multicast be similar to IP unicast; that is, it is expected that IP multicast use multiple equal-cost paths on a best-effort basis. Load splitting for IPv4 multicast, therefore, could not be enabled by default because of the anomaly of polarization.

---

**Note** Load splitting for CEF unicast also uses a method that does not exhibit polarization and likewise cannot be used to predict the results of load splitting or engineer the outcome of load splitting.

---

The next-hop-based hash function avoids polarization because it introduces the actual next-hop IP address of PIM neighbors into the calculation, so the hash results are different for each device, and in effect, there is no problem of polarization. In addition to avoiding polarization, this hash mechanism also increases stability of the RPF paths chosen in the face of path failures. Consider a device with four equal-cost paths and a large number of states that are load split across these paths. Suppose that one of these paths fails, leaving only three available paths. With the hash mechanism used by the polarizing hash mechanisms (the hash mechanism used by the S-hash and basic S-G-hash algorithms), the RPF paths of all states would likely reconverge and thus change between those three paths, especially those paths that were already using one of those three paths. These states, therefore, may unnecessarily change their RPF interface and next-hop neighbor. This problem exists simply because the chosen path is determined by taking the total number of paths available into consideration by the algorithm, so once a path changes, the RPF selection for all states is subject to change too. For the next-hop-based hash mechanism, only the states that were using the changed path for RPF would need to reconverge onto one of the three remaining paths. The states that were already using one of those paths would not change. If the fourth path came back up, the states that initially used it would immediately reconverge back to that path without affecting the other states.

---

**Note** The next-hop-based S-G-hash algorithm ignores bidir-PIM groups.

## Effect of ECMP Multicast Load Splitting on PIM Neighbor Query and Hello Messages for RPF Path Selection

If load splitting of IP multicast traffic over ECMP is *not* enabled and there are multiple equal-cost paths towards an RP or a source, IPv4 multicast will first elect the highest IP address PIM neighbor. A PIM neighbor is a device from which PIM hello (or PIMv1 query) messages are received. For example, consider a device that has two equal-cost paths learned by an IGP or configured through two static routes. The next hops of these two paths are 10.1.1.1 and 10.1.2.1. If both of these next-hop devices send PIM hello messages, then 10.1.2.1 would be selected as the highest IP address PIM neighbor. If only 10.1.1.1 sends PIM hello messages, then 10.1.1.1 would be selected. If neither of these devices sends PIM hello messages, then 10.1.2.1 would be selected. This deference to PIM hello messages allows the construction of certain types of dynamic failover scenarios with only static multicast routes (mroutes); it is otherwise not very useful.

---

**Note** For more information about configuring static mroutes, see the [Configuring Multiple Static Mroutes in Cisco IOS](#) configuration note on the Cisco IOS IP multicast FTP site, which is available at: <ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt>.

---

When load splitting of IP multicast traffic over ECMP is enabled, the presence of PIM hello message from neighbors is not considered; that is, the chosen RPF neighbor does not depend on whether or not PIM hello

messages are received from that neighbor--it only depends on the presence or absence of an equal-cost route entry.

## Effect of ECMP Multicast Loading Splitting on Assert Processing in PIM-DM and DF Election in Bidir-PIM

The **ip multicast multipath** command only changes the RPF selection on the downstream device; it does not have an effect on designated forwarder (DF) election in bidir-PIM or the assert processing on upstream devices in PIM-DM.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on assert processing in PIM-DM and DF election in bidir-PIM.

**Note** Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

**Figure 35: ECMP Multicast Load Splitting and Assert Processing in PIM-DM and DF Election in Bidir-PIM**

In the figure, Device 2 has two equal-cost paths to S1 and S2 and the RP addresses on Device 1. Both paths are across Gigabit Ethernet interface 1/0/0: one path towards Device 3 and one path towards Device 4. For PIM-SM and PIM-SSM (\*, G) and (S, G) RPF selection, there is no difference in the behavior of Device 2 in this topology versus Device 2 in the topology illustrated in the figure. There is, however, a difference when using PIM-DM or bidir-PIM.

If PIM-DM is used in the topology illustrated in the figure, Device 3 and Device 4 would start flooding traffic for the states onto Gigabit Ethernet interface 1/0/0 and would use the PIM assert process to elect one device among them to forward the traffic and to avoid traffic duplication. As both Device 3 and Device 4 would have the same route cost, the device with the higher IP address on Gigabit Ethernet interface 1/0/0 would always win the assert process. As a result, if PIM-DM is used in this topology, traffic would not be load split across Device 3 and Device 4.

If bidir-PIM is used in the topology illustrated in the figure, a process called DF election would take place between Device 2, Device 3, and Device 4 on Gigabit Ethernet interface 1/0/0. The process of DF election would elect one device for each RP to forward traffic across Gigabit Ethernet interface 1/0/0 for any groups using that particular RP, based on the device with the highest IP address configured for that interface. Even if multiple RPs are used (for example one for G1 and another one for G2), the DF election for those RPs would always be won by the device that has the higher IP address configured on Gigabit Ethernet interface 1/0/0 (either Device 3 or Device 4 in this topology). The election rules used for DF election are virtually the same as the election rules used for the PIM assert process, only the protocol mechanisms to negotiate them

are more refined for DF election (in order to return the results more expediently). As a result, when bidir-PIM is used in this topology, load splitting would always occur across Gigabit Ethernet interface 1/0/0.

The reason that ECMP multicast load splitting does influence the RPF selection but not the assert process in PIM-DM or DF election in bidir-PIM is because both the assert process and DF election are cooperative processes that need to be implemented consistently between participating devices. Changing them would require some form of protocol change that would also need to be agreed upon by the participating devices. RPF selection is a purely device local policy and, thus, can be enabled or disabled without protocol changes individually on each device.

For PIM-DM and bidir-PIM, configuring ECMP multicast load splitting with the **ip multicast multipath** command is only effective in topologies where the equal-cost paths are not upstream PIM neighbors on the same LAN, but rather neighbors on different LANs or point-to-point links.

## Effect of ECMP Multicast Load Splitting on the PIM Assert Process in PIM-SM and PIM-SSM

There are also cases where ECMP multicast load splitting with the **ip multicast multipath** command can become ineffective due to the PIM assert process taking over, even when using PIM-SM with (\*, G) or (S, G) forwarding or PIM-SSM with (S, G) forwarding.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on the PIM assert process in PIM-SM and PIM-SSM.

**Note** Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

**Figure 36: ECMP Multicast Load Splitting and the PIM Assert Process in PIM-SM and PIM-SSM**

In the topology illustrated in the figure, if both Device 2 and Device 5 are Cisco devices and are consistently configured for ECMP multicast load splitting with the **ip multicast multipath** command, then load splitting would continue to work as expected; that is, both devices would have Device 3 and Device 4 as equal-cost next hops and would sort the list of equal-cost paths in the same way (by IP address). When applying the multipath hash function, for each (S, G) or (\*, G) state, they would choose the same RPF neighbor (either Device 3 or Device 4) and send their PIM joins to this neighbor.

If Device 5 and Device 2 are inconsistently configured with the **ip multicast multipath** command, or if Device 5 is a third-party device, then Device 2 and Device 5 may choose different RPF neighbors for some (\*, G) or (S, G) states. For example Device 2 could choose Device 3 for a particular (S, G) state or Device 5 could choose Device 4 for a particular (S, G) state. In this scenario, Device 3 and Device 4 would both start to forward traffic for that state onto Gigabit Ethernet interface 1/0/0, see each other's forwarded traffic, and--to

avoid traffic duplication--start the assert process. As a result, for that (S, G) state, the device with the higher IP address for Gigabit Ethernet interface 1/0/0 would forward the traffic. However, both Device 2 and Device 5 would be tracking the winner of the assert election and would send their PIM joins for that state to this assert winner, even if this assert winner is not the same device as the one that they calculated in their RPF selection. For PIM-SM and PIM-SSM, therefore, the operation of ECMP multicast load splitting can only be guaranteed when all downstream devices on a LAN are consistently configured Cisco devices.

## ECMP Multicast Load Splitting and Reconvergence When Unicast Routing Changes

When unicast routing changes, all IP multicast routing states reconverge immediately based on the available unicast routing information. Specifically, if one path goes down, the remaining paths reconverge immediately, and if the path comes up again, multicast forwarding will subsequently reconverge to the same RPF paths that were used before the path failed. Reconvergence occurs whether load splitting of IP multicast traffic over ECMP is configured or not.

## Use of BGP with ECMP Multicast Load Splitting

ECMP multicast load splitting works with RPF information learned through BGP in the same way as with RPF information learned from other protocols: It chooses one path out of the multiple paths installed by the protocol. The main difference with BGP is that it only installs a single path, by default. For example, when a BGP speaker learns two identical external BGP (eBGP) paths for a prefix, it will choose the path with the lowest device ID as the best path. The best path is then installed in the IP routing table. If BGP multipath support is enabled and the eBGP paths are learned from the same neighboring AS, instead of picking the single best path, BGP installs multiple paths in the IP routing table. By default, BGP will install only one path to the IP routing table.

To leverage ECMP multicast load splitting for BGP learned prefixes, you must enable BGP multipath. Once configured, when BGP installs the remote next-hop information, RPF lookups will execute recursively to find the best next hop towards that BGP next hop (as in unicast). If for example there is only a single BGP path for a given prefix, but there are two IGP paths to reach that BGP next hop, then multicast RPF will correctly load split between the two different IGP paths.

## Use of ECMP Multicast Load Splitting with Static Mroutes

If it is not possible to use an IGP to install equal cost routes for certain sources or RPs, static routes can be configured to specify the equal-cost paths for load splitting. You cannot use static mroutes to configure equal-cost paths because the software does not support the configuration of one static mroute per prefix. There are some workarounds for this limitation using recursive route lookups but the workarounds cannot be applied to equal-cost multipath routing.

**Note** For more information about configuring static mroutes, see the [Configuring Multiple Static Mroutes in Cisco IOS](http://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt) configuration note on the Cisco IOS IP multicast FTP site at [ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt](http://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt).

You can specify only static mroutes for equal-cost multipaths in IPv4 multicast; however, those static mroutes would only apply to multicast, or you can specify that the equal-cost multipaths apply to both unicast and multicast routing. In IPv6 multicast, there is no such restriction. Equal-cost multipath mroutes can be configured for static IPv6 mroutes that apply to only unicast routing, only multicast routing, or both unicast and multicast routing.

## Alternative Methods of Load Splitting IP Multicast Traffic

Load splitting of IP multicast traffic can also be achieved by consolidating multiple parallel links into a single tunnel over which the multicast traffic is then routed. This method of load splitting is more complex to configure than ECMP multicast load splitting. One such case where configuring load splitting across equal-cost paths using GRE links can be beneficial is the case where the total number of (S, G) or (\*, G) states is so small and the bandwidth carried by each state so variable that even the manual engineering of the source or RP addresses cannot guarantee the appropriate load splitting of the traffic.

---

**Note** With the availability of ECMP multicast load splitting, tunnels typically only need to be used if per-packet load sharing is required.

---

IP multicast traffic can also be used to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, MLPPP link bundles or Multilink Frame Relay (FRF.16) bundles. GRE or other type of tunnels can also constitute such forms of Layer 2 link bundles. Before using such a Layer 2 mechanism, it is necessary to understand how unicast and multicast traffic is load split.

Before load splitting IP multicast traffic across equal-cost paths over a tunnel, you must configure CEF per-packet load balancing or else the GRE packets will not be load balanced per packet.

## How to Load Split IP Multicast Traffic over ECMP

### Enabling ECMP Multicast Load Splitting

Perform the following tasks to load split IP multicast traffic across multiple equal-cost paths, based on source address.

If two or more equal-cost paths from a source are available, unicast traffic will be load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the RPF neighbor. According to PIM specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.

Configuring load splitting with the **ip multicast multipath** command causes the system to load split multicast traffic across multiple equal-cost paths based on source address using the S-hash algorithm. When the **ip multicast multipath** command is configured and multiple equal-cost paths exist, the path in which multicast traffic will travel is selected based on the source IP address. Multicast traffic from different sources will be load split across the different equal-cost paths. Load splitting will not occur across equal-cost paths for multicast traffic from the same source sent to different multicast groups.

---

**Note** The **ip multicast multipath** command load splits the traffic and does not load balance the traffic. Traffic from a source will use only one path, even if the traffic far outweighs traffic from other sources.

---

### Prerequisites for IP Multicast Load Splitting - ECMP

- You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.

- You must have multiple paths available to the RP to configure ECMP multicast load splitting.

---

**Note** Use the **show ip route** command with either the IP address of the source for the *ip-address* argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

---

- When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.
- Before configuring ECMP multicast load splitting, it is best practice to use the **show ip rpf** command to validate whether sources can take advantage of IP multicast multipath capabilities.
- BGP does not install multiple equal-cost paths by default. Use the **maximum-paths** command to configure multipath (for example in BGP). For more information, see the [Use of BGP with ECMP Multicast Load Splitting, on page 672](#) section.

## Restrictions

- If two or more equal-cost paths from a source are available, unicast traffic will be load split across those paths. However, by default, multicast traffic is not load split across multiple equal-cost paths. In general, multicast traffic flows down from the RPF neighbor. According to PIM specifications, this neighbor must have the highest IP address if more than one neighbor has the same metric.
- The **ip multicast multipath** command does not support configurations in which the same PIM neighbor IP address is reachable through multiple equal-cost paths. This situation typically occurs if unnumbered interfaces are used. Use different IP addresses for all interfaces when configuring the **ip multicast multipath** command.
- The **ip multicast multipath** command load splits the traffic and does not load balance the traffic. Traffic from a source will use only one path, even if the traffic far outweighs traffic from other sources.

## Enabling ECMP Multicast Load Splitting Based on Source Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source address (using the S-hash algorithm) to take advantage of multiple paths through the network. The S-hash algorithm is predictable because no randomization is used in calculating the hash value. The S-hash algorithm, however, is subject to polarization because for a given source, the same hash is always picked irrespective of the device on which the hash is being calculated.

---

**Note** Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

---

**Before you begin**

- You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.
- You must have multiple paths available to the RP to configure ECMP multicast load splitting.

**Note** Use the **show ip route** command with either the IP address of the source for the *ip-address* argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

- When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.
- Before configuring ECMP multicast load splitting, it is best practice to use the **show ip rpf** command to validate whether sources can take advantage of IP multicast multipath capabilities.
- BGP does not install multiple equal-cost paths by default. Use the **maximum-paths** command to configure multipath (for example in BGP). For more information, see the [Use of BGP with ECMP Multicast Load Splitting, on page 672](#) section.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip multicast multipath**
4. Repeat step 3 on all the devices in a redundant topology.
5. **exit**
6. **show ip rpf** *source-address* [*group-address*]
7. **show ip route** *ip-address*

**DETAILED STEPS**

## Enabling ECMP Multicast Load Splitting Based on Source and Group Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source and group address (using the basic S-G-hash algorithm) to take advantage of multiple paths through the network. The

basic S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. The basic S-G-hash algorithm, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device on which the hash is being calculated.

The basic S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than the the S-hash algorithm. Using the basic S-G-hash algorithm for load splitting, in particular, enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

**Note** Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip multicast multipath s-g-hash basic**
4. Repeat Step 3 on all the devices in a redundant topology.
5. **exit**
6. **show ip rpf source-address [group-address]**
7. **show ip route ip-address**

**Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address**

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source, group, and next-hop address (using the next-hop-based S-G-hash algorithm) to take advantage of multiple paths through the network. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

The next-hop-based S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than S-hash algorithm and eliminates the polarization problem. Using the next-hop-based S-G-hash algorithm for ECMP multicast load splitting enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

**SUMMARY STEPS**

- enable**
- configure terminal**
- ip multicast multipath s-g-hash next-hop-based**
- Repeat Steps 1 through 3 on all the routers in a redundant topology.
- end**
- show ip rpf** *source-address* [*group-address*]
- show ip route** *ip-address*

## DETAILED STEPS

|               | Command or Action                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Router&gt; enable</pre>                                                                                      | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Router# configure terminal</pre>                                                                 | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 3</b> | <b>ip multicast multipath s-g-hash next-hop-based</b><br><b>Example:</b><br><pre>Router(config)# ip multicast multipath s-g-hash next-hop-based</pre> | Enables ECMP multicast load splitting based on source, group, and next-hop-address using the next-hop-based S-G-hash algorithm. <ul style="list-style-type: none"> <li>• Because this command changes the way an RPF neighbor is selected, it must be configured consistently on all routers in a redundant topology to avoid looping.</li> </ul> <p><b>Note</b> Be sure to enable the <b>ip multicast multipath</b> command on the router that is supposed to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending router connecting to more than one outgoing interfaces.</p> |
| <b>Step 4</b> | Repeat Steps 1 through 3 on all the routers in a redundant topology.                                                                                  | --                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br><pre>Router(config)# end</pre>                                                                                       | Exits global configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 6</b> | <b>show ip rpf source-address [group-address]</b><br><b>Example:</b><br><pre>Router# show ip rpf 10.1.1.2</pre>                                       | (Optional) Displays the information that IP multicast routing uses to perform the RPF check. <ul style="list-style-type: none"> <li>• Use this command to verify RPF selection so as to ensure that IP multicast traffic is being properly load split.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 7</b> | <b>show ip route ip-address</b><br><b>Example:</b><br><pre>Router# show ip route 10.1.1.2</pre>                                                       | (Optional) Displays the current state of the IP routing table. <ul style="list-style-type: none"> <li>• Use this command to verify that there multiple paths available to a source or RP for ECMP multicast load splitting.</li> <li>• For the <i>ip-address</i> argument, enter the IP address of a source to validate that there are multiple paths available</li> </ul>                                                                                                                                                                                                                                                                                                                               |

|  | Command or Action | Purpose                                                                                                                                              |
|--|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
|  |                   | to the source (for shortest path trees) or the IP address of an RP to validate that there are multiple paths available to the RP (for shared trees). |

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for SSM Channel Based Filtering for Multicast Boundaries

IP multicast is enabled on the device using the tasks described in the "Configuring Basic IP Multicast" module of the *IP Multicast: PIM Configuration Guide*.

# Information About the SSM Channel Based Filtering for Multicast Boundaries Feature

## Rules for Multicast Boundaries

The SSM Channel Based Filtering for Multicast Boundaries feature expands the **ip multicast boundary** command for control plane filtering support. More than one **ip multicast boundary** command can be applied to an interface.

The following rules govern the **ip multicast boundary** command:

- One instance of the **in** and **out** keywords can be configured on an interface.
- The **in** and **out** keywords can be used for standard or extended access lists.
- Only standard access lists are permitted with the use of the **filter-autorp** keyword or no keyword.
- A maximum of three instances of a command will be allowed on an interface: one instance of **in**, one instance of **out**, and one instance of **filter-autorp** or no keyword.
- When multiple instances of the command are used, the filtering will be cumulative. If a boundary statement with no keyword exists with a boundary statement with the **in** keyword, both access lists will be applied on the in direction and a match on either one will be sufficient.
- All instances of the command apply to both control and data plane traffic.
- Protocol information on the extended access list is parsed to allow reuse and filtering for consistency. An (S,G) operation will be filtered by an extended access list under all conditions stated above for keywords if the access list filters (S,G) traffic for all protocols.

## Benefits of SSM Channel Based Filtering for Multicast Boundaries

- This feature allows input on the source interface.
- The access control capabilities are the same for SSM and Any Source Multicast (ASM).

# How to Configure SSM Channel Based Filtering for Multicast Boundaries

## Configuring Multicast Boundaries

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list {standard| extended} access-list-name**
4. **permit protocol host address host address**
5. **deny protocol host address host address**
6. Repeat Step 4 or Step 5 as needed.
7. **interface type interface-number port -number**
8. **ip multicast boundary access-list-name [in| out | filter-autorp]**

### DETAILED STEPS

|        | Command or Action                                                                                                                             | Purpose                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> enable                                                                                            | Enables privileged EXEC mode.                           |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                                                    | Enters global configuration mode.                       |
| Step 3 | <b>ip access-list {standard  extended} access-list-name</b><br><b>Example:</b><br>Device(config)# ip access-list 101                          | Configures the standard or extended access list.        |
| Step 4 | <b>permit protocol host address host address</b><br><b>Example:</b><br>Device(config-ext-nacl)# permit ip host 181.1.2.201<br>host 232.1.1.11 | Permits specified ip host traffic.                      |
| Step 5 | <b>deny protocol host address host address</b><br><b>Example:</b><br>Device(config-acl-nacl)# deny ip host 181.1.2.203<br>host 232.1.1.1      | Denies specified multicast ip group and source traffic. |

|               | Command or Action                                                                                                                                                                  | Purpose                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 6</b> | Repeat Step 4 or Step 5 as needed.                                                                                                                                                 | Permits and denies specified host and source traffic.                                                                          |
| <b>Step 7</b> | <b>interface</b> <i>type</i> <b>interface-number</b> <i>port-number</i><br><b>Example:</b><br>Device(config)# interface gigabitethernet 2/3/0                                      | Enables interface configuration mode.                                                                                          |
| <b>Step 8</b> | <b>ip multicast boundary</b> <i>access-list-name</i> [ <b>in</b>   <b>out</b>   <b>filter-autorp</b> ]<br><b>Example:</b><br>Device(config-if)# ip multicast boundary acc_grp1 out | Configures the multicast boundary.<br><br><b>Note</b> The <b>filter-autorp</b> keyword does not support extended access lists. |

## Configuration Examples for SSM Channel Based Filtering for Multicast Boundaries

### Configuring the Multicast Boundaries Permitting and Denying Traffic Example

The following example permits outgoing traffic for (181.1.2.201, 232.1.1.1) and (181.1.2.202, 232.1.1.1) and denies all other (S,G)s.

```
configure terminal
ip access-list extended acc_grp1
permit ip host 0.0.0.0 232.1.1.1 0.0.0.255
permit ip host 181.1.2.201 host 232.1.1.1
permit udp host 181.1.2.202 host 232.1.1.1
permit ip host 181.1.2.202 host 232.1.1.1
deny igmp host 181.2.3.303 host 232.1.1.1
interface gigabitethernet 2/3/0
ip multicast boundary acc_grp1 out
```

### Configuring the Multicast Boundaries Permitting Traffic Example

The following example permits outgoing traffic for (192.168.2.201, 232.1.1.5) and (192.168.2.202, 232.1.1.5).

```

configure terminal
ip access-list extended acc_grp6
 permit ip host 0.0.0.0 232.1.1.1 5.0.0.255
 deny udp host 192.168.2.201 host 232.1.1.5
 permit ip host 192.168.2.201 host 232.1.1.5
 deny pim host 192.168.2.201 host 232.1.1.5
 permit ip host 192.168.2.202 host 232.1.1.5
 deny igmp host 192.2.3.303 host 232.1.1.1
interface gigabitethernet 2/3/0
 ip multicast boundary acc_grp6 out

```

## Configuring the Multicast Boundaries Denying Traffic Example

The following example denies a group-range that is announced by the candidate RP. Because the group range is denied, no pim auto-rp mappings are created.

```

configure terminal
ip access-list standard acc_grp10
 deny 225.0.0.0 0.255.255.255
 permit any
access-list extended acc_grp12
 permit pim host 181.1.2.201 host 232.1.1.8
 deny udp host 181.1.2.201 host 232.1.1.8
 permit pim host 181.1.2.203 0.0.0.255 host 227.7.7.7
 permit ip host 0.0.0.0 host 227.7.7.7
 permit ip 181.1.2.203 0.0.0.255 host 227.7.7.7
 permit ip host 181.1.2.201 host 232.1.1.7
ip access-list extended acc_grp13
 deny ip host 181.1.2.201 host 232.1.1.8
 permit ip any any
interface gigabitethernet 2/3/0
 ip multicast boundary acc_grp10 filter-autorp
 ip multicast boundary acc_grp12 out
 ip multicast boundary acc_grp13 in

```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisite for PIM Dense Mode State Refresh

- You must have PIM dense mode enabled on an interface before configuring the PIM Dense Mode State Refresh feature.

## Restrictions on PIM Dense Mode State Refresh

- All routers in a PIM dense mode network must run a software release that supports the PIM Dense Mode State Refresh feature to process and forward state refresh control messages.

- The origination interval for the state refresh control message must be the same for all PIM routers on the same LAN. Specifically, the same origination interval must be configured on each router interface that is directly connected to the LAN.

## Information About PIM Dense Mode State Refresh

### PIM Dense Mode State Refresh Overview

The PIM Dense Mode State Refresh feature is an extension of the PIM Version 2 multicast routing architecture.

PIM dense mode builds source-based multicast distribution trees that operate on a flood and prune principle. Multicast packets from a source are flooded to all areas of a PIM dense mode network. PIM routers that receive multicast packets and have no directly connected multicast group members or PIM neighbors send a prune message back up the source-based distribution tree toward the source of the packets. As a result, subsequent multicast packets are not flooded to pruned branches of the distribution tree. However, the pruned state in PIM dense mode times out approximately every 3 minutes and the entire PIM dense mode network is reflooded with multicast packets and prune messages. This reflooding of unwanted traffic throughout the PIM dense mode network consumes network bandwidth.

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out by periodically forwarding a control message down the source-based distribution tree. The control message refreshes the prune state on the outgoing interfaces of each router in the distribution tree.

#### Related Topics

[Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example](#), on page 692

[Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example](#), on page 693

### Benefits of PIM Dense Mode State Refresh

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out, which saves network bandwidth by greatly reducing the reflooding of unwanted multicast traffic to pruned branches of the PIM dense mode network. This feature also enables PIM routers in a PIM dense mode multicast network to recognize topology changes (sources joining or leaving a multicast group) before the default 3-minute state refresh timeout period.

## How to Configure PIM Dense Mode State Refresh

### Configuring PIM Dense Mode State Refresh

There are no configuration tasks for enabling the PIM Dense Mode State Refresh feature. By default, all PIM routers that are running a Cisco IOS XE software release that supports the PIM Dense Mode State Refresh feature automatically process and forward state refresh control messages.

To disable the processing and forwarding of state refresh control messages on a PIM router, use the **ip pim state-refresh disable** global configuration command. To enable state refresh again if it has been disabled, use the **no ip pim state-refresh disable** global configuration command.

The origination of state refresh control messages is disabled by default. To configure the origination of the control messages on a PIM router, use the following commands beginning in global configuration mode:

| Command                                                                                 | Purpose                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>interface</b> <i>type number</i>                                     | Specifies an interface and places the router in interface configuration mode.                                                                                                                                                                                                          |
| Router(config-if)# <b>ip pim state-refresh origination-interval</b> [ <i>interval</i> ] | Configures the origination of the PIM Dense Mode State Refresh control message. Optionally, you can configure the number of seconds between control messages by using the <i>interval</i> argument. The default interval is 60 seconds. The interval range is 1 second to 100 seconds. |

#### Related Topics

[PIM Dense Mode State Refresh Overview](#), on page 690

## Verifying PIM Dense Mode State Refresh Configuration

Use the **show ip pim interface** [*type number*] **detail** and the **show ip pim neighbor** [*interface*] commands to verify that the PIM Dense Mode State Refresh feature is configured correctly. The following output of the **show ip pim interface** [*type number*] **detail** command indicates that processing, forwarding, and origination of state refresh control messages is enabled.

```
Router# show ip pim interface fastethernet 0/1/0 detail
FastEthernet0/1/0 is up, line protocol is up
  Internet address is 172.16.8.1/24
  Multicast switching:process
  Multicast packets in/out:0/0
  Multicast boundary:not set
  Multicast TTL threshold:0
  PIM:enabled
    PIM version:2, mode:dense
    PIM DR:172.16.8.1 (this system)
    PIM neighbor count:0
    PIM Hello/Query interval:30 seconds
  PIM State-Refresh processing:enabled
  PIM State-Refresh origination:enabled, interval:60 seconds
    PIM NBMA mode:disabled
    PIM ATM multipoint signalling:disabled
    PIM domain border:disabled
  Multicast Tagswitching:disabled
```

The S in the Mode field of the following **show ip pim neighbor** [*interface*] command output indicates that the neighbor has the PIM Dense Mode State Refresh feature configured.

```
Router# show ip pim neighbor
PIM Neighbor Table
```

| Neighbor Address | Interface   | Uptime/Expires    | Ver | DR Priority/Mode |
|------------------|-------------|-------------------|-----|------------------|
| 172.16.5.1       | Ethernet1/1 | 00:09:03/00:01:41 | v2  | 1 / B S          |

## Monitoring and Maintaining PIM DM State Refresh

Following are the PIM Dense Mode State Refresh control messages that are sent and received by a PIM router after the **debug ip pim** privileged EXEC command is configured for multicast group 239.0.0.1:

```
Router# debug ip pim 239.0.0.1
*Mar 1 00:25:10.416:PIM:Originating refresh message for
(172.16.8.3,239.0.0.1)
*Mar 1 00:25:10.416:PIM:Send SR on GigabitEthernet1/1/0 for (172.16.8.3,239.0.0.1)
TTL=9
```

The following output from the **show ip mroute** command displays are the resulting prune timer changes for GigabitEthernet interface 1/0/0 and multicast group 239.0.0.1. (The following output assumes that the **debug ip pim** privileged EXEC command has already been configured on the router.) In the first output from the **show ip mroute** command, the prune timer reads 00:02:06. The debug messages indicate that a PIM Dense Mode State Refresh control message is received and sent on Ethernet interface 1/0, and that other PIM Dense Mode State Refresh routers were discovered. In the second output from the **show ip mroute** command, the prune timer has been reset to 00:02:55.

```
Router# show ip mroute 239.0.0.1
(172.16.8.3, 239.0.0.1), 00:09:50/00:02:06, flags:PT
  Incoming interface:GigabitEthernet1/1/0, RPF nbr 172.16.5.2
  Outgoing interface list:
  GigabitEthernet1/0/0, Prune/Dense, 00:09:43/00:02:06
Router#
*Mar 1 00:32:06.657:PIM:SR on iif from 172.16.5.2 orig 172.16.8.1 for
(172.16.8.3,239.0.0.1)
*Mar 1 00:32:06.661:      flags:prune-indicator
*Mar 1 00:32:06.661:PIM:Cached metric is [0/0]
*Mar 1 00:32:06.661:PIM:Keep RPF nbr 172.16.5.2
*Mar 1 00:32:06.661:PIM:Send SR on Ethernet1/0 for (172.16.8.3,239.0.0.1)
TTL=8
*Mar 1 00:32:06.661:      flags:prune-indicator
Router# show ip mroute 239.0.0.1
(172.16.8.3, 239.0.0.1), 00:10:01/00:02:55, flags:PT
  Incoming interface:GigabitEthernet1/1/0, RPF nbr 172.16.5.2
  Outgoing interface list:
  GigabitEthernet1/0/0, Prune/Dense, 00:09:55/00:02:55
```

## Configuration Examples for PIM Dense Mode State Refresh

### Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is originating, processing, and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 0/1/0 every 60 seconds:

```
ip multicast-routing distributed
interface FastEthernet0/1/0
```

```
ip address 172.16.8.1 255.255.255.0
ip pim state-refresh origination-interval 60
ip pim dense-mode
```

## Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is just processing and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 1/1/0:

```
ip multicast-routing
interface FastEthernet1/1/0
 ip address 172.16.7.3 255.255.255.0
 ip pim dense-mode
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for IGMP State Limit

- IP multicast is enabled and the Protocol Independent Multicast (PIM) interfaces are configured using the tasks described in the "Configuring Basic IP Multicast" module of the *IP Multicast: PIM Configuration Guide*.
- ALL ACLs must be configured. For information, see the "Creating an IP Access List and Applying It to an Interface" module of the *Security Configuration Guide: Access Control Lists* guide.

## Restrictions for IGMP State Limit

You can configure only one global limit per device and one limit per interface.

# Information About IGMP State Limit

## IGMP State Limit

The IGMP State Limit feature allows for the configuration of IGMP state limiters, which impose limits on mroute states resulting from IGMP membership reports (IGMP joins) on a global or per interface basis. Membership reports exceeding the configured limits are not entered into the IGMP cache. This feature can be used to prevent DoS attacks or to provide a multicast CAC mechanism in network environments where all the multicast flows roughly utilize the same amount of bandwidth.

---

**Note** IGMP state limiters impose limits on the number of mroute states resulting from IGMP, IGMP v3lite, and URL Rendezvous Directory (URD) membership reports on a global or per interface basis.

---

### Related Topics

- [Configuring IGMP State Limiters Example](#), on page 699

## IGMP State Limit Feature Design

- Configuring IGMP state limiters in global configuration mode specifies a global limit on the number of IGMP membership reports that can be cached.
- Configuring IGMP state limiters in interface configuration mode specifies a limit on the number of IGMP membership reports on a per interface basis.
- Use ACLs to prevent groups or channels from being counted against the interface limit. A standard or an extended ACL can be specified. A standard ACL can be used to define the (\*, G) state to be excluded from the limit on an interface. An extended ACLs can be used to define the (S, G) state to be excluded from the limit on an interface. An extended ACL also can be used to define the (\*, G) state to be excluded from the limit on an interface, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.
- You can only configure one global limit per device and one limit per interface.

## Mechanics of IGMP State Limiters

The mechanics of IGMP state limiters are as follows:

- Each time a router receives an IGMP membership report for a particular group or channel, the Cisco IOS software checks to see if either the limit for the global IGMP state limiter or the limit for the per interface IGMP state limiter has been reached.
- If only a global IGMP state limiter has been configured and the limit has not been reached, IGMP membership reports are honored. When the configured limit has been reached, subsequent IGMP membership reports are then ignored (dropped) and a warning message in one of the following formats is generated:

- %IGMP-6-IGMP\_GROUP\_LIMIT: IGMP limit exceeded for <group (\*, group address)> on <interface type number> by host <ip address>
  - %IGMP-6-IGMP\_CHANNEL\_LIMIT: IGMP limit exceeded for <channel (source address, group address)> on <interface type number> by host <ip address>
- If only per interface IGMP state limiters are configured, then each limit is only counted against the interface on which it was configured.
  - If both a global IGMP state limiter and per interface IGMP state limiters are configured, the limits configured for the per interface IGMP state limiters are still enforced but are constrained by the global limit.

## How to Configure IGMP State Limit

### Configuring IGMP State Limiters

**Note** IGMP state limiters impose limits on the number of mroute states resulting from IGMP, IGMP v3lite, and URD membership reports on a global or per interface basis.

### Configuring Global IGMP State Limiters

Perform this optional task to configure one global IGMP state limiter per device.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip igmp limit *number***
4. **end**
5. **show ip igmp groups**

## Configuration examples for IGMP State Limit

### Configuring IGMP State Limiters Example

The following example shows how to configure IGMP state limiters to provide multicast CAC in a network environment where all the multicast flows roughly utilize the same amount of bandwidth.

This example uses the topology illustrated in the figure.

**Note** Although the following illustration and example uses routers in the configuration, any device (router or switch) can be used.

**Figure 37: IGMP State Limit Example Topology**

In this example, a service provider is offering 300 Standard Definition (SD) TV channels. Each SD channel utilizes approximately 4 Mbps.

The service provider must provision the Gigabit Ethernet interfaces on the PE router connected to the Digital Subscriber Line Access Multiplexers (DSLAMs) as follows: 50% of the link’s bandwidth (500 Mbps) must be available to subscribers of the Internet, voice, and video on demand (VoD) service offerings while the remaining 50% (500 Mbps) of the link’s bandwidth must be available to subscribers of the SD channel offerings.

Because each SD channel utilizes the same amount of bandwidth (4 Mbps), per interface IGMP state limiters can be used to provide the necessary CAC to provision the services being offered by the service provider. To determine the required CAC needed per interface, the total number of channels is divided by 4 (because each channel utilizes 4 Mbps of bandwidth). The required CAC needed per interface, therefore, is as follows:

$$500\text{Mbps} / 4\text{Mbps} = 125 \text{ mroutes}$$

Once the required CAC is determined, the service provider uses the results to configure the per IGMP state limiters required to provision the Gigabit Ethernet interfaces on the PE router. Based on the network’s CAC requirements, the service provider must limit the SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 125. Configuring a per interface IGMP state limit of 125 for the SD channels provisions the interface for 500 Mbps of bandwidth, the 50% of the link’s bandwidth that must always be available (but never exceeded) for the SD channel offerings.

The following configuration shows how the service provider uses a per interface mroute state limiter to provision interface Gigabit Ethernet 0/0/0 for the SD channels and Internet, Voice, and VoD services being offered to subscribers:

```
interface GigabitEthernet0/0/0
description --- Interface towards the DSLAM ---
```

```

.
.
.
ip igmp limit 125

```

## Restrictions for STP

- An attempt to configure a device as the root device fails if the value necessary to be the root device is less than 1.
- If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected devices running older software.
- The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

## Information About Spanning Tree Protocol

### Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Devices might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

The STP uses a spanning-tree algorithm to select one device of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

- Root—A forwarding port elected for the spanning-tree topology
- Designated—A forwarding port elected for every switched LAN segment
- Alternate—A blocked port providing an alternate path to the root bridge in the spanning tree
- Backup—A blocked port in a loopback configuration

The device that has *all* of its ports as the designated role or as the backup role is the root device. The device that has at least *one* of its ports in the designated role is called the designated device.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Devices send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The devices do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending device and its ports, including device and MAC addresses, device priority, port priority, and path cost. Spanning tree uses this information to elect the root device and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a device are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

---

**Note** By default, the device sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the `[no] keepalive` interface configuration command with no keywords.

---

## Spanning-Tree Topology and BPDUs

The stable, active spanning-tree topology of a switched network is controlled by these elements:

- The unique bridge ID (device priority and MAC address) associated with each VLAN on each device. In a device stack, all devices use the same bridge ID for a given spanning-tree instance.
- The spanning-tree path cost to the root device.
- The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the devices in a network are powered up, each functions as the root device. Each device sends a configuration BPDU through all of its ports. The BPDUs communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the device that the sending device identifies as the root device
- The spanning-tree path cost to the root
- The bridge ID of the sending device
- Message age

- The identifier of the sending interface
- Values for the hello, forward delay, and max-age protocol timers

When a device receives a configuration BPDU that contains *superior* information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the device, the device also forwards it with an updated message to all attached LANs for which it is the designated device.

If a device receives a configuration BPDU that contains *inferior* information to that currently stored for that port, it discards the BPDU. If the device is a designated device for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:

- One device in the network is elected as the root device (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.

For each VLAN, the device with the highest device priority (the lowest numerical priority value) is elected as the root device. If all devices are configured with the default priority (32768), the device with the lowest MAC address in the VLAN becomes the root device. The device priority value occupies the most significant bits of the bridge ID, as shown in the following figure.

- A root port is selected for each device (except the root device). This port provides the best path (lowest cost) when the device forwards packets to the root device.

When selecting the root port on a device stack, spanning tree follows this sequence:

- Selects the lowest root bridge ID
  - Selects the lowest path cost to the root device
  - Selects the lowest designated bridge ID
  - Selects the lowest designated path cost
  - Selects the lowest port ID
- Only one outgoing port on the stack root device is selected as the root port. The remaining devices in the stack become its designated devices (Device 2 and Device 3) as shown in the following figure.
  - The shortest distance to the root device is calculated for each device based on the path cost.
  - A designated device for each LAN segment is selected. The designated device incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.

Figure 38: Spanning-Tree Port States in a Device Stack

One stack member is elected as the stack root device. The stack root device contains the outgoing root port (Device 1).

All paths that are not needed to reach the root device from anywhere in the switched network are placed in the spanning-tree blocking mode.

## Bridge ID, Device Priority, and Extended System ID

The IEEE 802.1D standard requires that each device has a unique bridge identifier (bridge ID), which controls the selection of the root device. Because each VLAN is considered as a different *logical bridge* with PVST+ and Rapid PVST+, the same device must have a different bridge ID for each configured VLAN. Each VLAN on the device has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the device priority, and the remaining 6 bytes are derived from the device MAC address.

The device supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the device priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for the device, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.

The 2 bytes previously used for the device priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

**Table 55: Device Priority Value and Extended System ID**

| Priority Value |        |        |        | Extended System ID (Set Equal to the VLAN ID) |        |        |       |       |       |       |       |       |       |       |       |  |
|----------------|--------|--------|--------|-----------------------------------------------|--------|--------|-------|-------|-------|-------|-------|-------|-------|-------|-------|--|
| Bit 16         | Bit 15 | Bit 14 | Bit 13 | Bit 12                                        | Bit 11 | Bit 10 | Bit 9 | Bit 8 | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 |  |
| 32768          | 16384  | 8192   | 4096   | 2048                                          | 1024   | 512    | 256   | 128   | 64    | 32    | 16    | 8     | 4     | 2     | 1     |  |

Spanning tree uses the extended system ID, the device priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the device stack appears as a single device to the rest of the network, all devices in the stack use the same bridge ID for a given spanning tree. If the stack master fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack master.

Support for the extended system ID affects how you manually configure the root device, the secondary root device, and the device priority of a VLAN. For example, when you change the device priority value, you change the probability that the device will be elected as the root device. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root device for the specified VLAN has a device priority lower than 24576, the device sets its own priority for the specified VLAN to 4096 less than the lowest device priority. 4096 is the value of the least-significant bit of a 4-bit device priority value as shown in the table.

## Port Priority Versus Path Cost

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your device is a member of a device stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see Related Topics.

## Spanning-Tree Interface States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface

transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

Each Layer 2 interface on a device using spanning tree exists in one of these states:

- Blocking—The interface does not participate in frame forwarding.
- Listening—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.
- Learning—The interface prepares to participate in frame forwarding.
- Forwarding—The interface forwards frames.
- Disabled—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:

- From initialization to blocking
- From blocking to listening or to disabled
- From listening to learning or to disabled
- From learning to forwarding or to disabled
- From forwarding to disabled

**Figure 39: Spanning-Tree Interface States**

An interface moves through the states.

When you power up the device, spanning tree is enabled by default, and every interface in the device, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:

1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.
2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.
3. In the learning state, the interface continues to block frame forwarding as the device learns end-station location information for the forwarding database.
4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

## Blocking State

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each device interface. A device initially functions as the root until it exchanges BPDUs with other devices. This exchange establishes which device in the network is the root or root device. If there is only one device in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after device initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

## Listening State

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

## Learning State

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs

## Forwarding State

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface
- Forwards frames switched from another interface
- Learns addresses
- Receives BPDUs

## Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Does not receive BPDUs

## How a Device or Port Becomes the Root Device or Root Port

If all devices in a network are enabled with default spanning-tree settings, the device with the lowest MAC address becomes the root device.

**Figure 40: Spanning-Tree Topology**

Device A is elected as the root device because the device priority of all the devices is set to the default (32768) and Device A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Device A might not be the ideal root device. By increasing the priority (lowering the numerical value) of the ideal device so that it becomes the root device, you force a spanning-tree recalculation

RP = Root Port  
DP = Designated Port

to form a new topology with the ideal device as the root.

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.

For example, assume that one port on Device B is a Gigabit Ethernet link and that another port on Device B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.

## Spanning Tree and Redundant Connectivity

Figure 41: Spanning Tree and Redundant Connectivity

You can create a redundant backbone with spanning tree by connecting two device interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds are the same, the port priority and port ID are added together, and spanning tree disables the link with the

highest value.

You can also create redundant links between devices by using EtherChannel groups.

## Spanning-Tree Address Management

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C2000000 to 0x00180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each device in the stack receives but does not forward packets destined for addresses between 0x00180C2000000 and 0x00180C200000F.

If spanning tree is enabled, the CPU on the device or on each device in the stack receives packets destined for 0x00180C2000000 and 0x00180C2000010. If spanning tree is disabled, the device or each device in the stack forwards those packets as unknown multicast addresses.

## Accelerated Aging to Retain Connectivity

The default for aging dynamic addresses is 5 minutes, the default setting of the **mac address-table aging-time** global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (**spanning-tree vlan *vlan-id* forward-time *seconds*** global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the device accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be

subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the device.

## Spanning-Tree Modes and Protocols

The device supports these spanning-tree modes and protocols:

- **PVST+**—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. The PVST+ runs on each VLAN on the device up to the maximum supported, ensuring that each has a loop-free path through the network.

The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root device. This root device propagates the spanning-tree information associated with that VLAN to all other devices in the network. Because each device has the same information about the network, this process ensures that the network topology is maintained.

- **Rapid PVST+**—Rapid PVST+ is the default STP mode on your device. This spanning-tree mode is the same as PVST+ except that it uses a rapid convergence based on the IEEE 802.1w standard. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to reprovision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

- **MSTP**—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a device stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

## Supported Spanning-Tree Instances

In PVST+ or Rapid PVST+ mode, the device or device stack supports up to 128 spanning-tree instances.

In MSTP mode, the device or device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

### Related Topics

[Default MSTP Configuration](#), on page 747

## Spanning-Tree Interoperability and Backward Compatibility

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ device cannot connect to multiple MST regions.

When a network contains devices running Rapid PVST+ and devices running PVST+, we recommend that the Rapid PVST+ devices and PVST+ devices be configured for different spanning-tree instances. In the

Rapid PVST+ spanning-tree instances, the root device must be a Rapid PVST+ device. In the PVST+ instances, the root device must be a PVST+ device. The PVST+ devices should be at the edge of the network.

All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

**Table 56: PVST+, MSTP, and Rapid-PVST+ Interoperability and Compatibility**

|             | PVST+                   | MSTP                    | Rapid PVST+            |
|-------------|-------------------------|-------------------------|------------------------|
| PVST+       | Yes                     | Yes (with restrictions) | Yes (reverts to PVST+) |
| MSTP        | Yes (with restrictions) | Yes                     | Yes (reverts to PVST+) |
| Rapid PVST+ | Yes (reverts to PVST+)  | Yes (reverts to PVST+)  | Yes                    |

## STP and IEEE 802.1Q Trunks

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for *all* VLANs allowed on the trunks. However, in a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for *each* VLAN allowed on the trunks.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the device uses it instead of PVST+. The device combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.

Rapid PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

## Spanning Tree and Device Stacks

When the device stack is operating in PVST+ or Rapid PVST+ mode:

- A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.
- When a new device joins the stack, it sets its bridge ID to the active switch bridge ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root.
- When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

- If the device stack is the spanning-tree root and the active switch fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.
- If a neighboring device external to the device stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a device in the active topology.
- If a new device external to the device stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a device in the network.

## Default Spanning-Tree Configuration

*Table 57: Default Spanning-Tree Configuration*

| Feature                                                             | Default Setting                                                                                                           |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|

# How to Configure Spanning-Tree Features

## Changing the Spanning-Tree Mode (CLI)

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the device runs the Rapid PVST+ protocol.

If you want to enable a mode that is different from the default mode, this procedure is required.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `spanning-tree mode {pvst | mst | rapid-pvst}`
4. `interface interface-id`
5. `spanning-tree link-type point-to-point`
6. `end`
7. `clear spanning-tree detected-protocols`

### DETAILED STEPS

|        | Command or Action                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><code>enable</code></p> <p><b>Example:</b></p> <pre>Device&gt; enable</pre>                                                             | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                               |
| Step 2 | <p><code>configure terminal</code></p> <p><b>Example:</b></p> <pre>Device# configure terminal</pre>                                        | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                        |
| Step 3 | <p><code>spanning-tree mode {pvst   mst   rapid-pvst}</code></p> <p><b>Example:</b></p> <pre>Device(config)# spanning-tree mode pvst</pre> | <p>Configures a spanning-tree mode. All stack members run the same version of spanning tree.</p> <ul style="list-style-type: none"> <li>• Select <b>pvst</b> to enable PVST+.</li> <li>• Select <b>mst</b> to enable MSTP.</li> <li>• Select <b>rapid-pvst</b> to enable rapid PVST+.</li> </ul> <p><b>Note</b> By default, the device runs Rapid PVST+.</p> |
| Step 4 | <p><code>interface interface-id</code></p> <p><b>Example:</b></p>                                                                          | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port channels. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48.                                                                                                                                          |

|               | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device(config)# <b>interface</b> GigabitEthernet1/0/1                                                                                |                                                                                                                                                                                                                                                                                                            |
| <b>Step 5</b> | <b>spanning-tree link-type point-to-point</b><br><b>Example:</b><br>Device(config-if)# <b>spanning-tree link-type point-to-point</b> | Specifies that the link type for this port is point-to-point.<br>If you connect this port (local port) to a remote port through a point-to-point link and the local port becomes a designated port, the device negotiates with the remote port and rapidly changes the local port to the forwarding state. |
| <b>Step 6</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                           |
| <b>Step 7</b> | <b>clear spanning-tree detected-protocols</b><br><b>Example:</b><br>Device# <b>clear spanning-tree detected-protocols</b>            | If any port on the device is connected to a port on a legacy IEEE 802.1D device, this command restarts the protocol migration process on the entire device.<br>This step is optional if the designated device detects that this device is running rapid PVST+.                                             |

## Disabling Spanning Tree (CLI)

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

### Caution

When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no spanning-tree vlan** *vlan-id*
4. **end**

### DETAILED STEPS

|               | Command or Action                                         | Purpose                                                        |
|---------------|-----------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. Enter your password if prompted. |

|        | Command or Action                                                                                                        | Purpose                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                  | Enters the global configuration mode.        |
| Step 3 | <b>no spanning-tree vlan <i>vlan-id</i></b><br><b>Example:</b><br>Device(config)# <code>no spanning-tree vlan 300</code> | For <i>vlan-id</i> , the range is 1 to 4094. |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                        | Returns to privileged EXEC mode.             |

## Configuring the Root Device (CLI)

To configure a device as the root for the specified VLAN, use the **spanning-tree vlan *vlan-id* root** global configuration command to modify the device priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the device priority of the root devices for each VLAN. Because of the extended system ID support, the device sets its own priority for the specified VLAN to 24576 if this value will cause this device to become the root for the specified VLAN.

Use the **diameter** keyword to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* root primary [*diameter net-diameter*]**
4. **end**

### DETAILED STEPS

|        | Command or Action                                               | Purpose                                                        |
|--------|-----------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                                                                  | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 3</b> | <b>spanning-tree vlan <i>vlan-id</i> root primary [<i>diameter net-diameter</i>]</b><br><b>Example:</b><br>Device(config)# <code>spanning-tree vlan 20-24 root primary diameter 4</code> | Configures a device to become the root for the specified VLAN. <ul style="list-style-type: none"> <li>• For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</li> <li>• (Optional) For <b>diameter</b> <i>net-diameter</i>, specify the maximum number of devices between any two end stations. The range is 2 to 7.</li> </ul> |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                                                                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### What to do next

After configuring the device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the **spanning-tree vlan *vlan-id* hello-time**, **spanning-tree vlan *vlan-id* forward-time**, and the **spanning-tree vlan *vlan-id* max-age** global configuration commands.

## Configuring a Secondary Root Device (CLI)

When you configure a device as the secondary root, the device priority is modified from the default value (32768) to 28672. With this priority, the device is likely to become the root device for the specified VLAN if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768, and therefore, are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the **spanning-tree vlan *vlan-id* root primary** global configuration command.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* root secondary [*diameter net-diameter*]**
4. **end**

|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                      | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 3 | <b>spanning-tree vlan <i>vlan-id</i> root secondary [diameter <i>net-diameter</i>]</b><br><b>Example:</b><br>Device(config)# <b>spanning-tree vlan 20-24 root secondary diameter 4</b> | Configures a device to become the secondary root for the specified VLAN. <ul style="list-style-type: none"> <li>• For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</li> <li>• (Optional) For <b>diameter</b> <i>net-diameter</i>, specify the maximum number of devices between any two end stations. The range is 2 to 7.</li> </ul> Use the same network diameter value that you used when configuring the primary root device. |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                                                            | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Configuring Port Priority (CLI)

**Note** If your device is a member of a device stack, you must use the **spanning-tree [vlan *vlan-id*] cost *cost*** interface configuration command instead of the **spanning-tree [vlan *vlan-id*] port-priority *priority*** interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

## SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree port-priority** *priority*
5. **spanning-tree vlan** *vlan-id* **port-priority** *priority*
6. **end**

## DETAILED STEPS

| <b>Step 6</b> | <b>end</b><br><b>Example:</b>                                                                                                                                                 | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|  | Command or Action             | Purpose |
|--|-------------------------------|---------|
|  | Device(config-if)# <b>end</b> |         |

## Configuring Path Cost (CLI)

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree cost** *cost*
5. **spanning-tree vlan** *vlan-id* **cost** *cost*
6. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><br>Device> <b>enable</b>                                                               | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><br>Device# <b>configure terminal</b>                                       | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                             |
| <b>Step 3</b> | <b>interface</b> <i>interface-id</i><br><b>Example:</b><br><br>Device(config)# <b>interface</b> <b>gigabitethernet1/0/1</b> | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces ( <b>port-channel</b> <i>port-channel-number</i> ).                                                                                                                                     |
| <b>Step 4</b> | <b>spanning-tree cost</b> <i>cost</i><br><b>Example:</b><br><br>Device(config-if)# <b>spanning-tree cost</b> <b>250</b>     | Configures the cost for an interface.<br><br>If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.<br><br>For <i>cost</i> , the range is 1 to 200000000; the default value is derived from the media speed of the interface. |
| <b>Step 5</b> | <b>spanning-tree vlan</b> <i>vlan-id</i> <b>cost</b> <i>cost</i><br><b>Example:</b>                                         | Configures the cost for a VLAN.                                                                                                                                                                                                                                                                                                                   |

|               | Command or Action                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|--------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device(config-if) # <b>spanning-tree vlan 10,12-15,20 cost 300</b>             | <p>If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.</p> <ul style="list-style-type: none"> <li>• For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</li> <li>• For <i>cost</i>, the range is 1 to 200000000; the default value is derived from the media speed of the interface.</li> </ul> |
| <b>Step 6</b> | <p><b>end</b></p> <p><b>Example:</b></p> <p>Device(config-if) # <b>end</b></p> | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The **show spanning-tree interface *interface-id*** privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the **show running-config** privileged EXEC command to confirm the configuration.

## Configuring the Device Priority of a VLAN (CLI)

You can configure the device priority and make it more likely that a standalone device or a device in the stack will be chosen as the root device.

**Note** Exercise care when using this command. For most situations, we recommend that you use the **spanning-tree vlan *vlan-id* root primary** and the **spanning-tree vlan *vlan-id* root secondary** global configuration commands to modify the device priority.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* priority *priority***
4. **end**

### DETAILED STEPS

|               | Command or Action                           | Purpose                                                        |
|---------------|---------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <p><b>enable</b></p> <p><b>Example:</b></p> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device> <b>enable</b>                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                  | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 3</b> | <b>spanning-tree vlan <i>vlan-id</i> priority <i>priority</i></b><br><b>Example:</b><br>Device(config)# <b>spanning-tree vlan 20 priority 8192</b> | Configures the device priority of a VLAN. <ul style="list-style-type: none"> <li>For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</li> <li>For <i>priority</i>, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device.</li> </ul> Valid priority values are 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. All other values are rejected. |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                                                     | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Configuring the Hello Time (CLI)

The hello time is the time interval between configuration messages generated and sent by the root device.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **spanning-tree vlan *vlan-id* hello-time *seconds***
3. **end**

|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device> <b>enable</b>                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>spanning-tree vlan <i>vlan-id</i> hello-time <i>seconds</i></b><br><b>Example:</b><br>Device(config)# <b>spanning-tree vlan 20-24 hello-time 3</b> | Configures the hello time of a VLAN. The hello time is the time interval between configuration messages generated and sent by the root device. These messages mean that the device is alive. <ul style="list-style-type: none"> <li>• For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</li> <li>• For <i>seconds</i>, the range is 1 to 10; the default is 2.</li> </ul> |
| <b>Step 3</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Configuring the Forwarding-Delay Time for a VLAN (CLI)

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* forward-time *seconds***
4. **end**

### DETAILED STEPS

|               | Command or Action                                                                 | Purpose                                                        |
|---------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                         | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters the global configuration mode.                          |

|        | Command or Action                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>spanning-tree vlan <i>vlan-id</i> forward-time <i>seconds</i></b><br><b>Example:</b><br><pre>Device(config)# spanning-tree vlan 20,25 forward-time 18</pre> | Configures the forward time of a VLAN. The forwarding delay is the number of seconds an interface waits before changing from its spanning-tree learning and listening states to the forwarding state. <ul style="list-style-type: none"> <li>For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</li> <li>For <i>seconds</i>, the range is 4 to 30; the default is 15.</li> </ul> |
| Step 4 | <b>end</b><br><b>Example:</b><br><pre>Device(config)# end</pre>                                                                                                | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring the Maximum-Aging Time for a VLAN (CLI)

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree vlan *vlan-id* max-age *seconds***
4. **end**

### DETAILED STEPS

|        | Command or Action                                                                     | Purpose                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Device&gt; enable</pre>                      | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                          |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><pre>Device# configure terminal</pre> | Enters the global configuration mode.                                                                                                                                                                   |
| Step 3 | <b>spanning-tree vlan <i>vlan-id</i> max-age <i>seconds</i></b><br><b>Example:</b>    | Configures the maximum-aging time of a VLAN. The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration. |

| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b> | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                   |

## Configuring the Transmit Hold-Count (CLI)

You can configure the BPDU burst size by changing the transmit hold count value.

### Note

Changing this parameter to a higher value can have a significant impact on CPU utilization, especially in Rapid PVST+ mode. Lowering this value can slow down convergence in certain scenarios. We recommend that you maintain the default setting.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree transmit hold-count** *value*
4. **end**

### DETAILED STEPS

|               | Command or Action                                                                 | Purpose                                                        |
|---------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                         | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters the global configuration mode.                          |

|        | Command or Action                                                                                                                         | Purpose                                                                                                                                    |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>spanning-tree transmit hold-count</b> <i>value</i><br><b>Example:</b><br>Device(config)# <b>spanning-tree transmit hold-count</b><br>6 | Configures the number of BPDUs that can be sent before pausing for 1 second.<br>For <i>value</i> , the range is 1 to 20; the default is 6. |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                               | Returns to privileged EXEC mode.                                                                                                           |

## Monitoring Spanning-Tree Status

Table 58: Commands for Displaying Spanning-Tree Status

|                                                                         |                                                                                              |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <b>show spanning-tree active</b>                                        | Displays spanning-tree information on active interfaces only.                                |
| <b>show spanning-tree detail</b>                                        | Displays a detailed summary of interface information.                                        |
| <b>show spanning-tree vlan</b> <i>vlan-id</i>                           | Displays spanning-tree information for the specified VLAN.                                   |
| <b>show spanning-tree interface</b> <i>interface-id</i>                 | Displays spanning-tree information for the specified interface.                              |
| <b>show spanning-tree interface</b> <i>interface-id</i> <b>portfast</b> | Displays spanning-tree portfast information for the specified interface.                     |
| <b>show spanning-tree summary</b> [totals]                              | Displays a summary of interface states or displays the total lines of the STP state section. |

To clear spanning-tree counters, use the **clear spanning-tree** [**interface** *interface-id*] privileged EXEC command.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for MSTP

- For two or more devices to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.
- For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.
- For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a device stack by manually configuring the path cost.
- For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the internal spanning tree (IST) master of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST regions must contain the CST root, and all of the other MST regions must have a better path to the root.

contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the devices in the clouds.

## Restrictions for MSTP

- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.
- The device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.
- PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)
- All stack members must run the same version of spanning tree (all PVST+, Rapid PVST+, or MSTP).
- VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each device within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.
- Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.
- A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.
- After configuring a device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the **spanning-tree mst hello-time**, **spanning-tree mst forward-time**, and the **spanning-tree mst max-age** global configuration commands.

**Table 59: PVST+, MSTP, and Rapid PVST+ Interoperability and Compatibility**

|             | PVST+                   | MSTP                    | Rapid PVST+            |
|-------------|-------------------------|-------------------------|------------------------|
| PVST+       | Yes                     | Yes (with restrictions) | Yes (reverts to PVST+) |
| MSTP        | Yes (with restrictions) | Yes                     | Yes (reverts to PVST+) |
| Rapid PVST+ | Yes (reverts to PVST+)  | Yes (reverts to PVST+)  | Yes                    |

## Information About MSTP

### MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing, and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

**Note** The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment.

When the device is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.

Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same device ID.

### MSTP Configuration Guidelines

- When you enable MST by using the **spanning-tree mode mst** global configuration command, RSTP is automatically enabled.
- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.
- When the device is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

| Speed    | Path Cost Value |
|----------|-----------------|
| 10 Mb/s  | 2,000,000       |
| 100 Mb/s | 200,000         |
| 1 Gb/s   | 20,000          |

| Speed    | Path Cost Value |
|----------|-----------------|
| 10 Gb/s  | 2,000           |
| 100 Gb/s | 200             |

## Root Switch

The device maintains a spanning-tree instance for the group of VLANs mapped to it. A device ID, consisting of the device priority and the device MAC address, is associated with each instance. For a group of VLANs, the device with the lowest device ID becomes the root device.

When you configure a device as the root, you modify the device priority from the default value (32768) to a significantly lower value so that the device becomes the root device for the specified spanning-tree instance. When you enter this command, the device checks the device priorities of the root devices. Because of the extended system ID support, the device sets its own priority for the specified instance to 24576 if this value will cause this devices to become the root for the specified spanning-tree instance.

If any root device for the specified instance has a device priority lower than 24576, the device sets its own priority to 4096 less than the lowest device priority. (4096 is the value of the least-significant bit of a 4-bit device priority value. For more information, select "Bridge ID, Device Priority, and Extended System ID" link in Related Topics.

If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected switches running older software.

The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Use the **diameter** keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

## Multiple Spanning-Tree Regions

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each device belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the device for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the "Specifying the MST Region Configuration and Enabling MSTP" link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

## IST, CIST, and CST

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- An internal spanning tree (IST), which is the spanning tree that runs in an MST region.

Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because the MSTP BPDUs carry information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root device ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- A common and internal spanning tree (CIST), which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.

The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

## Operations Within an MST Region

The IST connects all the MSTP switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the *IST master* before the implementation of the IEEE 802.1s standard). It is the device within the region with the lowest device ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MSTP switches at the boundary of the region is selected as the CIST regional root.

When an MSTP device initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The device also initializes all of its MST instances and claims to be the root for all of them. If the device receives superior MST root information (lower device ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

### Related Topics

[Illustration of MST Regions](#), on page 737

## Operations Between MST Regions

If there are multiple regions or legacy IEEE 802.1D devices within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP devices in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP devices in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual device to adjacent STP devices and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring devices and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPDU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, device priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.

MSTP devices use Version 3 RSTP BPDUs or IEEE 802.1D STP BPDUs to communicate with legacy IEEE 802.1D devices. MSTP devices use MSTP BPDUs to communicate with MSTP devices.

## IEEE 802.1s Terminology

Some MST naming conventions used in Cisco's prestandard implementation have been changed to identify some *internal* or *regional* parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root device for the unique instance that spans the whole network, the CIST.
- The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single device for the CIST. The CIST external root path cost is the root path cost calculated between these virtual devices and devices that do not belong to any region.
- The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest device to the CIST root in the region. The CIST regional root acts as a root device for the IST.
- The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

**Table 60: Prestandard and Standard Terminology**

| IEEE Standard                | Cisco Prestandard    | Cisco Standard          |
|------------------------------|----------------------|-------------------------|
| CIST regional root           | IST master           | CIST regional root      |
| CIST internal root path cost | IST master path cost | CIST internal path cost |
| CIST external root path cost | Root path cost       | Root path cost          |
| MSTI regional root           | Instance root        | Instance root           |
| MSTI internal root path cost | Root path cost       | Root path cost          |

## Illustration of MST Regions

This figure displays three MST regions and a legacy IEEE 802.1D device (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.

Figure 42: MST Regions, CIST Masters, and CST Root

- [Operations Between MST Regions](#), on page 736

## Hop Count

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the **spanning-tree mst max-hops** global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root device of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a device receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDUs it generates. When the count reaches zero, the device discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.

## Boundary Ports

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both devices and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

---

**Note** If there is a legacy STP device on the segment, messages are always considered external.

---

The other change from the Cisco prestandard implementation is that the CIST regional root device ID field is now inserted where an RSTP or legacy IEEE 802.1Q device has the sender device ID. The whole region performs like a single virtual device by sending a consistent sender device ID to neighboring devices. In this example, device C would receive a BPDU with the same consistent sender device ID of root, whether or not A or B is designated for the segment.

## IEEE 802.1s Implementation

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

### Port Role Naming Change

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco's implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special *master* role.

- The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the **show** commands identify a port as boundary in the *type* column of the output.

## Interoperation Between Legacy and Standard Devices

Because automatic detection of prestandard devices can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard device, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a device receives a prestandard BPDU on a port that has not been configured for prestandard BPDU transmission.

**Figure 43: Standard and Prestandard Device Interoperation**

Assume that A is a standard device and B a prestandard device, both configured to be in the same region. A is the root device for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPDU, AY cannot detect that a prestandard device is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology

**Note** We recommend that you minimize the interaction between standard and prestandard MST implementations.

## Detecting Unidirectional Link Failure

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

**Figure 44: Detecting Unidirectional Link Failure**

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Device A is the root device, and its BPDUs are lost on the link leading to device B. RSTP and MST BPDUs include the role and state of the sending port. With this information, device A can detect that device B does not react to the superior BPDUs it sends and that device B is the designated, not root device. As a result, device A blocks (or keeps

blocking) its port, which prevents the bridging loop.

11  
12  
13

## MSTP and Device Stacks

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active switch.

The active switch is the stack root when the stack is the root of the network and no root selection has been made within the stack.

If the device stack is the spanning-tree root and the active switch fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.

If a device that does not support MSTP is added to a device stack that does support MSTP or the reverse, the device is put into a version mismatch state. If possible, the device is automatically upgraded or downgraded to the same version of software that is running on the device stack.

## Interoperability with IEEE 802.1D STP

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device might also continue to assign a boundary role to a port when the device to which this device is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring devices), use the **clear spanning-tree detected-protocols** privileged EXEC command.

If all the legacy devices on the link are RSTP devices, they can process MSTP BPDUs as if they are RSTP BPDUs. Therefore, MSTP devices send either a Version 0 configuration and TCN BPDUs or Version 3 MSTP BPDUs on a boundary port. A boundary port connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

## RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).

### Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the device with the highest device priority (lowest numerical priority value) as the root device. The RSTP then assigns one of these port roles to individual ports:

- Root port—Provides the best path (lowest cost) when the device forwards packets to the root device.
- Designated port—Connects to the designated device, which incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
- Alternate port—Offers an alternate path toward the root device to that provided by the current root port.
- Backup port—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a device has two or more connections to a shared LAN segment.
- Disabled port—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

**Table 61: Port State Comparison**

| Operational Status | STP Port State (IEEE 802.1D) | RSTP Port State | Is Port Included in the Active Topology? |
|--------------------|------------------------------|-----------------|------------------------------------------|
| Enabled            | Blocking                     | Discarding      | No                                       |
| Enabled            | Listening                    | Discarding      | No                                       |
| Enabled            | Learning                     | Learning        | Yes                                      |
| Enabled            | Forwarding                   | Forwarding      | Yes                                      |
| Disabled           | Disabled                     | Discarding      | No                                       |

To be consistent with Cisco STP implementations, this guide defines the port state as *blocking* instead of *discarding*. Designated ports start in the listening state.

## Rapid Convergence

The RSTP provides for rapid recovery of connectivity following the failure of a device, a device port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

- **Edge ports**—If you configure a port as an edge port on an RSTP device by using the **spanning-tree portfast** interface configuration command, the edge port immediately transitions to the forwarding state. An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.
- **Root ports**—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.
- **Point-to-point links**—If you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

### *Figure 45: Proposal and Agreement Handshaking for Rapid Convergence*

Device A is connected to Device B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Device A is a smaller numerical value than the priority of Device B. Device A sends a proposal message (a configuration BPDU with the proposal flag set) to Device B, proposing itself as the designated device.

After receiving the proposal message, Device B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Device B's agreement message, Device A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Device B blocked all of its nonedge ports and because there is a point-to-point link between Devices A and B.

When Device C is connected to Device B, a similar set of handshaking messages are exchanged. Device C selects the port connected to Device B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more device joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a device stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the device is in MST mode.

The device learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the **spanning-tree link-type** interface configuration command.

## Synchronization of Port Roles

When the device receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The device is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the device is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

### *Figure 46: Sequence of Events During Rapid Convergence*

After ensuring that all of the ports are synchronized, the device sends an agreement message to the designated device corresponding to its root port. When the devices connected by a point-to-point link are in agreement

about their port roles, the RSTP immediately transitions the port states to forwarding.

## Bridge Protocol Data Unit Format and Processing

The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

**Table 62: RSTP BPDU Flags**

| Bit  | Function                              |
|------|---------------------------------------|
| 0    | Topology change (TC)                  |
| 1    | Proposal                              |
| 2–3: | Port role:                            |
| 00   | Unknown                               |
| 01   | Alternate port                        |
| 10   | Root port                             |
| 11   | Designated port                       |
| 4    | Learning                              |
| 5    | Forwarding                            |
| 6    | Agreement                             |
| 7    | Topology change acknowledgement (TCA) |

The sending device sets the proposal flag in the RSTP BPDU to propose itself as the designated device on that LAN. The port role in the proposal message is always set to the designated port.

The sending device sets the agreement flag in the RSTP BPDU to accept the previous proposal. The port role in the agreement message is always set to the root port.

The RSTP does not have a separate topology change notification (TCN) BPDU. It uses the topology change (TC) flag to show the topology changes. However, for interoperability with IEEE 802.1D devices, the RSTP device processes and generates TCN BPDUs.

The learning and forwarding flags are set according to the state of the sending port.

### Processing Superior BPDU Information

If a port receives superior root information (lower device ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDU received is an RSTP BPDU with the proposal flag set, the device sends an agreement message after all of the other ports are synchronized. If the BPDU is an IEEE 802.1D BPDU, the device does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

### Processing Inferior BPDU Information

If a designated port receives an inferior BPDU (such as a higher device ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.

## Topology Changes

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- **Detection**—Unlike IEEE 802.1D in which *any* transition between the blocking and the forwarding state causes a topology change, *only* transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP device detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.
- **Notification**—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP device processes and generates TCN BPDUs.
- **Acknowledgement**—When an RSTP device receives a TCN message on a designated port from an IEEE 802.1D device, it replies with an IEEE 802.1D configuration BPDU with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D device and a configuration BPDU with the TCA bit set is received, the TC-while timer is reset.

This behavior is only required to support IEEE 802.1D devices. The RSTP BPDUs never have the TCA bit set.

- **Propagation**—When an RSTP device receives a TC message from another device through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding

the port on which it is received). The device starts the TC-while timer for all such ports and flushes the information learned on them.

- Protocol migration—For backward compatibility with IEEE 802.1D devices, RSTP selectively sends IEEE 802.1D configuration BPDUs and TCN BPDUs on a per-port basis.

When a port is initialized, the migrate-delay timer is started (specifies the minimum time during which RSTP BPDUs are sent), and RSTP BPDUs are sent. While this timer is active, the device processes all BPDUs received on that port and ignores the protocol type.

If the device receives an IEEE 802.1D BPDU after the port migration-delay timer has expired, it assumes that it is connected to an IEEE 802.1D device and starts using only IEEE 802.1D BPDUs. However, if the RSTP device is using IEEE 802.1D BPDUs on a port and receives an RSTP BPDU after the timer has expired, it restarts the timer and starts using RSTP BPDUs on that port.

## Protocol Migration Process

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device also might continue to assign a boundary role to a port when the device to which it is connected has joined the region.

## How to Configure MSTP Features

### Specifying the MST Region Configuration and Enabling MSTP (CLI)

For two or more switches to be in the same MST region, they must have the same VLAN-to-instance mapping, the same configuration revision number, and the same name.

A region can have one member or multiple members with the same MST configuration; each member must be capable of processing RSTP BPDUs. There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **spanning-tree mst configuration**
4. **instance** *instance-id* **vlan** *vlan-range*
5. **name** *name*
6. **revision** *version*
7. **show pending**
8. **exit**
9. **spanning-tree mode mst**
10. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>enable</b></p> <p><b>Example:</b></p> <pre>Device&gt; enable</pre>                                                                     | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Device# configure terminal</pre>                                                | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 3 | <p><b>spanning-tree mst configuration</b></p> <p><b>Example:</b></p> <pre>Device(config)# spanning-tree mst configuration</pre>              | Enters MST configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 4 | <p><b>instance <i>instance-id</i> vlan <i>vlan-range</i></b></p> <p><b>Example:</b></p> <pre>Device(config-mst)# instance 1 vlan 10-20</pre> | <p>Maps VLANs to an MST instance.</p> <ul style="list-style-type: none"> <li>• For <i>instance-id</i>, the range is 0 to 4094.</li> <li>• For <b>vlan <i>vlan-range</i></b>, the range is 1 to 4094.</li> </ul> <p>When you map VLANs to an MST instance, the mapping is incremental, and the VLANs specified in the command are added to or removed from the VLANs that were previously mapped.</p> <p>To specify a VLAN range, use a hyphen; for example, <b>instance 1 vlan 1-63</b> maps VLANs 1 through 63 to MST instance 1.</p> <p>To specify a VLAN series, use a comma; for example, <b>instance 1 vlan 10, 20, 30</b> maps VLANs 10, 20, and 30 to MST instance 1.</p> |
| Step 5 | <p><b>name <i>name</i></b></p> <p><b>Example:</b></p> <pre>Device(config-mst)# name region1</pre>                                            | Specifies the configuration name. The <i>name</i> string has a maximum length of 32 characters and is case sensitive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 6 | <p><b>revision <i>version</i></b></p> <p><b>Example:</b></p> <pre>Device(config-mst)# revision 1</pre>                                       | Specifies the configuration revision number. The range is 0 to 65535.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 7 | <p><b>show pending</b></p> <p><b>Example:</b></p>                                                                                            | Verifies your configuration by displaying the pending configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                | Command or Action                                                                                  | Purpose                                                                                                                                                                                                                                                                                   |
|----------------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Device(config-mst) # <b>show pending</b>                                                           |                                                                                                                                                                                                                                                                                           |
| <b>Step 8</b>  | <b>exit</b><br><b>Example:</b><br>Device(config-mst) # <b>exit</b>                                 | Applies all changes, and returns to global configuration mode.                                                                                                                                                                                                                            |
| <b>Step 9</b>  | <b>spanning-tree mode mst</b><br><b>Example:</b><br>Device(config) # <b>spanning-tree mode mst</b> | Enables MSTP. RSTP is also enabled.<br><br>Changing spanning-tree modes can disrupt traffic because all spanning-tree instances are stopped for the previous mode and restarted in the new mode.<br><br>You cannot run both MSTP and PVST+ or both MSTP and Rapid PVST+ at the same time. |
| <b>Step 10</b> | <b>end</b><br><b>Example:</b><br>Device(config) # <b>end</b>                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                          |

## Configuring the Root Device (CLI)

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. Step 2 in the example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mst *instance-id* root primary**
4. **end**

### DETAILED STEPS

|        | Command or Action                                                                                                                      | Purpose                                                                                                                                                                                                                                                                   |
|--------|----------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                            |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                      | Enters the global configuration mode.                                                                                                                                                                                                                                     |
| Step 3 | <b>spanning-tree mst <i>instance-id</i> root primary</b><br><b>Example:</b><br>Device(config)# <b>spanning-tree mst 0 root primary</b> | Configures a device as the root device. <ul style="list-style-type: none"> <li>• For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.</li> </ul> |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                            | Returns to privileged EXEC mode.                                                                                                                                                                                                                                          |

## Configuring a Secondary Root Device (CLI)

When you configure a device with the extended system ID support as the secondary root, the device priority is modified from the default value (32768) to 28672. The device is then likely to become the root device for the specified instance if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768 and therefore are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the **spanning-tree mst *instance-id* root primary** global configuration command.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree mst *instance-id* root secondary**
4. **end**

### DETAILED STEPS

|        | Command or Action                                                                 | Purpose                                                                                                                                                                                                                  |
|--------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                         | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters the global configuration mode.                                                                                                                                                                                    |
| Step 3 | <b>spanning-tree mst <i>instance-id</i> root secondary</b><br><b>Example:</b>     | Configures a device as the secondary root device. <ul style="list-style-type: none"> <li>• For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series</li> </ul> |

|               | Command or Action                                             | Purpose                                                    |
|---------------|---------------------------------------------------------------|------------------------------------------------------------|
|               | Device (config) # <b>spanning-tree mst 0 root secondary</b>   | of instances separated by a comma. The range is 0 to 4094. |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device (config) # <b>end</b> | Returns to privileged EXEC mode.                           |

[Configuring the Root Device \(CLI\)](#), on page 751

## Configuring Port Priority (CLI)

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

**Note** If the device is a member of a device stack, you must use the **spanning-tree mst [instance-id] cost cost** interface configuration command instead of the **spanning-tree mst [instance-id] port-priority priority** interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree mst** *instance-id* **port-priority** *priority*
5. **end**

[Configuring Path Cost \(CLI\)](#), on page 755

## Configuring Path Cost (CLI)

The MSTP path cost default value is derived from the media speed of an interface. If a loop occurs, the MSTP uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree mst** *instance-id* **cost** *cost*
5. **end**

## Configuring the Device Priority (CLI)

Changing the priority of a device makes it more likely to be chosen as the root device whether it is a standalone device or a device in the stack.

**Note** Exercise care when using this command. For normal network configurations, we recommend that you use the **spanning-tree mst instance-id root primary** and the **spanning-tree mst instance-id root secondary** global configuration commands to specify a device as the root or secondary root device. You should modify the device priority only in circumstances where these commands do not work.

This procedure is optional.

#### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

### SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **spanning-tree mst *instance-id* priority *priority***
4. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                            | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                    | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 3 | <b>spanning-tree mst <i>instance-id</i> priority <i>priority</i></b><br><b>Example:</b><br>Device(config)# <b>spanning-tree mst 0 priority 40960</b> | Configures the device priority. <ul style="list-style-type: none"> <li>• For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094.</li> <li>• For <i>priority</i>, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device.</li> </ul> Priority values are 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. These are the only acceptable values. |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                   | Returns to privileged EXEC mode.                                                                                                                                                        |

## Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 748

## Specifying the Link Type to Ensure Rapid Transitions (CLI)

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote device running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **spanning-tree link-type point-to-point**
5. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                            | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                        |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                    | Enters the global configuration mode.                                                                                                                                                                                                 |
| <b>Step 3</b> | <b>interface <i>interface-id</i></b><br><b>Example:</b><br>Device(config)# <b>interface GigabitEthernet1/0/1</b>                     | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port-channel logical interfaces. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48. |
| <b>Step 4</b> | <b>spanning-tree link-type point-to-point</b><br><b>Example:</b><br>Device(config-if)# <b>spanning-tree link-type point-to-point</b> | Specifies that the link type of a port is point-to-point.                                                                                                                                                                             |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                      |

## Related Topics

[Specifying the MST Region Configuration and Enabling MSTP \(CLI\)](#), on page 748

## Designating the Neighbor Type (CLI)

A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.

You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the **show** commands, even if the port is in STP compatibility mode.

This procedure is optional.

### Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **spanning-tree mst pre-standard**
5. **end**

## Restarting the Protocol Migration Process (CLI)

This procedure restarts the protocol migration process and forces renegotiation with neighboring devices. It reverts the device to MST mode. It is needed when the device no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Follow these steps to restart the protocol migration process (force the renegotiation with neighboring devices) on the device.

**Before you begin**

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

If you want to use the interface version of the command, you must also know the MST interface used. This example uses GigabitEthernet1/0/1 as the interface because that was the interface set up by the instructions listed under Related Topics.

**SUMMARY STEPS**

1. **enable**
2. Enter one of the following commands:
  - **clear spanning-tree detected-protocols**
  - **clear spanning-tree detected-protocols interface *interface-id***

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                           |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                                                                                                                                                                                                                                            | Enables privileged EXEC mode. Enter your password if prompted.                    |
| <b>Step 2</b> | Enter one of the following commands: <ul style="list-style-type: none"> <li>• <b>clear spanning-tree detected-protocols</b></li> <li>• <b>clear spanning-tree detected-protocols interface <i>interface-id</i></b></li> </ul> <b>Example:</b><br>Device# <b>clear spanning-tree detected-protocols</b><br>OR<br>Device# <b>clear spanning-tree detected-protocols interface GigabitEthernet1/0/1</b> | The device reverts to the MSTP mode, and the protocol migration process restarts. |

**What to do next**

This procedure may need to be repeated if the device receives more legacy IEEE 802.1D configuration BPDUs (BPDUs with the protocol version set to 0).

### Information About Optional Spanning-Tree Features

#### PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

**Figure 47: PortFast-Enabled Interfaces**

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to

Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.

**Related Topics**

[Enabling PortFast \(CLI\)](#), on page 777

[Restriction for Optional Spanning-Tree Features](#)

## BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast edge-enabled ports, spanning tree shuts down ports that are in a PortFast edge-operational state if any BPDU is received on them. In a valid configuration, PortFast edge-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast edge-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast edge feature, and the port receives a BPDU, it is put in the error-disabled state.

The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.

**Related Topics**

[Enabling BPDU Guard \(CLI\)](#), on page 778

## BPDU Filtering

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast edge-enabled interfaces at the global level keeps those interfaces that are in a PortFast edge-operational state from sending or receiving BPDUs. The interfaces still send a few BPDUs at link-up before the switch begins to filter outbound BPDUs. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDUs. If a BPDU is received on a PortFast edge-enabled interface, the interface loses its PortFast edge-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast edge feature keeps the interface from sending or receiving BPDUs.

**Caution**

---

Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

---

You can enable the BPDU filtering feature for the entire switch or for an interface.

## UplinkFast

**Figure 48: Switches in a Hierarchical Network**

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one redundant link that spanning tree blocks to prevent loops.

If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.

When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

**Note** UplinkFast is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.

**Figure 49: UplinkFast Example Before Direct Link Failure**

This topology has no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in

a blocking state.

**Figure 50: UplinkFast Example After Direct Link Failure**

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked interface on Switch C and transitions it to the forwarding state without going through the listening and learning states. This change takes approximately 1 to

5 seconds.

## Cross-Stack UplinkFast

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see Related Topics.

**Related Topics**

[Enabling UplinkFast for Use with Redundant Links \(CLI\)](#), on page 781

[Events That Cause Fast Convergence](#), on page 772

**How Cross-Stack UplinkFast Works**

Cross-Stack UplinkFast (CSUF) ensures that one link in the stack is elected as the path to the root.

**Figure 51: Cross-Stack UplinkFast Topology**

The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.

When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.

Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate ( $2 * \text{forward-delay time} + \text{max-age time}$ ).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

### Related Topics

[Enabling UplinkFast for Use with Redundant Links \(CLI\)](#), on page 781

[Events That Cause Fast Convergence](#), on page 772

## Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur.

Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.

If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.

- The failed link, which connects the stack root to the spanning-tree root, recovers.
- A network reconfiguration causes a new stack-root switch to be selected.
- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

---

**Note** The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

---

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.
- The stack-root switch, which was powered off or failed, is powered on.
- A new switch, which might become the stack root, is added to the stack.

## BackboneFast

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches.

BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDUs from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDUs for the maximum aging time (default is 20 seconds).

The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.

**Figure 52: BackboneFast Example Before Indirect Link Failure**

This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B is in the blocking state.

B is in the blocking state.

**Figure 53: BackboneFast Example After Indirect Link Failure**

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDUs to Switch C, identifying itself as the root. When Switch C receives the inferior BPDUs from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is set. BackboneFast reconfigures the topology to account for the failure of link

L1.

**Figure 54: Adding a Switch in a Shared-Medium Topology**

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDUs did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDUs that indicate it is the root switch. However, the other switches ignore these inferior

BPDUs, and the new switch learns that Switch B is the designated switch to Switch A, the root

switch.

## EtherChannel Guard

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel, but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.

### Related Topics

[Enabling EtherChannel Guard \(CLI\)](#), on page 785

## Root Guard

*Figure 55: Root Guard in a Service-Provider Network*

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer's network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer's switch from becoming the root switch or being in the path to the root.

If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer's switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

#### Caution

Misuse of the root guard feature can cause a loss of connectivity.

#### Related Topics

[Enabling Root Guard \(CLI\)](#), on page 786

## Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in MST mode, BPDUs are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.

**Related Topics**

[Enabling Loop Guard \(CLI\)](#), on page 787

# How to Configure Optional Spanning-Tree Features

## Enabling PortFast (CLI)

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

**Caution** Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

### SUMMARY STEPS

|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                       | Enables privileged EXEC mode. Enter your password if prompted.                                |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                               | Enters the global configuration mode.                                                         |
| Step 3 | <b>spanning-tree portfast edge bpduguard default</b><br><b>Example:</b><br>Device(config)# <b>spanning-tree portfast edge bpduguard default</b> | Globally enables BPDU guard.<br>By default, BPDU guard is disabled.                           |
| Step 4 | <b>interface <i>interface-id</i></b><br><b>Example:</b><br>Device(config)# <b>interface gigabitethernet1/0/2</b>                                | Specifies the interface connected to an end station, and enters interface configuration mode. |
| Step 5 | <b>spanning-tree portfast edge</b><br><b>Example:</b><br>Device(config-if)# <b>spanning-tree portfast edge</b>                                  | Enables the PortFast edge feature.                                                            |
| Step 6 | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                                                  | Returns to privileged EXEC mode.                                                              |

### What to do next

To prevent the port from shutting down, you can use the **errdisable detect cause bpduguard shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

You also can use the **spanning-tree bpduguard enable** interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put it in the error-disabled state.

## Enabling BPDU Filtering (CLI)

You can also use the **spanning-tree bpdudfilter enable** interface configuration command to enable BPDU filtering on any interface without also enabling the PortFast edge feature. This command prevents the interface from sending or receiving BPDUs.

**Caution** Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

**Caution** Configure PortFast edge only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree portfast edge bpdudfilter default**
4. **interface *interface-id***
5. **spanning-tree portfast edge**
6. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                                                   | Purpose                                                                     |

## Enabling UplinkFast for Use with Redundant Links (CLI)

**Note** When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable UplinkFast and CSUF.

#### Before you begin

UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the **no spanning-tree vlan *vlan-id* priority** global configuration command.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree uplinkfast** [**max-update-rate** *pkts-per-second*]
4. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Device&gt; enable</pre>                                                                                                        | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Device# configure terminal</pre>                                                                                   | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 3</b> | <b>spanning-tree uplinkfast [max-update-rate<br/>pkts-per-second]</b><br><b>Example:</b><br><pre>Device(config)# spanning-tree uplinkfast<br/>max-update-rate 200</pre> | <p>Enables UplinkFast.</p> <p>(Optional) For <i>pkts-per-second</i>, the range is 0 to 32000 packets per second; the default is 150.</p> <p>If you set the rate to 0, station-learning frames are not generated, and the spanning-tree topology converges more slowly after a loss of connectivity.</p> <p>When you enter this command, CSUF also is enabled on all nonstack port interfaces.</p> |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br><pre>Device(config)# end</pre>                                                                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                  |

When UplinkFast is enabled, the switch priority of all VLANs is set to 49152. If you change the path cost to a value less than 3000 and you enable UplinkFast or UplinkFast is already enabled, the path cost of all interfaces and VLAN trunks is increased by 3000 (if you change the path cost to 3000 or above, the path cost is not altered). The changes to the switch priority and the path cost reduce the chance that a switch will become the root switch.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you enable the UplinkFast feature using these instructions, CSUF is automatically globally enabled on nonstack port interfaces.

## Disabling UplinkFast (CLI)

This procedure is optional.

Follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

### Before you begin

UplinkFast must be enabled.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no spanning-tree uplinkfast**
4. **end**

### DETAILED STEPS

|               | Command or Action                                                                                           | Purpose                                                          |
|---------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                   | Enables privileged EXEC mode. Enter your password if prompted.   |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                           | Enters the global configuration mode.                            |
| <b>Step 3</b> | <b>no spanning-tree uplinkfast</b><br><b>Example:</b><br>Device(config)# <b>no spanning-tree uplinkfast</b> | Disables UplinkFast and CSUF on the switch and all of its VLANs. |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                 | Returns to privileged EXEC mode.                                 |

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you disable the UplinkFast feature using these instructions, CSUF is automatically globally disabled on nonstack port interfaces.

## Enabling BackboneFast (CLI)

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable BackboneFast on the switch.

### Before you begin

If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree backbonefast**
4. **end**

### DETAILED STEPS

|               | Command or Action                                                                                         | Purpose                                                        |
|---------------|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                 | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                         | Enters the global configuration mode.                          |
| <b>Step 3</b> | <b>spanning-tree backbonefast</b><br><b>Example:</b><br>Device(config)# <b>spanning-tree backbonefast</b> | Enables BackboneFast.                                          |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                               | Returns to privileged EXEC mode.                               |

## Enabling EtherChannel Guard (CLI)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable EtherChannel Guard on the device.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **spanning-tree etherchannel guard misconfig**
4. **end**

### DETAILED STEPS

|        | Command or Action                                                                                                                         | Purpose                                                        |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                 | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                         | Enters the global configuration mode.                          |
| Step 3 | <b>spanning-tree etherchannel guard misconfig</b><br><b>Example:</b><br>Device(config)# <b>spanning-tree etherchannel guard misconfig</b> | Enables EtherChannel guard.                                    |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                               | Returns to privileged EXEC mode.                               |

### What to do next

You can use the **show interfaces status err-disabled** privileged EXEC command to show which device ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the **show etherchannel summary** privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the **shutdown** and **no shutdown** interface configuration commands on the port-channel interfaces that were misconfigured.

**Related Topics**

[EtherChannel Guard](#), on page 775

## Enabling Root Guard (CLI)

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.

**Note** You cannot enable both root guard and loop guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable root guard on the switch.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **spanning-tree guard root**
5. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                | Purpose                                                                       |
|---------------|------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                        | Enables privileged EXEC mode. Enter your password if prompted.                |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                | Enters the global configuration mode.                                         |
| <b>Step 3</b> | <b>interface <i>interface-id</i></b><br><b>Example:</b><br>Device(config)# <b>interface gigabitethernet1/0/2</b> | Specifies an interface to configure, and enters interface configuration mode. |
| <b>Step 4</b> | <b>spanning-tree guard root</b>                                                                                  | Enables root guard on the interface.                                          |

|               | Command or Action                                                      | Purpose                                               |
|---------------|------------------------------------------------------------------------|-------------------------------------------------------|
|               | <b>Example:</b><br>Device(config-if) # <b>spanning-tree guard root</b> | By default, root guard is disabled on all interfaces. |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config-if) # <b>end</b>        | Returns to privileged EXEC mode.                      |

## Enabling Loop Guard (CLI)

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

**Note** You cannot enable both loop guard and root guard at the same time.

You can enable this feature if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional. Follow these steps to enable loop guard on the device.

### SUMMARY STEPS

1. Enter one of the following commands:
  - **show spanning-tree active**
  - **show spanning-tree mst**
2. **configure terminal**
3. **spanning-tree loopguard default**
4. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                    | Purpose                                                |

## Monitoring the Spanning-Tree Status

Table 64: Commands for Monitoring the Spanning-Tree Status

| Command                                                                         | Purpose                                                                                                |
|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>show spanning-tree active</code>                                          | Displays spanning-tree information on active interfaces only.                                          |
| <code>show spanning-tree detail</code>                                          | Displays a detailed summary of interface information.                                                  |
| <code>show spanning-tree interface <i>interface-id</i></code>                   | Displays spanning-tree information for the specified interface.                                        |
| <code>show spanning-tree mst interface <i>interface-id</i></code>               | Displays MST information for the specified interface.                                                  |
| <code>show spanning-tree summary [totals]</code>                                | Displays a summary of interface states or displays the total lines of the spanning-tree state section. |
| <code>show spanning-tree mst interface <i>interface-id</i> portfast edge</code> | Displays spanning-tree portfast information for the specified interface.                               |

- [Feature Information for EtherChannels, on page 830](#)

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions for EtherChannels

The following are restrictions for EtherChannels:

- All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.
- Layer 3 EtherChannels are not supported if running the LAN Base license feature set.
- You cannot have a switch stack containing a mix of Catalyst 3850 and Catalyst 3650 switches.

# Information About EtherChannels

## EtherChannel Overview

EtherChannel provides fault-tolerant high-speed links between switches, routers, and servers. You can use the EtherChannel to increase the bandwidth between the wiring closets and the data center, and you can deploy it anywhere in the network where bottlenecks are likely to occur. EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention.

An EtherChannel consists of individual Ethernet links bundled into a single logical link.

**Figure 56: Typical EtherChannel Configuration**

The EtherChannel provides full-duplex bandwidth up to 8 Gb/s (Gigabit EtherChannel) or 80 Gb/s (10-Gigabit EtherChannel) between your switch and another switch or host.

Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The number of EtherChannels is limited to 128.

The LAN Base feature set supports up to 24 EtherChannels.

All ports in each EtherChannel must be configured as either Layer 2 or Layer 3 ports. The EtherChannel Layer 3 ports are made up of routed ports. Routed ports are physical ports configured to be in Layer 3 mode by using the **no switchport** interface configuration command. For more information, see the Configuring Interface Characteristics chapter.

### Related Topics

- [EtherChannel Configuration Guidelines](#), on page 804
- [Default EtherChannel Configuration](#), on page 803
- [Layer 2 EtherChannel Configuration Guidelines](#), on page 805

## EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as would any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.
- When you configure an EtherChannel in the **on** mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the **on** mode; otherwise, packet loss can occur.

[EtherChannel Configuration Guidelines](#), on page 804

[Default EtherChannel Configuration](#), on page 803

[Layer 2 EtherChannel Configuration Guidelines](#), on page 805

## EtherChannel on Devices

You can create an EtherChannel on a device, on a single device in the stack, or on multiple devices in the stack (known as cross-stack EtherChannel).

**Figure 57: Single-Switch EtherChannel**

Figure 58: Cross-Stack EtherChannel

**Related Topics**

- [EtherChannel Configuration Guidelines](#), on page 804
- [Default EtherChannel Configuration](#), on page 803
- [Layer 2 EtherChannel Configuration Guidelines](#), on page 805

**EtherChannel Link Failover**

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

- [Default EtherChannel Configuration](#), on page 803
- [Layer 2 EtherChannel Configuration Guidelines](#), on page 805

**Channel Groups and Port-Channel Interfaces**

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.

Figure 59: Relationship of Physical Ports, Channel Group and Port-Channel Interface

The **channel-group** command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 128. This port-channel interface number corresponds to the one specified with the **channel-group** interface configuration command.

- With Layer 2 ports, use the **channel-group** interface configuration command to dynamically create the port-channel interface.

You also can use the **interface port-channel** *port-channel-number* global configuration command to manually create the port-channel interface, but then you must use the **channel-group** *channel-group-number* command to bind the logical interface to a physical port. The *channel-group-number* can be the same as the *port-channel-number*; or you can use a new number. If you use a new number, the **channel-group** command dynamically creates a new port channel.

- With Layer 3 ports, you should manually create the logical interface by using the **interface port-channel** global configuration command followed by the **no switchport** interface configuration command. You then manually assign an interface to the EtherChannel by using the **channel-group** interface configuration command.
- With Layer 3 ports, use the **no switchport** interface command to configure the interface as a Layer 3 interface, and then use the **channel-group** interface configuration command to dynamically create the port-channel interface.

## Port Aggregation Protocol

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco devices and on those devices licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP can be enabled on cross-stack EtherChannels.

By using PAgP, the device or device stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single device in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed,

duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single device port.

## PAgP Modes

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

**Table 65: EtherChannel PAgP Modes**

| Mode             | Description                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>auto</b>      | Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets.                                                      |
| <b>desirable</b> | Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel). |

Switch ports exchange PAgP packets only with partner ports configured in the **auto** or **desirable** modes. Ports configured in the **on** mode do not exchange PAgP packets.

Both the **auto** and **desirable** modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed. and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the **desirable** mode can form an EtherChannel with another port that is in the **desirable** or **auto** mode.
- A port in the **auto** mode can form an EtherChannel with another port in the **desirable** mode.

A port in the **auto** mode cannot form an EtherChannel with another port that is also in the **auto** mode because neither port starts PAgP negotiation.

## Silent Mode

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the **non-silent** keyword. If you do not specify **non-silent** with the **auto** or **desirable** mode, silent mode is assumed.

Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever

becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

## PAgP Learn Method and Priority

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.

When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.

PAgP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the **pagp port-priority** interface configuration command. The higher the priority, the more likely that the port will be selected.

#### Note

The device supports address learning only on aggregate ports even though the **physical-port** keyword is provided in the CLI. The **pagp learn-method** command and the **pagp port-priority** command have no effect on the device hardware, but they are required for PAgP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the device is a physical learner, we recommend that you configure the device as a physical-port learner by using the **pagp learn-method physical-port** interface configuration command. Set the load-distribution method based on the source MAC address by using the **port-channel load-balance src-mac** global configuration command. The device then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the **pagp learn-method** command in this situation.

[Layer 2 EtherChannel Configuration Guidelines](#), on page 805

## PAgP Interaction with Other Features

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAgP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created (through the **interface port-channel** global configuration command).

PAgP sends and receives PAgP PDUs only from ports that are up and have PAgP enabled for the auto or desirable mode.

## Link Aggregation Control Protocol

The LACP is defined in IEEE 802.3ad and enables Cisco devices to manage Ethernet channels between devices that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the device or device stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single device port.

The independent mode behavior of ports in a port channel is changed. With CSCtn96950, by default, standalone mode is enabled. When no response is received from an LACP peer, ports in the port channel are moved to suspended state.

## LACP Modes

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

*Table 66: EtherChannel LACP Modes*

| Mode           | Description                                                                                                                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>active</b>  | Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.                                                                                   |
| <b>passive</b> | Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets. |

Both the **active** and **passive LACP** modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the **active** mode can form an EtherChannel with another port that is in the **active** or **passive** mode.
- A port in the **passive** mode cannot form an EtherChannel with another port that is also in the **passive** mode because neither port starts LACP negotiation.

- [EtherChannel Configuration Guidelines](#), on page 804
- [Default EtherChannel Configuration](#), on page 803
- [Layer 2 EtherChannel Configuration Guidelines](#), on page 805

## LACP and Link Redundancy

LACP port-channel operation, bandwidth availability, and link redundancy can be further refined with the LACP port-channel min-links and the LACP max-bundle features.

The LACP port-channel min-links feature:

- Configures the minimum number of ports that must be linked up and bundled in the LACP port channel.
- Prevents a low-bandwidth LACP port channel from becoming active.
- Causes an LACP port channel to become inactive if there are too few active members ports to supply the required minimum bandwidth.

The LACP max-bundle feature:

- Defines an upper limit on the number of bundled ports in an LACP port channel.
- Allows hot-standby ports with fewer bundled ports. For example, in an LACP port channel with five ports, you can specify a max-bundle of three, and the two remaining ports are designated as hot-standby ports.

#### Related Topics

## LACP Interaction with Other Features

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel. For Layer 3 EtherChannels, the MAC address is allocated by the active device as soon as the interface is created through the **interface port-channel** global configuration command.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

## EtherChannel On Mode

EtherChannel **on** mode can be used to manually configure an EtherChannel. The **on** mode forces a port to join an EtherChannel without negotiations. The **on** mode can be useful if the remote device does not support PAgP or LACP. In the **on** mode, a usable EtherChannel exists only when the devices at both ends of the link are configured in the **on** mode.

Ports that are configured in the **on** mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the **on** mode.

### Caution

You should use care when using the **on** mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

## Load-Balancing and Forwarding Methods

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the device.

### Note

Layer 3 Equal-cost multi path (ECMP) load balancing is based on source IP address, destination IP address, source port, destination port, and layer 4 protocol. Fragmented packets will be treated on two different links based on the algorithm calculated using these parameters. Any changes in one of these parameters will result in load balancing.

You configure the load-balancing and forwarding method by using the **port-channel load-balance** and the **port-channel load-balance extended** global configuration commands.

[Layer 3 EtherChannel Configuration Guidelines](#), on page 806

## MAC Address Forwarding

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host's MAC address of the incoming packet. Therefore,

packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular device. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

#### Related Topics

[Layer 3 EtherChannel Configuration Guidelines](#), on page 806

## IP Address Forwarding

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel. Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular device. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

[Layer 2 EtherChannel Configuration Guidelines](#), on page 805

[Default EtherChannel Configuration](#), on page 803

[Layer 3 EtherChannel Configuration Guidelines](#), on page 806

## Load-Balancing Advantages

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the device in the network and the kind of traffic that needs to be load-distributed.

#### *Figure 60: Load Distribution and Forwarding Methods*

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the device EtherChannel ensures that the device

uses all available bandwidth to the router. The router is configured for destination-based forwarding because the large number of workstations ensures that the traffic is evenly distributed from the router EtherChannel.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

## EtherChannel and Device Stacks

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active device removes the failed stack member device ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a device is added to an existing stack, the new device receives the running configuration from the active device and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAgP or LACP configuration on a winning device stack is not affected, but the PAgP or LACP configuration on the losing device stack is lost after the stack reboots.

## Device Stack and PAgP

With PAgP, if the active device fails or leaves the stack, the standby device becomes the new active device. A spanning-tree reconvergence is not triggered unless there is a change in the EtherChannel bandwidth. The

new active device synchronizes the configuration of the stack members to that of the active device. The PAgP configuration is not affected after an active device change unless the EtherChannel has ports residing on the old active device.

## Device Stacks and LACP

With LACP, the system ID uses the stack MAC address from the active device. When an active device fails or leaves the stack and the standby device becomes the new active device change, the LACP system ID is unchanged. By default, the LACP configuration is not affected after the active device changes.

## Default EtherChannel Configuration

The default EtherChannel configuration is described in this table.

**Table 67: Default EtherChannel Configuration**

| Feature                        | Default Setting                                                                            |
|--------------------------------|--------------------------------------------------------------------------------------------|
| Channel groups                 | None assigned.                                                                             |
| Port-channel logical interface | None defined.                                                                              |
| PAgP mode                      | No default.                                                                                |
| PAgP learn method              | Aggregate-port learning on all ports.                                                      |
| PAgP priority                  | 128 on all ports.                                                                          |
| LACP mode                      | No default.                                                                                |
| LACP learn method              | Aggregate-port learning on all ports.                                                      |
| LACP port priority             | 32768 on all ports.                                                                        |
| LACP system priority           | 32768.                                                                                     |
| LACP system ID                 | LACP system priority and the device or stack MAC address.                                  |
| Load-balancing                 | Load distribution on the device is based on the source-MAC address of the incoming packet. |

## EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

- Do not try to configure more than 128 EtherChannels on the device or device stack.
- Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
- Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
- Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
- Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the **shutdown** interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.
- When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:
  - Allowed-VLAN list
  - Spanning-tree path cost for each VLAN
  - Spanning-tree port priority for each VLAN
  - Spanning-tree Port Fast setting
- Do not configure a port to be a member of more than one EtherChannel group.
- Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same device or on different devices in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.
- Do not configure a secure port as part of an EtherChannel or the reverse.
- Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.

- If EtherChannels are configured on device interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a device by using the **dot1x system-auth-control** global configuration command.
- If cross-stack EtherChannel is configured and the device stack partitions, loops and forwarding issues can occur.

## Layer 2 EtherChannel Configuration Guidelines

When configuring Layer 2 EtherChannels, follow these guidelines:

- Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.
- An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAGP is set to the **auto** or **desirable** mode.
- Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

## Auto-LAG

The auto-LAG feature provides the ability to auto create EtherChannels on ports connected to a switch. By default, auto-LAG is disabled globally and is enabled on all port interfaces. The auto-LAG applies to a switch only when it is enabled globally.

On enabling auto-LAG globally, the following scenarios are possible:

- All port interfaces participate in creation of auto EtherChannels provided the partner port interfaces have EtherChannel configured on them. For more information, see the *"The supported auto-LAG configurations between the actor and partner devices"* table below.
- Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.
- When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:

**Table 68: The supported auto-LAG configurations between the actor and partner devices**

| Actor/Partner | Active | Passive | Auto |
|---------------|--------|---------|------|
| Active        | Yes    | Yes     | Yes  |
| Passive       | Yes    | No      | Yes  |
| Auto          | Yes    | Yes     | Yes  |

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels.

You cannot add any configurations in an existing auto created EtherChannel. To add, you should first convert it into a manual EtherChannel by executing the **port-channel<channel-number>persistent**.

**Note** Auto-LAG uses the LACP protocol to create auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

## Auto-LAG Configuration Guidelines

Follow these guidelines when configuring the auto-LAG feature.

- When auto-LAG is enabled globally and on the port interface , and if you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.
- A port interface will not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.
- When auto-LAG is enabled and auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.
- The auto-LAG is supported only on Layer 2 EtherChannel. It is not supported on Layer 3 interface and Layer 3 EtherChannel.
- The auto-LAG is supported on cross-stack EtherChannel.

## How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

### Configuring Layer 2 EtherChannels (CLI)

You configure Layer 2 EtherChannels by assigning ports to a channel group with the **channel-group** interface configuration command. This command automatically creates the port-channel logical interface.

## SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. **switchport mode** {access | trunk}
4. **switchport access vlan** *vlan-id*
5. **channel-group** *channel-group-number* **mode** {auto [non-silent] | desirable [non-silent] | on } | { active | passive}
6. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                                               | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 2</b> | <b>interface</b> <i>interface-id</i><br><b>Example:</b><br>Device(config)# <b>interface gigabitethernet2/0/1</b>                                                                                                | Specifies a physical port, and enters interface configuration mode.<br><br>Valid interfaces are physical ports.<br><br>For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group.<br><br>For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.                     |
| <b>Step 3</b> | <b>switchport mode</b> {access   trunk}<br><b>Example:</b><br>Device(config-if)# <b>switchport mode access</b>                                                                                                  | Assigns all ports as static-access ports in the same VLAN, or configure them as trunks.<br><br>If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.                                                                                                                                                                                                                             |
| <b>Step 4</b> | <b>switchport access vlan</b> <i>vlan-id</i><br><b>Example:</b><br>Device(config-if)# <b>switchport access vlan 22</b>                                                                                          | (Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.                                                                                                                                                                                                                                                                                                                 |
| <b>Step 5</b> | <b>channel-group</b> <i>channel-group-number</i> <b>mode</b> {auto [non-silent]   desirable [non-silent]   on }   { active   passive}<br><b>Example:</b><br>Device(config-if)# <b>channel-group 5 mode auto</b> | Assigns the port to a channel group, and specifies the PAgP or the LACP mode.<br><br>For <i>channel-group-number</i> , the range is 1 to 128.<br><br>For <b>mode</b> , select one of these keywords: <ul style="list-style-type: none"> <li>• <b>auto</b> —Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives</li> </ul> |

|               | Command or Action                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                             | <p>but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack.</p> <ul style="list-style-type: none"> <li>• <b>desirable</b> –Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack.</li> <li>• <b>on</b> –Forces the port to channel without PAgP or LACP. In the <b>on</b> mode, an EtherChannel exists only when a port group in the <b>on</b> mode is connected to another port group in the <b>on</b> mode.</li> <li>• <b>non-silent</b> –(Optional) If your device is connected to a partner that is PAgP-capable, configures the device port for nonsilent operation when the port is in the <b>auto</b> or <b>desirable</b> mode. If you do not specify <b>non-silent</b>, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.</li> <li>• <b>active</b>—Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets.</li> <li>• <b>passive</b> –Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.</li> </ul> |
| <b>Step 6</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config-if) # end</pre> | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Configuring Layer 3 EtherChannels (CLI)

Follow these steps to assign an Ethernet port to a Layer 3 EtherChannel. This procedure is required.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **no ip address**
5. **no switchport**
6. **channel-group** *channel-group-number* **mode** { **auto** [ **non-silent** ] | **desirable** [ **non-silent** ] | **on** } | { **active** | **passive** }
7. **end**

### DETAILED STEPS

## Configuring EtherChannel Load-Balancing (CLI)

You can configure EtherChannel load-balancing to use one of several different forwarding methods.

This task is optional.

### SUMMARY STEPS

1. **configure terminal**
2. **port-channel load-balance { dst-ip | dst-mac | dst-mixed-ip-port | dst-port | extended [dst-ip | dst-mac | dst-port | ipv6-label | l3-proto | src-ip | src-mac | src-port ] | src-dst-ip | src-dst-mac src-dst-mixed-ip-port src-dst-portsrc-ip | src-mac | src-mixed-ip-port | src-port }**
3. **end**

### DETAILED STEPS

## Configuring EtherChannel Extended Load-Balancing (CLI)

Configure EtherChannel extended load-balancing when you want to use a combination of load-balancing methods.

This task is optional.

## SUMMARY STEPS

1. `configure terminal`
2. `port-channel load-balance extended [ dst-ip | dst-mac dst-port | ipv6-label | l3-protocol | src-ip | src-mac | src-port ]`
3. `end`

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Step 3</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                                                                                                                                            | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring the PAgP Learn Method and Priority (CLI)

This task is optional.

## SUMMARY STEPS

1. `configure terminal`

2. `interface interface-id`
3. `pagp learn-method physical-port`
4. `pagp port-priority priority`
5. `end`

## DETAILED STEPS

|               | Command or Action                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                      | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>interface interface-id</b><br><b>Example:</b><br>Device(config)# <code>interface gigabitethernet 1/0/2</code>             | Specifies the port for transmission, and enters interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 3</b> | <b>pagp learn-method physical-port</b><br><b>Example:</b><br>Device(config-if)# <code>pagp learn-method physical port</code> | <p>Selects the PAgP learning method.</p> <p>By default, <b>aggregation-port learning</b> is selected, which means the device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.</p> <p>Selects <b>physical-port</b> to connect with another device that is a physical learner. Make sure to configure the <b>port-channel load-balance</b> global configuration command to <b>src-mac</b>.</p> <p>The learning method must be configured the same at both ends of the link.</p> |
| <b>Step 4</b> | <b>pagp port-priority priority</b><br><b>Example:</b><br>Device(config-if)# <code>pagp port-priority 200</code>              | <p>Assigns a priority so that the selected port is chosen for packet transmission.</p> <p>For <i>priority</i>, the range is 0 to 255. The default is 128. The higher the priority, the more likely that the port will be used for PAgP transmission.</p>                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <code>end</code>                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Configuring LACP Hot-Standby Ports

When LACP is enabled, the software, by default, tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time; the remaining eight links are placed in hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.

You can override the default behavior by specifying the maximum number of active ports in a channel, in which case, the remaining ports become hot-standby ports. For example, if you specify a maximum of five ports in a channel, up to 11 ports become hot-standby ports.

If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the device MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

## Configuring the LACP Max Bundle Feature (CLI)

When you specify the maximum number of bundled LACP ports allowed in a port channel, the remaining ports in the port channel are designated as hot-standby ports.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of LACP ports in a port channel. This procedure is optional.

### SUMMARY STEPS

1. **configure terminal**
2. **interface port-channel** *channel-number*
3. **lACP max-bundle** *max-bundle-number*
4. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                         | Purpose                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                         | Enters global configuration mode.                                                              |
| Step 2 | <b>interface port-channel <i>channel-number</i></b><br><b>Example:</b><br>Device(config)# <b>interface port-channel 2</b> | Enters interface configuration mode for a port channel.<br>The range is 1 to 128.              |
| Step 3 | <b>lACP max-bundle <i>max-bundle-number</i></b><br><b>Example:</b><br>Device(config-if)# <b>lACP max-bundle 3</b>         | Specifies the maximum number of LACP ports in the port-channel bundle.<br>The range is 1 to 8. |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                               | Returns to privileged EXEC mode.                                                               |

## Configuring LACP Port-Channel Standalone Disable

To disable the standalone EtherChannel member port state on a port channel, perform this task on the port channel interface:

## SUMMARY STEPS

1. **configure terminal**
2. **interface port-channel *channel-group***
3. **port-channel standalone-disable**
4. **end**
5. **show etherchannel**

## Configuring the LACP Port Channel Min-Links Feature (CLI)

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

To configure the minimum number of links that are required for a port channel. Perform the following tasks.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface port-channel *channel-number***
4. **port-channel min-links *min-links-number***
5. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                              | Purpose                                                                                                                                                                                                                                 |
|--------|--------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                      | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                          |

## Configuring the LACP System Priority (CLI)

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the **lacp system-priority** global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Follow these steps to configure the LACP system priority. This procedure is optional.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **lacp system-priority *priority***
4. **end**

**DETAILED STEPS**

|               | Command or Action                                                                                                       | Purpose                                                                                                                                                |

**Configuring the LACP Port Priority (CLI)**

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

**Note** If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Follow these steps to configure the LACP port priority. This procedure is optional.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *interface-id*
4. **lacp port-priority** *priority*
5. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                        | Purpose                                                                                                                                                                     |

## Configuring LACP Fast Rate Timer

You can change the LACP timer rate to modify the duration of the LACP timeout. Use the **lACP rate** command to set the rate at which LACP control packets are received by an LACP-supported interface. You can change the timeout rate from the default rate (30 seconds) to the fast rate (1 second). This command is supported only on LACP-enabled interfaces.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface { fastethernet | gigabitethernet | tengigabitethernet } slot/port**
4. **lACP rate { normal | fast }**
5. **end**
6. **show lACP internal**

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                                                                                           |

## Configuring Auto-LAG Globally

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **[no] port-channel auto**
4. **end**
5. **show etherchannel auto**

### DETAILED STEPS

|        | Command or Action                                                                            | Purpose                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                    | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                         |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>            | Enters the global configuration mode.                                                                                                                                                                                  |
| Step 3 | <b>[no] port-channel auto</b><br><b>Example:</b><br>Device(config)# <b>port-channel auto</b> | Enables the auto-LAG feature on a switch globally. Use the no form of this command to disable the auto-LAG feature on the switch globally.<br><br><b>Note</b> By default, the auto-LAG feature is enabled on the port. |
| Step 4 | <b>end</b><br><b>Example:</b>                                                                | Returns to privileged EXEC mode.                                                                                                                                                                                       |

|               | Command or Action                                                                         | Purpose                                              |
|---------------|-------------------------------------------------------------------------------------------|------------------------------------------------------|
|               | Device(config)# <b>end</b>                                                                |                                                      |
| <b>Step 5</b> | <b>show etherchannel auto</b><br><b>Example:</b><br>Device# <b>show etherchannel auto</b> | Displays that EtherChannel is created automatically. |

## Configuring Auto-LAG on a Port Interface

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface *interface-id***
4. **[no] channel-group auto**
5. **end**
6. **show etherchannel auto**

### DETAILED STEPS

|               | Command or Action                                                                                                 | Purpose                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                         | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                              |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                 | Enters the global configuration mode.                                                                                                                                                                                                       |
| <b>Step 3</b> | <b>interface <i>interface-id</i></b><br><b>Example:</b><br>Device(config)# <b>interface gigabitethernet 1/0/1</b> | Specifies the port interface to be enabled for auto-LAG, and enters interface configuration mode.                                                                                                                                           |
| <b>Step 4</b> | <b>[no] channel-group auto</b><br><b>Example:</b><br>Device(config-if)# <b>channel-group auto</b>                 | (Optional) Enables auto-LAG feature on individual port interface. Use the no form of this command to disable the auto-LAG feature on individual port interface.<br><br><b>Note</b> By default, the auto-LAG feature is enabled on the port. |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# <b>end</b>                                                    | Returns to privileged EXEC mode.                                                                                                                                                                                                            |

|        | Command or Action                                                                               | Purpose                                              |
|--------|-------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Step 6 | <b>show etherchannel auto</b><br><b>Example:</b><br>Device# <code>show etherchannel auto</code> | Displays that EtherChannel is created automatically. |

#### What to do next

## Configuring Persistence with Auto-LAG

You use the persistence command to convert the auto created EtherChannel into a manual one and allow you to add configuration on the existing EtherChannel.

### SUMMARY STEPS

1. `enable`
2. `port-channel channel-number persistent`
3. `show etherchannel summary`

### DETAILED STEPS

|        | Command or Action                                                                                                  | Purpose                                                                                                           |
|--------|--------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code>                                                    | Enables privileged EXEC mode. Enter your password if prompted.                                                    |
| Step 2 | <b>port-channel channel-number persistent</b><br><b>Example:</b><br>Device# <code>port-channel 1 persistent</code> | Converts the auto created EtherChannel into a manual one and allows you to add configuration on the EtherChannel. |
| Step 3 | <b>show etherchannel summary</b><br><b>Example:</b><br>Device# <code>show etherchannel summary</code>              | Displays the EtherChannel information.                                                                            |

## Monitoring EtherChannel, PAgP, and LACP Status

You can display EtherChannel, PAgP, and LACP status using the commands listed in this table.

*Table 69: Commands for Monitoring EtherChannel, PAgP, and LACP Status*

| Command                                                              | Description                                                 |
|----------------------------------------------------------------------|-------------------------------------------------------------|
| <code>clear lacp { channel-group-number counters   counters }</code> | Clears LACP channel-group information and traffic counters. |

| Command                                                                                                                                                                                                                                                                                              | Description                                                                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>clear pagp</b> { <i>channel-group-number</i> <b>counters</b>   <b>counters</b> }                                                                                                                                                                                                                  | Clears PAgP channel-group information and traffic counters.                                                                                                                                             |
| <b>show etherchannel</b> [ <i>channel-group-number</i> { <b>detail</b>   <b>load-balance</b>   <b>port</b>   <b>port-channel</b>   <b>protocol</b>   <b>summary</b> } ] [ <b>detail</b>   <b>load-balance</b>   <b>port</b>   <b>port-channel</b>   <b>protocol</b>   <b>auto</b>   <b>summary</b> ] | Displays EtherChannel information in a brief, detailed, and one-line summary form. Also displays the load-balance or frame-distribution scheme, port, port-channel, protocol, and Auto-LAG information. |
| <b>show pagp</b> [ <i>channel-group-number</i> ] { <b>counters</b>   <b>internal</b>   <b>neighbor</b> }                                                                                                                                                                                             | Displays PAgP information such as traffic information, the internal PAgP configuration, and neighbor information.                                                                                       |
| <b>show pagp</b> [ <i>channel-group-number</i> ] <b>dual-active</b>                                                                                                                                                                                                                                  | Displays the dual-active detection status.                                                                                                                                                              |
| <b>show lacp</b> [ <i>channel-group-number</i> ] { <b>counters</b>   <b>internal</b>   <b>neighbor</b>   <b>sys-id</b> }                                                                                                                                                                             | Displays LACP information such as traffic information, the internal LACP configuration, and neighbor information.                                                                                       |
| <b>show running-config</b>                                                                                                                                                                                                                                                                           | Verifies your configuration entries.                                                                                                                                                                    |
| <b>show etherchannel load-balance</b>                                                                                                                                                                                                                                                                | Displays the load balance or frame distribution scheme among ports in the port channel.                                                                                                                 |

## Configuration Examples for Configuring EtherChannels

### Configuring Layer 2 EtherChannels: Examples

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAgP mode **desirable**:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode desirable non-silent
Device(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode **active**:

```

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end

```

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

```

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode passive
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# switchport mode access
Device(config-if)# switchport access vlan 10
Device(config-if)# channel-group 5 mode passive
Device(config-if)# exit

```

PoE or LACP negotiation errors may occur if you configure two ports from switch to the access point (AP). This scenario can be avoided if the port channel configuration is on the switch side. For more details, see the following example:

```

interface Port-channel1
  switchport access vlan 20
  switchport mode access
  switchport nonegotiate
  no port-channel standalone-disable    <--this one
  spanning-tree portfast

```

---

**Note** If the port reports LACP errors on port flap, you should include the following command as well: **no errdisable detect cause pagp-flap**

---

## Configuring Layer 3 EtherChannels: Examples

This example shows how to configure a Layer 3 EtherChannel. It assigns two ports to channel 5 with the LACP mode **active**:

```

Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end

```

This example shows how to configure a cross-stack Layer 3 EtherChannel. It assigns two ports on stack member 2 and one port on stack member 3 to channel 7 using LACP active mode:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# no ip address
Device(config-if-range)# no switchport
Device(config-if-range)# channel-group 7 mode active
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# no ip address
Device(config-if)# no switchport
Device(config-if)# channel-group 7 mode active
Device(config-if)# exit
```

## Configuring LACP Hot-Standby Ports: Example

This example shows how to configure an Etherchannel (port channel 2) that will be active when there are at least three active ports, will comprise up to seven active ports and the remaining ports (up to nine) as hot-standby ports :

```
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# port-channel min-links 3
Device(config-if)# lacp max-bundle 7
```

This example shows how to disable the standalone EtherChannel member port state on port channel 42:

```
Device(config)# interface port-channel channel-group
Device(config-if)# port-channel standalone-disable
```

This example shows how to verify the configuration:

```
Device# show etherchannel 42 port-channel | include Standalone
Standalone Disabled = enabled

## Configuring Auto LAG: Examples

This example shows how to configure Auto-LAG on a switch

```
device> enable
device# configure terminal
device (config)# port-channel auto
device (config-if)# end
device# show etherchannel auto
```

The following example shows the summary of EtherChannel that was created automatically.

```
device# show etherchannel auto
Flags: D - down          P - bundled in port-channel
       I - stand-alone  s - suspended
       H - Hot-standby (LACP only)
       R - Layer3       S - Layer2
       U - in use       f - failed to allocate aggregator
       M - not in use, minimum links not met
       u - unsuitable for bundling
       w - waiting to be aggregated
       d - default port
       A - formed by Auto LAG
```

```
Number of channel-groups in use: 1
Number of aggregators:          1
```

```

# Configuring Resilient Ethernet Protocol

- [Finding Feature Information, on page 831](#)
- [REP Overview, on page 831](#)
- [How to Configure REP, on page 836](#)
- [Monitoring REP, on page 844](#)

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## REP Overview

Resilient Ethernet Protocol (REP) is a Cisco proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

**Note** REP is supported on Catalyst switches running IP Base and IP Services. REP is not supported on the LAN Base license.

A REP segment is a chain of ports connected to each other and configured with a segment ID. Each segment consists of standard (non-edge) segment ports and two user-configured edge ports. A router can have no more than two ports that belong to the same segment, and each segment port can have only one external neighbor. A segment can go through a shared medium, but on any link only two ports can belong to the same segment. REP is supported only on Trunk Ethernet Flow Point (EFP) interfaces.

The figure below shows an example of a segment consisting of six ports spread across four switches. Ports E1 and E2 are configured as edge ports. When all ports are operational (as in the segment on the left), a single port is blocked, shown by the diagonal line. When there is a failure in the network, the blocked port returns to the forwarding state to minimize network disruption.

**Figure 61: REP Open Segment**

The segment shown in the figure above is an open segment; there is no connectivity between the two edge ports. The REP segment cannot cause a bridging loop, and you can safely connect the segment edges to any network. All hosts connected to routers inside the segment have two possible connections to the rest of the network through the edge ports, but only one connection is accessible at any time. If a failure occurs on any segment or on any port on a REP segment, REP unblocks all ports to ensure that connectivity is available through the other gateway.

The segment shown in the figure below is a ring segment with both edge ports located on the same router. With this configuration, you can create a redundant connection between any two routers in the segment.

**Figure 62: REP Ring Segment**

REP segments have the following characteristics:

- If all ports in a segment are operational, one port (referred to as the *alternate* port) is in the blocked state for each VLAN. If VLAN load balancing is configured, two ports in the segment control the blocked state of VLANs.
- If one or more ports in a segment is not operational, and cause a link failure, all ports forward traffic on all VLANs to ensure connectivity.
- In case of a link failure, alternate ports are unblocked as quickly as possible. When the failed link is up, a logically blocked port per VLAN is selected with minimal disruption to the network.

You can construct almost any type of network based on REP segments. REP also supports VLAN load balancing, which is controlled by the primary edge port occurring at any port in the segment.

In access ring topologies, the neighboring switch might not support REP as shown in the figure below. In this case, you can configure the non-REP facing ports (E1 and E2) as edge no-neighbor ports. These ports inherit all properties of edge ports, and you can configure them the same as any edge port, including configuring them to send STP or REP topology change notices to the aggregation switch. In this case, the STP topology change notice (TCN) that is sent is a multiple spanning-tree (MST) STP message.

**Figure 63: Edge No-Neighbor Ports**

REP has these limitations:

- You must configure each segment port; an incorrect configuration can cause forwarding loops in the networks.
- REP can manage only a single failed port within the segment; multiple port failures within the REP segment cause loss of network connectivity.
- You should configure REP only in networks with redundancy. Configuring REP in a network without redundancy causes loss of connectivity.

## Link Integrity

REP does not use an end-to-end polling function between edge ports to verify link integrity. It implements local link failure detection. The REP Link Status Layer (LSL) detects its REP-aware neighbor and establishes connectivity within the segment. All VLANs are blocked on an interface until it detects the neighbor. After the neighbor is identified, REP determines which neighbor port should become the alternate port and which ports should forward traffic.

Each port in a segment has a unique port ID. The port ID format is similar to that used by the spanning tree algorithm: a port number (unique on the bridge), associated to a MAC address (unique in the network). When a segment port is coming up, its LSL starts sending packets that include the segment ID and the port ID. The port is declared as operational after it performs a three-way handshake with a neighbor in the same segment.

A segment port does not become operational if:

- No neighbor has the same segment ID.
- More than one neighbor has the same segment ID.
- The neighbor does not acknowledge the local port as a peer.

Each port creates an adjacency with its immediate neighbor. Once the neighbor adjacencies are created, the ports negotiate to determine one blocked port for the segment, the alternate port. All other ports become unblocked. By default, REP packets are sent to a BPDU class MAC address. The packets can also be sent to the Cisco multicast address, which is used only to send blocked port advertisement (BPA) messages when there is a failure in the segment. The packets are dropped by devices not running REP.

## Fast Convergence

REP runs on a physical link basis and not on a per-VLAN basis. Only one hello message is required for all VLANs, and it reduces the load on the protocol. We recommend that you create VLANs consistently on all switches in a given segment and configure the same allowed VLANs on the REP trunk ports. To avoid the delay introduced by relaying messages in software, REP also allows some packets to be flooded to a regular multicast address. These messages operate at the hardware flood layer (HFL) and are flooded to the whole network, not just the REP segment. Switches that do not belong to the segment treat them as data traffic. You can control flooding of these messages by configuring an administrative VLAN for the whole domain or for a particular segment.

The estimated convergence recovery time is between 150-500ms upto 1000 MACs, 5 VLANs. The estimated convergence recovery time for multicast traffic is between 300-500ms upto 100Groups and 5 VLANs.

## VLAN Load Balancing

One edge port in the REP segment acts as the primary edge port; the other as the secondary edge port. It is the primary edge port that always participates in VLAN load balancing in the segment. REP VLAN balancing is achieved by blocking some VLANs at a configured alternate port and all other VLANs at the primary edge port. When you configure VLAN load balancing, you can specify the alternate port in one of three ways:

- By entering the port ID of the interface. To identify the port ID of a port in the segment, enter the **show interface rep** detail interface configuration command for the port.
- By entering the neighbor offset number of a port in the segment, which identifies the downstream neighbor port of an edge port. The neighbor offset number range is  $-256$  to  $+256$ ; a value of 0 is invalid. The primary edge port has an offset number of 1; positive numbers above 1 identify downstream neighbors of the primary edge port. Negative numbers indicate the secondary edge port (offset number -1) and its downstream neighbors.

**Note** You configure offset numbers on the primary edge port by identifying a port's downstream position from the primary (or secondary) edge port. You would never enter an offset value of 1 because that is the offset number of the primary edge port itself.

The figure below shows neighbor offset numbers for a segment where E1 is the primary edge port and E2 is the secondary edge port. The red numbers inside the ring are numbers offset from the primary edge port; the black numbers outside of the ring show the offset numbers from the secondary edge port. Note that you can identify all ports (except the primary edge port) by either a positive offset number (downstream position from the primary edge port) or a negative offset number (downstream position from the secondary edge port). If E2 became the primary edge port, its offset number would then be 1 and E1 would be -1.

- By entering the **preferred** keyword to select the port that you previously configured as the preferred alternate port with the **rep segment segment-id preferred** interface configuration command.

Figure 64: Neighbor Offset Numbers in a Segment

When the REP segment is complete, all VLANs are blocked. When you configure VLAN load balancing, you must also configure triggers in one of two ways:

- Manually trigger VLAN load balancing at any time by entering the **rep preempt segment** *segment-id* privileged EXEC command on the switch that has the primary edge port.
- Configure a preempt delay time by entering the **rep preempt delay** *seconds* interface configuration command. After a link failure and recovery, VLAN load balancing begins after the configured preemption time period elapses. Note that the delay timer restarts if another port fails before the time has elapsed.

**Note** When VLAN load balancing is configured, it does not start working until triggered by either manual intervention or a link failure and recovery.

When VLAN load balancing is triggered, the primary edge port sends out a message to alert all interfaces in the segment about the preemption. When the secondary port receives the message, it is reflected into the network to notify the alternate port to block the set of VLANs specified in the message and to notify the primary edge port to block the remaining VLANs.

You can also configure a particular port in the segment to block all VLANs. Only the primary edge port initiates VLAN load balancing, which is not possible if the segment is not terminated by an edge port on each end. The primary edge port determines the local VLAN load balancing configuration.

Reconfigure the primary edge port to reconfigure load balancing. When you change the load balancing configuration, the primary edge port again waits for the **rep preempt segment** command or for the configured preempt delay period after a port failure and recovery before executing the new configuration. If you change an edge port to a regular segment port, the existing VLAN load balancing status does not change. Configuring a new edge port might cause a new topology configuration.

## Spanning Tree Interaction

REP does not interact with STP or with the Flex Link feature, but can coexist with both. A port that belongs to a segment is removed from spanning tree control and STP BPDUs are not accepted or sent from segment ports. Therefore, STP cannot run on a segment.

To migrate from an STP ring configuration to REP segment configuration, begin by configuring a single port in the ring as part of the segment and continue by configuring contiguous ports to minimize the number of segments. Each segment always contains a blocked port, so multiple segments means multiple blocked ports

and a potential loss of connectivity. When the segment has been configured in both directions up to the location of the edge ports, you then configure the edge ports.

## REP Ports

REP segments consists of Failed, Open, or Alternate ports.

- A port configured as a regular segment port starts as a failed port.
- After the neighbor adjacencies are determined, the port transitions to alternate port state, blocking all VLANs on the interface. Blocked port negotiations occur and when the segment settles, one blocked port remains in the alternate role and all other ports become open ports.
- When a failure occurs in a link, all ports move to the failed state. When the alternate port receives the failure notification, it changes to the open state, forwarding all VLANs.

A regular segment port converted to an edge port, or an edge port converted to a regular segment port, does not always result in a topology change. If you convert an edge port into a regular segment port, VLAN load balancing is not implemented unless it has been configured. For VLAN load balancing, you must configure two edge ports in the segment.

A segment port that is reconfigured as a spanning tree port restarts according the spanning tree configuration. By default, this is a designated blocking port. If PortFast is configured or if STP is disabled, the port goes into the forwarding state.

## How to Configure REP

A segment is a collection of ports connected one to the other in a chain and configured with a segment ID. To configure REP segments, you configure the REP administrative VLAN (or use the default VLAN 1) and then add the ports to the segment using interface configuration mode. You should configure two edge ports in the segment, with one of them the primary edge port and the other by default the secondary edge port. A segment has only one primary edge port. If you configure two ports in a segment as the primary edge port, for example, ports on different switches, the REP selects one of them to serve as the segment primary edge port. You can also optionally configure where to send segment topology change notices (STCNs) and VLAN load balancing.

## Default REP Configuration

REP is disabled on all interfaces. When enabled, the interface is a regular segment port unless it is configured as an edge port.

When REP is enabled, the sending of segment topology change notices (STCNs) is disabled, all VLANs are blocked, and the administrative VLAN is VLAN 1.

When VLAN load balancing is enabled, the default is manual preemption with the delay timer disabled. If VLAN load balancing is not configured, the default after manual preemption is to block all VLANs at the primary edge port.

## REP Configuration Guidelines

Follow these guidelines when configuring REP:

- We recommend that you begin by configuring one port and then configure contiguous ports to minimize the number of segments and the number of blocked ports.
- If more than two ports in a segment fail when no external neighbors are configured, one port goes into a forwarding state for the data path to help maintain connectivity during configuration. In the **show rep interface** command output, the Port Role for this port is displayed as **Fail Logical Open**; the Port Role for the other failed port is displayed as **Fail No Ext Neighbor**. When the external neighbors for the failed ports are configured, the ports go through the alternate port transitions and eventually go to an open state, or remain as the alternate port, based on the alternate port selection mechanism.
- REP ports must be Layer 2 IEEE 802.1Q or Trunk ports.
- We recommend that you configure all the trunk ports in a segment with the same set of allowed VLANs.
- Be careful when configuring REP through a Telnet connection because REP blocks all the VLANs until another REP interface sends a message to unblock it. You might lose connectivity to the router if you enable REP in a Telnet session that accesses the router through the same interface.
- You cannot run REP and STP or REP and Flex Links on the same segment or interface.
- If you connect an STP network to an REP segment, be sure that the connection is at the segment edge. An STP connection that is not at the edge might cause a bridging loop because STP does not run on REP segments. All the STP BPDUs are dropped at REP interfaces.
- You must configure all the trunk ports in a segment with the same set of allowed VLANs. If this is not done, misconfiguration occurs.
- If REP is enabled on two ports on a switch, both the ports must be either regular segment ports or edge ports. REP ports follow these rules:
  - There is no limit to the number of REP ports on a switch. However, only two ports on a switch can belong to the same REP segment.
  - If only one port on a switch is configured in a segment, the port should be an edge port.
  - If two ports on a switch belong to the same segment, they must both be edge ports, regular segment ports, or one regular port and one edge no-neighbor port. An edge port and regular segment port on a switch cannot belong to the same segment.
  - If two ports on a switch belong to the same segment, and one is configured as an edge port and one as a regular segment port (a misconfiguration), the edge port is treated as a regular segment port.
- REP interfaces come up in a blocked state and remain in a blocked state until they are safe to be unblocked. You must, therefore, be aware of the status of REP interfaces to avoid sudden connection losses.
- REP sends all the LSL PDUs in the untagged frames to the native VLAN. The BPA message sent to a Cisco multicast address is sent to the administration VLAN, which is VLAN 1 by default.
- You can configure the duration for which a REP interface remains up without receiving a hello from a neighbor. Use the **rep lsl-age-timer** value interface configuration command to set the time from 120 ms to 10000 ms. The LSL hello timer is then set to the age-timer value divided by 3. In normal operation, three LSL hellos are sent before the age timer on the peer switch expires and checks for hello messages.
  - EtherChannel port channel interfaces do not support LSL age-timer values less than 1000 ms. If you try to configure a value less than 1000 ms on a port channel, you receive an error message and the command is rejected.

- REP ports cannot be configured as one of the following port types:
  - Switched Port Analyzer (SPAN) destination port
  - Tunnel port
  - Access port
- REP is supported on EtherChannels, but not on an individual port that belongs to an EtherChannel.
- There can be a maximum of 26 REP segments per switch.

## Configuring REP Administrative VLAN

To avoid the delay created by link-failure messages, and VLAN-blocking notifications during load balancing, REP floods packets to a regular multicast address at the hardware flood layer (HFL). These messages are flooded to the whole network, and not just the REP segment. You can control the flooding of these messages by configuring an administrative VLAN.

Follow these guidelines when configuring the REP administrative VLAN:

- If you do not configure an administrative VLAN, the default is VLAN 1.
- You can configure one admin VLAN on the switch for all segments.
- The administrative VLAN cannot be the RSPAN VLAN.

To configure the REP administrative VLAN, follow these steps, beginning in privileged EXEC mode:

### SUMMARY STEPS

1. **configure terminal**
2. **rep admin vlan *vlan-id***
3. **end**
4. **show interface [*interface-id*] rep detail**
5. **copy running-config startup config**

### DETAILED STEPS

|               | Command or Action                                                                                  | Purpose                                                                                                                                                                                   |
|---------------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                  | Enters global configuration mode.                                                                                                                                                         |

|        | Command or Action                                                                                                                 | Purpose                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Step 3 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                       | Exits global configuration mode and returns to privileged EXEC mode.    |
| Step 4 | <b>show interface [interface-id] rep detail</b><br><b>Example:</b><br>Device# <b>show interface gigabitethernet1/1 rep detail</b> | (Optional) Verifies the configuration on a REP interface.               |
| Step 5 | <b>copy running-config startup config</b><br><b>Example:</b><br>Device# <b>copy running-config startup config</b>                 | (Optional) Saves your entries in the switch startup configuration file. |

## Configuring REP Interfaces

For the REP operation, you must enable REP on each segment interface and identify the segment ID. This task is required and must be done before other REP configurations. You must also configure a primary and secondary edge port on each segment. All other steps are optional.

Follow these steps to enable and configure REP on an interface:

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface interface-id**
4. **switchport mode trunk**
5. **rep segment segment-id [edge [no-neighbor] [ [primary]] [preferred]**
6. **rep stcn {interface interface id | segment id-list | stp}**
7. **rep block port {id port-id | neighbor-offset | preferred} vlan {vlan-list | all}**
8. **rep preempt delay seconds**
9. **rep lsl-age-timer value**
10. **end**
11. **show interface [interface-id] rep [detail]**
12. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                         | Purpose                                                        |
|--------|-----------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. Enter your password if prompted. |

|        | Command or Action                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | <code>configure terminal</code>                                                | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 3 | <code>interface interface-id</code>                                            | Specifies the interface, and enter interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 48.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 4 | <code>switchport mode trunk</code>                                             | Configures the interface as a Layer 2 trunk port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 5 | <code>rep segment segment-id [edge [no-neighbor] [primary]] [preferred]</code> | <p>Enables REP on the interface and identifies a segment number. The segment ID range is from 1 to 1024. These optional keywords are available:</p> <p><b>Note</b> You must configure two edge ports, including one primary edge port for each segment.</p> <ul style="list-style-type: none"> <li>• (Optional) <b>edge</b>—Configures the port as an edge port. Each segment has only two edge ports. Entering the <b>edge</b> without the <b>primary</b> keyword configures the port as the secondary edge port.</li> <li>• (Optional) <b>primary</b>—Configures the port as the primary edge port, the port on which you can configure VLAN load balancing.</li> <li>• (Optional) <b>no-neighbor</b>—configures a port with no external REP neighbors as an edge port. The port inherits all properties of edge ports, and you can configure them the same as any edge port.</li> </ul> <p><b>Note</b> Although each segment can have only one primary edge port, if you configure edge ports on two different switches and enter the <b>primary</b> keyword on both switches, the configuration is valid. However, REP selects only one of these ports as the segment primary edge port. You can identify the primary edge port for a segment by entering the <b>show rep topology</b> privileged EXEC command.</p> <ul style="list-style-type: none"> <li>• (Optional) <b>preferred</b>—Indicates that the port is the preferred alternate port or the preferred port for VLAN load balancing.</li> </ul> <p><b>Note</b> Configuring a port as preferred does not guarantee that it becomes the alternate port; it merely gives the port a slight edge over equal contenders. The alternate port is usually a previously failed port.</p> |

|        | Command or Action                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <pre>rep stcn {interface <i>interface id</i>   segment <i>id-list</i>   stp}</pre>                        | <p>(Optional) Configures the edge port to send segment topology change notices (STCNs).</p> <ul style="list-style-type: none"> <li>• <b>interface</b> <i>interface -id</i>—designates a physical interface or port channel to receive STCNs.</li> <li>• <b>segment</b> <i>id-list</i>—identifies one or more segments to receive STCNs. The range is from 1 to 1024.</li> <li>• <b>stp</b>—sends STCNs to STP networks.</li> </ul> <p><b>Note</b> spanning-tree mode mst is required on edge no-neighbor nodes when rep stcn stp is configured for sending STCNs to STP networks.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 7 | <pre>rep block port {id <i>port-id</i>   neighbor-offset   preferred} vlan {<i>vlan-list</i>   all}</pre> | <p>(Optional) Configures VLAN load balancing on the primary edge port, identifies the REP alternate port in one of three ways, and configures the VLANs to be blocked on the alternate port.</p> <ul style="list-style-type: none"> <li>• <b>id</b> <i>port-id</i>—identifies the alternate port by port ID. The port ID is automatically generated for each port in the segment. You can view interface port IDs by entering the <b>show interface type number rep [detail]</b> privileged EXEC command.</li> <li>• <b>neighbor</b> <i>offset</i>—number to identify the alternate port as a downstream neighbor from an edge port. The range is from -256 to 256, with negative numbers indicating the downstream neighbor from the secondary edge port. A value of 0 is invalid. Enter -1 to identify the secondary edge port as the alternate port. See <a href="#">Figure 64: Neighbor Offset Numbers in a Segment, on page 835</a> for an example of neighbor offset numbering.</li> </ul> <p><b>Note</b> Because you enter this command at the primary edge port (offset number 1), you cannot enter an offset value of 1 to identify an alternate port.</p> <ul style="list-style-type: none"> <li>• <b>preferred</b>—selects the regular segment port previously identified as the preferred alternate port for VLAN load balancing.</li> <li>• <b>vlan</b> <i>vlan-list</i>—blocks one VLAN or a range of VLANs.</li> <li>• <b>vlan all</b>— blocks all VLANs.</li> </ul> <p><b>Note</b> Enter this command only on the REP primary edge port.</p> |

|         | Command or Action                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 8  | <code>rep preempt delay seconds</code>                  | <p>(Optional) Configures a preempt time delay.</p> <ul style="list-style-type: none"> <li>Use this command if you want VLAN load balancing to automatically trigger after a link failure and recovery.</li> <li>The time delay range is between 15 to 300 seconds. The default is manual preemption with no time delay.</li> </ul> <p><b>Note</b> Enter this command only on the REP primary edge port.</p>                                                                                             |
| Step 9  | <code>rep lsl-age-timer value</code>                    | <p>(Optional) Configures a time (in milliseconds) for which the REP interface remains up without receiving a hello from a neighbor.</p> <p>The range is from 120 to 10000 ms in 40-ms increments. The default is 5000 ms (5 seconds).</p> <p><b>Note</b></p> <ul style="list-style-type: none"> <li>EtherChannel port channel interfaces do not support LSL age-timer values less than 1000 ms.</li> <li>Both ports on the link should have the same LSL-age configured to avoid link flaps.</li> </ul> |
| Step 10 | <code>end</code>                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 11 | <code>show interface [interface-id] rep [detail]</code> | (Optional) Displays the REP interface configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 12 | <code>copy running-config startup-config</code>         | (Optional) Saves your entries in the router startup configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Setting Manual Preemption for VLAN Load Balancing

If you do not enter the `rep preempt delay seconds` `rep preempt delay seconds` interface configuration command on the primary edge port to configure a preemption time delay, the default is to manually trigger VLAN load balancing on the segment. Be sure that all other segment configuration has been completed before manually preempting VLAN load balancing. When you enter the `rep preempt delay segment segment-id` command, a confirmation message appears before the command is executed because preemption can cause network disruption.

### SUMMARY STEPS

1. `rep preempt segment segment-id`
2. `show rep topology segment segment-id`

## DETAILED STEPS

|        | Command or Action                                        | Purpose                                                                                                              |
|--------|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>rep preempt segment <i>segment-id</i></code>       | Manually triggers VLAN load balancing on the segment.<br>You will need to confirm the command before it is executed. |
| Step 2 | <code>show rep topology segment <i>segment-id</i></code> | Displays REP topology information.                                                                                   |

## Configuring SNMP Traps for REP

You can configure the router to send REP-specific traps to notify the Simple Network Management Protocol (SNMP) server of link operational status changes and any port role changes.

## SUMMARY STEPS

1. `configure terminal`
2. `snmp mib rep trap-rate value`
3. `end`
4. `show running-config`
5. `copy running-config startup-config`

## DETAILED STEPS

|        | Command or Action                                                                                                              | Purpose                                                                                                                                                                                                                                                                                   |
|--------|--------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>configure terminal</code><br><b>Example:</b><br><code>Switch# configure terminal</code>                                  | Enters global configuration mode.                                                                                                                                                                                                                                                         |
| Step 2 | <code>snmp mib rep trap-rate <i>value</i></code><br><b>Example:</b><br><code>Switch(config)# snmp mib rep trap-rate 500</code> | Enables the switch to send REP traps, and sets the number of traps sent per second.<br><ul style="list-style-type: none"><li>• Enter the number of traps sent per second. The range is from 0 to 1000. The default is 0 (no limit imposed; a trap is sent at every occurrence).</li></ul> |
| Step 3 | <code>end</code><br><b>Example:</b><br><code>Switch(config)# end</code>                                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                          |
| Step 4 | <code>show running-config</code><br><b>Example:</b><br><code>Switch# show running-config</code>                                | (Optional) Displays the running configuration, which can be used to verify the REP trap configuration.                                                                                                                                                                                    |
| Step 5 | <code>copy running-config startup-config</code><br><b>Example:</b>                                                             | (Optional) Saves your entries in the switch startup configuration file.                                                                                                                                                                                                                   |

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another device.
- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

---

**Caution**

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.

---

# Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

## Modes of Operation

UDLD supports two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

## Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

[Enabling UDLD on an Interface \(CLI\)](#), on page 850

## Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
- One of the fiber strands in the cable is disconnected.

In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heart beat whose presence guarantees the health of the link. Conversely, the loss of the heart beat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

**Note** Udd is enabled with `udd aggressive mode` globally. When Rx cable or Tx is cable from switch1 , then the switch1 and switch2 ports will go into **Not connected** state. They do not go to **error disabled** state. Also the port does not show any light if you check the physical connection.

## Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

#### Related Topics

[Enabling UDLD Globally \(CLI\)](#), on page 849

[Enabling UDLD on an Interface \(CLI\)](#), on page 850

## Neighbor Database Maintenance

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the device receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the device receives a new hello message before an older cache entry ages, the device replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the device is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

## Event-Driven Detection and Echoing

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

## UDLD Reset Options

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The **udld reset** interface configuration command.
- The **shutdown** interface configuration command followed by the **no shutdown** interface configuration command restarts the disabled port.
- The **no udld {aggressive | enable}** global configuration command followed by the **udld {aggressive | enable}** global configuration command reenables the disabled ports.
- The **no udld port** interface configuration command followed by the **udld port [aggressive]** interface configuration command reenables the disabled fiber-optic port.
- The **errdisable recovery cause udld** global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the **errdisable recovery interval interval** global configuration command specifies the time to recover from the UDLD error-disabled state.

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring the Device for Access Point Discovery

- Ensure that the Control and Provisioning of Wireless Access Points (CAPWAP) UDP ports 5246 and 5247 (similar to the Lightweight Access Point Protocol (LWAPP) UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the device.
- If access control lists (ACLs) are in the control path between the device and its access points, you must open new protocol ports to prevent access points from being stranded.
- If an access point is in the UP state and its IP address changes, the access point tears down the existing CAPWAP tunnel and rejoins the device.

- Access points must be discovered by a device before they can become an active part of the network. The lightweight access points support the following device discovery processes:
  - Layer 3 CAPWAP discovery—You can enable this feature on different subnets from the access point. This feature uses IP addresses and UDP packets rather than the MAC addresses used by Layer 2 discovery.
  - Locally stored device IP address discovery—If the access point was previously associated to a device, the IP addresses of the primary, secondary, and tertiary devices are stored in the access point's nonvolatile memory. This process of storing device IP addresses on an access point for later deployment is called *priming the access point*.
  - DHCP server discovery—This feature uses DHCP option 43 to provide device IP addresses to the access points. Cisco switches support a DHCP server option that is typically used for this capability.
  - DNS discovery—The access point can discover devices through your domain name server (DNS). You must configure your DNS to return device IP addresses in response to `CISCO-CAPWAP-CONTROLLER.localdomain`, where *localdomain* is the access point domain name. When an access point receives an IP address and DNS information from a DHCP server, it contacts the DNS to resolve `CISCO-CAPWAP-CONTROLLER.localdomain`. When the DNS sends a list of device IP addresses, the access point sends discovery requests to the devices.

## Restrictions for Configuring the Device for Access Point Discovery

- Ensure that the devices are configured with the correct date and time. If the date and time configured on the device precedes the creation and installation date of certificates on the access points, the access point fails to join the device.
- During the discovery process, access points that are supported by the Cisco device, such as the 1140, 1260, 3500, 1040, 1600, 2600, or 3600 query only for Cisco devices.

## Information About Configuring the Device for Access Point Discovery

In a CAPWAP environment, a lightweight access point discovers a device by using CAPWAP discovery mechanisms and then sends a CAPWAP join request to the device. The device sends a CAPWAP join response to the access point that allows the access point to join the device. When the access point joins the device, the device manages its configuration, firmware, control transactions, and data transactions.

## Access Point Communication Protocols

Cisco lightweight access points use the IETF standard CAPWAP to communicate with the device and other lightweight access points on the network.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a device to manage a collection of wireless access points. CAPWAP is implemented in device for these reasons:

- To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP
- To manage RFID readers and similar devices
- To enable devices to interoperate with third-party access points in the future

## Viewing Access Point Join Information

Join statistics for an access point that sends a CAPWAP discovery request to the device at least once are maintained on the device even if the access point is rebooted or disconnected. These statistics are removed only when the device is rebooted or when you choose to clear the statistics.

## Troubleshooting the Access Point Join Process

Access points can fail to join a device for many reasons such as a RADIUS authorization is pending, self-signed certificates are not enabled on the device, the access point and device's regulatory domains do not match, and so on.

You can configure the access points to send all CAPWAP-related errors to a syslog server. You do not need to enable any debug commands on the device because all of the CAPWAP error messages can be viewed from the syslog server itself.

The state of the access point is not maintained on the device until it receives a CAPWAP join request from the access point, so it can be difficult to determine why the CAPWAP discovery request from a certain access point was rejected. In order to troubleshoot such joining issues without enabling CAPWAP debug commands on the device, the device collects information for all access points that send a discovery message to this device and maintains information for any access points that have successfully joined this device.

The device collects all join-related information for each access point that sends a CAPWAP discovery request to the device. Collection begins when the first discovery message is received from the access point and ends when the last configuration payload is sent from the device to the access point.

When the device is maintaining join-related information for the maximum number of access points, it does not collect information for any more access points.

You can also configure a DHCP server to return a syslog server IP address to the access point using option 7 on the server. The access point then starts sending all syslog messages to this IP address.

You can configure the syslog server IP address through the access point CLI, if the access point is not connected to the device by entering the **capwap ap log-server *syslog\_server\_IP\_address*** command.

When the access point joins a device for the first time, the device pushes the global syslog server IP address (the default is 255.255.255.255) to the access point. After that, the access point sends all syslog messages to this IP address, until it is overridden by one of the following scenarios:

- The access point is still connected to the same device, and you changed the global syslog server IP address configuration on the device by using the **ap syslog host *Syslog\_Server\_IP\_Address*** command. In this case, the device pushes the new global syslog server IP address to the access point.
- The access point is still connected to the same device, and you configured a specific syslog server IP address for the access point on the device by using the **ap name *Cisco\_AP* syslog host *Syslog\_Host\_IP\_Address*** command. In this case, the device pushes the new specific syslog server IP address to the access point.

- The access point gets disconnected from the device, and you configured the syslog server IP address from the access point CLI by using the **capwap ap log-server syslog\_server\_IP\_address** command. This command works only if the access point is not connected to any device.
- The access point gets disconnected from the device and joins another device. In this case, the new device pushes its global syslog server IP address to the access point.

Whenever a new syslog server IP address overrides the existing syslog server IP address, the old address is erased from persistent storage, and the new address is stored in its place. The access point also starts sending all syslog messages to the new IP address, if the access point can reach the syslog server IP address.

## How to Configure Access Point Discovery

### Configuring the Syslog Server for Access Points (CLI)

#### SUMMARY STEPS

1. **show ap config global**
2. **show ap name *Cisco\_AP* config general**

#### DETAILED STEPS

|               | Command or Action                                                                                                 | Purpose                                                                                |
|---------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>show ap config global</b><br><b>Example:</b><br>Device# show ap config global                                  | Displays the global syslog server settings for all access points that join the device. |
| <b>Step 2</b> | <b>show ap name <i>Cisco_AP</i> config general</b><br><b>Example:</b><br>Device# show ap name AP03 config general | Displays the syslog server settings for a specific access point.                       |

### Monitoring Access Point Join Information (CLI)

**Note** The procedure to perform this task using the device GUI is not currently available.

#### SUMMARY STEPS

1. **enable**
2. **show ap join stats summary**
3. **show ap mac-address *mac\_address* join stats summary**
4. **show ap mac-address *mac\_address* join stats detailed**
5. **clear ap join statistics**

## DETAILED STEPS

|        | Command or Action                                                                                                                                        | Purpose                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device# enable                                                                                                       | Enters privileged EXEC mode.                                                                                                                                                                                                   |
| Step 2 | <b>show ap join stats summary</b><br><b>Example:</b><br>Device# show ap join stats summary                                                               | Displays the MAC addresses of all the access points that are joined to the device or that have tried to join.                                                                                                                  |
| Step 3 | <b>show ap mac-address <i>mac_address</i> join stats summary</b><br><b>Example:</b><br>Device# show ap mac-address<br>000.2000.0400 join stats summary   | Displays all the statistics for the AP including the last join error detail.                                                                                                                                                   |
| Step 4 | <b>show ap mac-address <i>mac_address</i> join stats detailed</b><br><b>Example:</b><br>Device# show ap mac-address<br>000.2000.0400 join stats detailed | Displays all join-related statistics collected for a specific access point.                                                                                                                                                    |
| Step 5 | <b>clear ap join statistics</b><br><b>Example:</b><br>Device# clear ap join statistics                                                                   | Clears the join statistics for all access points.<br><br><b>Note</b> To clear the join statistics that correspond to specific access points, enter the <b>clear ap mac-address <i>mac_address</i> join statistics</b> command. |

# Configuration Examples for Configuring the Device for Access Point Discovery

## Displaying the MAC Addresses of all Access Points: Example

This example shows how to display MAC addresses of all the access points that are joined to the device:

```
Device# show ap join stats summary
Number of APs..... 4

Base Mac           EthernetMac       AP Name IP Address      Status
-----
00:0b:85:57:bc:c0 00:0b:85:57:bc:c0 AP1130 10.10.163.217  Joined
```

```
00:1c:0f:81:db:80 00:1c:63:23:ac:a0 AP1140 10.10.163.216 Not joined
00:1c:0f:81:fc:20 00:1b:d5:9f:7d:b2 AP1    10.10.163.215 Joined
00:21:1b:ea:36:60 00:0c:d4:8a:6b:c1 AP2    10.10.163.214 Not joined
```

This example shows how to display the last join error details for a specific access point:

```
Device# show ap mac-address 000.2000.0400 join stats summary
Is the AP currently connected to controller..... Yes
Time at which the AP joined this
controller last time..... Aug 21 12:50:36.061
Type of error
that occurred last..... AP got or has been disconnected
Reason for error
that occurred last..... The AP has been reset by the controller
Time at which the last join error occurred..... Aug 21 12:50:34.374
```

This example shows how to display all join-related statistics collected for a specific access point:

```
Device# show ap mac-address 000.2000.0400 join stats detailed
Discovery phase statistics
- Discovery requests received..... 2
- Successful discovery responses sent..... 2
- Unsuccessful discovery request processing..... 0
- Reason for last unsuccessful discovery attempt..... Not applicable
- Time at last successful discovery attempt..... Aug 21 12:50:23.335
- Time at last unsuccessful discovery attempt..... Not applicable

Join phase statistics
- Join requests received..... 1
- Successful join responses sent..... 1

# DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example

For more information about the AP join process, see *DHCP OPTION 43 for Lightweight Cisco Aironet Access Points Configuration Example*.

## Configuring AP Pass Through

### Information About AP Pass Through

AP pass through allows all the access points connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join another controller on the network.

Prior to this release, all access points connected Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches would be terminated on the device when the wireless management vlan is turned on. Unsupported access points connected to the device were unable join a controller on a different vlan. AP pass through allows the connected AP to join another wireless controller on the network by assigning different vlan.

The advantages of AP pass through are:

- Allows partial deployment of Cisco New Generation Wireless Controllers where some APs are connected to Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches but other APs continue to join other controllers on the network.
- The APs that are not supported on the Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches are allowed to join other controllers on the network.
- The wireless LAN controller is used to provide access to both wired and wireless guests. AP Pass through allows the AP to pass through Cisco Catalyst 3850 Series Switches and Cisco Catalyst 3650 Series Switches to join any other controller when wired guest accessing is turned on.

### Configuring AP Pass Through

All access points on VLANs other than the one with supported access points will be put into the AP pass-through mode and will not terminate on the device.

#### Procedure

|        | Command or Action                                                               | Purpose                                                                                                  |
|--------|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Device# configure terminal  | Enters global configuration mode.                                                                        |
| Step 2 | <b>wireless management interface vlan <i>vlan_id</i></b><br><br><b>Example:</b> | Configures the ports that are connected to the supported access points with the wireless management VLAN |

|               | Command or Action                                                                                                                    | Purpose                                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
|               | Device(config)# wireless management interface<br>vlan10                                                                              |                                                                                                                               |
| <b>Step 3</b> | <b>interface GigabitEthernet1/0/1</b><br><b>Example:</b><br>Device(config)# interface TenGigabitEthernet1/0/1                        | Sets the 10-Gigbit Ethernet interface.<br><br>The command prompt changes from (config)# to (config-if)#.                      |
| <b>Step 4</b> | <b>description Supported AP switchport access <i>vlan_id</i></b><br><b>Example:</b><br>Device(config-if)# switchport access vlan10   | Specifies the VLAN for which this access port will carry traffic                                                              |
| <b>Step 5</b> | <b>description Unsupported AP switchport access <i>vlan_id</i></b><br><b>Example:</b><br>Device(config-if)# switchport access vlan20 | Configures the ports that are connected to the unsupported access points with a vlan other than the wireless management VLAN. |

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring Data Encryption

- Cisco 1260, 3500, 3600, 801, 1140, 1310, and 1520 series access points support Datagram Transport Layer Security (DTLS) data encryption.
- You can use the device to enable or disable DTLS data encryption for a specific access point or for all access points.
- Non-Russian customers who use the Cisco device do not need a data DTLS license.

## Restrictions for Configuring Data Encryption

- Encryption limits throughput at both the device and the access point, and maximum throughput is desired for most enterprise networks.
- If your device does not have a data DTLS license and if the access point associated with the device has DTLS enabled, the data path will be unencrypted.

- In images that do not have a DTLS license, the DTLS commands are not available.

## Information About Data Encryption

The device enables you to encrypt Control and Provisioning of Wireless Access Points (CAPWAP) control packets (and optionally, CAPWAP data packets) that are sent between the access point and the device using DTLS. DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS. CAPWAP control packets are management packets exchanged between a device and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data). If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

## How to Configure Data Encryption

### Configuring Data Encryption (CLI)

#### SUMMARY STEPS

1. **configure terminal**
2. **ap link-encryption**
3. **end**
4. **show ap link-encryption**
5. **show wireless dtls connections**

#### DETAILED STEPS

|               | Command or Action                                                                         | Purpose                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>         | Enters global configuration mode.                                                                                                                                                                                           |
| <b>Step 2</b> | <b>ap link-encryption</b><br><b>Example:</b><br>Device(config)# <b>ap link-encryption</b> | Enables data encryption for all access points or a specific access point by entering this command. The default value is disabled.<br><br>Changing the data encryption mode requires the access points to rejoin the device. |
| <b>Step 3</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                         |
| <b>Step 4</b> | <b>show ap link-encryption</b><br><b>Example:</b>                                         | Displays the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity                                                           |

|               | Command or Action                                                                                      | Purpose                                                                                                                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device# show ap link-encryption                                                                        | check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet.                                                                                                              |
| <b>Step 5</b> | <b>show wireless dtls connections</b><br><br><b>Example:</b><br>Device# show wireless dtls connections | Displays a summary of all active DTLS connections.<br><br><b>Note</b> If you experience any problems with DTLS data encryption, enter the <b>debug dtls ap {all   event   trace}</b> command to debug all DTLS messages, events, or traces. |

# Configuration Examples for Configuring Data Encryption

## Displaying Data Encryption States for all Access Points: Examples

This example shows how to display the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet:

```
Device# show ap link-encryption
      Encryption  Dnstream  Upstream  Last
AP Name      State      Count      Count      Update
-----
3602a          Enabled          0          0      Never
```

This example shows how to display a summary of all active DTLS connections:

```
Device# show wireless dtls connections
AP Name      Local Port  Peer IP      Peer Port  Ciphersuite
-----
3602a          Capwap_Ctrl  10.10.21.213  46075      TLS_RSA_WITH_AES_128_CBC_SHA
3602a          Capwap_Data  10.10.21.213  46075      TLS_RSA_WITH_AES_128_CBC_SHA
```

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count

- You can configure the retransmission intervals and retry count both at a global and a specific access point level. A global configuration applies these configuration parameters to all the access points. Alternatively, when you configure the retransmission level and retry count at a specific access point level, the values are applied to that particular access point. The access point specific configuration has a higher precedence than the global configuration.

# Information About Retransmission Interval and Retry Count

The device and the access points exchange packets using the Control and Provisioning of Wireless Access Points (CAPWAP) reliable transport protocol. For each request, a response is defined. This response is used to acknowledge the receipt of the request message. Response messages are not explicitly acknowledged; therefore, if a response message is not received, the original request message is retransmitted after the retransmit interval. If the request is not acknowledged after a maximum number of retransmissions, the session is closed and the access points reassociate with another device.

## How to Configure Access Point Retransmission Interval and Retry Count

### Configuring the Access Point Retransmission Interval and Retry Count (CLI)

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap capwap retransmit interval interval_time`
4. `ap capwap retransmit count count_value`
5. `end`
6. `ap name Cisco_AP capwap retransmit interval interval_time`
7. `ap name Cisco_AP capwap retransmit count count_value`
8. `show ap capwap retransmit`

#### DETAILED STEPS

|               | Command or Action                                                                                                                            | Purpose                                                                                                                                               |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device# <code>enable</code>                                                                              | Enters privileged EXEC mode.                                                                                                                          |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                      | Enters global configuration mode.                                                                                                                     |
| <b>Step 3</b> | <b>ap capwap retransmit interval <i>interval_time</i></b><br><b>Example:</b><br>Device(config)# <code>ap capwap retransmit interval 2</code> | Configures the control packet retransmit interval for all access points globally.<br><b>Note</b> The range for the interval parameter is from 2 to 5. |

|        | Command or Action                                                                                                                                             | Purpose                                                                                                                                                                                                                                              |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>ap capwap retransmit count</b> <i>count_value</i><br><b>Example:</b><br>Device(config)# ap capwap retransmit count 3                                       | Configures the control packet retry count for all access points globally.<br><b>Note</b> The range for the count is from 3 to 8.                                                                                                                     |
| Step 5 | <b>end</b><br><b>Example:</b><br>Device(config)# end                                                                                                          | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                  |
| Step 6 | <b>ap name</b> <i>Cisco_AP</i> <b>capwap retransmit interval</b> <i>interval_time</i><br><b>Example:</b><br>Device# ap name AP02 capwap retransmit interval 2 | Configures the control packet retransmit interval for the individual access point that you specify.<br><b>Note</b> The range for the interval is from 2 to 5.<br><b>Note</b> You must be in privileged EXEC mode to use the <b>ap name</b> commands. |
| Step 7 | <b>ap name</b> <i>Cisco_AP</i> <b>capwap retransmit count</b> <i>count_value</i><br><b>Example:</b><br>Device# ap name AP02 capwap retransmit count 3         | Configures the control packet retry count for the individual access point that you specify.<br><b>Note</b> The range for the retry count is from 3 to 8.                                                                                             |
| Step 8 | <b>show ap capwap retransmit</b><br><b>Example:</b><br>Device# show ap capwap retransmit                                                                      | Displays the CAPWAP retransmit details.                                                                                                                                                                                                              |

## Viewing CAPWAP Maximum Transmission Unit Information (CLI)

### SUMMARY STEPS

1. enable
2. show ap name *Cisco\_AP* config general

### DETAILED STEPS

# Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count

## Viewing the CAPWAP Retransmission Details: Example

Enter the following command:

```
Device# show ap capwap retransmit
Global control packet retransmit interval : 3
Global control packet retransmit count : 5
```

| AP Name | Retransmit Interval | Retransmit Count |
|---------|---------------------|------------------|
| -----   | -----               | -----            |
| 3602a   | 5                   | 3                |

## Viewing Maximum Transmission Unit Information: Example

This example shows how to view the maximum transmission unit (MTU) for the CAPWAP path on the device. The MTU specifies the maximum size of any packet (in bytes) in a transmission:

```
Device# show ap name cisco-ap-name config general | include MTU
CAPWAP Path MTU..... 1500
```

## CHAPTER 51

# Configuring Adaptive Wireless Intrusion Prevention System

---

- [Finding Feature Information, on page 871](#)
- [Prerequisites for Configuring wIPS, on page 871](#)
- [How to Configure wIPS on Access Points, on page 871](#)
- [Monitoring wIPS Information, on page 873](#)
- [Configuration Examples for Configuring wIPS on Access Points, on page 874](#)

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring wIPS

- The regular local mode access point has been extended with a subset of Wireless Intrusion Prevention System (wIPS) capabilities. This feature enables you to deploy your access points to provide protection without needing a separate overlay network.

## How to Configure wIPS on Access Points

### Configuring wIPS on an Access Point (CLI)

#### SUMMARY STEPS

1. `ap name Cisco_AP mode local`
2. `ap name Cisco_AP dot11 5ghz shutdown`

3. `ap name Cisco_AP dot11 24ghz shutdown`
4. `ap name Cisco_AP mode monitor submode wips`
5. `ap name Cisco_AP monitor-mode wips-optimized`
6. `show ap dot11 24ghz monitor`
7. `ap name Cisco_AP no dot11 5ghz shutdown`
8. `ap name Cisco_AP no dot11 24ghz shutdown`

## DETAILED STEPS

|               | Command or Action                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><code>ap name Cisco_AP mode local</code></p> <p><b>Example:</b></p> <pre>Device# ap name AP01 mode local</pre>                                   | <p>Configures an access point for monitor mode.</p> <p>A message appears that indicates that changing the AP's mode causes the access point to reboot. This message also displays a prompt that enables you to specify whether or not you want to continue with changing the AP mode. Enter <b>y</b> at the prompt to continue.</p>                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 2</b> | <p><code>ap name Cisco_AP dot11 5ghz shutdown</code></p> <p><b>Example:</b></p> <pre>Device# ap name AP01 dot11 5ghz shutdown</pre>                 | <p>Disables the 802.11a radio on the access point.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 3</b> | <p><code>ap name Cisco_AP dot11 24ghz shutdown</code></p> <p><b>Example:</b></p> <pre>Device# ap name AP02 dot11 24ghz shutdown</pre>               | <p>Disables the 802.11b radio on the access point.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 4</b> | <p><code>ap name Cisco_AP mode monitor submode wips</code></p> <p><b>Example:</b></p> <pre>Device# ap name AP01 mode monitor submode wips</pre>     | <p>Configures the wIPS submode on the access point.</p> <p><b>Note</b> To disable wIPS on the access point, enter the <code>ap name Cisco_AP modemonitor submode none</code> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 5</b> | <p><code>ap name Cisco_AP monitor-mode wips-optimized</code></p> <p><b>Example:</b></p> <pre>Device# ap name AP01 monitor-mode wips-optimized</pre> | <p>Enables wIPS optimized channel scanning for the access point.</p> <p>The access point scans each channel for 250 milliseconds. It derives the list of channels to be scanned from the monitor configuration. You can choose the following options:</p> <ul style="list-style-type: none"> <li>• <b>All</b>—All channels supported by the access point's radio.</li> <li>• <b>Country</b>—Only the channels supported by the access point's country of operation.</li> <li>• <b>DCA</b>—Only the channel set used by the dynamic channel assignment (DCA) algorithm, which by default includes all of the nonoverlapping channels allowed in the access point's country of operation.</li> </ul> |

|        | Command or Action                                                                                                     | Purpose                                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <b>show ap dot11 24ghz monitor</b><br><b>Example:</b><br>Device# show ap dot11 24ghz monitor                          | Displays the monitor configuration channel set.<br><b>Note</b> The 802.11b Monitor Channels value in the output of the command indicates the monitor configuration channel set. |
| Step 7 | <b>ap name Cisco_AP no dot11 5ghz shutdown</b><br><b>Example:</b><br>Device# ap name AP01 no dot11<br>5ghz shutdown   | Enables the 802.11a radio on the access point.                                                                                                                                  |
| Step 8 | <b>ap name Cisco_AP no dot11 24ghz shutdown</b><br><b>Example:</b><br>Device# ap name AP01 no dot11<br>24ghz shutdown | Enables the 802.11b radio on the access point.                                                                                                                                  |

## Monitoring WPS Information

**Note** The procedure to perform this task using the device GUI is not currently available.

### SUMMARY STEPS

1. **show ap name Cisco\_AP config general**
2. **show ap monitor-mode summary**
3. **show wireless wps wips summary**
4. **show wireless wps wips statistics**
5. **clear wireless wips statistics**

### DETAILED STEPS

|        | Command or Action                                                                                          | Purpose                                                                        |
|--------|------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Step 1 | <b>show ap name Cisco_AP config general</b><br><b>Example:</b><br>Device# show ap name AP01 config general | Displays information on the WPS submode on the access point.                   |
| Step 2 | <b>show ap monitor-mode summary</b><br><b>Example:</b><br>Device# show ap monitor-mode summary             | Displays the WPS optimized channel scanning configuration on the access point. |
| Step 3 | <b>show wireless wps wips summary</b><br><b>Example:</b>                                                   | Displays the WPS configuration forwarded by NCS or Prime to the device.        |

|               | Command or Action                                                                                        | Purpose                                                    |
|---------------|----------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
|               | Device# show wireless wps wips summary                                                                   |                                                            |
| <b>Step 4</b> | <b>show wireless wps wips statistics</b><br><b>Example:</b><br>Device# show wireless wps wips statistics | Displays the current state of WPS operation on the device. |
| <b>Step 5</b> | <b>clear wireless wips statistics</b><br><b>Example:</b><br>Device# clear wireless wips statistics       | Clears the WPS statistics on the device.                   |

# Configuration Examples for Configuring WPS on Access Points

## Displaying the Monitor Configuration Channel Set: Example

This example shows how to display the monitor configuration channel set:

```
Device# show ap dot11 24ghz monitor
Default 802.11b AP monitoring
802.11b Monitor Mode..... enable
802.11b Monitor Channels..... Country channels
802.11b AP Coverage Interval..... 180 seconds
802.11b AP Load Interval..... 60 seconds
802.11b AP Noise Interval..... 180 seconds
802.11b AP Signal Strength Interval..... 60 seconds
```

## Displaying WPS Information: Examples

This example shows how to display information on the WPS submode on the access point:

```
Device# show ap name AP01 config general
Cisco AP Identifier..... 3
Cisco AP Name..... AP1131:46f2.98ac
...
AP Mode ..... Monitor
Public Safety ..... Disabled Disabled
AP SubMode ..... WIPS
```

This example shows how to display the WPS optimized channel scanning configuration on the access point:

```
Device# show ap monitor-mode summary
AP Name      Ethernet MAC  Status  Scanning
Channel
List
-----
AP1131:4f2.9a 00:16:4:f2:9:a WIPS    1,6,NA,NA
```

This example shows how to display the WPS configuration forwarded by WCS to the device:

```
Device# show wireless wps wips summary
Policy Name..... Default
Policy Version..... 3
```

This example shows how to display the current state of wIPS operation on the device:

```
Device# show wireless wps wips statistics
Policy Assignment Requests..... 1
Policy Assignment Responses..... 1
Policy Update Requests..... 0
Policy Update Responses..... 0
Policy Delete Requests..... 0
Policy Delete Responses..... 0
Alarm Updates..... 13572
Device Updates..... 8376
Device Update Requests..... 0
Device Update Responses..... 0
Forensic Updates..... 1001
Invalid WIPS Payloads..... 0
Invalid Messages Received..... 0
CAPWAP Enqueue Failed..... 0
NMSP Enqueue Failed..... 0
NMSP Transmitted Packets..... 22950
NMSP Transmit Packets Dropped..... 0
NMSP Largest Packet..... 1377
```

# Configuring Authentication for Access Points

- [Finding Feature Information, on page 877](#)
- [Prerequisites for Configuring Authentication for Access Points, on page 877](#)
- [Restrictions for Configuring Authentication for Access Points, on page 878](#)
- [Information about Configuring Authentication for Access Points, on page 878](#)
- [How to Configure Authentication for Access Points, on page 878](#)
- [Configuration Examples for Configuring Authentication for Access Points, on page 884](#)

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring Authentication for Access Points

- You can set a global username, password, and enable password for all access points that are currently joined to the device and any that join in the future inherit as they join the device. If desired, you can override the global credentials and assign a unique username, password, and enable password for a specific access point.
- After an access point joins the device, the access point enables console port security, and you are prompted for your username and password whenever you log into the access point's console port. When you log in, you are in nonprivileged mode, and you must enter the enable password in order to use the privileged mode.
- The global credentials that you configure on the device are retained across device and access point reboots. They are overwritten only if the access point joins a new device that is configured with a global username and password. If the new device is not configured with global credentials, the access point retains the global username and password configured for the first device.
- You must track the credentials used by the access points. Otherwise, you might not be able to log into an access point's console port. If you need to return the access points to the default *Cisco/Cisco* username

and password, you must clear the device's configuration and the access point's configuration to return them to factory-default settings. To reset the default access point configuration, enter the **ap name Cisco\_AP mgmtuser username Cisco password Cisco** command. Entering the command does not clear the static IP address of the access point. Once the access point rejoins a device, it adopts the default *Cisco/Cisco* username and password.

- You can configure global authentication settings for all access points that are currently joined to the device and any that join in the future. If desired, you can override the global authentication settings and assign unique authentication settings for a specific access point.
- This feature is supported on the following hardware:
  - All Cisco switches that support authentication.
  - Cisco Aironet 1140, 1260, 1310, 1520, 1600, 2600, 3500, and 3600 access points

## Restrictions for Configuring Authentication for Access Points

- The device name in the AP configuration is case sensitive. Therefore, make sure to configure the exact system name on the AP configuration. Failure to do this results in the AP fallback not working.

## Information about Configuring Authentication for Access Points

Cisco IOS access points are shipped from the factory with *Cisco* as the default enable password. This password allows users to log into the nonprivileged mode and enter the **show** and **debug** commands that pose a security threat to your network. You must change the default enable password to prevent unauthorized access and to enable users to enter configuration commands from the access point's console port.

You can configure 802.1X authentication between a lightweight access point and a Cisco switch. The access point acts as an 802.1X supplicant and is authenticated by the switch where it uses EAP-FAST with anonymous PAC provisioning.

## How to Configure Authentication for Access Points

### Configuring Global Credentials for Access Points (CLI)

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap mgmtuser username *user\_name* password 0 *password* secret 0 *secret\_value***
4. **end**
5. **ap name *Cisco\_AP* mgmtuser username *user\_name* password *password* secret *secret***
6. **show ap summary**
7. **show ap name *Cisco\_AP* config general**

## DETAILED STEPS

|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device# enable                                                                                                                                        | Enters privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 3 | <b>ap mgmtuser username user_name password 0 password secret 0 secret_value</b><br><b>Example:</b><br>Device(config)# ap mgmtuser apusr1 password appass 0 secret 0 appass1               | Configures the global username and password and enables the password for all access points that are currently joined to the device and any access points that join the device in the future. In the command, the parameter 0 specifies that an unencrypted password will follow and 8 specifies that an AES encrypted password will follow.                                                                                                                                                                                                                                            |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                                                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 5 | <b>ap name Cisco_AP mgmtuser username user_name password password secret secret</b><br><b>Example:</b><br>Device(config)# ap name TSIM_AP-2 mgmtuser apusr1 password appass secret secret | <p>Overrides the global credentials for a specific access point and assigns a unique username and password and enables password to this access point.</p> <p>The credentials that you enter in this command are retained across device and access point reboots and if the access point joins a new device.</p> <p><b>Note</b> If you want to force this access point to use the device's global credentials, enter the <b>ap name Cisco_AP no mgmtuser</b> command. The following message appears after you execute this command: "AP reverted to global username configuration."</p> |
| Step 6 | <b>show ap summary</b><br><b>Example:</b><br>Device# show ap summary                                                                                                                      | Displays a summary of all connected Cisco APs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 7 | <b>show ap name Cisco_AP config general</b><br><b>Example:</b><br>Device# show ap name AP02 config general                                                                                | <p>Displays the global credentials configuration for a specific access point.</p> <p><b>Note</b> If this access point is configured for global credentials, the AP User Mode text boxes shows "Automatic." If the global credentials have been overwritten for this access point, the AP User Mode text box shows "Customized."</p>                                                                                                                                                                                                                                                    |

## Configuring Authentication for Access Points (CLI)

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap dot1x username user_name_value password 0 password_value`
4. `end`
5. `ap name Cisco_AP dot1x-user username username_value password password_value`
6. `configure terminal`
7. `no ap dot1x username user_name_value password 0 password_value`
8. `end`
9. `show ap summary`
10. `show ap name Cisco_AP config general`

### DETAILED STEPS

|        | Command or Action                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device# <code>enable</code>                                                                                                               | Enters privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 3 | <b>ap dot1x username <i>user_name_value</i> password 0 <i>password_value</i></b><br><b>Example:</b><br>Device(config)# <code>ap dot1x username AP3 password 0 password</code> | Configures the global authentication username and password for all access points that are currently joined to the device and any access points that join the device in the future. This command contains the following keywords and arguments: <ul style="list-style-type: none"> <li>• <b>username</b>—Specifies an 802.1X username for all access points.</li> <li>• <i>user-id</i>—Username.</li> <li>• <b>password</b>—Specifies an 802.1X password for all access points.</li> <li>• <b>0</b>—Specifies an unencrypted password.</li> <li>• <b>8</b>—Specifies an AES encrypted password.</li> <li>• <i>passwd</i>—Password.</li> </ul> |

|               | Command or Action                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                                                                                                                        | <p><b>Note</b> You must enter a strong password for the password parameter. Strong passwords are at least eight characters long, contain a combination of uppercase and lowercase letters, numbers, and symbols, and are not a word in any language.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 4</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# end</pre>                                                                                                                                                                | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 5</b> | <p><b>ap name</b> <i>Cisco_AP</i> <b>dot1x-user</b> <b>username</b> <i>username_value</i> <b>password</b> <i>password_value</i></p> <p><b>Example:</b></p> <pre>Device# ap name AP03 dot1x-user username apuser1 password appass</pre> | <p>Overrides the global authentication settings and assigns a unique username and password to a specific access point. This command contains the following keywords and arguments:</p> <ul style="list-style-type: none"> <li>• <b>username</b>—Specifies to add a username.</li> <li>• <i>user-id</i>—Username.</li> <li>• <b>password</b>—Specifies to add a password.</li> <li>• <b>0</b>—Specifies an unencrypted password.</li> <li>• <b>8</b>—Specifies an AES encrypted password.</li> <li>• <i>passwd</i>—Password.</li> </ul> <p><b>Note</b> You must enter a strong password for the password parameter. See the note in Step 2 for the characteristics of strong passwords.</p> <p>The authentication settings that you enter in this command are retained across device and access point reboots and whenever the access point joins a new device.</p> |
| <b>Step 6</b> | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Device# configure terminal</pre>                                                                                                                                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 7</b> | <p><b>no ap dot1x</b> <b>username</b> <i>user_name_value</i> <b>password</b> <b>0</b> <i>password_value</i></p> <p><b>Example:</b></p> <pre>Device(config)# no ap dot1x username dot1xusr password 0 dot1xpass</pre>                   | <p>Disables 802.1X authentication for all access points or for a specific access point.</p> <p>The following message appears after you execute this command: “AP reverted to global username configuration.”</p> <p><b>Note</b> You can disable 802.1X authentication for a specific access point only if global 802.1X authentication is not enabled. If global 802.1X authentication is enabled, you can disable 802.1X for all access points only.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |

|                | Command or Action                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                            |
| <b>Step 9</b>  | <b>show ap summary</b><br><b>Example:</b><br>Device# show ap summary                                       | Displays the authentication settings for all access points that join the device.<br><br><b>Note</b> If global authentication settings are not configured, the Global AP Dot1x User Name text box shows “Not Configured.”                                                                                                                       |
| <b>Step 10</b> | <b>show ap name Cisco_AP config general</b><br><b>Example:</b><br>Device# show ap name AP02 config general | Displays the authentication settings for a specific access point.<br><br><b>Note</b> If this access point is configured for global authentication, the AP Dot1x User Mode text boxes shows “Automatic.” If the global authentication settings have been overwritten for this access point, the AP Dot1x User Mode text box shows “Customized.” |

## Configuring the Switch for Authentication (CLI)

**Note** The procedure to perform this task using the device GUI is not currently available.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **dot1x system-auth-control**
4. **aaa new-model**
5. **aaa authentication dot1x default group radius**
6. **radius-server host *host\_ip\_adress* acct-port *port\_number* auth-port *port\_number* key 0 unencrypted\_server\_key**
7. **interface TenGigabitEthernet1/0/1**
8. **switch mode access**
9. **dot1x pae authenticator**
10. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                             | Purpose                                                                                                                       |

# Configuration Examples for Configuring Authentication for Access Points

## Displaying the Authentication Settings for Access Points: Examples

This example shows how to display the authentication settings for all access points that join the device:

```
Device# show ap summary
Number of APs..... 1
Global AP User Name..... globalap
Global AP Dot1x User Name..... globalDot1x
```

This example shows how to display the authentication settings for a specific access point:

```
Device# show ap name AP02 config dot11 24ghz general
Cisco AP Identifier..... 0
Cisco AP Name..... TSIM_AP2
...
AP Dot1x User Mode..... AUTOMATIC
AP Dot1x User Name..... globalDot1x
```

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Converting Autonomous Access Points to Lightweight Mode

- Access points that are converted to lightweight mode do not support Wireless Domain Services (WDS). Converted access points communicate only with Cisco wireless LAN devices and cannot communicate with WDS devices. However, the device provides functionality that is equivalent to WDS when the access point associates to it.
- All Cisco lightweight access points support 16 Basic Service Set Identifiers (BSSIDs) per radio and a total of 16 wireless LANs per access point. When a converted access point associates to a device, only

wireless LANs with IDs 1 through 16 are pushed to the access point unless the access point is a member of an access point group.

- Access points that are converted to lightweight mode must get an IP address and discover the device using DHCP, DNS, or IP subnet broadcast.

## Information About Autonomous Access Points Converted to Lightweight Mode

You can convert autonomous Cisco Aironet access points to lightweight mode. When you upgrade the access points to lightweight mode, the access point communicates with the device and receives a configuration and software image from the device.

### Reverting from Lightweight Mode to Autonomous Mode

After you convert an autonomous access point to lightweight mode, you can convert the access point from a lightweight unit back to an autonomous unit by loading a Cisco IOS release that supports autonomous mode (Cisco IOS Release 12.3(7)JA or earlier releases). If the access point is associated with a device, you can use the device to load the Cisco IOS release. If the access point is not associated to a device, you can load the Cisco IOS release using TFTP. In either method, the access point must be able to access a TFTP server that contains the Cisco IOS release to be loaded.

### Using DHCP Option 43 and DHCP Option 60

Cisco Aironet access points use the type-length-value (TLV) format for DHCP option 43. You must program the DHCP servers to return the option based on the access point's DHCP Vendor Class Identifier (VCI) string (DHCP option 60).

See the product documentation for your DHCP server for instructions on configuring DHCP option 43. The *Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode* document contains example steps for configuring option 43 on a DHCP server.

If the access point is ordered with the Service Provider Option - AIR-OPT60-DHCP selected, the VCI string for that access point will be different than those strings listed in the previous table. The VCI string has the following suffix: ServiceProvider. For example, a 1260 with this option returns this VCI string: Cisco AP c1260-ServiceProvider.

**Note**

The device IP address that you obtain from the DHCP server should be a unicast IP address. Do not configure the device IP address as a multicast address when configuring DHCP option 43.

### How Converted Access Points Send Crash Information to the Device

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the device. If the unit rebooted because of a crash, the device pulls up the crash file using existing CAPWAP messages and

stores it in the device flash memory. The crash information copy is removed from the access point flash memory when the device pulls it from the access point.

## Uploading Memory Core Dumps from Converted Access Points

By default, access points converted to lightweight mode do not send memory core dumps to the device. This section provides instructions to upload access point core dumps using the device GUI or CLI.

## Displaying MAC Addresses for Converted Access Points

There are some differences in the way that controllers display the MAC addresses of converted access points on information pages in the controller GUI:

- On the AP Summary page, the controller lists the Ethernet MAC addresses of converted access points.
- On the AP Detail page, the controller lists the BSS MAC addresses and Ethernet MAC addresses of converted access points.
- On the Radio Summary page, the device lists converted access points by the radio MAC address.

## Configuring a Static IP Address for a Lightweight Access Point

If you want to specify an IP address for an access point rather than having one assigned automatically by a DHCP server, you can use the controller GUI or CLI to configure a static IP address for the access point. Static IP addresses are generally used only for deployments with a limited number of APs.

An access point cannot discover the device using domain name system (DNS) resolution if a static IP address is configured for the access point, unless you specify a DNS server and the domain to which the access point belongs. You can configure these parameters using either the device CLI or the GUI.

---

**Note** If you configure an access point to use a static IP address that is not on the same subnet on which the access point's previous DHCP address was, the access point falls back to a DHCP address after the access point reboots. If the access point falls back to a DHCP address, enter the **show ap config general Cisco\_AP** CLI command to show that the access point is using a fallback IP address. However, the GUI shows both the static IP address and the DHCP address, but it does not identify the DHCP address as a fallback address.

---

# How to Convert a Lightweight Access Point Back to an Autonomous Access Point

## Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)

### SUMMARY STEPS

1. `enable`
2. `ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                             | Purpose                                                                                                                                                                                                                        |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><code>enable</code></p> <p><b>Example:</b></p> <pre>Device# enable</pre>                                                                                                                   | Enters privileged EXEC mode.                                                                                                                                                                                                   |
| <b>Step 2</b> | <p><code>ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename</code></p> <p><b>Example:</b></p> <pre>Device# ap name AP02 tftp-downgrade 10.0.0.1 tsrvname</pre> | <p>Converts the lightweight access point back to autonomous mode.</p> <p><b>Note</b> After entering this command, you must wait until the access point reboots and then reconfigure the access point using the CLI or GUI.</p> |

## Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)

- Step 1** Configure the PC on which your TFTP server software runs with a static IP address in the range of 10.0.0.2 to 10.0.0.30.
- Step 2** Make sure that the PC contains the access point image file (such as `c1140-k9w7-tar.123-7.JA.tar` for a 1140 series access point) in the TFTP server folder and that the TFTP server is activated.
- Step 3** Rename the access point image file in the TFTP server folder to `c1140-k9w7-tar.default` for a 1140 series access point.
- Step 4** Connect the PC to the access point using a Category 5 (CAT5) Ethernet cable.
- Step 5** Disconnect power from the access point.
- Step 6** Press and hold the **MODE** button while you reconnect power to the access point.
 

**Note** The **MODE** button on the access point must be enabled.
- Step 7** Hold the **MODE** button until the status LED turns red (approximately 20 to 30 seconds), and release the **MODE** button.
- Step 8** Wait until the access point reboots as indicated by all LEDs turning green followed by the Status LED blinking green.

**Step 9** After the access point reboots, reconfigure the access point using the GUI or the CLI.

## Authorizing Access Points (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap auth-list ap-policy authorize-ap**
4. **username *user\_name* mac aaa attribute list *list\_name***
5. **aaa new-model**
6. **aaa authorization credential-download *auth\_list* local**
7. **aaa attribute list *list***
8. **aaa session-id common**
9. **aaa local authentication default authorization default**
10. **show ap name *Cisco\_AP* config general**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                              | Purpose                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Device# <b>enable</b>                                                                                                                  | Enters privileged EXEC mode.                           |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                          | Enters global configuration mode.                      |
| <b>Step 3</b> | <b>ap auth-list ap-policy authorize-ap</b><br><br><b>Example:</b><br>Device(config)# <b>ap auth-list ap-policy authorize-ap</b>                                                | Configures an access point authorization policy.       |
| <b>Step 4</b> | <b>username <i>user_name</i> mac aaa attribute list <i>list_name</i></b><br><br><b>Example:</b><br>Device(config)# <b>username aaa.bbb.ccc mac aaa attribute list attrlist</b> | Configures the MAC address of an access point locally. |
| <b>Step 5</b> | <b>aaa new-model</b><br><br><b>Example:</b><br>Device(config)# <b>aaa new-model</b>                                                                                            | Enables new access control commands and functions.     |

|                | Command or Action                                                                                                                                                              | Purpose                                                                             |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Step 6</b>  | <b>aaa authorization credential-download <i>auth_list</i> local</b><br><b>Example:</b><br><pre>Device(config)# aaa authorization credential-download auth_download local</pre> | Downloads EAP credentials from the local server.                                    |
| <b>Step 7</b>  | <b>aaa attribute list <i>list</i></b><br><b>Example:</b><br><pre>Device(config)# aaa attribute list alist</pre>                                                                | Configures AAA attribute list definitions.                                          |
| <b>Step 8</b>  | <b>aaa session-id common</b><br><b>Example:</b><br><pre>Device(config)# aaa session-id common</pre>                                                                            | Configures the AAA common session ID.                                               |
| <b>Step 9</b>  | <b>aaa local authentication default authorization default</b><br><b>Example:</b><br><pre>Device(config)# aaa local authentication default authorization default</pre>          | Configures the local authentication method list.                                    |
| <b>Step 10</b> | <b>show ap name <i>Cisco_AP</i> config general</b><br><b>Example:</b><br><pre>Device(config)# show ap name AP01 config general</pre>                                           | Displays the configuration information that corresponds to a specific access point. |

## Disabling the Reset Button on Converted Access Points (CLI)

You can enable or disable the Reset button on access points that are converted to lightweight mode. The Reset button is labeled MODE on the outside of the access point.

**Note** The procedure to perform this task using the controller GUI is not currently available.

### SUMMARY STEPS

1. enable
2. configure terminal
3. no ap reset-button
4. end
5. ap name *Cisco\_AP* reset-button

## DETAILED STEPS

|               | Command or Action                                                                            | Purpose                                                                                                                                                                                                                                                 |

| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device# enable                                           | Enters privileged EXEC mode.                                                                                                                                                                                                                            |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>            | Enters global configuration mode.                                                                                                                                                                                                                       |
| <b>Step 3</b> | <b>no ap reset-button</b><br><b>Example:</b><br>Device(config)# no ap reset-button           | Disables the Reset buttons on all converted access points that are associated to the device.<br><br><b>Note</b> To enable the Reset buttons on all converted access points that are associated to the device, enter the <b>ap reset-button</b> command. |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                  | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                     |
| <b>Step 5</b> | <b>ap name Cisco_AP reset-button</b><br><b>Example:</b><br>Device# ap name AP02 reset-button | Enables the Reset button on the converted access point that you specify.                                                                                                                                                                                |

## Monitoring the AP Crash Log Information

**Note** The procedure to perform this task using the device GUI is not currently available.

## SUMMARY STEPS

1. enable
2. show ap crash-file

## DETAILED STEPS

|               | Command or Action                                  | Purpose                      |
|---------------|----------------------------------------------------|------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device# enable | Enters privileged EXEC mode. |

|               | Command or Action                                                              | Purpose                                                      |
|---------------|--------------------------------------------------------------------------------|--------------------------------------------------------------|
| <b>Step 2</b> | <b>show ap crash-file</b><br><br><b>Example:</b><br>Device# show ap crash-file | Verifies whether the crash file is downloaded to the device. |

# How to Configure a Static IP Address on an Access Point

## Configuring a Static IP Address on an Access Point (CLI)

### SUMMARY STEPS

1. enable
2. ap name *Cisco\_AP* static-ip ip-address *static\_ap\_address* netmask *static\_ip\_netmask* gateway *static\_ip\_gateway*
3. enable
4. configure terminal
5. ap static-ip name-server *nameserver\_ip\_address*
6. ap static-ip domain *static\_ip\_domain*
7. end
8. show ap name *Cisco\_AP* config general

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Device# enable                                                                                                                                                                                                          | Enters privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 2</b> | <b>ap name <i>Cisco_AP</i> static-ip ip-address <i>static_ap_address</i> netmask <i>static_ip_netmask</i> gateway <i>static_ip_gateway</i></b><br><br><b>Example:</b><br>Device# ap name AP03 static-ip ip-address 9.9.9.16 netmask 255.255.0.0 gateway 9.9.9.2 | Configures a static IP address on the access point. This command contains the following keywords and arguments: <ul style="list-style-type: none"> <li>• <b>ip-address</b>— Specifies the Cisco access point static IP address.</li> <li>• <i>ip-address</i>— Cisco access point static IP address.</li> <li>• <b>netmask</b>— Specifies the Cisco access point static IP netmask.</li> <li>• <i>netmask</i>— Cisco access point static IP netmask.</li> <li>• <b>gateway</b>— Specifies the Cisco access point gateway.</li> <li>• <i>gateway</i>— IP address of the Cisco access point gateway.</li> </ul> |

|               | Command or Action                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                             | The access point reboots and rejoins the device, and the static IP address that you specify is pushed to the access point. After the static IP address has been sent to the access point, you can configure the DNS server IP address and domain name. You must perform Steps 3 and 4 after the access points reboot. |
| <b>Step 3</b> | <b>enable</b><br><b>Example:</b><br>Device# enable                                                                                          | Enters privileged EXEC mode.                                                                                                                                                                                                                                                                                          |
| <b>Step 4</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                                                  | Enters global configuration mode.                                                                                                                                                                                                                                                                                     |
| <b>Step 5</b> | <b>ap static-ip name-server <i>nameserver_ip_address</i></b><br><b>Example:</b><br>Device(config)# ap static-ip name-server<br>10.10.10.205 | Configures a DNS server so that a specific access point or all access points can discover the device using DNS resolution.<br><b>Note</b> To undo the DNS server configuration, enter the <b>no ap static-ip name-server <i>nameserver_ip_address</i></b> command.                                                    |
| <b>Step 6</b> | <b>ap static-ip domain <i>static_ip_domain</i></b><br><b>Example:</b><br>Device(config)# ap static-ip domain domain1                        | Configures the domain to which a specific access point or all access points belong.<br><b>Note</b> To undo the domain name configuration, enter the <b>no ap static-ip domain <i>static_ip_domain</i></b> command.                                                                                                    |
| <b>Step 7</b> | <b>end</b><br><b>Example:</b><br>Device(config)# end                                                                                        | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                   |
| <b>Step 8</b> | <b>show ap name <i>Cisco_AP</i> config general</b><br><b>Example:</b><br>Device# show ap name AP03 config general                           | Displays the IP address configuration for the access point.                                                                                                                                                                                                                                                           |

## Recovering the Access Point Using the TFTP Recovery Procedure

- Step 1** Download the required recovery image from Cisco.com (ap3g2-k9w8-tar.152-2.JA.tar) and install it in the root directory of your TFTP server.

- Step 2** Connect the TFTP server to the same subnet as the target access point and power-cycle the access point. The access point boots from the TFTP image and then joins the device to download the oversized access point image and complete the upgrade procedure.
- Step 3** After the access point has been recovered, you can remove the TFTP server.
- 

## Configuration Examples for Converting Autonomous Access Points to Lightweight Mode

### Displaying the IP Address Configuration for Access Points: Example

This example shows how to display the IP address configuration for the access point:

```
Device# show ap name AP03 dot11 24ghz config general
Cisco AP Identifier..... 4
Cisco AP Name..... AP6
IP Address Configuration..... Static IP assigned
IP Address..... 10.10.10.118
IP NetMask..... 255.255.255.0
Gateway IP Addr..... 10.10.10.1
Domain..... Domain1
Name Server..... 10.10.10.205
...
```

### Displaying Access Point Crash File Information: Example

This example shows how to display access point crash file information. Using this command, you can verify whether the file is downloaded to the device:

```
Device# show ap crash-file
Local Core Files:
lrad_AP1130.rdump0 (156)
```

The number in parentheses indicates the size of the file. The size should be greater than zero if a core dump file is available.

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges

A WGB is a mode that can be configured on an autonomous Cisco IOS access point to provide wireless connectivity to a lightweight access point on behalf of clients that are connected by Ethernet to the WGB access point. A WGB connects a wired network over a single wireless segment by learning the MAC addresses of its wired clients on the Ethernet interface and reporting them to the lightweight access point using Internet Access Point Protocol (IAPP) messaging. The WGB provides wireless access connectivity to wired clients by establishing a single wireless connection to the lightweight access point.

When a Cisco WGB is used, the WGB informs the access points of all the clients that it is associated with. The device is aware of the clients that are associated with the access point. When non-Cisco WGBs are used, the device has no information about the IP address of the clients on the wired segment behind the WGB. Without this information, the device drops the following types of messages:

- ARP REQ from the distribution system for the WGB client.
- ARP RPLY from the WGB client.
- DHCP REQ from the WGB client.

- DHCP RPLY for the WGB client.

## Monitoring the Status of Workgroup Bridges

**Note** The procedure to perform this task using the device GUI is not currently available.

### SUMMARY STEPS

1. `enable`
2. `show wireless wgb summary`
3. `show wireless wgb mac-address wgb_mac_address detail`

### DETAILED STEPS

|               | Command or Action                                                                                                                                   | Purpose                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device# enable                                                                                                  | Enters privileged EXEC mode.                                                      |
| <b>Step 2</b> | <b>show wireless wgb summary</b><br><b>Example:</b><br>Device# show wireless wgb summary                                                            | Displays the WGBs on your network.                                                |
| <b>Step 3</b> | <b>show wireless wgb mac-address wgb_mac_address detail</b><br><b>Example:</b><br>Device# show wireless wgb mac-address<br>00:0d:ed:dd:25:82 detail | Displays the details of any wired clients that are connected to a particular WGB. |

## Debugging WGB Issues (CLI)

**Note** The procedure to perform this task using the device GUI is not currently available.

### SUMMARY STEPS

1. `enable`
2. `debug iapp all`
3. `debug iapp error`
4. `debug iapp packet`

5. `debug mobility handoff [switch switch_number]`
6. `debug dhcp`
7. `debug dot11 mobile`
8. `debug dot11 state`

## DETAILED STEPS

|               | Command or Action                                                                                         | Purpose                                                                              |
|---------------|-----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device# enable                                                        | Enters privileged EXEC mode.                                                         |
| <b>Step 2</b> | <b>debug iapp all</b><br><b>Example:</b><br>Device# debug iapp all                                        | Enables debugging for IAPP messages.                                                 |
| <b>Step 3</b> | <b>debug iapp error</b><br><b>Example:</b><br>Device# debug iapp error                                    | Enables debugging for IAPP error events.                                             |
| <b>Step 4</b> | <b>debug iapp packet</b><br><b>Example:</b><br>Device# debug iapp packet                                  | Enables debugging for IAPP packets.                                                  |
| <b>Step 5</b> | <b>debug mobility handoff [switch switch_number]</b><br><b>Example:</b><br>Device# debug mobility handoff | Enables debugging for any roaming issues.                                            |
| <b>Step 6</b> | <b>debug dhcp</b><br><b>Example:</b><br>Device# debug dhcp                                                | Debug an IP assignment issue when DHCP is used.                                      |
| <b>Step 7</b> | <b>debug dot11 mobile</b><br><b>Example:</b><br>Device# debug dot11 mobile                                | Enables dot11/mobile debugging. Debug an IP assignment issue when static IP is used. |
| <b>Step 8</b> | <b>debug dot11 state</b><br><b>Example:</b><br>Device# debug dot11 state                                  | Enables dot11/state debugging. Debug an IP assignment issue when static IP is used.  |

# Configuration Examples for Configuring Workgroup Bridges

## WGB Configuration: Example

This example shows how to configure a WGB access point using static WEP with a 40-bit WEP key:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# dot11 ssid WGB_with_static_WEP
Device(config-ssid)# authentication open
Device(config-ssid)# guest-mode
Device(config-ssid)# exit
Device(config)# interface dot11Radio 0
Device(config)# station-role workgroup-bridge
Device(config-if)# encry mode wep 40
Device(config-if)# encry key 1 size 40 0 1234567890
Device(config-if)# ssid WGB_with_static_WEP
Device(config-if)# end
```

Verify that the WGB is associated to an access point by entering this command on the WGB:

### **show dot11 association**

Information similar to the following appears:

```
Device# show dot11 associations
802.11 Client Stations on Dot11Radio0:
SSID [FCVTESTING] :
MAC Address      IP address      Device          Name           Parent          State
000b.8581.6aee  10.11.12.1     WGB-client     map1           -               Assoc
ap#
```

## CHAPTER 55

# Configuring Probe Request Forwarding

- [Finding Feature Information, on page 899](#)
- [Information About Configuring Probe Request Forwarding, on page 899](#)
- [How to Configure Probe Request Forwarding \(CLI\), on page 899](#)

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About Configuring Probe Request Forwarding

Probe requests are 802.11 management frames that are sent by clients to request information about the capabilities of Service Set Identifiers (SSIDs). By default, access points forward acknowledged probe requests to the device for processing. Acknowledged probe requests are probe requests for SSIDs that are supported by the access point. If desired, you can configure access points to forward both acknowledged and unacknowledged probe requests to the device. The device can use the information from unacknowledged probe requests to improve the location accuracy.

## How to Configure Probe Request Forwarding (CLI)

**Note** The procedure to perform this task using the device GUI is not currently available.

### SUMMARY STEPS

1. **configure terminal**
2. **wireless probe filter**
3. **wireless probe filter *num\_probes interval***

4. end
5. show wireless probe

## DETAILED STEPS

|               | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>wireless probe filter</b><br><b>Example:</b><br>Device(config)# <code>wireless probe filter</code>                                | Enables or disables the filtering of probe requests forwarded from an access point to the device.<br><br><b>Note</b> If you enable probe filtering, the default filter setting, the access point forwards only acknowledged probe requests to the device. If you disable probe filtering, the access point forwards both acknowledged and unacknowledged probe requests to the device.                                                                                               |
| <b>Step 3</b> | <b>wireless probe filter <i>num_probes interval</i></b><br><b>Example:</b><br>Device(config)# <code>wireless probe filter 5 5</code> | Limits the number of probe requests sent to the device per client per access point radio in a given interval. You must specify the following arguments with this command: <ul style="list-style-type: none"> <li>• <i>num_probes</i>—Number of probe requests forwarded to the device per client per access point radio in a given interval. The range is from 1 to 100.</li> <li>• <i>interval</i>—Probe limit interval in milliseconds. The range is from 100 to 10000.</li> </ul> |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                                    | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 5</b> | <b>show wireless probe</b><br><b>Example:</b><br>Device# <code>show wireless probe</code>                                            | Displays the advanced probe request configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# Optimizing RFID Tracking

- [Finding Feature Information](#), on page 901
- [Optimizing RFID Tracking on Access Points](#), on page 901
- [How to Optimize RFID Tracking on Access Points](#), on page 901
- [Configuration Examples for Optimizing RFID Tracking](#), on page 903

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Optimizing RFID Tracking on Access Points

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

## How to Optimize RFID Tracking on Access Points

### Optimizing RFID Tracking on Access Points (CLI)

#### SUMMARY STEPS

1. `ap name Cisco_AP mode monitor submode none`
2. `ap name Cisco_AP dot11 24ghz shutdown`
3. `ap name Cisco_AP monitor-mode tracking-opt`
4. `ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]}`

5. `ap name Cisco_AP no dot11 24ghz shutdown`
6. `show ap monitor-mode summary`

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>ap name Cisco_AP mode monitor submode none</b><br><b>Example:</b><br><pre>Device# ap name 3602a mode monitor submode none</pre>                                                                                    | Specifies the monitor submode for the access point as none.<br><br><b>Note</b> A warning message indicates that changing the access point's mode will cause the access point to reboot and prompts you to specify whether you want to continue by entering <b>Y</b> .<br><br>After you enter <b>Y</b> , the access point reboots. |
| <b>Step 2</b> | <b>ap name Cisco_AP dot11 24ghz shutdown</b><br><b>Example:</b><br><pre>Device# ap name AP01 dot11 24ghz shutdown</pre>                                                                                               | Disables the access point radio.                                                                                                                                                                                                                                                                                                  |
| <b>Step 3</b> | <b>ap name Cisco_AP monitor-mode tracking-opt</b><br><b>Example:</b><br><pre>Device# ap name TSIM_AP1 monitor-mode tracking-opt</pre>                                                                                 | Configures the access point to scan only the Dynamic Channel Assignment (DCA) channels supported by its country of operation.<br><br><b>Note</b> To disable tracking optimization for an access point, enter the <b>ap name Cisco_AP monitor-mode tracking-opt no-optimization</b> command.                                       |
| <b>Step 4</b> | <b>ap name Cisco_AP monitor-mode dot11b {fast-channel [first_channel second_channel third_channel fourth_channel]}</b><br><b>Example:</b><br><pre>Device# ap name AP01 monitor-mode dot11b fast-channel 1 2 3 4</pre> | Chooses up to four specific 802.11b channels to be scanned by the access point.<br><br><b>Note</b> In the United States, you can assign any value from 1 to 11 (inclusive) to the channel variable. Other countries support additional channels. You must assign at least one channel.                                            |
| <b>Step 5</b> | <b>ap name Cisco_AP no dot11 24ghz shutdown</b><br><b>Example:</b><br><pre>Device# ap name AP01 no dot11 24ghz shutdown</pre>                                                                                         | Enables the access point radio.                                                                                                                                                                                                                                                                                                   |
| <b>Step 6</b> | <b>show ap monitor-mode summary</b><br><b>Example:</b><br><pre>Device# show ap monitor-mode summary</pre>                                                                                                             | Displays all the access points in monitor mode.                                                                                                                                                                                                                                                                                   |

# Configuration Examples for Optimizing RFID Tracking

## Displaying all the Access Points in Monitor Mode: Example

This example shows how to display all the access points in monitor mode:

```
Device# show ap monitor-mode summary
```

| AP Name       | Ethernet MAC   | Status   | Scanning<br>Channel<br>List |
|---------------|----------------|----------|-----------------------------|
| -----         | -----          | -----    | -----                       |
| AP1131:4f2.9a | 00:16:4:f2:9:a | Tracking | 1,6,NA,NA                   |

## CHAPTER 57

# Configuring Country Codes

- [Finding Feature Information, on page 905](#)
- [Prerequisites for Configuring Country Codes, on page 905](#)
- [Information About Configuring Country Codes, on page 906](#)
- [How to Configure Country Codes \(CLI\), on page 906](#)
- [Configuration Examples for Configuring Country Codes, on page 909](#)

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring Country Codes

- Generally, you configure one country code per device; you configure one code that matches the physical location of the device and its access points. You can configure up to 20 country codes per device. This multiple-country support enables you to manage access points in various countries from a single device.
- When the multiple-country feature is used, all devices that are going to join the same RF group must be configured with the same set of countries, configured in the same order.
- Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.
- The country list configured on the RF group leader determines which channels the members would operate on. This list is independent of which countries have been configured on the RF group members.
- For devices in the Japan regulatory domain, you must have had one or more Japan country codes (JP, J2, or J3) configured on your device at the time you last booted your device.
- For devices in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your device.

# Information About Configuring Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio's broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

## Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- JP—Allows only -J radios to join the controller
- J2—Allows only -P radios to join the controller
- J3—Uses the -U frequencies but allows -U, -P and -Q (other than 1550/1600/2600/3600) radios to join the WLC
- J4—Allows 2.4G JPQU and 5G PQU to join the controller.

---

**Note** The 1550, 1600, 2600, and 3600 APs require J4.

---

See the *Channels and Maximum Power Settings for Cisco Aironet Lightweight Access Points* document for the list of channels and power levels supported by access points in the Japanese regulatory domains.

# How to Configure Country Codes (CLI)

---

**Note** The procedure to perform this task using the device GUI is not currently available.

---

## SUMMARY STEPS

1. `enable`
2. `show wireless country supported`
3. `configure terminal`
4. `ap dot11 24ghz shutdown`
5. `ap dot11 5ghz shutdown`
6. `ap country country_code`
7. `end`
8. `show wireless country channels`
9. `configure terminal`
10. `no ap dot11 5ghz shutdown`

11. `no ap dot11 24ghz shutdown`
12. `end`
13. `ap name Cisco_AP shutdown`
14. `configure terminal`
15. `ap country country_code`
16. `end`
17. `ap name Cisco_AP no shutdown`

## DETAILED STEPS

|        | Command or Action                                                                                    | Purpose                                                                                                                                                                                          |
|--------|------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device# enable                                                   | Enters privileged EXEC mode.                                                                                                                                                                     |
| Step 2 | <b>show wireless country supported</b><br><b>Example:</b><br>Device# show wireless country supported | Displays a list of all available country codes.                                                                                                                                                  |
| Step 3 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                    | Enters global configuration mode.                                                                                                                                                                |
| Step 4 | <b>ap dot11 24ghz shutdown</b><br><b>Example:</b><br>Device(config)# ap dot11 5ghz shutdown          | Disables the 802.11a network.                                                                                                                                                                    |
| Step 5 | <b>ap dot11 5ghz shutdown</b><br><b>Example:</b><br>Device(config)# ap dot11 24ghz shutdown          | Disables the 802.11b/g network.                                                                                                                                                                  |
| Step 6 | <b>ap country country_code</b><br><b>Example:</b><br>Device(config)# ap country IN                   | Assigns access points to a specific country.<br><b>Note</b> Make sure that the country code you choose is compatible with the regulatory domain of at least one of the access point's radios.    |
| Step 7 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                          | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                              |
| Step 8 | <b>show wireless country channels</b><br><b>Example:</b><br>Device# show wireless country channels   | Displays the list of available channels for the country codes configured on your device.<br><b>Note</b> Perform Steps 9 through 17 only if you have configured multiple country codes in Step 6. |

|                | Command or Action                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 9</b>  | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 10</b> | <b>no ap dot11 5ghz shutdown</b><br><b>Example:</b><br>Device(config)# <code>no ap dot11 5ghz shutdown</code>   | Enables the 802.11a network.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 11</b> | <b>no ap dot11 24ghz shutdown</b><br><b>Example:</b><br>Device(config)# <code>no ap dot11 24ghz shutdown</code> | Enables the 802.11b/g network.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 12</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 13</b> | <b>ap name Cisco_AP shutdown</b><br><b>Example:</b><br>Device# <code>ap name AP02 shutdown</code>               | Disables the access point.<br><b>Note</b> Ensure that you disable only the access point for which you are configuring country codes.                                                                                                                                                                                                                                                                                                                      |
| <b>Step 14</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 15</b> | <b>ap country country_code</b><br><b>Example:</b><br>Device# <code>ap country IN</code>                         | Assigns an access point to a specific country.<br><b>Note</b> Ensure that the country code that you choose is compatible with the regulatory domain of at least one of the access point's radios.<br><b>Note</b> If you enabled the networks and disabled some access points and then enter the <b>ap country country_code</b> command, the specified country code is configured on only the disabled access points. All other access points are ignored. |
| <b>Step 16</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 17</b> | <b>ap name Cisco_AP no shutdown</b><br><b>Example:</b><br>Device# <code>ap name AP02 no shutdown</code>         | Enables the access point.                                                                                                                                                                                                                                                                                                                                                                                                                                 |

# Configuration Examples for Configuring Country Codes

## Displaying Channel List for Country Codes: Example

This example shows how to display the list of available channels for the country codes configured on your device:

```
Device# show wireless country channels

Configured Country.....: US - United States
KEY: * = Channel is legal in this country and may be configured manually.
A = Channel is the Auto-RF default in this country.
. = Channel is not legal in this country.
C = Channel has been configured for use by Auto-RF.
x = Channel is available to be configured for use by Auto-RF.
(-,-) = (indoor, outdoor) regulatory domain allowed by this country.
-----:+++++-----
802.11bg :

- [Performing a Link Test \(CLI\), on page 916](#)
- [Configuration Examples for Configuring Link Latency, on page 917](#)

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring Link Latency

- The device displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the device is up or can be cleared and allowed to restart.
- You can configure link latency for a specific access point using the device GUI or CLI or for all access points joined to the device using the CLI.

## Restrictions for Configuring Link Latency

- Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the device. It does not measure network latency or ping responses.

# Information About Configuring Link Latency

You can configure link latency on the device to measure the link between an access point and the device. You can use this feature with all access points that are joined to the device where the link can be a slow or unreliable WAN connection.

## TCP MSS

If the client's maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the device or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

## Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the *ping link test*, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the *CCX link test*, the device can also test the link quality in the access point-to-client direction. The device issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and device. Not only can the access point or device initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or device.

The device shows the link-quality metrics for CCX link tests in both directions (out—the access point to the client; in—the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)
- Total number of packets that are retried
- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet

The controller shows this metric regardless of direction:

- Link test request/reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCXv4 or v5, the controller performs a ping link test on the client. If a client supports CCXv4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

## How to Configure Link Latency

### Configuring Link Latency (CLI)

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ap link-latency`
4. `ap tcp-adjust-mss size size`
5. `show ap name Cisco_AP config general`
6. `ap name Cisco_AP link-latency [reset]`
7. `show ap name Cisco_AP config general`

#### DETAILED STEPS

|        | Command or Action                                                                               | Purpose                                                                                                                                                                                                                                        |
|--------|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><b>Example:</b><br>Device# <code>enable</code>                           | Enters privileged EXEC mode.                                                                                                                                                                                                                   |
| Step 2 | <code>configure terminal</code><br><b>Example:</b><br>Device# <code>configure terminal</code>   | Enters global configuration mode.                                                                                                                                                                                                              |
| Step 3 | <code>ap link-latency</code><br><b>Example:</b><br>Device(config)# <code>ap link-latency</code> | Enables link latency for all access points that are currently associated with the device.<br><br><b>Note</b> To disable link latency for all the access points that are associated with the device, use the <b>no ap link-latency</b> command. |

|               | Command or Action                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                       | <p><b>Note</b> These commands enable or disable link latency only for access points that are currently joined to the device. You have to enable or disable link latency for the access points that join in the future.</p> <p><b>Note</b> To enable or disable link latency for specific access points that are associated with the device, enter the following commands in Privileged EXEC mode:</p> <ul style="list-style-type: none"> <li>• <b>ap name Cisco_AP link-latency</b>—Enables link latency.</li> <li>• <b>ap name Cisco_AP no link-latency</b>—Disables link latency.</li> </ul>                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 4</b> | <p><b>ap tcp-adjust-mss size size</b></p> <p><b>Example:</b></p> <pre>Device(config)# ap tcp-adjust-mss size 537</pre>                | Configures TCP MSS adjust size for all access points. The range is from 536 to 1363.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <p><b>show ap name Cisco_AP config general</b></p> <p><b>Example:</b></p> <pre>Device(config)# show ap name AP02 config general</pre> | <p>Displays the general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.</p> <p>The output of this command contains the following link latency results:</p> <ul style="list-style-type: none"> <li>• <b>Current Delay</b>—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.</li> <li>• <b>Maximum Delay</b>—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.</li> <li>• <b>Minimum Delay</b>—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the device and back.</li> </ul> |
| <b>Step 6</b> | <p><b>ap name Cisco_AP link-latency [reset]</b></p> <p><b>Example:</b></p> <pre>Device(config)# ap name AP02 link-latency reset</pre> | Clears the current, minimum, and maximum link latency statistics on the device for a specific access point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|        | Command or Action                                                                                                         | Purpose                                                                                                                    |
|--------|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Step 7 | <b>show ap name <i>Cisco_AP</i> config general</b><br><b>Example:</b><br>Device(config)# show ap name AP02 config general | Displays the general configuration details of the access point. Use this command to see the result of the reset operation. |

# How to Configure TCP MSS

## Configuring TCP MSS (CLI)

### SUMMARY STEPS

1. configure terminal
2. ap tcp-adjust-mss size *size\_value*
3. reload
4. show ap tcp-adjust-mss

### DETAILED STEPS

|        | Command or Action                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                              |
| Step 2 | <b>ap tcp-adjust-mss size <i>size_value</i></b><br><b>Example:</b><br>Device(config)# ap tcp-adjust-mss size 537 | Enables the TCP MSS on the particular access point that you specify.<br><br><b>Note</b> To enable TCP MSS on all the access points that are associated with the device, enter the <b>ap tcp-adjust-mss size <i>size_value</i></b> command, where the size parameter is from 536 to 1363 bytes. The default value varies for different clients. |
| Step 3 | <b>reload</b><br><b>Example:</b><br>Device# reload                                                               | Reboots the device in order for your change to take effect.                                                                                                                                                                                                                                                                                    |
| Step 4 | <b>show ap tcp-adjust-mss</b><br><b>Example:</b><br>Device# show ap tcp-adjust-mss                               | Displays the current TCP MSS setting for all the access points that are associated with the device.<br><br><b>Note</b> To display the TCP MSS settings that correspond to a specific access point, enter the <b>show ap name <i>Cisco_AP</i> tcp-adjust-mss</b> command.                                                                       |

# Performing a Link Test (CLI)

**Note** The procedure to perform this task using the device GUI is not currently available.

## SUMMARY STEPS

1. `test wireless linktest mac_address`
2. `configure terminal`
3. `wireless linktest frame-size frame_size`
4. `wireless linktest number-of-frames number_of_frames`
5. `end`

## DETAILED STEPS

|               | Command or Action                                                                                                                         | Purpose                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>test wireless linktest mac_address</b><br><b>Example:</b><br>Device# test wireless linktest<br>00:0d:88:c5:8a:d1                       | Runs a link test.                                                                                                   |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                         | Enters global configuration mode.                                                                                   |
| <b>Step 3</b> | <b>wireless linktest frame-size frame_size</b><br><b>Example:</b><br>Device(config)# wireless linktest<br>frame-size 41                   | Configures the link test frame size for each packet.                                                                |
| <b>Step 4</b> | <b>wireless linktest number-of-frames number_of_frames</b><br><b>Example:</b><br>Device(config)# wireless linktest<br>number-of-frames 50 | Configures the number of frames to send for the link test.                                                          |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

# Configuration Examples for Configuring Link Latency

## Running a Link Test: Example

This example shows how to run a link test:

```
Device# test wireless linktest 6470.0227.ca55
Device# show wireless linktest statistic

Link Test to 64700227CA55 with 500 frame-size.
Client MAC Address           : 6470.0227.ca55
AP Mac Address               : 44e4.d901.19c0
Link Test Packets Sent       : 20
Link Test Packets Received   : 20
Link Test Pkts Lost (Total/AP->Clnt/Clnt->AP) : 0/0/0
Link Test Pkts round trip time (min/max/avg) : 9ms/31ms/14ms
RSSI at AP (min/max/average) : -53dBm/-51dBm/-52dBm
RSSI at Client (min/max/average) : -48dBm/-40dBm/-44dBm
```

## Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

```
Device# show ap name AP01 config general

Cisco AP Name                : AP01
Cisco AP Identifier           : 55
Country Code                  : US - United States
Regulatory Domain Allowed by Country : 802.11bg:-A      802.11a:-A

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About Configuring Power over Ethernet

When an access point that has been converted to lightweight mode (such as an AP1262) access point is powered by a power injector that is connected to a Cisco pre-Intelligent Power Management (pre-IPM) switch, you must configure Power over Ethernet (PoE), which is also known as *inline power*.

## How to Configure Power over Ethernet

### Configuring Power over Ethernet (CLI)

#### SUMMARY STEPS

1. `ap name Cisco_AP power injector installed`
2. `ap name Cisco_AP power injector override`
3. `ap name Cisco_AP power injector switch-mac-address switch_mac_address`
4. `show ap name Cisco_AP config general`

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>ap name <i>Cisco_AP</i> power injector installed</b><br><b>Example:</b><br>Device# ap name AP02 power injector installed                                                          | Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified.<br><br><b>Note</b> Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail. |
| <b>Step 2</b> | <b>ap name <i>Cisco_AP</i> power injector override</b><br><b>Example:</b><br>Device# ap name AP02 power injector override                                                            | Removes the safety checks and allows the access point to be connected to any switch port. You can use this command if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The access point assumes that a power injector is always connected. If you relocate the access point, it continues to assume that a power injector is present.                                                                                                                                                    |
| <b>Step 3</b> | <b>ap name <i>Cisco_AP</i> power injector switch-mac-address <i>switch_mac_address</i></b><br><b>Example:</b><br>Device# ap name AP02 power injector switch-mac-address 10a.2d.5c.3d | Sets the MAC address of the switch port that has a power injector.<br><br><b>Note</b> Enter this command if you know the MAC address of the connected switch port and do not want to automatically detect it using the installed option.                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 4</b> | <b>show ap name <i>Cisco_AP</i> config general</b><br><b>Example:</b><br>Device# show ap name AP02 config general                                                                    | Displays common information that includes the PoE settings for a specific access point.<br><br><b>Note</b> The Power Type/Mode text box shows “degraded mode” if the access point is not operating at full power.                                                                                                                                                                                                                                                                                                                                                         |

## Configuration Examples for Configuring Power over Ethernet

### Displaying Power over Ethernet Information: Example

This example shows how to display common information that includes the PoE settings for a specific access point:

```
Device# show ap name AP01 config general

Cisco AP Identifier..... 1
```

```
Cisco AP Name..... AP1
...
PoE Pre-Standard Switch..... Enabled
PoE Power Injector MAC Addr..... Disabled
Power Type/Mode..... PoE/Low Power (degraded mode)
...
```

- [Platform Specific Scale Requirement for the Mobility Controller, on page 929](#)

## Overview

The delivers more services at access layer other than merely providing increased speeds and feeds. Wireless services is now integrated with the switch, which ensures that the access layer switch terminates the wireless users data plane, thereby delivering on the promise of Cisco's unified architecture. Unification implies that mobility services are provided to both wireless and wired stations.

The provides seamless roaming, which requires transparency of the network configuration and deployment options to the client.

From the end user's perspective, any mobility event must not change its IP address, its default router or DHCP server. This means that as stations roam, they must be able to

- Send an ARP to their default router, or
- Transmit a DHCP request to the server that had previously assigned their address.

From the infrastructure's perspective, as mobility events occur, the station's traffic must follow its current point of attachment, which can either be a mobility agent (MA) or mobility controller (MC). This must be true regardless of whether the station has moved to a network that is configured for a different subnet. The period from which the station is not receiving traffic following its mobility event must be as short as possible, even below 40 ms whenever possible, which includes any authentication procedures that are required.

From the infrastructure's perspective, the mobility management solution must have four main components, and all of these functions must be performed within the constraints of roaming:

- **Initial Association**—This function is used to identify the user's new point of attachment in the network.
- **Context Transfer**—This function is used to transfer state information associated with the station. This ensures that the station's static and real-time policies, including security and application ACLs, and services, remain the same across handoffs.

- Handoff—This function is used to signal that the station's point of attachment has changed, and control of the station should be relinquished by the previous access .
- Data Plane—This function is typically tied to the handoff process, and ensures that the station's traffic continues to be delivered and received from the station without any noticeable performance degradation.

**Caution**

If you have configured virtual routing and forwarding (VRF) on wireless management interface VLAN, the mobility feature may not work expected.

**Note**

You must enable PIM, IP ROUTING and IP MULTICAST Routing for wireless mobility multicast to work.

## Wired and Wireless Mobility

One of the key features of the Converged access solution (applicable to both the Cisco Catalyst 3850 Switch and Cisco WLC 5700 Series Controller) is its ability to provide a device with an IP address and maintain its session persistence, across mobility events from ethernet connections to wireless and vice-versa. This feature allows users to remain on an ethernet network when possible, and make use of the freedom of mobility associated with wireless when necessary.

This feature leverages support from both the client and the infrastructure and uses the two factor authentication-device and user. The device authentication credentials is cached in the mobility controller (MC). When a device transitions across link layers, the device credentials is validated, and if a match is found, the MC ensures that the same IP address is assigned to the new interface.

## Features of Mobility

- Mobility Controller (MC)—The controller provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and policy based control protocols, such as RADIUS. This eliminates the need for the infrastructure servers to maintain a user's location as it transitions throughout the network. The MC sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members. A sub-domain is synonymous to the MC that forms it. Each sub-domain consists of an MC and zero or more access switches that have AP's associated to them.
- Mobility Agents (MA)— A mobility agent is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. A mobility agent is the wireless component that maintains client mobility state machine for a mobile client that is connected via an AP to the device that the MA is running on.
- Mobility Sub Domain— It is an autonomous portion of the mobility domain network. A mobility sub-domain comprises of a single mobility controller and its associated mobility agents (MAs).

---

**Note** Even when more than one mobility controller is present, only one MC can be active at any given time.

---

A mobility sub-domain is the set of devices managed by the active mobility controller. A mobility sub-domain comprises of a set of mobility agents and associated access points.

- **Mobility Group**— A collection of mobility controllers (MCs) across which fast roaming is supported. The concept of mobility group is the same as a collection of buildings in a campus across which frequent roaming is expected.
- **Mobility Domain**— A collection of mobility sub-domains across which mobility is supported. The term mobility domain may be the same as a campus network.
- **Mobility Oracle (MO)**—The mobility oracle acts as the point of contact for mobility events that occur across mobility sub-domains. It also maintains a local database of each station in the entire mobility domain, their home and current sub-domain. A mobility domain includes one or more mobility oracle, though only one would be active at any given time.
- **Mobility Tunnel Endpoint (MTE)**— The mobility tunnel endpoint (MTE) provides data plane services for mobile devices through the use of tunneling. This minimizes the impact of roaming events on the network by keeping the user's point of presence on the network a constant.
- **Point of Attachment**— A station's point of attachment is where its data path is initially processed upon entry in the network. This could either be the access switch that is currently providing it service, or the wireless LAN controller.
- **Point of Presence**— A station's point of presence is the place in the network where the station is being advertised. For instance, if an access switch is advertising reachability to the station via a routing protocol, the interface on which the route is being advertised is considered the station's point of presence.
- **Switch Peer Group (SPG)**— A peer group is a statically created list of neighboring access switches between which fast mobility services is provided. A peer group limits the scope of interactions between switches during handoffs to only those that are geographically proximate.
- **Station**—A user's device that connects to and requests service from the network. The device may have a wired, wireless or both interfaces.
- **Switch in the same SPG**—A peer switch that is part of the peer group of the local switch.
- **Switch outside the SPG**—A peer access switch that is not part of the local switch's peer group.
- **Foreign Mobility Controller**— The mobility controller providing mobility management service for the station in a foreign mobility sub-domain. The foreign mobility controller acts as a liaison between access switches in the foreign sub-domain and the mobility controller in the home domain.
- **Foreign Mobility Sub-Domain**— The mobility sub-domain, controlled by a mobility controller, supporting a station which is anchored in another mobility sub-domain
- **Foreign Switch**— The access switch in the foreign mobility sub-domain currently providing service to the station.
- **Anchor Mobility Controller**— The mobility controller providing a single point of control and mobility management service for stations in their home mobility sub-domain.

- Anchor Mobility Sub-Domain— The mobility sub-domain, controlled by a mobility controller, for a station where its IP address was assigned.
- Anchor Switch— The switch in the home mobility sub-domain that last provided service to a station.

## Sticky Anchoring for Low Latency Roaming

Sticky Anchoring ensures low roaming latency from the client's point of presence is maintained at the switch where the client initially joins the network. It is expensive to apply client policies at a switch for a roaming client. There can be considerable delay as it involves contacting the AAA server for downloadable ACLs which is not acceptable for restoring time sensitive client traffic.

To manage this delay, when the client roams between APs connected to different switches, irrespective of whether it is an intra sub-domain roam or inter sub-domain roam, the client traffic is always tunneled to the switch where the client first associates. The client is anchored at its first point of attachment for its lifetime in the network.

This behavior is enabled by default. You can also disable this behavior to allow the client anchoring only for inter-subnet roams. This configuration is per WLAN config and is available under the WLAN config mode. The customer can configure different SSIDs for time sensitive and non time sensitive applications.

## Bridge Domain ID and L2/L3 Roaming

Bridge domain ID provides the mobility nodes with information to decide on specific roam type, either as L2 or L3 roam. It also allows the network administrators to reuse the VLAN IDs across network distribution. When the VLAN IDs do not have the associated subnet configurations, they may require additional parameter to use in conjunction with VLAN ID. The network administrator ensures that the given VLAN under the same bridge domain ID are associated with the unique subnet. The mobility nodes will first check for the bridge domain ID for the given node and the VLAN ID associated with the client to identify the roam type. The bridge domain ID and the VLAN ID must be same to treat a roam as L2 roam.

The bridge domain ID is configured for each SPG when creating a SPG and later on the MC. The bridge domain ID could be same for more than one SPG and all the MAs under the SPG will share the same bridge domain ID. This information is pushed to the MAs as part of the configuration download when MA comes up initially. If the bridge domain ID is modified when the system is up, it will be pushed to all the MAs in the modified SPG and will take immediate effect for the future roams.

## Link Down Behavior

This section provides information about data synchronization between MA-MC and MC-MO when MC or MO faces downtime in absence of redundancy manager. When Keepalive is configured between MA-MC or MC-MO the clients database is synchronized between the MO and the MCs and the MC and its MAs respectively.

## Platform Specific Scale Requirement for the Mobility Controller

The Mobility Controller (MC) role is supported on a number of different platforms like, the Cisco WLC 5700 Series, CUWN and Catalyst 3850 Switches. The scale requirements on these three platforms are summarized in the table below:

| Scalability                               | Catalyst 3850 as MC | Catalyst 3650 as MC | Cisco WLC 5700 as MC | CUWN 5508 as MC | WiSM2 as MC |
|-------------------------------------------|---------------------|---------------------|----------------------|-----------------|-------------|
| Max number of MC in Mobility Domain       | 8                   | 8                   | 72                   | 72              | 72          |
| Max number of MC in Mobility Group        | 8                   | 8                   | 24                   | 24              | 24          |
| Max number of MAs in Sub-domain (per MC)  | 16                  | 16                  | 350                  | 350             | 350         |
| Max number of SPGs in Sub-domain (per MC) | 8                   | 8                   | 24                   | 24              | 24          |
| Max number of MAs in a SPG                | 16                  | 16                  | 64                   | 64              | 64          |

## CHAPTER 61

# Mobility Network Elements

- [Mobility Agent, on page 931](#)
- [Mobility Controller, on page 932](#)
- [Mobility Oracle, on page 933](#)
- [Guest Controller, on page 933](#)

## Mobility Agent

A Mobility Controller resides on the switch. It is both, control path and data path entity and is responsible for:

- Handling the mobility events on the switch
- Configuring the datapath elements on the switch for mobility, and
- Communicating with the mobility controller

As MA, the device performs the datapath functions by terminating the CAPWAP tunnels that encapsulate 802.11 traffic sourced by wireless stations.

This allows the device to apply features to wired and wireless traffic in a uniform fashion. As far as device is concerned, 802.11 is just another access medium.

The MA performs the following functions:

- Support the mobility protocol – The MA is responsible for responding in a timely manner, ensuring the device is capable of achieving its roaming budget.
- Point of presence – If the wireless subnets are not available at the MC, the MA assumes the point of presence if the wireless client VLAN is not available at the new point of attachment and tunnel the client traffic accordingly.
- ARP Server – When the network is configured in a layer 2 mode, the MA is responsible for advertising reachability for the stations connected to it. If tunneling is employed, the ARP request is transmitted on behalf of the station through the tunnel, which the point of presence (anchor switch) would bridge onto its uplink interface.
- Proxy IGMP – The MA on the device is responsible for subscribing to multicast groups on behalf of a station after a roaming event has occurred. This information is passed as part of the context to the new device. This ensures the multicast flows follow the user as it roams.
- Routing – When the device is connected to a layer 3 access network, the MA is responsible for injecting routes for the stations that are associated with it for which tunneling is not provided.

- 802.1X Authenticator – The authenticator function is included in the MA, and handles both wired and wireless stations.
- Secure PMK Sharing – When a station successfully authenticates to the network, the MA forwards the PMK to the MC. The MC is responsible for flooding the PMK to all the MAs under its sub-domain and to the peer MCs in the mobility group.

The MA also performs the following datapath functions:

- Mobility tunnel – If tunneling is used, the MA encapsulates and decapsulates packets from the mobility tunnel to the MC, and to other MA in the peer group, if the access switches are serving as points of presence. The MA supports the tunneling of client data traffic between the point of attachment and the point of attachment. The packet format used for other switches is CAPWAP with an 802.3 payload. The MA also supports reassembly and fragmentation for mobility tunnels.
- Encryption – The mobility control traffic between the mobility nodes is DTLS encrypted. The MA also encrypts the CAPWAP control and data (optional) at the point of attachment.
- CAPWAP – The device supports the CAPWAP control and data planes. The device forwarding logic is responsible for terminating the CAPWAP tunnels with 802.11 as well as 802.3 payloads. Since support for large frames (greater than 1500bytes) is not universally available, the device supports CAPWAP fragmentation and reassembly.

---

**Note** Mobility tunnel path via an L3 interface on the 4500 or the L3 interface on the uplink port is not supported. It is not possible to have an L3 wireless management interface. Even if the tunnel comes up, packet forwarding is not possible as it is not supported. 4510 drops DHCP packets from wireless clients if SSID is anchored to a different Cisco WLC.

---

## Mobility Controller

The main function of mobility controller is to coordinate the client roaming beyond a switch peer group. The other features of the mobility controller are:

- Station Database—The Mobility Controller maintains a database of all the clients that are connected within the local mobility sub-domain.
- Mobility Protocol—The MC supports the mobility protocol which ensures the target roaming point responds in a timely manner and achieves the 150ms roaming budget
- Interface to Mobility Oracle—The Mobility Controller acts as a gateway between the and the Mobility Oracle. When the Mobility Controller does not find a match in its local database, it suggests a match for a wireless client entry (in its database) and forwards the request to the Mobility Oracle, which manages the Mobility Domain.

---

**Note** Mobility Oracle function can be enabled on an MC only if it is supported by the platform.

---

- ARP Server—When tunneling is employed for a station, its point of presence on the network is the Mobility Tunnel Endpoint (MTE). The Mobility Controller responds to any ARP requests received for the stations it is responsible for.
- Routing—When the Mobility Controller is connected to a layer three network, the Mobility Controller is responsible for injecting routes for the stations it supports into the network.
- Configures MTE—The Mobility Controller is the control point for the for all mobility management related requests. When a change in a station's point of attachment occurs, the Mobility Controller is responsible for configuring the forwarding policy on the MTE.
- NTP Server—The Mobility Controller acts as an NTP server to the and supports all the nodes to have their clocks synchronized with it.

---

**Note** The Cisco 5700 series WLC and other controller platforms that have the Mobility Controller function enabled by default should not be added to a switch peer group (SPG).

---

## Mobility Oracle

The Mobility Oracle coordinates the client roams beyond the subdomain on a need basis and consists of the following features:

- Station Database—The Mobility Oracle maintains a database of all stations that are serviced within the mobility domain. This database is populated during the Mobility Oracle's interactions with all the Mobility Controllers, in all of the mobility sub-domains it supports.
- Interface to Mobility Controller—When the Mobility Oracle receives a request from a Mobility Controller, it performs a station lookup, and forwards, whenever needed, the request to the proper Mobility Controller.
- NTP Server—The Mobility Oracle acts as an NTP server to the Mobility Controllers and synchronizes all the clocks within the mobility domain.

## Guest Controller

The guest access feature provides guest access to wireless clients. The guest tunnels use the same format as the mobility tunnels. Using the guest access feature, there is no need to configure guest VLANs on the access switch. Traffic from the wired and wireless clients terminates on Guest Controller. Since the guest VLAN is not present on the access switch, the traffic is tunneled to the MTE over the existing mobility tunnel, and then via a guest tunnel to the Guest Controller.

The advantage of this approach is that all guest traffic passes through the MTE before it is tunneled to the Guest Controller. The Guest Controller only needs to support tunnels between itself and all the MTEs.

The disadvantage is that the traffic from the guest client is tunneled twice - once to the MTE and then again to the Guest Controller.

Clients cannot roam to Guest Controllers because roaming is not supported on Guest Controllers. This restriction is applicable only for the IOS-XE guest anchor, and not for AireOS.

## CHAPTER 62

# Mobility Control Protocols

---

- [About Mobility Control Protocols, on page 935](#)
- [Initial Association and Roaming, on page 935](#)
- [Initial Association, on page 936](#)
- [Intra Switch Handoff, on page 937](#)
- [Intra Switch Peer Group Handoff, on page 937](#)
- [Inter Switch Peer Group Handoff, on page 938](#)
- [Inter Sub Domain Handoff, on page 939](#)
- [Inter Mobility Group Handoff, on page 941](#)

## About Mobility Control Protocols

The mobility control protocol is used regardless of whether tunneled or routed. The mobility control protocol is used for mobility events between the MO, MC and MA.

The mobility architecture uses both,

- Distributed approach, using the direct communication with the switches in their respective SPG, as well as
- Centralized approach, using the MC and MO.

The goal is to reduce the overhead on the centralized MC, while limiting the interactions between switches to help scale the overall system.

## Initial Association and Roaming

The following scenarios are applicable to the mobility management protocol:

- Initial Association
- Intra Switch Roam
- Intra Switch Peer Group Roam
- Inter Switch Peer Group Roam
- Inter Sub-Domain Roam
- Inter Group Roam

# Initial Association

The illustration below explains the initial association process followed by the device:

Figure 65: Initial Association

1. When a station initially associates with a mobility agent, the MA performs a lookup to determine whether keying information for key caching is locally available in the MA. If no keying information is available, which is the case when the station first appears in the network, the device prompts the device to authenticate itself to generate the Pairwise Master Key (PMK). The PMK is generated on the client and the RADIUS server side, and the RADIUS server forwards the PMK to the authenticator, the MA.
2. The MA sends the PMK to the MC.
3. After receiving the PMK from the MA, the MC transmits the PMK to all the MAs in its sub-domain, and to all the other MCs in its mobility group.

345839

4. The mobility group is a single key domain. This ensures that 802.11r compliant stations recognize the key domain, and attempts to utilize the fast transition procedures defined in 802.11r.

---

**Note** The 802.11r protocol defines a key domain, which is a collection of access points that share keying information.

---

5. (Refer to step 2B in the illustration). Since the station is new to the mobility sub-domain, as indicated by the fact that the PMK is not in the MA local key cache, the MA transmits a mobile announce message to the MC.
6. The MC checks if the client exists in its database. As the client cannot be found, the MC in turn forwards it to the MO, if available.
7. (Refer to step 5 in the illustration). As the station is new to the network, the MO returns a negative response (NACK), which is forwarded by the MC to the device. If the Mobility Oracle is not available then the MC is responsible for not responding to the Mobile Announce.

---

**Note** In new mobility if there are many peers, the IOS controller will not react on a NACK message from the AirOS peer and sends two more probes. NACK is ignored if the client is not present it just drops it, is such a scenario AIREOS sends the NACK. So NACK from mobility controller is not processed.

---

8. The MA on the device informs the MC about the station's new point of attachment via the Handoff Complete message.
9. The MA then informs the other MAs in its switch peer group (SPG) about the station's new point of attachment via the Handoff Notification message. It is necessary to transmit this notification to the MAs in its SPG to allow local handoff without interacting with the MC. The Handoff Notification message sent to MAs in SPG need not carry all the information in Handoff Complete message sent to the MC.
10. (Refer to step 7B in the illustration). The MC updates its database and forwards the Handoff Complete message to the Mobility Oracle. This ensures that the Mobility Oracle's database is updated to record the station's current home mobility sub-domain.

To eliminate race conditions that could occur with devices moving quickly across device, regardless of whether they are within a mobility sub-domain or not, the messages between MA and MC/MO are time synchronized. This would allow the MC and MO to properly process requests, if they are received out of order.

The Handoff Notification sent to MAs in the SPG are not acknowledged.

## Intra Switch Handoff

Mobility events within an MA are completely transparent to the SPG and the MC. When a station moves across APs on the same MA and attempts to perform a fast handoff, the PMK is present on the MA. The MA will complete the fast handoff without invoking any additional signal.

## Intra Switch Peer Group Handoff

The switch peer group (SPG) is a group of MAs between which users may roam, and expect fast roaming services. Allowing the MA to handoff directly within a SPG reduces the overhead on the MC as it requires fewer messages to be exchanged.

After the initial association is complete the station moves to another MA belonging to its SPG. In an intra switch peer group roam, the initial association, the stations PMK was forwarded to all MAs in the mobility sub-domain.

Figure 66: Intra Switch Peer Group Handoff

The following process explains the intra switch peer group handoff:

1. In the initial association example, the Handoff Notification message is sent to all MAs in its SPG to know the station's current point of attachment.
2. The new MA sends a unicast Mobile Announce message to the previous MA to which the client is associated.
3. After the handoff completion, the new MA transmits a Handoff Complete message to the MC.
4. The new device sends a Handoff Notification to all MA in its own SPG to inform them about the clients new point of presence.

## Inter Switch Peer Group Handoff

The Intra SPG roams do not cover all possible scenarios and there can be cases where it is possible for mobility events to occur between two MAs that are not in the same SPG.

When a MA does not have any information about a station's current point of attachment, because of the Handoff Notification message getting lost in the network, or because of the the station roaming to an MA that is not in the new SPG, the MA consults the MC. The MC provides information about the clients point of presence within the mobility sub-domain. This eliminates the need to consult all other MCs within the mobility sub-domain.

Figure 67: Inter Switch Peer Group Handoff

345841

The image above illustrates an example of a mobility event that occurs across MAs that are not in the same SPG, but within the same mobility sub-domain.

**Note** The MA color matches the circle representing its SPG.

1. The new MA will have the PMK for the station, which was forwarded to each MA in the mobility sub-domain upon client initial authentication.
2. Since the MA had not been previously notified of the station's presence on a neighboring MA inside a different SPG transmits the mobile announce to the sub-domain's MC.
3. (Refer to step 2 in the illustration) On receiving the mobile announce message, the MC performs a lookup in its database, and forwards the request to the MA that was previously providing service to the station. This information is known to the MC through a previously received Handoff Complete message sent in a reliable fashion from the old MA.
4. (Refer to step 3 in the illustration) The old MA, shown in green above, transmits a Handoff message directly to the new MA.
5. The old MA needs to notify other MAs within its SPG of the fact that the station has left the group using a Station Left message. This ensures that if the station were to come back to one of the MA , they would be aware of the fact that the station is no longer being serviced by the old MA.
6. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the MC.
7. The new MA then transmits the Handoff Notification to the other MAs within its SPG.

## Inter Sub Domain Handoff

A sub-domain is an ensemble formed by a mobility controller and the mobility agents it directly manages. An inter sub-domain mobility event implies communication between two mobility controllers. These 2 mobility controllers can be configured with the same mobility group value and recognize each other. They will appear in each other's mobility list, or they can be configured with different mobility group values, and still recognize each other.

When the roaming event occurs across sub-domains between MCs in the same mobility group, the 802.11r key domain advertised by the new APs are the same. Additionally, the client PMK is also transmitted to all MCs upon the client's initial authentication. The new MC does not need to force the client to reauthenticate, and the new MC also knows which previous MC was managing the wireless client mobility.

Figure 68: Inter Sub Domain Handoff

345842

The following steps are involved in the inter sub domain handoff, when mobility controllers belong to the same mobility group:

1. When a client's PMK was sent by the initial MA to all the MCs in the mobility group, the new MA already had already received the client PMK from its MC, and re-authentication is not required.
2. The new MA was not notified previously of the station's presence on a neighboring MA inside a different SPG it transmits the mobile announce to the sub-domain's MC.
3. On receiving the mobile announce message, the MC forwards the mobile announce to the MO, which performs a lookup in its database, and forwards the request to the MC that was previously providing service to the station.
4. The previous MC, in turn, forwards the request to the MA that was previously providing service to the station.
5. The old MA, shown in yellow color above, transmits a Handoff message directly to the new MA.
6. The old MA must notify the other MAs within its SPG of the fact that the station has left the SPG using a Station Left message. This ensures that if the station comes back to one of the MA, the MA is aware of the fact that the station is no longer serviced by the old MA.
7. Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the new Mobility Controller.
8. The new MA then transmits the Handoff Notification to all other MAs.
9. The new MC then transmits the Handoff Complete to the old MC.

## Inter Mobility Group Handoff

A mobility group is formed by MCs sharing the same mobility group name, and knowing each other.

Since the roaming event occurs across mobility groups, the 802.11r key domain advertised by the new APs differ. This forces the client to re-authenticate. They are propagated only within a mobility group, and roaming across mobility groups requires the stations to re-authenticate when they cross mobility group boundaries. When the authentication is complete, the PMK that is generated is pushed to the MAs and MCs within the same mobility group. The stations cache the PMK from the previous sub-domain because each PMK is associated to a given sub-domain (802.11y key domain). This ensures that you do not have to re-authenticate when the PMK roams back to the previous sub-domain within the pmk cache timeout interval. The remaining procedure follows the inter-sub-domain handoff steps, except that these steps relate to inter mobility group roaming.

# CHAPTER 63

## Configuring Mobility

- [Configuring Mobility Controller, on page 943](#)
- [Configuring Mobility Agent, on page 949](#)
- [Managing Mobility Agents with Mobility Controller, on page 952](#)

### Configuring Mobility Controller

### Configuring Converged Access Controllers

### Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)

#### Before you begin

- On the mobility agent, you can only configure the IP address of the mobility controller.
- On the mobility controller, you can define the peer group and the IP address of each peer group member.

#### SUMMARY STEPS

1. **wireless mobility controller**
2. **wireless mobility controller peer-group *SPG1***
3. **wireless mobility controller peer-group *SPG1* member ip *member-ip-addr* public-ip *public-ip-addr***
4. **wireless mobility controller peer-group *SPG1* member ip *member-ip-addr* public-ip *public-ip-addr***
5. **wireless mobility controller peer-group *SPG2***
6. **wireless mobility controller peer-group *SPG2* member ip *member-ip-addr* public-ip *public-ip-addr***
7. **wireless mobility controller peer-group *SPG1* bridge-domain-id *id***

#### DETAILED STEPS

|        | Command or Action                                                                                             | Purpose                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>wireless mobility controller</b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller</b> | Enables the mobility controller functionality on the device. This command is applicable only to the switch. The controller is by default a mobility controller. |

|               | Command or Action                                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>wireless mobility controller peer-group <i>SPG1</i></b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller peer-group SPG1</b>                                                                                                             | Creates a peer group named SPG1.                                                                                                                                                                                                                                                                                                                   |
| <b>Step 3</b> | <b>wireless mobility controller peer-group <i>SPG1</i> member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i></b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip 10.10.20.2</b>   | Adds a mobility agent to the peer group.<br><b>Note</b> The <b>10.10.20.2</b> is the mobility agent's direct IP address. When NAT is used, use the optional public IP address to enter the mobility agent's NATed address. When NAT is not used, the public IP address is not used and the device displays the mobility agent's direct IP address. |
| <b>Step 4</b> | <b>wireless mobility controller peer-group <i>SPG1</i> member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i></b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller peer-group SPG1 member ip 10.10.20.6 public-ip 10.10.20.6</b>   | Adds another member to the peer group SPG1.                                                                                                                                                                                                                                                                                                        |
| <b>Step 5</b> | <b>wireless mobility controller peer-group <i>SPG2</i></b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller peer-group SPG2</b>                                                                                                             | Creates another peer group SPG2.                                                                                                                                                                                                                                                                                                                   |
| <b>Step 6</b> | <b>wireless mobility controller peer-group <i>SPG2</i> member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i></b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip 10.10.10.20</b> | Adds a member to peer group SPG2.                                                                                                                                                                                                                                                                                                                  |
| <b>Step 7</b> | <b>wireless mobility controller peer-group <i>SPG1</i> bridge-domain-id <i>id</i></b><br><b>Example:</b><br>Device(config)# <b>wireless mobility controller peer-group SPG1 bridge-domain-id 54</b>                                                              | (Optional) Adds a bridge domain to SPG1 used for defining the subnet-VLAN mapping with other SPGs.                                                                                                                                                                                                                                                 |

### Example

This example shows how to create peer group and add members to it:

```
Device(config)# wireless mobility controller
Device(config)# wireless mobility controller peer-group SPG1
Device(config)# wireless mobility controller peer-group SPG1
Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip
```

```

10.10.20.2
Device(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.6 public-ip
10.10.20.6
Device(config)# wireless mobility controller peer-group SPG2
Device(config)# wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip
10.10.10.20
Device(config)# wireless mobility controller peer-group SPG1 bridge-domain-id 54

```

## Configuring Local Mobility Group (CLI)

Configuration for wireless mobility groups and mobility group members where the mobility group is a group of MCs.

### Before you begin

MCs can belong only to one mobility group, and can know MCs in several mobility groups.

### SUMMARY STEPS

1. **wireless mobility group name** *group-name*
2. **wireless mobility group member ip** *member-ip-addr* **public-ip** *public-ip-addr*
3. **wireless mobility group keepalive interval** *time-in-seconds*
4. **wireless mobility group keepalive count** *count*

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                        |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>wireless mobility group name</b> <i>group-name</i><br><b>Example:</b><br>Device(config)# <b>wireless mobility group name</b><br><b>Mygroup</b>                                                                                   | Creates a mobility group named <b>Mygroup</b> .                                                                                                                                                |
| Step 2 | <b>wireless mobility group member ip</b> <i>member-ip-addr</i><br><b>public-ip</b> <i>public-ip-addr</i><br><b>Example:</b><br>Device(config)# <b>wireless mobility group member ip</b><br><b>10.10.34.10 public-ip 10.10.34.28</b> | Adds a mobility controller to the <b>Mygroup</b> mobility group.<br><b>Note</b> When NAT is used, use the optional public IP address to enter the NATed IP address of the mobility controller. |
| Step 3 | <b>wireless mobility group keepalive interval</b> <i>time-in-seconds</i><br><b>Example:</b><br>Device(config)# <b>wireless mobility group keepalive</b><br><b>interval 5</b>                                                        | Configures the interval between two keepalives sent to a mobility member.                                                                                                                      |
| Step 4 | <b>wireless mobility group keepalive count</b> <i>count</i><br><b>Example:</b><br>Device(config)# <b>wireless mobility group keepalive</b><br><b>count 3</b>                                                                        | Configures the keep alive retries before a member status is termed DOWN.                                                                                                                       |

**Example**

```
Device(config)# wireless mobility group name Mygroup
Device(config)# wireless mobility group member ip 10.10.34.10 public-ip 10.10.34.28
Device(config)# wireless mobility group keepalive interval 5
Device(config)# wireless mobility group keepalive count 3
```

**Adding a Peer Mobility Group (CLI)****Before you begin**

MCs belong to only one group, and can know MCs in several groups.

**SUMMARY STEPS**

1. `wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name`

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                                                                                                 | Purpose                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>Step 1</b> | <b>wireless mobility group member ip <i>member-ip-addr</i> public-ip <i>public-ip-addr</i> group <i>group-name</i></b><br><br><b>Example:</b><br>Device(config)# wireless mobility group member ip 10.10.10.24 public-ip 10.10.10.25 group Group2 | Adds the member as a peer MC in a different group than the <b>Mygroup</b> . |

**Configuring Optional Parameters for Roaming Behavior**

Use this configuration to disable the sticky anchor. This command can also be used, if required, between all MA's and MC's where roaming is expected for the target SSID.

**SUMMARY STEPS**

1. `wlan open21`
2. `no mobility anchor sticky`

**DETAILED STEPS**

|               | Command or Action                                                        | Purpose                                      |
|---------------|--------------------------------------------------------------------------|----------------------------------------------|
| <b>Step 1</b> | <b>wlan open21</b><br><br><b>Example:</b><br>Device(config)# wlan open20 | Configures a WLAN.                           |
| <b>Step 2</b> | <b>no mobility anchor sticky</b><br><br><b>Example:</b>                  | Disables the default sticky mobility anchor. |

|  | Command or Action                              | Purpose |
|--|------------------------------------------------|---------|
|  | Device(config-wlan)# no mobility anchor sticky |         |

**Example**

```
Device(config)# wlan open20
Device(config-wlan)# no mobility anchor sticky
```

## Pointing the Mobility Controller to a Mobility Oracle (CLI)

**Before you begin**

You can configure a mobility oracle on a known mobility controller.

**SUMMARY STEPS**

1. wireless mobility group member ip *member-ip-addr* group *group-name*
2. wireless mobility oracle ip *oracle-ip-addr*

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                                                                     | Purpose                                                |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| <b>Step 1</b> | <p><b>wireless mobility group member ip</b> <i>member-ip-addr</i><br/><b>group</b> <i>group-name</i></p> <p><b>Example:</b></p> <pre>Device(config)# wireless mobility group member ip 10.10.10.10 group Group3</pre> | Creates and adds a MC to a mobility group.             |
| <b>Step 2</b> | <p><b>wireless mobility oracle ip</b> <i>oracle-ip-addr</i></p> <p><b>Example:</b></p> <pre>Device(config)# wireless mobility oracle ip 10.10.10.10</pre>                                                             | Configures the mobility controller as mobility oracle. |

**Example**

```
Device(config)# wireless mobility group member ip 10.10.10.10 group Group3
Device(config)# wireless mobility oracle ip 10.10.10.10
```

## Configuring Guest Controller

A guest controller is used when the client traffic is tunneled to a guest anchor controller in the demilitarized zone (DMZ). The guest client goes through a web authentication process. The web authentication process is optional, and the guest is allowed to pass traffic without authentication too.

Enable the WLAN on the mobility agent on which the guest client connects with the mobility anchor address of the guest controller.

On the guest controller WLAN, which can be Cisco 5500 Series WLC, Cisco WiSM2, or Cisco 5700 Series WLC, configure the IP address of the mobility anchor as its own IP address. This allows the traffic to be tunneled to the guest controller from the mobility agent.

**Note** With Cisco 5700 Series WLC as the guest anchor controller and Cisco 5500 Series WLC or Cisco WiSM2 as export foreign controller, the guest user role per user is not supported on the Cisco 5700 Series WLC.

## SUMMARY STEPS

1. **wlan** *wlan-id*
2. **mobility anchor** *guest-anchor-ip-addr*
3. **client vlan** *vlan-name*
4. **security open**

## DETAILED STEPS

|               | Command or Action                                                                                                                | Purpose                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>wlan</b> <i>wlan-id</i><br><b>Example:</b><br>Device(config) # <b>wlan</b> Mywlan1                                            | Creates a WLAN for the client.                                                                                                                                                                                                                                             |
| <b>Step 2</b> | <b>mobility anchor</b> <i>guest-anchor-ip-addr</i><br><b>Example:</b><br>Device(config-wlan) # <b>mobility anchor</b> 10.10.10.2 | Enables the guest anchors (GA) IP address on the MA.<br><b>Note</b> To enable guest anchor on the mobility controller, you need not enter the IP address. Enter the <b>mobility anchor</b> command in the WLAN configuration mode to enable GA on the mobility controller. |
| <b>Step 3</b> | <b>client vlan</b> <i>vlan-name</i><br><b>Example:</b><br>Device(config-wlan) # <b>client vlan</b> gc_ga_vlan1                   | Assigns a VLAN to the client's WLAN.                                                                                                                                                                                                                                       |
| <b>Step 4</b> | <b>security open</b><br><b>Example:</b><br>Device(config-wlan) # <b>security open</b>                                            | Assigns a security type to the WLAN.                                                                                                                                                                                                                                       |

### Example

```
Device(config)# wlan Mywlan1
Device(config-wlan)# mobility anchor 10.10.10.2
Device(config-wlan)# client vlan gc_ga_vlan1
Device(config-wlan)# security open
```

## Configuring Guest Anchor

### SUMMARY STEPS

1. wlan Mywlan1
2. mobility anchor <guest-anchors-own-ip-address>
3. client vlan<vlan-name>
4. security open

### DETAILED STEPS

|        | Command or Action                                                                                                                           | Purpose                                                                                                  |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Step 1 | <b>wlan Mywlan1</b><br><b>Example:</b><br>Device(config)# wlan Mywlan1                                                                      | Creates a wlan for the client.                                                                           |
| Step 2 | <b>mobility anchor</b><br><b>&lt;guest-anchors-own-ip-address&gt;</b><br><b>Example:</b><br>Device(config-wlan)# mobility anchor 10.10.10.2 | Enables the guest anchors IP address on the guest anchor (GA). The GA assigns its own address on itself. |
| Step 3 | <b>client vlan&lt;vlan-name&gt;</b><br><b>Example:</b><br>Device(config-wlan)# client vlan gc_ga_vlan1                                      | Assigns a vlan to the clients wlan.                                                                      |
| Step 4 | <b>security open</b><br><b>Example:</b><br>Device(config-wlan)# security open                                                               | Assigns a security type to the wlan.                                                                     |

### Example

```
Device(config)# wlan Mywlan1
Device(config-wlan)# mobility anchor 10.10.10.2
Device(config-wlan)# client vlan gc_ga_vlan1
Device(config-wlan)# security open
```

## Configuring Mobility Agent

### Configuring Mobility Agent by Pointing to Mobility Controller (CLI)

#### Before you begin

- By default, the switches are configured as mobility agents.

- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.
- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

## SUMMARY STEPS

1. **configure terminal**
2. **wireless management interface vlan 21**

## DETAILED STEPS

|               | Command or Action                                                                                                                          | Purpose                                                                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                | Enters global configuration mode.                                                                                                                             |
| <b>Step 2</b> | <b>wireless management interface vlan 21</b><br><br><b>Example:</b><br>Device (config)# <code>wireless management interface vlan 21</code> | Enables the wireless functionality on the device and activates the mobility agent function. This ensures the APs have a place to terminate the CAPWAP tunnel. |

### Example

This example shows how to add a mobility agent into the mobility group by pointing it to a mobility controller:

```
Device(config)# wireless management interface vlan 21
```

## Configuring the Mobility Controller for the Mobility Agent (CLI)

### SUMMARY STEPS

1. **wireless mobility controller**
2. **wireless mobility controller ip ip-addr**

### DETAILED STEPS

|               | Command or Action                                          | Purpose                                      |
|---------------|------------------------------------------------------------|----------------------------------------------|

|               | Command or Action                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device (config)# <b>wireless mobility controller</b><br>Mobility role changed to Mobility Controller.<br>Please save config and reboot the whole stack. | <b>Note</b> After you enter this command, save the configuration and reboot the device for the mobility controller function to take effect.                                                                                                                                         |
| <b>Step 2</b> | <b>wireless mobility controller ip</b> <i>ip-addr</i><br><br><b>Example:</b><br>Device (config)# <b>wireless mobility controller ip</b><br>10.10.21.3   | Specifies the mobility controller to which the mobility agent relates.<br><br><b>Note</b> If a mobility agent is configured and the mobility controller exists on a different device, configure the SPG on the mobility controller to ensure the mobility agent functions properly. |

**What to do next**

After you add a mobility controller role to the mobility agent, you can configure optional parameters on the mobility agent.

## Adding a Mobility Controller Role to the Mobility Agent

**SUMMARY STEPS**

1. **wireless mobility controller ip 10.10.21.3**

**DETAILED STEPS**

|               | Command or Action                                                                                                                         | Purpose                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| <b>Step 1</b> | <b>wireless mobility controller ip</b> 10.10.21.3<br><br><b>Example:</b><br>Device(config)# wireless mobility controller ip<br>10.10.21.3 | Converts the mobility agent to a mobility controller. |

**Example**

This example shows how to add the mobility controller role to a mobility agent:

```
Device(config)# wireless mobility controller ip 10.10.21.3
Mobility role changed to Mobility Controller.
Please save config and reboot the whole stack.
```

## Configuring Optional Parameters on a Mobility Agent (CLI)

This section shows how to configure load-balancing on a device.

- By default, the load-balancing is enabled and it cannot be disabled.

- The device supports a maximum of 2000 clients and the default threshold value is fifty percent of client max load.
- When the device reaches its threshold, it redistributes the new clients load to other mobility agents in the same SPG, if their client load is lower.

## SUMMARY STEPS

1. **wireless mobility load-balance threshold** *threshold-value*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                | Purpose                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Step 1 | <b>wireless mobility load-balance threshold</b> <i>threshold-value</i><br><b>Example:</b><br>Device(config)# <b>wireless mobility load-balance threshold 150</b> | Configures the threshold that triggers load-balancing. |

# Managing Mobility Agents with Mobility Controller

## Managing Mobility Agents with Mobility Controller

The Mobility Controller managing Mobility Agent feature pushes the wireless and common configurations from the Mobility Controller (MC) to the Mobility Agents (MAs). This helps you to easily configure, monitor, and troubleshoot all the MAs from the MC. An MC can support up to 16 MAs. Most of the wireless and common configurations such as AAA, ACL, and so on are generally the same across all the switches.

## Restrictions for Managing Mobility Agents with Mobility Controller

- The MC and MAs can become unsynchronized when a new MA joins the MC, and this MA is centrally managed, and when an MA is moved from one MC to another MC.
- When an MA is in centralized mode, the globally managed configuration is disabled and the rest of the configurations and monitoring are available on the Web GUI.
- This feature is not supported on Cisco Prime Infrastructure.
- When the MC detects an MA to be out of sync, the MA is forced to reload and then resync the entire configuration from the MC after coming up again.
- QoS configuration is not pushed from the MC to an MA.
- The MC pushes all the configurations to all the centrally managed MAs. It is not possible to select a subset of the configurations and then push to a particular group of MAs instead of all the MAs.
- L3 roaming is not supported because WLAN configuration is pushed from the MC.
- MAs using different software versions in the subdomain either in the same Switch Peer Group (SPG) or in a different SPG are not supported.

- If Catalyst 3850 and 3650 Switch act as an MC in a mobility subdomain, the MC and MAs only run Polaris release 16.2 and Polaris release 16.1.1.
- Since only Catalyst 3850 Switches are allowed in the mobility subdomain there cannot be a 5760 added to a MC when Polaris version acts as MA.
- In 16.2 Denali release, the Cisco 3850 controller supports a maximum of 50 APs in MA or MC. In MC-MA scenario, a maximum of 100 APs are supported, which includes APs of both MA and MC.

## Feature History

| Release                    | Remarks                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------|
| Cisco IOS XE Denali 16.2.1 | The feature was introduced on the Cisco Catalyst 3850 and Cisco Catalyst 3650 Series Switches. |

For a complete list of commands that are synchronized between the MC and the MA, see *MC Managing MA - List of Commands Synchronized Between MC and MA* at:

<http://www.cisco.com/c/en/us/td/docs/wireless/controller/mc-ma/mc-ma-sync.html>.

## Information About Managing Mobility Agents with Mobility Controller

A Mobility Controller (MC) can have both centrally managed and noncentrally managed Mobility Agents (MAs) at the same time. A centrally managed MA receives a set of configurations that are configured on the MC. A noncentrally managed MA does not receive any configuration from the MC. While an MA is being centrally managed, you can not modify any of the configurations that are pushed from the MC to an MA.

The MC pushes all the relevant configurations over the existing Control and Provisioning of Wireless Access Point (CAPWAP) tunnel to all the centrally managed MAs. The MC also pushes incremental configurations, if any, to the MAs.

**Note** Before using this feature, you must have the Day 0 configuration that is required to bring up the CAPWAP tunnel between the MC and an MA.

The following configurations are sent to the MAs:

- Common configuration—This is the configuration, that is shared between wired and wireless configurations such as the security configuration, for example, authentication, authorization, and accounting (AAA).
- Wireless configurations—All wireless configurations.

Figure 69: MC Managing MAs

## Distributed Mode and Centralized Mode

Distributed mode refers to configurations that are required to be performed explicitly on all the MAs.

Centralized mode refers to configurations where wireless and common configurations are pushed from the MC to the MAs. The following table lists the differences between the Distributed mode and the Centralized mode.

Table: Differences Between Distributed Mode and Centralized Mode

| Distributed Mode                                                                                                                                                                                                                                                                                                                                                  | Centralized Mode                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Configurations on the MC                                                                                                                                                                                                                                                                                                                                          | Configurations on the MC                                                                                                                                                                                                                                                                             |

## Restrictions for Managing Mobility Agents with Mobility Controller

- The MC and MAs can become unsynchronized when a new MA joins the MC, and this MA is centrally managed, and when an MA is moved from one MC to another MC.
- When an MA is in centralized mode, the globally managed configuration is disabled and the rest of the configurations and monitoring are available on the Web GUI.
- This feature is not supported on Cisco Prime Infrastructure.
- When the MC detects an MA to be out of sync, the MA is forced to reload and then resync the entire configuration from the MC after coming up again.
- QoS configuration is not pushed from the MC to an MA.
- The MC pushes all the configurations to all the centrally managed MAs. It is not possible to select a subset of the configurations and then push to a particular group of MAs instead of all the MAs.
- L3 roaming is not supported because WLAN configuration is pushed from the MC.
- MAs using different software versions in the subdomain either in the same Switch Peer Group (SPG) or in a different SPG are not supported.
- If Catalyst 3850 and 3650 Switch act as an MC in a mobility subdomain, the MC and MAs only run Polaris release 16.2 and Polaris release 16.1.1.
- Since only Catalyst 3850 Switches are allowed in the mobility subdomain there cannot be a 5760 added to a MC when Polaris version acts as MA.
- In 16.2 Denali release, the Cisco 3850 controller supports a maximum of 50 APs in MA or MC. In MC-MA scenario, a maximum of 100 APs are supported, which includes APs of both MA and MC.

## Configuring MC Managing MA (CLI)

The following procedure shows how to configure Managing Mobility Agents with Mobility Controller:

**Step 1** Configuring MC:

- a) Configure a wireless management interface by entering this command:

```
Device(config)# wireless management interface vlan vlan-id
```

- b) Configure a switch peer group by entering this command:

```
Device(config)# wireless mobility controller peer-group spg-name
```

- c) Add an MA to the SPG and configure it to be centrally managed by entering this command: (Use only centralized option)

```
Device(config)# wireless mobility controller peer-group spg-name member ip ip-addr mode centralized
```

**Step 2** Configuring MA:

- a) Specify the IP address of the MC by entering this command:

```
Device(config)# wireless mobility controller ip mc-ip-addr
```

- b) Configure the wireless management interface by entering this command:

```
Device(config)# wireless management interface vlan vlan-id
```

**Step 3** Configuring Centralized Mode:

- a) From the MC, you can see the status of the MA by entering this command:

```
Device(config)# show wireless mobility summary
```

```
Mobility Controller Summary:
```

```
Mobility Role                : Mobility Controller
Mobility Protocol Port       : 16666
Mobility Group Name          : default
Mobility Oracle IP Address   : 0.0.0.0
DTLS Mode                    : Enabled
Mobility Domain ID for 802.11r : 0xac34
Mobility Keepalive Interval  : 10
Mobility Keepalive Count     : 3
Mobility Control Message DSCP Value : 48
Mobility Domain Member Count : 1
```

```
IP          Public IP      Link  Status      Centralized(Cfgd : Running)
-----
1.1.1.1     1.1.1.1      UP   : UP        Enabled      Enabled
3.3.3.1     3.3.3.1      DOWN : DOWN      Enabled      Enabled
```

The following table shows the details of the Centralized Mode (both Configured and Running) in relation to the example above.

**Table 71: Centralized Mode (Configured and Running)**

| Sl. No. | Centralized Mode Configuration | Centralized Mode Running | What it Means                                            |
|---------|--------------------------------|--------------------------|----------------------------------------------------------|
| 1.      | Disabled                       | Disabled                 | The MA is not configured as centrally managed on the MC. |

| SI. No. | Centralized Mode Configuration | Centralized Mode Running | What it Means                                                                                                                                                                                                                   |
|---------|--------------------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2.      | Enabled                        | Disabled                 | The MA is configured as centrally managed on the MC, but the tunnel to the MA is still down, or the MA is yet to acknowledge the message from the MC (the message in which the MC informs the MA that it is centrally managed). |
| 3.      | Enabled                        | Enabled                  | The MA is configured as centrally managed on the MC and the MA is running in Centrally Managed mode.                                                                                                                            |
| 4.      | Disabled                       | Enabled                  | Not applicable.                                                                                                                                                                                                                 |

- b) You can see all the MAs that have been configured on the MC irrespective of the SPG and irrespective of whether they are centrally managed or not, by entering this command:

```
Device(config)# show cmm member-table

CMM Member Table
-----
Total No Of Members = 1
System Rev No on MC = 16

entry 0
-----
entry_status          = In use
ip_addr               = 10.5.84.155
SPG Name              = SPG1
Centrally Managed     = True
Applied Cfg rev on MA = 16
Last rcvd cfg rev on MA = 16
Tunnel State         = Up
Status                = CMM_MEMBER_STATUS_IN_SYNC
Last sent cfg rev to MA = 16
Last sent cfg timestamp = 1427826323 sec 936009397 nsec
-----

Members: No. of MAs configured on the MC
System Rev No on MC: What version number the MC is at

Entry
```

- c) To see the configurations that were executed on an MC and buffered in the CMM agent, enter this command:

```
Device(config)# show cmm config

Current version number: 17
To sync and save configuration to Mobility Agents execute: "write memory"

Config commands present in the buffer:
access-list 1 permit any
wlan MCMA_Demo 4 MCMA_Demo
client vlan 22
```

## Configuration of WLAN on the MC

```
no security wpa
no security wpa akm dot1x
no security wpa wpa2
no security wpa wpa2 ciphers aes
no shutdown
```

**Note** The configuration from the MC is synchronized with MAs only after the **write memory** command is run on the MC.

**Step 4** To execute the commands on an MA remotely from the MC, use this command. For example, you can enter this command on the MC to see if the client has reached the uptime.

```
Device(config)# remote command 1.1.1.1 show wcdb da all
Total Number of Wireless Clients = 1
Clients Waiting to Join = 0
Local Clients = 0
Anchor Clients = 1
Foreign Clients = 0
MTE Clients = 0
Mac Address VlanId IP Address Src If Auth Mob
-----
ec55.f9c6.35c3 22 53.1.1.2 0x00D19B00000001C5 RUN ANCHOR
```

**Step 5** To log in remotely to an MA from the MC, use this command:

```
DeviceControllerDevice(config)# remote login 1.1.1.1

Trying Switch ...
Entering CONSOLE for Switch
Type "^C^C^C" to end this session

User Access Verification

Password:
MA1>en
Password:
MA1#
```

## Configuration of WLAN on the MC

This following procedure shows how to create a WLAN on the MC and synchronize the WLAN configuration with centrally managed MCs.

**Step 1** On the MC, create a WLAN named MCMA\_Demo by entering this command:

```
Device(config)# wlan MCMA_Demo 1 MCMA_Demo
Device(config-wlan)# exit
Device(config)# exit
```

**Step 2** Enter this command to check the configuration:

```
Device(config)# show cmm config

Current version number: 3
To sync and save configuration to Mobility Agents execute: "write memory"
```

```
Config commands present in the buffer:
wlan MCMA_Demo 1 MCMA_Demo
exit
```

**Step 3** Enter this command to check the number of MAs that are configured to be centrally managed:

```
Device(config)# show cmm member-table

CMM Member Table
-----
Total No Of Members = 1
System Rev No on MC = 2

entry 0
-----
entry_status          = In use
ip_addr               = 10.5.84.12
SPG Name              = SPG1
Centrally Managed     = True
Applied Cfg rev on MA = 2
Last rcvd cfg rev on MA = 2
Tunnel State         = Up
Status                = CMM_MEMBER_STATUS_IN_SYNC
Last sent cfg rev to MA = 2
Last sent cfg timestamp = 1432843797 sec 57656031 nsec
-----
```

**Step 4** See the WLAN details by entering this command:

```
Device(config)# show wlan summary

Number of WLANs: 1

WLAN  Profile Name      SSID              VLAN Status
-----
1      MCMA_Demo           MCMA_Demo         1      DOWN
```

**Step 5** Save the configuration by entering this command:

```
Device(config)# write memory

Building configuration...
Compressed configuration from 7612 bytes to 3409 bytes[OK]
```

**Step 6** Check the synchronization status on an MA by entering this command:

```
Device(config)# show cmm member-table

CMM Member Table
-----
Total No Of Members = 1
System Rev No on MC = 3

entry 0
-----
entry_status          = In use
ip_addr               = 10.5.84.12
SPG Name              = SPG1
Centrally Managed     = True
Applied Cfg rev on MA = 2
Last rcvd cfg rev on MA = 2
```

```
Tunnel State          = Up
Status               = CMM_MEMBER_STATUS_STALE
Last sent cfg rev to MA = 3
Last sent cfg timestamp = 1432847325 sec 107200589 nsec
-----
```

**Step 7** On the MA, enter the following command to verify if the WLAN that was created in the MC is now synchronized with the MA:

```
Device(config)# show wlan summary
```

```
Number of WLANs: 1
```

| WLAN | Profile Name | SSID      | VLAN | Status |
|------|--------------|-----------|------|--------|
| 1    | MCMA_Demo    | MCMA_Demo | 1    | DOWN   |

### Example:

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.
- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured device.
- All devices configured with the **cns config partial** global configuration command must access the event bus. The DeviceID, as originated on the device, must match the DeviceID of the corresponding device definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

### Related Topics

[Cisco Networking Services IDs and Device Hostnames, on page 970](#)

[DeviceID, on page 970](#)

# Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured devices can share the same value for ConfigID.
- Within the scope of a single instance of the event bus, no two configured devices can share the same value for DeviceID.

# Information About Configuring the Configuration Engine

## Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (devices and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
  - Web server
  - File manager
  - Namespace mapping server
- Event service (event gateway)
- Data service directory (data models and schema)

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.

Figure 70: Cisco Configuration Engine Architectural Overview

## Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the device. The Configuration Service delivers device and service configurations to the device for initial configuration and mass reconfiguration by logical groups. Devices receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

## Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the device and facilitates the communication between the device and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.

**Related Topics**

[Enabling the CNS Event Agent](#), on page 974

## NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, `cisco.cns.config.load`. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

## Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured device. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term *ConfigID* is the unique identifier for a device. Within the scope of the event bus namespace, the term *DeviceID* is the CNS unique identifier for a device.

**Related Topics**

[Prerequisites for Configuring the Configuration Engine](#), on page 967

[Restrictions for Configuring the Configuration Engine](#), on page 968

## ConfigID

Each configured device has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of device CLI attributes. The ConfigID defined on the device must match the ConfigID for the corresponding device definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the device hostname is reconfigured.

## DeviceID

Each configured device participating on the event bus has a unique DeviceID, which is analogous to the device source address so that the device can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the device. However, the DeviceID variable and its usage reside within the event gateway adjacent to the device.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the device. The event gateway represents the device and its corresponding DeviceID to the event bus.

The device declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the device.

#### Related Topics

[Prerequisites for Configuring the Configuration Engine](#), on page 967

## Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the device hostname is reconfigured.

When changing the device hostname on the device, the only way to refresh the DeviceID is to break the connection between the device and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the device sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

#### Caution

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the device acquires *after*, not *before*, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

#### Related Topics

[Refreshing DeviceIDs](#), on page 982

## Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a device, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the `cn=<value>` of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the device.

These and other associated attributes (tag value pairs) are set when you run **Setup** on the Cisco Configuration Engine.

## Cisco IOS CNS Agents

The CNS event agent feature allows the device to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the device Cisco IOS software, allow the device to be connected and automatically configured.

#### Related Topics

[Enabling the Cisco IOS CNS Agent](#), on page 975

## Initial Configuration

When the device first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution

device acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new device and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the device.

The device automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the device loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the device.

The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

**Figure 71: Initial Configuration**

#### Related Topics

[Enabling an Initial Configuration for Cisco IOS CNS Agent](#), on page 977

[Monitoring CNS Configurations](#), on page 985

## Incremental (Partial) Configuration

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the device. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the device to initiate a pull operation.

The device can check the syntax of the configuration before applying it. If the syntax is correct, the device applies the incremental configuration and publishes an event that signals success to the configuration server. If the device does not apply the incremental configuration, it publishes an event showing an error status. When the device has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

#### Related Topics

[Enabling a Partial Configuration for Cisco IOS CNS Agent](#), on page 984

[Monitoring CNS Configurations](#), on page 985

## Synchronized Configuration

When the device receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the device not to save the updated configuration into its NVRAM. The device uses the updated configuration as its running configuration. This ensures that the device configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

## Automated CNS Configuration

To enable automated CNS configuration of the device, you must first complete the prerequisites listed in this topic. When you complete them, power on the device. At the **setup** prompt, do nothing; the device begins the initial configuration. When the full configuration file is loaded on your device, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

**Table 72: Prerequisites for Enabling Automatic Configuration**

| Device                   | Required Configuration                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access device            | Factory default (no configuration file)                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Distribution device      | <ul style="list-style-type: none"> <li>• IP helper address</li> <li>• Enable DHCP relay agent<sup>2</sup></li> <li>• IP routing (if used as default gateway)</li> </ul>                                                                                                                                                                                                                                                                                      |

| TFTP server              | <ul style="list-style-type: none"> <li>• A bootstrap configuration file that includes the CNS configuration commands that enable the device to communicate with the Configuration Engine</li> <li>• The device configured to use either the device MAC address or the serial number (instead of the default hostname) to generate the ConfigID and EventID</li> <li>• The CNS event agent configured to push the configuration file to the device</li> </ul> |
| CNS Configuration Engine | One or more templates for each type of device, with the ConfigID of the device mapped to the template.                                                                                                                                                                                                                                                                                                                                                       |

<sup>2</sup> A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.

# How to Configure the Configuration Engine

## Enabling the CNS Event Agent

**Note** You must enable the CNS event agent on the device before you enable the CNS configuration agent.

Follow these steps to enable the CNS event agent on the device.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cns event** *{hostname | ip-address}* [*port-number*] [ [**keepalive seconds** *retry-count*] [**failover-time seconds**] [**reconnect-time time**] | **backup**]
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                                                                                                                                             | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                                                                                                                                     | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 3</b> | <b>cns event</b> <i>{hostname   ip-address}</i> [ <i>port-number</i> ] [ [ <b>keepalive seconds</b> <i>retry-count</i> ] [ <b>failover-time seconds</b> ] [ <b>reconnect-time time</b> ]   <b>backup</b> ]<br><b>Example:</b><br>Device(config)# <b>cns event</b> 10.180.1.27 <b>keepalive</b> 120 10 | Enables the event agent, and enters the gateway parameters. <ul style="list-style-type: none"> <li>• For <i>{hostname   ip-address}</i>, enter either the hostname or the IP address of the event gateway.</li> <li>• (Optional) For <i>port number</i>, enter the port number for the event gateway. The default port number is 11011.</li> <li>• (Optional) For <b>keepalive seconds</b>, enter how often the device sends keepalive messages. For <i>retry-count</i>, enter the number of unanswered keepalive messages that the device sends before the connection is terminated. The default for each is 0.</li> </ul> |

|               | Command or Action                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                   | <ul style="list-style-type: none"> <li>• (Optional) For <b>failover-time</b> <i>seconds</i>, enter how long the device waits for the primary gateway route after the route to the backup gateway is established.</li> <li>• (Optional) For <b>reconnect-time</b> <i>time</i>, enter the maximum time interval that the device waits before trying to reconnect to the event gateway.</li> <li>• (Optional) Enter <b>backup</b> to show that this is the backup gateway. (If omitted, this is the primary gateway.)</li> </ul> <p><b>Note</b> Though visible in the command-line help string, the <b>encrypt</b> and the <b>clock-timeout</b> <i>time</i> keywords are not supported.</p> |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 5</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**What to do next**

To verify information about the event agent, use the **show cns event connections** command in privileged EXEC mode.

To disable the CNS event agent, use the **no cns event** { *ip-address* | *hostname* } global configuration command.

## Enabling the Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent on the device.

**Before you begin**

You must enable the CNS event agent on the device before you enable this agent.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **cns config initial** *{hostname | ip-address}* [*port-number*]
4. **cns config partial** *{hostname | ip-address}* [*port-number*]
5. **end**
6. **show running-config**
7. **copy running-config startup-config**
8. Start the Cisco IOS CNS agent on the device.

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Enabling an Initial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the CNS configuration agent and initiate an initial configuration on the device.

### SUMMARY STEPS

- enable**
- configure terminal**
- cns template connect** *name*
- cli** *config-text*
- Repeat Steps 3 to 4 to configure another CNS connect template.
- exit**
- cns connect** *name* [**retries** *number*] [**retry-interval** *seconds*] [**sleep** *seconds*] [**timeout** *seconds*]
- discover** {**controller** *controller-type* | **dlci** [**subinterface** *subinterface-number*] | **interface** [*interface-type*] | **line** *line-type*}
- template** *name* [... *name*]
- Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile.

11. **exit**
12. **hostname** *name*
13. **ip route** *network-number*
14. **cns id** *interface num* {**dns-reverse** | **ipaddress** | **mac-address**} [**event**] [**image**]
15. **cns id** {**hardware-serial** | **hostname** | **string string** | **udi**} [**event**] [**image**]
16. **cns config initial** {*hostname* | *ip-address*} [*port-number*] [**event**] [**no-persist**] [**page page**] [**source ip-address**] [**syntax-check**]
17. **end**
18. **show running-config**
19. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                         | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                            |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                 | Enters the global configuration mode.                                                                                                                                                                     |
| <b>Step 3</b> | <b>cns template connect</b> <i>name</i><br><b>Example:</b><br>Device (config)# <b>cns template connect template-dhcp</b>                                          | Enters CNS template connect configuration mode, and specifies the name of the CNS connect template.                                                                                                       |
| <b>Step 4</b> | <b>cli</b> <i>config-text</i><br><b>Example:</b><br>Device (config-tmpl-conn)# <b>cli ip address dhcp</b>                                                         | Enters a command line for the CNS connect template. Repeat this step for each command line in the template.                                                                                               |
| <b>Step 5</b> | Repeat Steps 3 to 4 to configure another CNS connect template.                                                                                                    |                                                                                                                                                                                                           |
| <b>Step 6</b> | <b>exit</b><br><b>Example:</b><br>Device (config)# <b>exit</b>                                                                                                    | Returns to global configuration mode.                                                                                                                                                                     |
| <b>Step 7</b> | <b>cns connect</b> <i>name</i> [ <b>retries number</b> ] [ <b>retry-interval seconds</b> ] [ <b>sleep seconds</b> ] [ <b>timeout seconds</b> ]<br><b>Example:</b> | Enters CNS connect configuration mode, specifies the name of the CNS connect profile, and defines the profile parameters. The device uses the CNS connect profile to connect to the Configuration Engine. |

|                | Command or Action                                                                                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                | <p><b>Example:</b></p> <pre>RemoteDevice(config)# <b>cns config initial 10.1.1.1</b> <b>no-persist</b></pre>                         | <ul style="list-style-type: none"> <li>• For <code>{hostname   ip-address}</code>, enter the hostname or the IP address of the configuration server.</li> <li>• (Optional) For <code>port-number</code>, enter the port number of the configuration server. The default port number is 80.</li> <li>• (Optional) Enable <b>event</b> for configuration success, failure, or warning messages when the configuration is finished.</li> <li>• (Optional) Enable <b>no-persist</b> to suppress the automatic writing to NVRAM of the configuration pulled as a result of entering the <b>cns config initial</b> global configuration command. If the <b>no-persist</b> keyword is not entered, using the <b>cns config initial</b> command causes the resultant configuration to be automatically written to NVRAM.</li> <li>• (Optional) For <b>page page</b>, enter the web page of the initial configuration. The default is <code>/Config/config/asp</code>.</li> <li>• (Optional) Enter <b>source ip-address</b> to use for source IP address.</li> <li>• (Optional) Enable <b>syntax-check</b> to check the syntax when this parameter is entered.</li> </ul> <p><b>Note</b> Though visible in the command-line help string, the <b>encrypt</b>, <b>status url</b>, and <b>inventory</b> keywords are not supported.</p> |
| <b>Step 17</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# <b>end</b></pre>                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 18</b> | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Device# <b>show running-config</b></pre>                               | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 19</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Device# <b>copy running-config startup-config</b></pre> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**What to do next**

To verify information about the configuration agent, use the **show cns config connections** command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the **no cns config initial** { *ip-address* | *hostname* } global configuration command.

## Refreshing DeviceIDs

Follow these steps to refresh a DeviceID when changing the hostname on the device.

**SUMMARY STEPS**

1. **enable**
2. **show cns config connections**
3. Make sure that the CNS event agent is properly connected to the event gateway.
4. **show cns event connections**
5. Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.
6. **configure terminal**
7. **no cns event** *ip-address port-number*
8. **cns event** *ip-address port-number*
9. **end**
10. Make sure that you have reestablished the connection between the device and the event connection by examining the output from **show cns event connections**.
11. **show running-config**
12. **copy running-config startup-config**

**DETAILED STEPS**

|               | Command or Action                                                                                   | Purpose                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                           | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                    |
| <b>Step 2</b> | <b>show cns config connections</b><br><b>Example:</b><br>Device# <b>show cns config connections</b> | Displays whether the CNS event agent is connecting to the gateway, connected, or active, and the gateway used by the event agent, its IP address and port number. |
| <b>Step 3</b> | Make sure that the CNS event agent is properly connected to the event gateway.                      | Examine the output of <b>show cns config connections</b> for the following:                                                                                       |

|                | Command or Action                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                          |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                                                                                                   | <ul style="list-style-type: none"> <li>• Connection is active.</li> <li>• Connection is using the currently configured device hostname. The DeviceID will be refreshed to correspond to the new hostname configuration using these instructions.</li> </ul>      |
| <b>Step 4</b>  | <b>show cns event connections</b><br><b>Example:</b><br>Device# <code>show cns event connections</code>                                                                                           | Displays the event connection information for your device.                                                                                                                                                                                                       |
| <b>Step 5</b>  | Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions. |                                                                                                                                                                                                                                                                  |
| <b>Step 6</b>  | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                                                                           | Enters global configuration mode.                                                                                                                                                                                                                                |
| <b>Step 7</b>  | <b>no cns event ip-address port-number</b><br><b>Example:</b><br>Device(config)# <code>no cns event 172.28.129.22 2012</code>                                                                     | Specifies the IP address and port number that you recorded in Step 5 in this command.<br>This command breaks the connection between the device and the event gateway. It is necessary to first break, then reestablish, this connection to refresh the DeviceID. |
| <b>Step 8</b>  | <b>cns event ip-address port-number</b><br><b>Example:</b><br>Device(config)# <code>cns event 172.28.129.22 2012</code>                                                                           | Specifies the IP address and port number that you recorded in Step 5 in this command.<br>This command reestablishes the connection between the device and the event gateway.                                                                                     |
| <b>Step 9</b>  | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                                                                                                 | Returns to privileged EXEC mode.                                                                                                                                                                                                                                 |
| <b>Step 10</b> | Make sure that you have reestablished the connection between the device and the event connection by examining the output from <b>show cns event connections</b> .                                 |                                                                                                                                                                                                                                                                  |
| <b>Step 11</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                                                                                                         | Verifies your entries.                                                                                                                                                                                                                                           |

|                | Command or Action                                                                                                       | Purpose                                                  |
|----------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 12</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

## Enabling a Partial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent and to initiate a partial configuration on the device.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `cns config partial {ip-address | hostname} [port-number] [source ip-address]`
4. `end`
5. `show running-config`
6. `copy running-config startup-config`

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code>                                                                                                              | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                                                      | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 3</b> | <b>cns config partial {ip-address   hostname} [port-number] [source ip-address]</b><br><b>Example:</b><br>Device(config)# <code>cns config partial 172.28.129.22 2013</code> | Enables the configuration agent, and initiates a partial configuration. <ul style="list-style-type: none"> <li>• For <code>{ip-address   hostname}</code>, enter the IP address or the hostname of the configuration server.</li> <li>• (Optional) For <code>port-number</code>, enter the port number of the configuration server. The default port number is 80.</li> </ul> |

|               | Command or Action                                                                                                     | Purpose                                                                                                                                                                                                                                              |
|---------------|-----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                       | <ul style="list-style-type: none"> <li>(Optional) Enter <b>source</b> <i>ip-address</i> to use for the source IP address.</li> </ul> <p><b>Note</b> Though visible in the command-line help string, the <b>encrypt</b> keyword is not supported.</p> |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br><pre>Device(config)# end</pre>                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                     |
| <b>Step 5</b> | <b>show running-config</b><br><b>Example:</b><br><pre>Device# show running-config</pre>                               | Verifies your entries.                                                                                                                                                                                                                               |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br><pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                             |

### What to do next

To verify information about the configuration agent, use either the **show cns config stats** or the **show cns config outstanding** command in privileged EXEC mode.

To disable the Cisco IOS agent, use the **no cns config partial** { *ip-address* | *hostname* } global configuration command. To cancel a partial configuration, use the **cns config cancel** global configuration command.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About CDP

### CDP Overview

CDP is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With CDP, network management applications can learn the device type and the Simple Network Management Protocol (SNMP) agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

CDP runs on all media that support Subnetwork Access Protocol (SNAP). Because CDP runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each CDP-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information, which is the length of time a receiving device holds CDP information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.

On the device, CDP enables Network Assistant to display a graphical view of the network. The device uses CDP to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command device by default.

## Default CDP Configuration

This table shows the default CDP configuration.

| Feature                             | Default Setting |
|-------------------------------------|-----------------|
| CDP global state                    | Enabled         |
| CDP interface state                 | Enabled         |
| CDP timer (packet update frequency) | 60 seconds      |
| CDP holdtime (before discarding)    | 180 seconds     |
| CDP Version-2 advertisements        | Enabled         |

## How to Configure CDP

### Configuring CDP Characteristics

You can configure these CDP characteristics:

- Frequency of CDP updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version-2 advertisements

**Note** Steps 3 through 5 are all optional and can be performed in any order.

Follow these steps to configure the CDP characteristics.

#### SUMMARY STEPS

1. enable

2. **configure terminal**
3. **cdp timer *seconds***
4. **cdp holdtime *seconds***
5. **cdp advertise-v2**
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                               | Purpose                                                                                                                                                                                             |

## Disabling CDP

CDP is enabled by default.

**Note** Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Follow these steps to disable the CDP device discovery capability.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **no cdp run**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

**DETAILED STEPS**

|               | Command or Action                                               | Purpose                                                        |
|---------------|-----------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b>                    | Enters the global configuration mode.                          |

|               | Command or Action                                                                                                       | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
|               | Device# <code>configure terminal</code>                                                                                 |                                                          |
| <b>Step 3</b> | <b>no cdp run</b><br><b>Example:</b><br>Device(config)# <code>no cdp run</code>                                         | Disables CDP.                                            |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                       | Returns to privileged EXEC mode.                         |
| <b>Step 5</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                               | Verifies your entries.                                   |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

**What to do next**

You must reenable CDP to use it.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for SNMP

### Supported SNMP Versions

This software release supports the following SNMP versions:

- SNMPv1—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- SNMPv2C replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:

- SNMPv2—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.
- SNMPv2C—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- SNMPv3—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
  - Message integrity—Ensures that a packet was not tampered with in transit.
  - Authentication—Determines that the message is from a valid source.
  - Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

**Note** To select encryption, enter the **priv** keyword.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent's MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

**Table 75: SNMP Security Models and Levels**

| Model   | Level        | Authentication   | Encryption | Result                                            |
|---------|--------------|------------------|------------|---------------------------------------------------|
| SNMPv1  | noAuthNoPriv | Community string | No         | Uses a community string match for authentication. |
| SNMPv2C | noAuthNoPriv | Community string | No         | Uses a community string match for authentication. |
| SNMPv3  | noAuthNoPriv | Username         | No         | Uses a username match for authentication.         |

| Model  | Level      | Authentication                                        | Encryption                                                           | Result                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|------------|-------------------------------------------------------|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SNMPv3 | authNoPriv | Message Digest 5 (MD5) or Secure Hash Algorithm (SHA) | No                                                                   | Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.                                                                                                                                                                                                                                                                                                                                                 |
| SNMPv3 | authPriv   | MD5 or SHA                                            | Data Encryption Standard (DES) or Advanced Encryption Standard (AES) | <p>Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.</p> <p>Allows specifying the User-based Security Model (USM) with these encryption algorithms:</p> <ul style="list-style-type: none"> <li>• DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard.</li> <li>• 3DES 168-bit encryption</li> <li>• AES 128-bit, 192-bit, or 256-bit encryption</li> </ul> |

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.

## Restrictions for SNMP

### Version Restrictions

- SNMPv1 does not support informs.

# Information About SNMP

## SNMP Overview

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime Infrastructure. The agent and MIB reside on the device. To configure SNMP on the device, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager's requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

## SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

**Table 76: SNMP Operations**

| Operation                     | Description                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| get-request                   | Retrieves a value from a specific variable.                                                                                                   |
| get-next-request              | Retrieves a value from a variable within a table. <sup>3</sup>                                                                                |
| get-bulk-request <sup>4</sup> | Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data. |
| get-response                  | Replies to a get-request, get-next-request, and set-request sent by an NMS.                                                                   |
| set-request                   | Stores a value in a specific variable.                                                                                                        |
| trap                          | An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.                                                 |

<sup>3</sup> With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

<sup>4</sup> The get-bulk command only works with SNMPv2 or later.

## SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- Get a MIB variable—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.

- Set a MIB variable—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

## SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the device, the community string definitions on the NMS must match at least one of the three community string definitions on the device.

A community string can have one of the following attributes:

- Read-only (RO)—Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.
- Read-write (RW)—Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.
- When a cluster is created, the command device manages the exchange of messages among member devices and the SNMP application. The Network Assistant software appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device and propagates them to the member devices.

## SNMP MIB Variables Access

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure 2.0 software uses the device MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in *get-request*, *get-next-request*, and *set-request* format.

**Figure 72: SNMP Network**

## SNMP Notifications

SNMP allows the device to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps or informs, or both. Use the **snmp-server host** command to specify whether to send SNMP notifications as traps or informs.

**Note** SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the device and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the device is a concern and notification is not required, use traps.

## SNMP ifIndex MIB Object Values

The SNMP agent's IF-MIB module comes up shortly after reboot. As various physical interface drivers are initialized they register with the IF-MIB module, essentially saying "Give me an ifIndex number". The IF-MIB module assigns the next available ifIndex number on a first-come-first-served basis. That is, minor differences in driver initialization order from one reboot to another can result in the same physical interface getting a different ifIndex number than it had before the reboot (unless ifIndex persistency is enabled of course).

## Default SNMP Configuration

| Feature                | Default Setting                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| SNMP agent             | Disabled <sup>5</sup> .                                                                   |
| SNMP trap receiver     | None configured.                                                                          |
| SNMP traps             | None enabled except the trap for TCP connections (tty).                                   |
| SNMP version           | If no version keyword is present, the default is Version 1.                               |
| SNMPv3 authentication  | If no keyword is entered, the default is the <b>noauth</b> (noAuthNoPriv) security level. |
| SNMP notification type | If no type is specified, all notifications are sent.                                      |

- <sup>5</sup> This is the default when the device starts and the startup configuration does not have any **snmp-server** global configuration commands.

## SNMP Configuration Guidelines

If the device starts and the device startup configuration has at least one **snmp-server** global configuration command, the SNMP agent is enabled.

An SNMP *group* is a table that maps SNMP users to SNMP views. An SNMP *user* is a member of an SNMP group. An SNMP *host* is the recipient of an SNMP trap operation. An SNMP *engine ID* is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The **snmp-server host** global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.
- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the **snmp-server engineID** global configuration command with the **remote** option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.
- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.
- If a local user is not associated with a remote host, the device does not send informs for the **auth** (authNoPriv) and the **priv** (authPriv) authentication levels.
- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the **snmp-server user username** global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

## How to Configure SNMP

### Disabling the SNMP Agent

The **no snmp-server** global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenables all versions of the SNMP agent by the first

**snmp-server** global configuration command that you enter. There is no Cisco IOS command specifically designated for enabling SNMP.

Follow these steps to disable the SNMP agent.

### Before you begin

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first **snmp-server** global configuration command entered on the device.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no snmp-server**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                   | Purpose                                                        |
|---------------|-------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                           | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>   | Enters the global configuration mode.                          |
| <b>Step 3</b> | <b>no snmp-server</b><br><b>Example:</b><br>Device(config)# <b>no snmp-server</b>   | Disables the SNMP agent operation.                             |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                         | Returns to privileged EXEC mode.                               |
| <b>Step 5</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b> | Verifies your entries.                                         |

|        | Command or Action                                                                                                       | Purpose                                                  |
|--------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 6 | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

## Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the device. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

Follow these steps to configure a community string on the device.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `snmp-server community string [view view-name] [ro | rw] [access-list-number]`
4. `access-list access-list-number {deny | permit} source [source-wildcard]`
5. `end`
6. `show running-config`
7. `copy running-config startup-config`

#### DETAILED STEPS

|        | Command or Action                                               | Purpose                                                        |
|--------|-----------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | <b>configure terminal</b><br><b>Example:</b>                    | Enters the global configuration mode.                          |

|               | Command or Action                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Step 7</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

### What to do next

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the **no snmp-server** community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

## Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Follow these steps to configure SNMP groups and users on the device.

### SUMMARY STEPS

- enable**
- configure terminal**
- snmp-server engineID** { **local** *engineid-string* | **remote** *ip-address* [**udp-port** *port-number*] *engineid-string* }
- snmp-server group** *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*]
- snmp-server user** *username* *group-name* { **remote** *host* [**udp-port** *port*] } { **v1** [**access** *access-list*] | **v2c** [**access** *access-list*] | **v3** [**encrypted**] [**access** *access-list*] [**auth** { **md5** | **sha** } *auth-password*] } [**priv** { **des** | **3des** | **aes** { **128** | **192** | **256** } } *priv-password*]

6. `end`
7. `show running-config`
8. `copy running-config startup-config`

## Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the device generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Devices running this Cisco IOS release can have an unlimited number of trap managers.

**Note** Many commands use the word **traps** in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword **traps** refers to traps, informs, or both. Use the **snmp-server host** global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the **snmp-server enable traps** global configuration command combined with the **snmp-server host** global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

**Note** The **snmp-server enable traps** command does not support traps for local-authentication on your device.

Table 77: Device Notification Types

| Notification Type Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>bridge</b>             | Generates STP bridge MIB traps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>cluster</b>            | Generates a trap when the cluster configuration changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>config</b>             | Generates a trap for SNMP configuration changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>copy-config</b>        | Generates a trap for SNMP copy configuration changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>cpu threshold</b>      | Allow CPU-related traps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>entity</b>             | Generates a trap for SNMP entity changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>envmon</b>             | Generates environmental monitor traps. You can enable any or all of these environmental traps: fan, shutdown, status, supply, temperature.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>flash</b>              | Generates SNMP FLASH notifications. In a device stack, you can optionally enable notification for flash insertion or removal, which would cause a trap to be issued whenever a device in the stack is removed or inserted (physical removal, power cycle, or reload).                                                                                                                                                                                                                                                                               |
| <b>fru-ctrl</b>           | Generates entity field-replaceable unit (FRU) control traps. In the device stack, this trap refers to the insertion or removal of a device in the stack.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>hsrp</b>               | Generates a trap for Hot Standby Router Protocol (HSRP) changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ipmulticast</b>        | Generates a trap for IP multicast routing changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>mac-notification</b>   | Generates a trap for MAC address notifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ospf</b>               | Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes.                                                                                                                                                                                                                                                                                                                                                |
| <b>pim</b>                | Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes.                                                                                                                                                                                                                                                                                                                                                     |
| <b>port-security</b>      | <p>Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.</p> <p><b>Note</b> When you configure a trap by using the notification type <b>port-security</b>, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> <li><b>snmp-server enable traps port-security</b></li> <li><b>snmp-server enable traps port-security trap-rate rate</b></li> </ol> |
| <b>snmp</b>               | Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down.                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Notification Type Keyword | Description                                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>storm-control</b>      | Generates a trap for SNMP storm-control. You can also set a maximum trap rate per minute. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence). |
| <b>stpx</b>               | Generates SNMP STP Extended MIB traps.                                                                                                                                                             |
| <b>syslog</b>             | Generates SNMP syslog traps.                                                                                                                                                                       |
| <b>tty</b>                | Generates a trap for TCP connections. This trap is enabled by default.                                                                                                                             |
| <b>vlan-membership</b>    | Generates a trap for SNMP VLAN membership changes.                                                                                                                                                 |
| <b>vlancreate</b>         | Generates SNMP VLAN created traps.                                                                                                                                                                 |
| <b>vlandelete</b>         | Generates SNMP VLAN deleted traps.                                                                                                                                                                 |
| <b>vtp</b>                | Generates a trap for VLAN Trunking Protocol (VTP) changes.                                                                                                                                         |

Follow these steps to configure the device to send traps or informs to a host.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server engineID remote** *ip-address engineid-string*
4. **snmp-server user** *username group-name* { **remote** *host* [ **udp-port** *port* ] } { **v1** [ **access** *access-list* ] | **v2c** [ **access** *access-list* ] | **v3** [ **encrypted** ] [ **access** *access-list* ] [ **auth** { **md5** | **sha** } *auth-password* ] }
5. **snmp-server group** *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [ **read** *readview* ] [ **write** *writeview* ] [ **notify** *notifyview* ] [ **access** *access-list* ]
6. **snmp-server host** *host-addr* [ **informs** | **traps** ] [ **version** { **1** | **2c** | **3** { **auth** | **noauth** | **priv** } } ] *community-string* [ *notification-type* ]
7. **snmp-server enable traps** *notification-types*
8. **snmp-server trap-source** *interface-id*
9. **snmp-server queue-length** *length*
10. **snmp-server trap-timeout** *seconds*
11. **end**
12. **show running-config**
13. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                         | Purpose                                                        |
|---------------|-----------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Device# configure terminal</pre>                                                                                                                                                                                                  | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 3</b> | <b>snmp-server engineID remote ip-address engineid-string</b><br><b>Example:</b><br><pre>Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b</pre>                                                                                                       | Specifies the engine ID for the remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 4</b> | <b>snmp-server user username group-name {remote host [udp-port port]} {v1 [access access-list]   v2c [access access-list]   v3 [encrypted] [access access-list] [auth {md5   sha} auth-password]}</b><br><b>Example:</b><br><pre>Device(config)# snmp-server user Pat public v2c</pre> | Configures an SNMP user to be associated with the remote host created in Step 3.<br><br><b>Note</b> You cannot configure a remote user for an address without first configuring the engine ID for the remote host. Otherwise, you receive an error message, and the command is not executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 5</b> | <b>snmp-server group group-name {v1   v2c   v3 {auth   noauth   priv}} [read readview] [write writeview] [notify notifyview] [access access-list]</b><br><b>Example:</b><br><pre>Device(config)# snmp-server group public v2c access lmnop</pre>                                       | Configures an SNMP group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 6</b> | <b>snmp-server host host-addr [informs   traps] [version {1   2c   3 {auth   noauth   priv}}] community-string [notification-type]</b><br><b>Example:</b><br><pre>Device(config)# snmp-server host 203.0.113.1 comaccess snmp</pre>                                                    | Specifies the recipient of an SNMP trap operation.<br>For <i>host-addr</i> , specify the name or Internet address of the host (the targeted recipient).<br>(Optional) Specify <b>traps</b> (the default) to send SNMP traps to the host.<br>(Optional) Specify <b>informs</b> to send SNMP informs to the host.<br>(Optional) Specify the SNMP <b>version (1, 2c, or 3)</b> . SNMPv1 does not support informs.<br>(Optional) For Version 3, select authentication level <b>auth</b> , <b>noauth</b> , or <b>priv</b> .<br><b>Note</b> The <b>priv</b> keyword is available only when the cryptographic software image is installed.<br><br>For <i>community-string</i> , when <b>version 1</b> or <b>version 2c</b> is specified, enter the password-like community string sent with the notification operation. When <b>version 3</b> is specified, enter the SNMPv3 username. |

|                | Command or Action                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                                                          | <p>The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <p>(Optional) For <i>notification-type</i>, use the keywords listed in the table above. If no type is specified, all notifications are sent.</p> <p><b>Note</b> In case of SNMP version 3, SNMPv3 user should be configured prior SNMPv3 host configuration, otherwise SNMP traps will not be sent.</p>                                                                                                                                                                                                                                       |
| <b>Step 7</b>  | <p><b>snmp-server enable traps</b> <i>notification-types</i></p> <p><b>Example:</b></p> <pre>Device(config)# snmp-server enable traps snmp</pre>         | <p>Enables the device to send traps or informs and specifies the type of notifications to be sent. For a list of notification types, see the table above, or enter <b>snmp-server enable traps ?</b></p> <p>To enable multiple types of traps, you must enter a separate <b>snmp-server enable traps</b> command for each trap type.</p> <p><b>Note</b> When you configure a trap by using the notification type <b>port-security</b>, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> <li>a. <b>snmp-server enable traps port-security</b></li> <li>b. <b>snmp-server enable traps port-security trap-rate rate</b></li> </ol> |
| <b>Step 8</b>  | <p><b>snmp-server trap-source</b> <i>interface-id</i></p> <p><b>Example:</b></p> <pre>Device(config)# snmp-server trap-source GigabitEthernet1/0/1</pre> | <p>(Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 9</b>  | <p><b>snmp-server queue-length</b> <i>length</i></p> <p><b>Example:</b></p> <pre>Device(config)# snmp-server queue-length 20</pre>                       | <p>(Optional) Establishes the message queue length for each trap host. The range is 1 to 1000; the default is 10.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 10</b> | <p><b>snmp-server trap-timeout</b> <i>seconds</i></p> <p><b>Example:</b></p> <pre>Device(config)# snmp-server trap-timeout 60</pre>                      | <p>(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 11</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# end</pre>                                                                                  | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|         | Command or Action                                                                                                       | Purpose                                                  |
|---------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 12 | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                               | Verifies your entries.                                   |
| Step 13 | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

### What to do next

The **snmp-server host** command specifies which hosts receive the notifications. The **snmp-server enable traps** command globally enables the method for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an **snmp-server host informs** command for the host and globally enable informs by using the **snmp-server enable traps** command.

To remove the specified host from receiving traps, use the **no snmp-server host** *host* global configuration command. The **no snmp-server host** command with no keywords disables traps, but not informs, to the host. To disable informs, use the **no snmp-server host informs** global configuration command. To disable a specific trap type, use the **no snmp-server enable traps** *notification-types* global configuration command.

## Setting the Agent Contact and Location Information

Follow these steps to set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server contact** *text*
4. **snmp-server location** *text*
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                                                                            | Purpose                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                    | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                            | Enters the global configuration mode.                          |
| <b>Step 3</b> | <b>snmp-server contact <i>text</i></b><br><b>Example:</b><br>Device(config)# <b>snmp-server contact Dial System Operator at beeper 21555</b> | Sets the system contact string.                                |
| <b>Step 4</b> | <b>snmp-server location <i>text</i></b><br><b>Example:</b><br>Device(config)# <b>snmp-server location Building 3/Room 222</b>                | Sets the system location string.                               |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                  | Returns to privileged EXEC mode.                               |
| <b>Step 6</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                                                          | Verifies your entries.                                         |
| <b>Step 7</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b>                            | (Optional) Saves your entries in the configuration file.       |

## Limiting TFTP Servers Used Through SNMP

Follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server tftp-server-list *access-list-number***
4. **access-list *access-list-number* {deny | permit} *source* [*source-wildcard*]**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Step 1 | <b>enable</b><br><b>Example:</b><br><pre>Device&gt; enable</pre>                                                                                                                    | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br><pre>Device# configure terminal</pre>                                                                                               | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>snmp-server tftp-server-list <i>access-list-number</i></b><br><b>Example:</b><br><pre>Device(config)# snmp-server tftp-server-list 44</pre>                                      | <p>Limits the TFTP servers used for configuration file copies through SNMP to the servers in the access list.</p> <p>For <i>access-list-number</i>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 4 | <b>access-list <i>access-list-number</i> {deny   permit} <i>source</i> [<i>source-wildcard</i>]</b><br><b>Example:</b><br><pre>Device(config)# access-list 44 permit 10.1.1.2</pre> | <p>Creates a standard access list, repeating the command as many times as necessary.</p> <p>For <i>access-list-number</i>, enter the access list number specified in Step 3.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched. The <b>permit</b> keyword permits access if the conditions are matched.</p> <p>For <i>source</i>, enter the IP address of the TFTP servers that can access the device.</p> <p>(Optional) For <i>source-wildcard</i>, enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore.</p> <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 5 | <b>end</b><br><b>Example:</b>                                                                                                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|               | Command or Action                                                                                                 | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
|               | Device(config)# <b>end</b>                                                                                        |                                                          |
| <b>Step 6</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                   |
| <b>Step 7</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

## Configuring Trap Flags for SNMP

### SUMMARY STEPS

1. **configure terminal**
2. **trapflags ap { interfaceup | register}**
3. **trapflags client {dot11 | excluded}**
4. **trapflags dot11-security {ids-sig-attack | wep-decrypt-error}**
5. **trapflags mesh**
6. **trapflags rogueap**
7. **trapflags rrm-params {channels | tx-power}**
8. **trapflags rrm-profile {coverage | interference | load | noise}**
9. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                      |
|---------------|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                   | Enters the global configuration mode.                                                                                                                                                                                                                                                                                        |
| <b>Step 2</b> | <b>trapflags ap { interfaceup   register}</b><br><b>Example:</b><br>Device(config)# <b>trapflags ap interfaceup</b> | Enables sending AP-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>interfaceup</b>– Enables trap when a Cisco AP interface (A or B) comes up.</li> <li>• <b>register</b>– Enables trap when a Cisco AP registers with a Cisco device.</li> </ul> |

|        | Command or Action                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>trapflags client {dot11   excluded}</b><br><b>Example:</b><br><pre>Device(config)# trapflags client excluded</pre>                                            | Enables sending client-related dot11 traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>dot11</b>– Enables Dot11 traps for clients.</li> <li>• <b>excluded</b>– Enables excluded traps for clients.</li> </ul>                                                                                                                                                                                                                                                                                    |
| Step 4 | <b>trapflags dot11-security {ids-sig-attack   wep-decrypt-error}</b><br><b>Example:</b><br><pre>Device(config)# trapflags dot11-security wep-decrypt-error</pre> | Enables sending 802.11 security-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>ids-sig-attack</b>– Enables IDS signature attack traps.</li> <li>• <b>wep-decrypt-error</b>– Enables traps for WEP decrypt error for clients.</li> </ul>                                                                                                                                                                                                                                               |
| Step 5 | <b>trapflags mesh</b><br><b>Example:</b><br><pre>Device(config)# trapflags mesh</pre>                                                                            | Enables trap for the mesh. Use the <b>no</b> form of the command to disable the trap flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 6 | <b>trapflags rogueap</b><br><b>Example:</b><br><pre>Device(config)# trapflags rogueap</pre>                                                                      | Enables trap for rogue AP detection. Use the <b>no</b> form of the command to disable the trap flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 7 | <b>trapflags rrm-params {channels   tx-power}</b><br><b>Example:</b><br><pre>Device(config)# trapflags rrm-params tx-power</pre>                                 | Enables sending RRM-parameter update-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>channels</b>– Enables trap when RF Manager automatically changes a channel number for the Cisco AP interface.</li> <li>• <b>tx-power</b>– Enables the trap when RF Manager automatically changes Tx-Power level for the Cisco AP interface.</li> </ul>                                                                                                                                            |
| Step 8 | <b>trapflags rrm-profile {coverage   interference   load   noise}</b><br><b>Example:</b><br><pre>Device(config)# trapflags rrm-profile interference</pre>        | Enables sending RRM-profile-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>coverage</b>– Enables the trap when the coverage profile maintained by RF Manager fails.</li> <li>• <b>interference</b>– Enables the trap when the interference profile maintained by RF Manager fails.</li> <li>• <b>load</b>– Enables trap when the load profile maintained by RF Manager fails.</li> <li>• <b>noise</b>– Enables trap when the noise profile maintained by RF Manager fails.</li> </ul> |

|               | Command or Action                                           | Purpose                          |
|---------------|-------------------------------------------------------------|----------------------------------|
| <b>Step 9</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b> | Returns to privileged EXEC mode. |

## Enabling SNMP Wireless Trap Notification

### SUMMARY STEPS

1. **configure terminal**
2. **snmp-server enable traps wireless [AP | RRM | bsn80211SecurityTrap | bsnAPPParamUpdate | bsnAPPProfile | bsnAccessPoint | bsnMobileStation | bsnRogue | client | mfp | rogue]**
3. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                                                                                                      | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 2</b> | <b>snmp-server enable traps wireless [AP   RRM   bsn80211SecurityTrap   bsnAPPParamUpdate   bsnAPPProfile   bsnAccessPoint   bsnMobileStation   bsnRogue   client   mfp   rogue]</b><br><b>Example:</b><br>Device(config)# <b>snmp-server enable traps wireless AP</b> | Enables SNMP wireless trap notification. <ul style="list-style-type: none"> <li>• <b>AP</b>– Enables access point traps.</li> <li>• <b>RRM</b>– Enables RRM traps.</li> <li>• <b>bsn80211SecurityTrap</b>– Enables the security-related trap.</li> <li>• <b>bsnAPPParamUpdate</b>– Enables the trap for AP parameters that get updated.</li> <li>• <b>bsnAPPProfile</b>– Enables BSN AP profile traps.</li> <li>• <b>bsnAccessPoint</b>– Enables BSN access point traps.</li> <li>• <b>bsnMobileStation</b>– Controls wireless client traps.</li> <li>• <b>bsnRogue</b>– Enables BSN rogue-related traps.</li> <li>• <b>client</b>– Enables client traps.</li> <li>• <b>mfp</b>– Enables MFP traps.</li> <li>• <b>rogue</b>– Enables rogue-related traps.</li> </ul> |

|        | Command or Action                                               | Purpose                          |
|--------|-----------------------------------------------------------------|----------------------------------|
| Step 3 | <b>end</b><br><b>Example:</b><br><pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |

## Monitoring SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the **show snmp** privileged EXEC command. You also can use the other privileged EXEC commands listed in the table to display SNMP information.

*Table 78: Commands for Displaying SNMP Information*

| Command                   | Purpose                                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show snmp</b>          | Displays SNMP statistics.                                                                                                                                                                                                                                                       |
| <b>show snmp engineID</b> | Displays information on the local SNMP engine and all remote engines that have been configured on the device.                                                                                                                                                                   |
| <b>show snmp group</b>    | Displays information on each SNMP group on the network.                                                                                                                                                                                                                         |
| <b>show snmp pending</b>  | Displays information on pending SNMP requests.                                                                                                                                                                                                                                  |
| <b>show snmp sessions</b> | Displays information on the current SNMP sessions.                                                                                                                                                                                                                              |
| <b>show snmp user</b>     | Displays information on each SNMP user name in the SNMP users table.<br><br><b>Note</b> You must use this command to display SNMPv3 configuration information for <b>auth   noauth   priv</b> mode. This information is not displayed in the <b>show running-config</b> output. |

## SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*. This configuration does not cause the device to send any traps.

```
Device(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string *public*. The device also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33 using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string *public* is sent with the traps.

```
Device(config)# snmp-server community public
Device(config)# snmp-server enable traps vtp
Device(config)# snmp-server host 192.180.1.27 version 2c public
Device(config)# snmp-server host 192.180.1.111 version 1 public
Device(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the *comaccess* community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host *cisco.com* using the community string *public*.

```
Device(config)# snmp-server community comaccess ro 4
Device(config)# snmp-server enable traps snmp authentication
Device(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host *cisco.com*. The community string is restricted. The first line enables the device to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous **snmp-server** host commands for the host *cisco.com*.

```
Device(config)# snmp-server enable traps entity
Device(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the device to send all traps to the host *myhost.cisco.com* using the community string *public*:

```
Device(config)# snmp-server enable traps
Device(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send **auth** (authNoPriv) authentication-level informs when the user enters global configuration mode:

```
Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Device(config)# snmp-server group authgroup v3 auth
Device(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Device(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Device(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Device(config)# snmp-server enable traps
Device(config)# snmp-server inform retries 0
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions on SLAs

This section lists the restrictions on SLAs.

The following are restrictions on IP SLAs network performance measurement:

- The device does not support VoIP service levels using the gatekeeper registration delay operations measurements.
- Only a Cisco IOS device can be a source for a destination IP SLAs responder.
- You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

# Information About SLAs

## Cisco IOS IP Service Level Agreements (SLAs)

Cisco IOS IP SLAs send data across the network to measure performance between multiple network locations or across multiple network paths. They simulate network data and IP services and collect network performance information in real time. Cisco IOS IP SLAs generate and analyze traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLA operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLA operations, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLA packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs are Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collect and analyze the following performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like Cisco Prime Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products.

Using IP SLAs can provide the following benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring
  - Measurement of jitter, latency, or packet loss in the network.
  - Continuous, reliable, and predictable measurements.

- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Network operation troubleshooting by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.
- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the device supports MPLS).

## Network Performance Measurement with Cisco IOS IP SLAs

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices.

**Figure 73: Cisco IOS IP SLAs Operation**

The following figure shows how IP SLAs begin when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

[Restrictions on SLAs](#), on page 1029

## IP SLA Responder and IP SLA Control Protocol

The IP SLA responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLA request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLA Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond.

**Note** The IP SLA responder can be a Cisco IOS Layer 2, responder-configurable device. The responder does not need to support full IP SLA functionality.

The following figure shows where the Cisco IOS IP SLA responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLA operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLA packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

**Figure 74: Cisco IOS IP SLAs Operation**

You do not need to enable the responder on the destination device for all IP SLA operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP).

#### Related Topics

[Restrictions on SLAs](#), on page 1029

## Response Time Computation for IP SLAs

Switches, controllers, and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimize these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLA test packets use time stamping to minimize the processing delays.

When the IP SLA responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

**Figure 75: Cisco IOS IP SLA Responder Time Stamping**

The following figure demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is

applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt

level to allow for greater accuracy.  $RTT$  (Round-trip time) =  $T4$  (Time stamp 4) -  $T1$  (Time stamp 1) -  $\Delta$

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

## IP SLAs Operation Scheduling

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the *pending* option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLA operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLA multi-operations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the *Cisco IOS IP SLAs Configuration Guide*.

## IP SLA Operation Threshold Monitoring

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as the following:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold
- One-way packet loss
- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency

An IP SLA threshold violation can also trigger another IP SLA operation for further analysis. For example, the frequency could be increased or an Internet Control Message Protocol (ICMP) path echo or ICMP path jitter operation could be initiated for troubleshooting.

### ICMP Echo

The ICMP echo operation measures the end-to-end response time between a Cisco device and any other device that uses IP. The response time is computed by measuring the time it takes to send an ICMP echo request message to a destination and receive an ICMP echo reply. Many customers use IP SLA ICMP-based operations, in-house ping testing, or ping-based dedicated probes to measure this response time. The IP SLA ICMP echo operation conforms to the same specifications as ICMP ping testing, and both methods result in the same response times.

## UDP Jitter

Jitter is a simple term that describes interpacket delay variance. When multiple packets are sent consecutively at an interval of 10 ms from source to destination, the destination should receive them 10 ms apart (if the network is behaving correctly). However, if there are delays in the network (such as queuing, arriving through alternate routes, and so on), the time interval between packet arrivals might be more or less than 10 ms. A positive jitter value indicates that the packets arrived more than 10 ms apart. A negative jitter value indicates that the packets arrived less than 10 ms apart. If the packets arrive 12 ms apart, the positive jitter is 2 ms; if the packets arrive 8 ms apart, the negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLA UDP jitter operation can be used as a multipurpose data gathering operation. The packets generated by IP SLAs carry sequence information and time stamps from the source and operational target that include packet sending and receiving data. Based on this data, UDP jitter operations measure the following:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), you can use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

To provide accurate one-way delay (latency) measurements, time synchronization (as provided by NTP) is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

## How to Configure IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the *Cisco IOS IP SLAs Configuration Guide*. It does include several operations as examples, including configuring the responder, configuring a UDP jitter operation, which requires a responder, and configuring an ICMP echo operation, which does not require a responder. For details about configuring other operations, see the *Cisco IOS IP SLAs Configuration Guide*.

### Default Configuration

No IP SLAs operations are configured.

### Configuration Guidelines

For information on the IP SLA commands, see the *Cisco IOS IP SLAs Command Reference, Release 12.4T* command reference.

For detailed descriptions and configuration procedures, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4TL*.

Not all of the IP SLA commands or operations described in the referenced guide are supported on the device. The device supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the **show ip sla application** privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

```
Device# show ip sla application

      IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

Supported Operation Types:
      icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
      dns, udpJitter, dhcp, ftp, udpApp, wspApp

Supported Features:
      IPSLAs Event Publisher

IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389

Estimated number of configurable operations: 24389
Number of Entries configured      : 0
Number of active Entries          : 0
Number of pending Entries         : 0
Number of inactive Entries        : 0
```

Time of last change in whole IP SLAs: \*13:04:37.668 UTC Wed Dec 19 2012

## Configuring the IP SLA Responder

The IP SLA responder is available only on Cisco IOS software-based devices, including some Layer 2 devices that do not support full IP SLA functionality.

Follow these steps to configure the IP SLA responder on the target device (the operational target):

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sla responder {tcp-connect | udp-echo} ipaddress *ip-address* port *port-number***
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                                       | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                               | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 3</b> | <b>ip sla responder {tcp-connect   udp-echo} ipaddress <i>ip-address</i> port <i>port-number</i></b><br><b>Example:</b><br>Device(config)# <b>ip sla responder udp-echo 172.29.139.134 5000</b> | Configures the device as an IP SLA responder.<br>The keywords have these meanings: <ul style="list-style-type: none"> <li>• <b>tcp-connect</b>—Enables the responder for TCP connect operations.</li> <li>• <b>udp-echo</b>—Enables the responder for User Datagram Protocol (UDP) echo or jitter operations.</li> <li>• <b>ipaddress <i>ip-address</i></b>—Enter the destination IP address.</li> <li>• <b>port <i>port-number</i></b>—Enter the destination port number.</li> </ul> <p><b>Note</b> The IP address and port number must match those configured on the source device for the IP SLA operation.</p> |

|        | Command or Action                                                                                                 | Purpose                                                  |
|--------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                       | Returns to privileged EXEC mode.                         |
| Step 5 | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                   |
| Step 6 | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

## Implementing IP SLA Network Performance Measurement

Follow these steps to implement IP SLA network performance measurement on your device:

### Before you begin

Use the **show ip sla application** privileged EXEC command to verify that the desired operation type is supported on your software image.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sla operation-number**
4. **udp-jitter** {destination-ip-address | destination-hostname} destination-port [source-ip {ip-address | hostname}] [source-port port-number] [control {enable | disable}] [num-packets number-of-packets] [interval interpacket-interval]
5. **frequency** seconds
6. **threshold** milliseconds
7. **exit**
8. **ip sla schedule** operation-number [life {forever | seconds}] [start-time {hh:mm[:ss] [month day | day month] | pending | now | after hh:mm:ss} [ageout seconds] [recurring]
9. **end**
10. **show running-config**
11. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### UDP Jitter Configuration

This example shows how to configure a UDP jitter IP SLA operation:

```

Device(config)# ip sla 10
Device(config-ip-sla)# udp-jitter 172.29.139.134 5000
Device(config-ip-sla-jitter)# frequency 30
Device(config-ip-sla-jitter)# exit
Device(config)# ip sla schedule 5 start-time now life forever
Device(config)# end
Device# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Entry number: 10
Owner:
Tag:
Type of operation to perform: udp-jitter
Target address/Source address: 1.1.1.1/0.0.0.0
Target port/Source port: 2/0
Request size (ARR data portion): 32
Operation timeout (milliseconds): 5000
Packet Interval (milliseconds)/Number of packets: 20/10
Type Of Service parameters: 0x0
Verify data: No
Vrf Name:
Control Packets: enabled
Schedule:
  Operation frequency (seconds): 30
  Next Scheduled Start Time: Pending trigger
  Group Scheduled : FALSE
  Randomly Scheduled : FALSE
  Life (seconds): 3600

```

```

Entry Ageout (seconds): never
Recurring (Starting Everyday): FALSE
Status of entry (SNMP RowStatus): notInService
Threshold (milliseconds): 5000
Distribution Statistics:
  Number of statistic hours kept: 2
  Number of statistic distribution buckets kept: 1
  Statistic distribution interval (milliseconds): 20
Enhanced History:

```

## Analyzing IP Service Levels by Using the UDP Jitter Operation

Follow these steps to configure a UDP jitter operation on the source device:

### Before you begin

You must enable the IP SLA responder on the target device (the operational target) to configure a UDP jitter operation on the source device.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip sla operation-number**
4. **udp-jitter** {*destination-ip-address* | *destination-hostname*} *destination-port* [**source-ip** {*ip-address* | *hostname*}] [**source-port** *port-number*] [**control** {**enable** | **disable**}] [**num-packets** *number-of-packets*] [**interval** *interpacket-interval*]
5. **frequency** *seconds*
6. **exit**
7. **ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]
8. **end**
9. **show running-config**
10. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                         | Purpose                                                        |
|--------|-----------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                                                                                                                                                                                                                                                                                                              | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 3</b> | <b>ip sla operation-number</b><br><b>Example:</b><br>Device (config)# <b>ip sla 10</b>                                                                                                                                                                                                                                                                                                                                                                                         | Creates an IP SLA operation, and enters IP SLA configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 4</b> | <b>udp-jitter</b> { <i>destination-ip-address</i>   <i>destination-hostname</i> }<br><i>destination-port</i> [ <b>source-ip</b> { <i>ip-address</i>   <i>hostname</i> }]<br>[ <b>source-port</b> <i>port-number</i> ] [ <b>control</b> { <b>enable</b>   <b>disable</b> }]<br>[ <b>num-packets</b> <i>number-of-packets</i> ] [ <b>interval</b><br><i>interpacket-interval</i> ]<br><b>Example:</b><br>Device (config-ip-sla)# <b>udp-jitter 172.29.139.134</b><br><b>5000</b> | Configures the IP SLA operation as a UDP jitter operation, and enters UDP jitter configuration mode. <ul style="list-style-type: none"> <li>• <i>destination-ip-address</i>   <i>destination-hostname</i>—Specifies the destination IP address or hostname.</li> <li>• <i>destination-port</i>—Specifies the destination port number in the range from 1 to 65535.</li> <li>• (Optional) <b>source-ip</b> {<i>ip-address</i>   <i>hostname</i>}—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination.</li> <li>• (Optional) <b>source-port</b> <i>port-number</i>—Specifies the source port number in the range from 1 to 65535. When a port number is not specified, IP SLA chooses an available port.</li> <li>• (Optional) <b>control</b>—Enables or disables sending of IP SLA control messages to the IP SLA responder. By default, IP SLA control messages are sent to the destination device to establish a connection with the IP SLA responder.</li> <li>• (Optional) <b>num-packets</b> <i>number-of-packets</i>—Enters the number of packets to be generated. The range is 1 to 6000; the default is 10.</li> <li>• (Optional) <b>interval</b> <i>inter-packet-interval</i>—Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.</li> </ul> |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Step 5 | <p><b>frequency</b> <i>seconds</i></p> <p><b>Example:</b></p> <pre>Device(config-ip-sla-jitter)# <b>frequency 45</b></pre>                                                                                                                                                                                                                                                                           | (Optional) Sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 6 | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Device(config-ip-sla-jitter)# <b>exit</b></pre>                                                                                                                                                                                                                                                                                                       | Exits UDP jitter configuration mode, and returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 7 | <p><b>ip sla schedule</b> <i>operation-number</i> [<b>life</b> {<b>forever</b>   <i>seconds</i>}] [<b>start-time</b> {<i>hh:mm [:ss]</i> [<i>month day   day month</i>]   <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i>}] [<b>ageout</b> <i>seconds</i>] [<b>recurring</b>]</p> <p><b>Example:</b></p> <pre>Device(config)# <b>ip sla schedule 10 start-time now life forever</b></pre> | <p>Configures the scheduling parameters for an individual IP SLA operation.</p> <ul style="list-style-type: none"> <li>• <i>operation-number</i>—Enter the RTR entry number.</li> <li>• (Optional) <b>life</b>—Sets the operation to run indefinitely (<b>forever</b>) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour).</li> <li>• (Optional) <b>start-time</b>—Enters the time for the operation to begin collecting information: <ul style="list-style-type: none"> <li>To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.</li> <li>Enter <b>pending</b> to select no information collection until a start time is selected.</li> <li>Enter <b>now</b> to start the operation immediately.</li> <li>Enter <b>after</b> <i>hh:mm:ss</i> to show that the operation should start after the entered time has elapsed.</li> </ul> </li> <li>• (Optional) <b>ageout</b> <i>seconds</i>—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out).</li> <li>• (Optional) <b>recurring</b>—Set the operation to automatically run every day.</li> </ul> |
| Step 8 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# <b>end</b></pre>                                                                                                                                                                                                                                                                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                | Command or Action                                                                                                 | Purpose                                                  |
|----------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 9</b>  | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                   |
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

### Configuring a UDP Jitter IP SLA Operation

This example shows how to configure a UDP jitter IP SLA operation:

```

Device(config)# ip sla 10
Device(config-ip-sla)# udp-jitter 172.29.139.134 5000
Device(config-ip-sla-jitter)# frequency 30
Device(config-ip-sla-jitter)# exit
Device(config)# ip sla schedule 5 start-time now life forever
Device(config)# end
Device# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Entry number: 10
Owner:
Tag:
Type of operation to perform: udp-jitter
Target address/Source address: 1.1.1.1/0.0.0.0
Target port/Source port: 2/0
Request size (ARR data portion): 32
Operation timeout (milliseconds): 5000
Packet Interval (milliseconds)/Number of packets: 20/10
Type Of Service parameters: 0x0
Verify data: No
Vrf Name:
Control Packets: enabled
Schedule:
  Operation frequency (seconds): 30
  Next Scheduled Start Time: Pending trigger
  Group Scheduled : FALSE
  Randomly Scheduled : FALSE
  Life (seconds): 3600
  Entry Ageout (seconds): never
  Recurring (Starting Everyday): FALSE
  Status of entry (SNMP RowStatus): notInService
Threshold (milliseconds): 5000
Distribution Statistics:
  Number of statistic hours kept: 2
  Number of statistic distribution buckets kept: 1
  Statistic distribution interval (milliseconds): 20
Enhanced History:

## Analyzing IP Service Levels by Using the ICMP Echo Operation

Follow these steps to configure an ICMP echo operation on the source device:

**Before you begin**

This operation does not require the IP SLA responder to be enabled.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip sla operation-number**
4. **icmp-echo** {*destination-ip-address* | *destination-hostname*} [**source-ip** {*ip-address* | *hostname*} | **source-interface** *interface-id*]
5. **frequency** *seconds*
6. **exit**
7. **ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]
8. **end**
9. **show running-config**
10. **copy running-config startup-config**

**DETAILED STEPS**

|               | Command or Action                                                                     | Purpose                                                           |
|---------------|---------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                             | Enables privileged EXEC mode. Enter your password if prompted.    |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>     | Enters the global configuration mode.                             |
| <b>Step 3</b> | <b>ip sla operation-number</b><br><b>Example:</b><br>Device(config)# <b>ip sla 10</b> | Creates an IP SLA operation and enters IP SLA configuration mode. |

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <p><b>icmp-echo</b> {<i>destination-ip-address</i>   <i>destination-hostname</i>} [<b>source-ip</b> {<i>ip-address</i>   <i>hostname</i>}   <b>source-interface</b> <i>interface-id</i>]</p> <p><b>Example:</b></p> <pre>Device(config-ip-sla)# icmp-echo 172.29.139.134</pre>                                                                                                                             | <p>Configures the IP SLA operation as an ICMP Echo operation and enters ICMP echo configuration mode.</p> <ul style="list-style-type: none"> <li>• <i>destination-ip-address</i>   <i>destination-hostname</i>—Specifies the destination IP address or hostname.</li> <li>• (Optional) <b>source-ip</b> {<i>ip-address</i>   <i>hostname</i>}—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination.</li> <li>• (Optional) <b>source-interface</b> <i>interface-id</i>—Specifies the source interface for the operation.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 5</b> | <p><b>frequency</b> <i>seconds</i></p> <p><b>Example:</b></p> <pre>Device(config-ip-sla-echo)# frequency 30</pre>                                                                                                                                                                                                                                                                                          | <p>(Optional) Sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 6</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Device(config-ip-sla-echo)# exit</pre>                                                                                                                                                                                                                                                                                                                      | <p>Exits UDP echo configuration mode, and returns to global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 7</b> | <p><b>ip sla schedule</b> <i>operation-number</i> [<b>life</b> {<b>forever</b>   <i>seconds</i>}] [<b>start-time</b> {<i>hh:mm</i> [:<i>ss</i>] [<i>month day</i>   <i>day month</i>]}   <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i>] [<b>ageout</b> <i>seconds</i>] [<b>recurring</b>]</p> <p><b>Example:</b></p> <pre>Device(config)# ip sla schedule 5 start-time now life forever</pre> | <p>Configures the scheduling parameters for an individual IP SLA operation.</p> <ul style="list-style-type: none"> <li>• <i>operation-number</i>—Enter the RTR entry number.</li> <li>• (Optional) <b>life</b>—Sets the operation to run indefinitely (<b>forever</b>) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour)</li> <li>• (Optional) <b>start-time</b>—Enter the time for the operation to begin collecting information: <ul style="list-style-type: none"> <li>To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.</li> <li>Enter <b>pending</b> to select no information collection until a start time is selected.</li> <li>Enter <b>now</b> to start the operation immediately.</li> <li>Enter <b>after</b> <i>hh:mm:ss</i> to indicate that the operation should start after the entered time has elapsed.</li> </ul> </li> </ul> |

|                | Command or Action                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|-------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                   | <ul style="list-style-type: none"> <li>• (Optional) <b>ageout seconds</b>—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds; the default is 0 seconds (never ages out).</li> <li>• (Optional) <b>recurring</b>—Sets the operation to automatically run every day.</li> </ul> |
| <b>Step 8</b>  | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 9</b>  | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                 |

### Configuring an ICMP Echo IP SLA Operation

This example shows how to configure an ICMP echo IP SLA operation:

```

Device(config)# ip sla 12
Device(config-ip-sla)# icmp-echo 172.29.139.134
Device(config-ip-sla-echo)# frequency 30
Device(config-ip-sla-echo)# exit
Device(config)# ip sla schedule 5 start-time now life forever
Device(config)# end
Device# show ip sla configuration 22
IP SLAs, Infrastructure Engine-II.

Entry number: 12
Owner:
Tag:
Type of operation to perform: echo
Target address: 2.2.2.2
Source address: 0.0.0.0
Request size (ARR data portion): 28
Operation timeout (milliseconds): 5000
Type Of Service parameters: 0x0
Verify data: No

## Monitoring IP SLA Operations

The following table describes the commands used to display IP SLA operation configurations and results:

**Table 79: Monitoring IP SLA Operations**

|                                                                                                                                                                                                            |                                                                                                                                                  |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show ip sla application</b>                                                                                                                                                                             | Displays global information about Cisco IOS IP SLAs.                                                                                             |
| <b>show ip sla authentication</b>                                                                                                                                                                          | Displays IP SLA authentication information.                                                                                                      |
| <b>show ip sla configuration</b> [ <i>entry-number</i> ]                                                                                                                                                   | Displays configuration values including all defaults for all IP SLA operations or a specific operation.                                          |
| <b>show ip sla enhanced-history</b> { <i>collection-statistics</i>   <i>distribution statistics</i> } [ <i>entry-number</i> ]                                                                              | Displays enhanced history statistics for collected history buckets or distribution statistics for all IP SLA operations or a specific operation. |
| <b>show ip sla ethernet-monitor configuration</b> [ <i>entry-number</i> ]                                                                                                                                  | Displays IP SLA automatic Ethernet configuration.                                                                                                |
| <b>show ip sla group schedule</b> [ <i>schedule-entry-number</i> ]                                                                                                                                         | Displays IP SLA group scheduling configuration and details.                                                                                      |
| <b>show ip sla history</b> [ <i>entry-number</i>   <b>full</b>   <b>tabular</b> ]                                                                                                                          | Displays history collected for all IP SLA operations.                                                                                            |
| <b>show ip sla mpls-lsp-monitor</b> { <i>collection-statistics</i>   <i>configuration</i>   <i>ldp operational-state</i>   <i>scan-queue</i>   <i>summary</i> [ <i>entry-number</i> ]   <i>neighbors</i> } | Displays MPLS label switched path (LSP) Health Monitor operations.                                                                               |
| <b>show ip sla reaction-configuration</b> [ <i>entry-number</i> ]                                                                                                                                          | Displays the configured proactive threshold monitoring settings for all IP SLA operations or a specific operation.                               |

|                                                                                            |                                                                                              |
|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <b>show ip sla reaction-trigger</b> [ <i>entry-number</i> ]                                | Displays the reaction trigger information for all IP SLA operations or a specific operation. |
| <b>show ip sla responder</b>                                                               | Displays information about the IP SLA responder.                                             |
| <b>show ip sla statistics</b> [ <i>entry-number</i>   <b>aggregated</b>   <b>details</b> ] | Displays current or aggregated operational status and statistics.                            |

## Monitoring IP SLA Operation Examples

The following example shows all IP SLAs by application:

```
Device# show ip sla application

      IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

Supported Operation Types:
      icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
      dns, udpJitter, dhcp, ftp, udpApp, wspApp

Supported Features:
      IPSLAs Event Publisher

IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389

Estimated number of configurable operations: 24389
Number of Entries configured      : 0
Number of active Entries          : 0
Number of pending Entries         : 0
Number of inactive Entries        : 0
Time of last change in whole IP SLAs: *13:04:37.668 UTC Wed Dec 19 2012
```

The following example shows all IP SLA distribution statistics:

```
Device# show ip sla enhanced-history distribution-statistics

Point by point Enhanced History
Entry   = Entry Number
Int     = Aggregation Interval
BucI    = Bucket Index
StartT  = Aggregation Start Time
Pth     = Path index
Hop     = Hop in path index
Comps   = Operations completed
OvrTh   = Operations completed over thresholds
SumCmp  = Sum of RTT (milliseconds)
SumCmp2L = Sum of RTT squared low 32 bits (milliseconds)
SumCmp2H = Sum of RTT squared high 32 bits (milliseconds)
TMax    = RTT maximum (milliseconds)
TMin    = RTT minimum (milliseconds)

Entry Int BucI StartT      Pth Hop Comps OvrTh SumCmp      SumCmp2L  SumCmp2H  T
Max   TMin

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions for Configuring Local Policies

The policy map attributes supported on the device are QoS, VLAN, session timeout, and ACL.

# Information About Configuring Local Policies

Local policies can profile devices based on HTTP and DHCP to identify the end devices on the network. Users can configure device-based policies and enforce the policies per user or per device policy on the network.

Local policies allow profiling of mobile devices and basic onboarding of the profiled devices to a specific VLAN. They also assign ACL and QoS or configure session timeouts.

You can configure local policies as two separate components:

- Defining policy attributes as service templates specific to clients joining the network and applying policy match criteria.
- Applying match criteria to the policy.

The following policy match attributes are used for configuring local policies:

- Device—Defines the type of device. Windows-based computer, Smart phone, Apple devices such as iPad and iPhone.
- Username—Defines the username of the user.
- User role—Defines the user type or the user group the user belongs to, such as a student or employee.
- MAC—Defines the mac-address of the end point.
- MAC OUI—Defines the mac-address OUI.

Once the device has a match corresponding to these parameters per end point, the policy can be added. Policy enforcement allows basic device on-boarding of mobile devices based on the following session attributes:

- VLAN
- QoS
- ACL
- Session timeout

You can configure these policies and enforce end points with specified policies. The wireless clients are profiled based on MAC OUI and DHCP. The device uses these attributes and predefined classification profiles to identify devices.

## Replacing Default Profile Text File

If a new device is not classified, contact the Cisco support team with the device MAC address. The Cisco support team will provide a new **dc\_default\_profile.txt** file with the MAC address included in the file. You need to replace the **dc\_default\_profile.txt** file with the earlier file. Follow these steps to change the **dc\_default\_profile.txt** file:

1. Stop device classifier by entering this command:  
`device(config)# no device classifier`
2. Copy the file by entering this command:  
`device# device classifier profile location filepath`
3. Start the device classifier by entering this command:

```
device(config)# device classifier
```

### Disabling session monitor on trunk ports

On uplink trunk ports, you should not create any session monitoring. By default, session monitoring is enabled. You should disable session monitoring.

1. Enter into global configuration mode by entering this command:  
device# **configure terminal**
2. Enter into interface configuration mode by entering this command:  
device(config)# **interface** *interface-id*
3. Disable session monitoring by entering this command:  
device(config-if)# **no access-session monitor**

# How to Configure Local Policies

## Configuring Local Policies (CLI)

To configure local policies, complete these procedures:

1. Create a service template.
2. Create an interface template.
3. Create a parameter map.
4. Create a policy map.
5. Apply a local policy on a WLAN.

### Creating an Interface Template (CLI)

#### Procedure

|        | Command or Action                                                                     | Purpose                           |
|--------|---------------------------------------------------------------------------------------|-----------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters global configuration mode. |

|               | Command or Action                                                                                                                                       | Purpose                                                                                                                                                                                |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>template</b> <i>interface-template-name</i><br><b>Example:</b><br>Device(config) # <b>template cisco-phone-template</b><br>Device(config-template) # | Enters interface template configuration mode.                                                                                                                                          |
| <b>Step 3</b> | <b>switchport mode access</b><br><b>Example:</b><br>Device(config-template) # <b>switchport mode access</b>                                             | Sets the interface as a nontrunking nontagged single-VLAN Ethernet interface. An access port can carry traffic in one VLAN only. By default, an access port carries traffic for VLAN1. |
| <b>Step 4</b> | <b>switchport voice vlan</b> <i>vlan_id</i><br><b>Example:</b><br>Device(config-template) # <b>switchport voice vlan 20</b>                             | Specifies to forward all voice traffic through the specified VLAN. You can specify a value from 1 to 4094.                                                                             |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config) # <b>end</b>                                                                                            | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                    |

## Creating a Parameter Map (CLI)

Parameter map is preferred to use than class map.

#### Procedure

|               | Command or Action                                                                                                                                                                                           | Purpose                                    |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                                                                                                                           | Enters global configuration mode.          |
| <b>Step 2</b> | <b>parameter-map type subscriber attribute-to-service</b><br><i>parameter-map-name</i><br><b>Example:</b><br>Device(config) # <b>parameter-map type subscriber attribute-to-service Aironet-Policy-para</b> | Specifies the parameter map type and name. |

|        | Command or Action                                                                                                                                                                                                                                     | Purpose                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><code>map-index map { device-type   mac-address   oui   user-role   username } { eq   not-eq   regex filter-name }</code></p> <p><b>Example:</b></p> <pre>Device(config-parameter-map-filter)# 10 map device-type eq "WindowsXP-Workstation"</pre> | Specifies parameter map attribute filter criteria.                                                                  |
| Step 4 | <p><code>interface-template interface-template-name</code></p> <p><b>Example:</b></p> <pre>Device(config-parameter-map-filter-submode)# interface-template cisco-phone-template Device(config-parameter-map-filter-submode)#</pre>                    | Enters service template configuration mode.                                                                         |
| Step 5 | <p><code>end</code></p> <p><b>Example:</b></p> <pre>Device(config)# end</pre>                                                                                                                                                                         | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

## Applying a Local Policy for a Device on a WLAN (CLI)

### Before you begin

If the service policy contains any device type-based rules in the parameter map, ensure that the device classifier is already enabled.

**Note** You should use the **device classification** command to classify the device for it to be displayed correctly on the show command output.

### Procedure

|        | Command or Action                                                                                                                                                               | Purpose                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| Step 1 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Device# configure terminal</pre>                                                                                   | Enters global configuration mode. |
| Step 2 | <p><b>wlan wlan-name</b></p> <p><b>Example:</b></p> <pre>Device(config)# wlan wlan1</pre>                                                                                       | Enters WLAN configuration mode.   |
| Step 3 | <p><b>service-policy type control subscriber polycymapname</b></p> <p><b>Example:</b></p> <pre>Device(config-wlan)# service-policy type control subscriber Aironet-Policy</pre> | Applies local policy to WLAN.     |

|        | Command or Action                                                                                                | Purpose                                                                                                             |
|--------|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>profiling local http (optional)</b><br><b>Example:</b><br>Device(config-wlan) # <b>profiling local http</b>   | Enables only profiling of devices based on HTTP protocol (optional).                                                |
| Step 5 | <b>profiling radius http (optional)</b><br><b>Example:</b><br>Device(config-wlan) # <b>profiling radius http</b> | Enables profiling of devices on ISE (optional).                                                                     |
| Step 6 | <b>no shutdown</b><br><b>Example:</b><br>Device(config-wlan) # <b>no shutdown</b>                                | Specifies not to shut down the WLAN.                                                                                |
| Step 7 | <b>end</b><br><b>Example:</b><br>Device(config) # <b>end</b>                                                     | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

## Monitoring Local Policies

The following commands can be used to monitor local policies configured on the device.

**Table 80: Monitoring Local Policies Command**

| Command                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show access-session</b>                         | Displays the summary of access session with authorization status, method and domain for each client or MAC address displayed.                                                                                                                                                                                                                                                                            |
| <b>show access-session cache</b>                   | Displays the latest classification for the client.                                                                                                                                                                                                                                                                                                                                                       |
| <b>show device classifier attached detail</b>      | Displays the latest classification for the client based on parameters such as Mac, DHCP, or HTTP.                                                                                                                                                                                                                                                                                                        |
| <b>show access-session mac mac-address details</b> | Displays the policy mapped, service template used, and attributes for the client.<br><br><b>Note</b> If the <b>show access-session detail</b> command output is not displaying session timeout details, you should enable client profiling with session timeout in client access session and then run the <b>show access-session mac mac-address details</b> command to see the session timeout details. |

|                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                   |

## Examples: Local Policies Configuration

**Note** At the end of each configuration command line, enter CTRL Z to execute the command and proceed to the next line.

This example shows how to create interface template:

```
Device# configure terminal  
Device(config)#template cisco-phone-template  
Device(config-template)#switchport mode access  
Device(config-template)#switchport voice vlan 20  
Device(config-template)# end
```

This example shows how to create parameter map:

```
Device# configure terminal  
Device(config)#parameter-map type subscriber attribute-to-service param-wired  
Device(config-parameter-map-filter)#10 map device-type regex Cisco-IP-Phone  
Device(config-parameter-map-filter-submode)#10 interface-template cisco-phone-template  
Device(config-parameter-map)# end
```

This example shows how to create policy map:

```
Device(config)# policy-map type control subscriber apple-tsim  
Device(config-policy-map)# event identity-update match-all  
Device(config-policy-map)# 1 class always do-until-failure  
Device(config-policy-map)# 1 map attribute-to-service table apple-tsim-param  
Device(config-policy-map)# end
```

This example shows how to apply policy to a device on a WLAN:

```

Device(config)# wlan wlan1
Device(config-wlan)# client vlan VLAN0054
Device(config-wlan)# profiling local http
Device(config-wlan)# service-policy type control subscriber apple-tsim
Device(config-wlan)# no shutdown
Device# end

```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for SPAN and RSPAN

### SPAN

- You can limit SPAN traffic to specific VLANs by using the **filter vlan** keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

### RSPAN

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.

# Restrictions for SPAN and RSPAN

## SPAN

The restrictions for SPAN are as follows:

- On each device, you can configure 66 sessions. A maximum of 8 source sessions can be configured and the remaining sessions can be configured as RSPAN destination sessions. A source session is either a local SPAN session or an RSPAN source session.
- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.
- The destination port cannot be a source port; a source port cannot be a destination port.
- You cannot have two SPAN sessions using the same destination port.
- When you configure a device port as a SPAN destination port, it is no longer a normal device port; only monitored traffic passes through the SPAN destination port.
- Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the **no monitor session** *{session\_number | all | local | remote}* global configuration command to delete configured SPAN parameters.
- For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the **encapsulation replicate** keywords are specified. If the keywords are not specified, the packets are sent in native form.
- You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.
- You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- Wireshark does not capture egress packets when egress span is active.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.

- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
  - An RSPAN source session cannot have a local destination port.
  - An RSPAN destination session cannot have a local source port.
  - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

## RSPAN

The restrictions for RSPAN are as follows:

- RSPAN does not support BPDU packet monitoring or other Layer 2 device protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating devices.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the device does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the device.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- To use RSPAN, the switch must be running the LAN Base image.

# Information About SPAN and RSPAN

## SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the device or on another device that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

## Local SPAN

Local SPAN supports a SPAN session entirely within one device; all source ports or source VLANs and destination ports are in the same device or device stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

**Figure 76: Example of Local SPAN Configuration on a Single Device**

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port

**Figure 77: Example of Local SPAN Configuration on a Device Stack**

This is an example of a local SPAN in a device stack, where the source and destination ports reside on different stack members.

### Related Topics

[Creating a Local SPAN Session and Configuring Incoming Traffic](#), on page 1081

[Example: Configuring Local SPAN](#), on page 1101

## Remote SPAN

RSPAN supports source ports, source VLANs, and destination ports on different devices (or different device stacks), enabling remote monitoring of multiple devices across your network.

**Figure 78: Example of RSPAN Configuration**

The figure below shows source ports on Device A and Device B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating devices. The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source device must have either ports or VLANs as RSPAN sources. The destination is always a physical port,

as shown on Device C in the figure.

## SPAN and RSPAN Concepts and Terminology

### SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination device.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

A single RSPAN session with multiple source and destination ports can be in the same session but more than one source session with the source being the same remote vlan is not allowed.

Traffic monitoring in a SPAN session has these restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.

- An RSPAN source session cannot have a local destination port.
- An RSPAN destination session cannot have a local source port.
- An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

### Related Topics

[Creating a Local SPAN Session and Configuring Incoming Traffic](#), on page 1081

[Example: Configuring Local SPAN](#), on page 1101

## Monitored Traffic

SPAN sessions can monitor these traffic types:

- Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the device. A copy of each packet received by the source is sent to the destination port for that SPAN session.

Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

- Transmit (Tx) SPAN—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the device. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- Both—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

The default configuration for local SPAN session ports is to send all packets untagged. However, when you enter the **encapsulation replicate** keywords while configuring a destination port, these changes occur:

- Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.
- Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Device congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

- A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
- An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.
- An egress packet dropped because of device congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the device through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

## Source Ports

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis.

In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions.

The device supports any number of source ports (up to the maximum number of available ports on the device) and any number of source VLANs (up to the maximum number of VLANs supported).

You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.
- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.

## Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.

- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

## VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

## Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same device or device stack as the source port. For an RSPAN session, it is located on the device containing the RSPAN destination session. There is no destination port on a device or device stack running only an RSPAN source session.
- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.

---

**Note** When QoS is configured on the SPAN destination port, QoS takes effect immediately.

---

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.
- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can be an EtherChannel group (**ON** mode only).

- It cannot be a VLAN.
- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).
- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- The maximum number of destination ports in a device or device stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

- For local SPAN, if the **encapsulation replicate** keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with **encapsulation replicate** enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.
- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

## RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the **remote-span** VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate devices.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

## SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

- **Routing**—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the device, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the device routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.
- **STP**—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.
- **CDP**—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.
- **VTP**—You can use VTP to prune an RSPAN VLAN between devices.
- **VLAN and trunking**—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.
- **EtherChannel**—You can configure an EtherChannel group as a source port or a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored.

If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.

A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

- **Multicast traffic** can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.
- A **private-VLAN** port cannot be a SPAN destination port.
- A **secure** port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

## SPAN and RSPAN and Device Stacks

Because the stack of devices represents one logical device, local SPAN source ports and destination ports can be in different devices in the stack. Therefore, the addition or deletion of devices in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a device is removed from the stack or an inactive session can become active when a device is added to the stack.

## Flow-Based SPAN

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session. The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.

You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL— Filters only IPv4 packets.
- IPv6 FSPAN ACL— Filters only IPv6 packets.
- MAC FSPAN ACL— Filters only non-IP packets.

If a VLAN-based FSPAN session configured on a stack cannot fit in the hardware memory on one or more devices, it is treated as unloaded on those devices, and traffic meant for the FSPAN ACL and sourcing on that device is not copied to the SPAN destination ports. The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the devices where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

IPv4 and MAC FSPAN ACLs are supported on all feature sets. IPv6 FSPAN ACLs are supported only in the advanced IP Services feature set.

## Default SPAN and RSPAN Configuration

*Table 81: Default SPAN and RSPAN Configuration*

| Feature                               | Default Setting                                                      |
|---------------------------------------|----------------------------------------------------------------------|
| SPAN state (SPAN and RSPAN)           | Disabled.                                                            |
| Source port traffic to monitor        | Both received and sent traffic ( <b>both</b> ).                      |
| Encapsulation type (destination port) | Native form (untagged packets).                                      |
| Ingress forwarding (destination port) | Disabled.                                                            |
| VLAN filtering                        | On a trunk interface used as a source port, all VLANs are monitored. |
| RSPAN VLANs                           | None configured.                                                     |

## Configuration Guidelines

### SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session session\_number source {interface interface-id | vlan vlan-id}** global configuration command or the **monitor session session\_number destination interface interface-id** global configuration command. For destination interfaces, the **encapsulation** options are ignored with the **no** form of the command.
- To monitor all VLANs on the trunk port, use the **no monitor session session\_number filter** global configuration command.

### RSPAN Configuration Guidelines

- All the SPAN configuration guidelines apply to RSPAN.
- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.
- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source devices.

- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple devices in your network.
- Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.
- You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
  - The same RSPAN VLAN is used for an RSPAN session in all the devices.
  - All participating devices support RSPAN.

## FSPAN and FRSPAN Configuration Guidelines

- When at least one FSPAN ACL is attached, FSPAN is enabled.
- When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

# How to Configure SPAN and RSPAN

## Creating a Local SPAN Session

Follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** *{session\_number | all | local | remote}*
4. **monitor session** *session\_number* **source** *{interface interface-id | vlan vlan-id}* [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session\_number* **destination** *{interface interface-id* [, | -] [**encapsulation replicate**]
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Device&gt; enable</pre>                                                                                                                                                                                                                          | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Creating a Local SPAN Session and Configuring Incoming Traffic

Follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]`
5. `monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate] [ingress {dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id}]}`
6. `end`
7. `show running-config`
8. `copy running-config startup-config`

### DETAILED STEPS

|               | Command or Action                                                                                                                                       | Purpose                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><code>enable</code></p> <p><b>Example:</b></p> <pre>Device&gt; enable</pre>                                                                          | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                              |
| <b>Step 2</b> | <p><code>configure terminal</code></p> <p><b>Example:</b></p> <pre>Device# configure terminal</pre>                                                     | Enters the global configuration mode.                                                                                                                                                                                       |
| <b>Step 3</b> | <p><code>no monitor session {session_number   all   local   remote}</code></p> <p><b>Example:</b></p> <pre>Device(config)# no monitor session all</pre> | <p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> <li>• For <code>session_number</code>, the range is 1 to 66.</li> <li>• <b>all</b>—Removes all SPAN sessions.</li> </ul> |

## Specifying VLANs to Filter

Follow these steps to limit SPAN source traffic to specific VLANs.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source interface interface-id`
5. `monitor session session_number filter vlan vlan-id [, | -]`
6. `monitor session session_number destination {interface interface-id [, | -] [encapsulation replicate]}`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

### DETAILED STEPS

|               | Command or Action                                                                             | Purpose                                                        |
|---------------|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <code>enable</code><br><b>Example:</b><br>Device> <code>enable</code>                         | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <code>configure terminal</code><br><b>Example:</b><br>Device# <code>configure terminal</code> | Enters the global configuration mode.                          |

|               | Command or Action                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>no monitor session</b> {<i>session_number</i>   <b>all</b>   <b>local</b>   <b>remote</b>}</p> <p><b>Example:</b></p> <pre>Device(config)# no monitor session all</pre>                                                                                         | <p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• <b>all</b>—Removes all SPAN sessions.</li> <li>• <b>local</b>—Removes all local sessions.</li> <li>• <b>remote</b>—Removes all remote SPAN sessions.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 4</b> | <p><b>monitor session</b> <i>session_number</i> <b>source interface</b> <i>interface-id</i></p> <p><b>Example:</b></p> <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx</pre>                                                          | <p>Specifies the characteristics of the source port (monitored port) and SPAN session.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• For <i>interface-id</i>, specify the source port to monitor. The interface specified must already be configured as a trunk port.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 5</b> | <p><b>monitor session</b> <i>session_number</i> <b>filter vlan</b> <i>vlan-id</i> [,   -]</p> <p><b>Example:</b></p> <pre>Device(config)# monitor session 2 filter vlan 1 - 5 , 9</pre>                                                                               | <p>Limits the SPAN source traffic to specific VLANs.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, enter the session number specified in Step 4.</li> <li>• For <i>vlan-id</i>, the range is 1 to 4094.</li> <li>• (Optional) Use a comma (,) to specify a series of VLANs, or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.</li> </ul>                                                                                                                                                                                                                                                                                                                              |
| <b>Step 6</b> | <p><b>monitor session</b> <i>session_number</i> <b>destination</b> {<b>interface</b> <i>interface-id</i> [,   -] [<b>encapsulation replicate</b>]}</p> <p><b>Example:</b></p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/1</pre> | <p>Specifies the SPAN session and the destination port (monitoring port).</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, specify the session number entered in Step 4.</li> <li>• For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.</li> <li>• (Optional) [,   -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.</li> <li>• (Optional) <b>encapsulation replicate</b> specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).</li> </ul> |
| <b>Step 7</b> | <p><b>end</b></p> <p><b>Example:</b></p>                                                                                                                                                                                                                              | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|               | Command or Action                                                                                                 | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
|               | Device(config)# <b>end</b>                                                                                        |                                                          |
| <b>Step 8</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                   |
| <b>Step 9</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

## Configuring a VLAN as an RSPAN VLAN

Follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vlan *vlan-id***
4. **remote-span**
5. **end**
6. **show running-config**
7. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                                                                 | Purpose                                                        |
|---------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                         | Enables privileged EXEC mode. Enter your password if prompted. |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters the global configuration mode.                          |

|               | Command or Action                                                                                                 | Purpose                                                                                                                                                                                                                                                                                      |
|---------------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>vlan <i>vlan-id</i></b><br><b>Example:</b><br>Device(config) # <b>vlan 100</b>                                 | Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094.<br><br>The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs). |
| <b>Step 4</b> | <b>remote-span</b><br><b>Example:</b><br>Device(config-vlan) # <b>remote-span</b>                                 | Configures the VLAN as an RSPAN VLAN.                                                                                                                                                                                                                                                        |
| <b>Step 5</b> | <b>end</b><br><b>Example:</b><br>Device(config-vlan) # <b>end</b>                                                 | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                             |
| <b>Step 6</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                               | Verifies your entries.                                                                                                                                                                                                                                                                       |
| <b>Step 7</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                     |

### What to do next

You must create the RSPAN VLAN in all devices that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one device, and VTP propagates it to the other devices in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination devices and any intermediate devices.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the **no remote-span** VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the **no monitor session *session\_number* source {interface *interface-id* | vlan *vlan-id*}** global configuration command. To remove the RSPAN VLAN from the session, use the **no monitor session *session\_number* destination remote vlan *vlan-id***.

## Creating an RSPAN Source Session

Follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
4. **monitor session** *session\_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session\_number* **destination remote vlan** *vlan-id*
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

### DETAILED STEPS

## Specifying VLANs to Filter

Follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source interface interface-id`
5. `monitor session session_number filter vlan vlan-id [, | -]`
6. `monitor session session_number destination remote vlan vlan-id`
7. `end`
8. `show running-config`
9. `copy running-config startup-config`

### DETAILED STEPS

|               | Command or Action                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                              |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><code>enable</code></p> <p><b>Example:</b></p> <pre>Device&gt; enable</pre>                                                                        | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <p><code>configure terminal</code></p> <p><b>Example:</b></p> <pre>Device# configure terminal</pre>                                                   | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                |
| <b>Step 3</b> | <p><code>no monitor session {session_number   all   local   remote}</code></p> <p><b>Example:</b></p> <pre>Device(config)# no monitor session 2</pre> | <p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• <b>all</b>—Removes all SPAN sessions.</li> <li>• <b>local</b>—Removes all local sessions.</li> <li>• <b>remote</b>—Removes all remote SPAN sessions.</li> </ul> |

|               | Command or Action                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <p><b>monitor session</b> <i>session_number</i> <b>source interface</b> <i>interface-id</i></p> <p><b>Example:</b></p> <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx</pre> | <p>Specifies the characteristics of the source port (monitored port) and SPAN session.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• For <i>interface-id</i>, specify the source port to monitor. The interface specified must already be configured as a trunk port.</li> </ul>                                                                                                                 |
| <b>Step 5</b> | <p><b>monitor session</b> <i>session_number</i> <b>filter vlan</b> <i>vlan-id</i> [,   -]</p> <p><b>Example:</b></p> <pre>Device(config)# monitor session 2 filter vlan 1 - 5 , 9</pre>                      | <p>Limits the SPAN source traffic to specific VLANs.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, enter the session number specified in step 4.</li> <li>• For <i>vlan-id</i>, the range is 1 to 4094.</li> <li>• (Optional) ,   - Use a comma (,) to specify a series of VLANs or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.</li> </ul> |
| <b>Step 6</b> | <p><b>monitor session</b> <i>session_number</i> <b>destination remote vlan</b> <i>vlan-id</i></p> <p><b>Example:</b></p> <pre>Device(config)# monitor session 2 destination remote vlan 902</pre>            | <p>Specifies the RSPAN session and the destination remote VLAN (RSPAN VLAN).</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, enter the session number specified in Step 4.</li> <li>• For <i>vlan-id</i>, specify the RSPAN VLAN to carry the monitored traffic to the destination port.</li> </ul>                                                                                                                                 |
| <b>Step 7</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# end</pre>                                                                                                                                      | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 8</b> | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Device# show running-config</pre>                                                                                                              | <p>Verifies your entries.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 9</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Device# copy running-config startup-config</pre>                                                                                | <p>(Optional) Saves your entries in the configuration file.</p>                                                                                                                                                                                                                                                                                                                                                                                             |

## Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different device or device stack; that is, not the device or device stack on which the source session was configured.

Follow these steps to define the RSPAN VLAN on that device, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vlan *vlan-id***
4. **remote-span**
5. **exit**
6. **no monitor session {*session\_number* | all | local | remote}**
7. **monitor session *session\_number* source remote vlan *vlan-id***
8. **monitor session *session\_number* destination interface *interface-id***
9. **end**
10. **show running-config**
11. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                                                 | Purpose                                                                                                                                                                                                                                                                                                  |
|--------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                         | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                                           |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b> | Enters the global configuration mode.                                                                                                                                                                                                                                                                    |
| Step 3 | <b>vlan <i>vlan-id</i></b><br><b>Example:</b><br>Device(config)# <b>vlan 901</b>  | Specifies the VLAN ID of the RSPAN VLAN created from the source device, and enters VLAN configuration mode.<br><br>If both devices are participating in VTP and the RSPAN VLAN ID is from 2 to 1005, Steps 3 through 5 are not required because the RSPAN VLAN ID is propagated through the VTP network. |
| Step 4 | <b>remote-span</b><br><b>Example:</b><br>Device(config-vlan)# <b>remote-span</b>  | Identifies the VLAN as the RSPAN VLAN.                                                                                                                                                                                                                                                                   |

|                | Command or Action                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 5</b>  | <b>exit</b><br><b>Example:</b><br>Device(config-vlan)# <b>exit</b>                                                                                                                                      | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 6</b>  | <b>no monitor session</b> { <i>session_number</i>   <b>all</b>   <b>local</b>   <b>remote</b> }<br><b>Example:</b><br>Device(config)# <b>no monitor session 1</b>                                       | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• <b>all</b>—Removes all SPAN sessions.</li> <li>• <b>local</b>—Removes all local sessions.</li> <li>• <b>remote</b>—Removes all remote SPAN sessions.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 7</b>  | <b>monitor session</b> <i>session_number</i> <b>source remote vlan</b> <i>vlan-id</i><br><b>Example:</b><br>Device(config)# <b>monitor session 1 source remote vlan 901</b>                             | Specifies the RSPAN session and the source RSPAN VLAN. <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 8</b>  | <b>monitor session</b> <i>session_number</i> <b>destination interface</b> <i>interface-id</i><br><b>Example:</b><br>Device(config)# <b>monitor session 1 destination interface gigabitethernet2/0/1</b> | Specifies the RSPAN session and the destination interface. <ul style="list-style-type: none"> <li>• For <i>session_number</i>, enter the number defined in Step 7.</li> <li>• In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port.</li> <li>• For <i>interface-id</i>, specify the destination interface. The destination interface must be a physical interface.</li> <li>• Though visible in the command-line help string, <b>encapsulation replicate</b> is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged.</li> </ul> |
| <b>Step 9</b>  | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                                                                             | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 10</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                                                                                                                     | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                | Command or Action                                                                                                     | Purpose                                                  |
|----------------|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 11</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br><pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

## Creating an RSPAN Destination Session and Configuring Incoming Traffic

Follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **no monitor session** *{session\_number | all | local | remote}*
4. **monitor session** *session\_number* **source remote vlan** *vlan-id*
5. **monitor session** *session\_number* **destination** *{interface interface-id [, | -] [ingress {dot1q vlan vlan-id | untagged vlan vlan-id | vlan vlan-id}]}*
6. **end**
7. **show running-config**
8. **copy running-config startup-config**

**DETAILED STEPS**

|               | Command or Action                                                                           | Purpose                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br><pre>Device&gt; enable</pre>                            | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br><pre>Device# configure terminal</pre>       | Enters the global configuration mode.                                                                                                                         |
| <b>Step 3</b> | <b>no monitor session</b> <i>{session_number   all   local   remote}</i><br><b>Example:</b> | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> </ul> |

## Configuring an FSPAN Session

Follow these steps to create a SPAN session, specify the source (monitored) ports or VLANs and the destination (monitoring) ports, and configure FSPAN for the session.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
4. **monitor session** *session\_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
5. **monitor session** *session\_number* **destination** {**interface** *interface-id* [, | -] [**encapsulation replicate**]}
6. **monitor session** *session\_number* **filter** {**ip** | **ipv6** | **mac**} **access-group** {*access-list-number* | *name*}
7. **end**
8. **show running-config**
9. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                                         | Purpose                                                        |
|---------------|-----------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Configuring an FRSPAN Session

Follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `no monitor session {session_number | all | local | remote}`
4. `monitor session session_number source {interface interface-id | vlan vlan-id} [, | -] [both | rx | tx]`
5. `monitor session session_number destination remote vlan vlan-id`
6. `vlan vlan-id`
7. `remote-span`
8. `exit`
9. `monitor session session_number filter {ip | ipv6 | mac} access-group {access-list-number | name}`
10. `end`
11. `show running-config`
12. `copy running-config startup-config`

### DETAILED STEPS

|               | Command or Action                                                     | Purpose                                                        |
|---------------|-----------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 1</b> | <code>enable</code><br><b>Example:</b><br>Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Monitoring SPAN and RSPAN Operations

The following table describes the command used to display SPAN and RSPAN operations configuration and results to monitor operations:

*Table 82: Monitoring SPAN and RSPAN Operations*

| Command                   | Purpose                                                           |
|---------------------------|-------------------------------------------------------------------|
| <code>show monitor</code> | Displays the current SPAN, RSPAN, FSPAN, or FRSPAN configuration. |

## SPAN and RSPAN Configuration Examples

### Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1
Device(config)# monitor session 1 destination interface gigabitethernet1/0/2
encapsulation replicate
Device(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```
Device> enable
Device# configure terminal
```

```
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1
Device(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source vlan 1 - 3 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2
Device(config)# monitor session 2 source vlan 10
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with IEEE 802.1Q encapsulation and VLAN 6 as the default ingress VLAN:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source gigabitethernet1/0/1 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation
  replicate ingress dot1q vlan 6
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination interface gigabitethernet1/0/1
Device(config)# end
```

## Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# vlan 901
Device(config-vlan)# remote span
Device(config-vlan)# end
```

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Device(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 1 source interface port-channel 2
Device(config)# monitor session 1 destination remote vlan 901
Device(config)# end
```

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination remote vlan 902
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 1 source remote vlan 901
Device(config)# monitor session 1 destination interface gigabitethernet2/0/1
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 2 source remote vlan 901
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6
Device(config)# end
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Packet Capture

### Prerequisites for Packet Capture

- Packet capture is supported on Catalyst 3850 and Catalyst 3650.
- Wireshark is supported only on switches running IP Base image or IP Services image.
- Embedded Packet Capture is supported only on switches running Lan Base image.

The Embedded Packet Capture (EPC) software subsystem consumes CPU and memory resources during its operation. You must have adequate system resources for different types of operations. Some guidelines for using the system resources are provided in the table below.

Table 83: System Requirements for the EPC Subsystem

| System Resources | Requirements                                                                                    |
|------------------|-------------------------------------------------------------------------------------------------|
| Hardware         | CPU utilization requirements are platform dependent.                                            |
| Memory           | The packet buffer is stored in DRAM. The size of the packet buffer is user specified.           |
| Diskspace        | Packets can be exported to external devices. No intermediate storage on flash disk is required. |

## Restrictions for Packet Capture

### Restrictions for Packet Capture

- Starting in Cisco IOS Release XE 3.3.0(SE), global packet capture on Wireshark is not supported.
- Display filters are supported on Wireshark.
- The CLI for configuring Wireshark requires that the feature be executed only from EXEC mode. Actions that usually occur in configuration submode (such as defining capture points), are handled at the EXEC mode instead. All key commands are not NVGEN'd and are not synchronized to the standby supervisor in NSF and SSO scenarios.
- Packets captured in the output direction of an interface might not reflect the changes made by rewrite (includes TTL, VLAN tag, CoS, checksum, MAC addresses, DSCP, precedent, UP, etc.).
- The Rewrite information of both ingress and egress packets are not captured.
- Limiting circular file storage by file size is not supported.
- File limit is limited to the size of the flash in IP Base and IP Services.
- Decoding of protocols such as Control and Provisioning of Wireless Access Points (CAPWAP) Is supported in IP Base and IP Services.
- In IP Base and IP Services, in file mode, the packets will be written to the files without export.
- The LAN Base image supports Embedded Wireshark with the following limitations:
  - Capture filters and display filters are not supported.
  - Active capture decoding is not available.
  - The output format is different from previous releases.
- Embedded Packet Capture (EPC) captures multicast packets only on ingress and does not capture the replicated packets on egress.

#### Wireless Packet Capture

- The only form of wireless capture is a CAPWAP tunnel capture.

- When capturing CAPWAP tunnels, no other interface types can be used as attachment points on the same capture point.
- Capturing multiple CAPWAP tunnels is supported.
- Core filters are not applied and should be omitted when capturing a CAPWAP tunnel.
- To capture a CAPWAP data tunnel, each CAPWAP tunnel is mapped to a physical port and an appropriate ACL will be applied to filter the traffic.
- To capture a CAPWAP non-data tunnel, the switch is set to capture traffic on all ports and apply an appropriate ACL to filter the traffic.

### Configuration Limitations

- Up to 8 capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.
- Neither VRFs, management ports, nor private VLANs can be used as attachment points.
- Only one ACL (IPv4, IPv6 or MAC) is allowed in a Wireshark class map.
- Wireshark cannot capture packets on a destination SPAN port.
- Wireshark stops capturing when one of the attachment points (interfaces) attached to a capture point stops working. For example, if the device that is associated with an attachment point is unplugged from the . To resume capturing, the capture must be restarted manually.
- CPU-injected packets are considered control plane packets. Therefore, these types of packets will not be captured on an interface egress capture.
- MAC ACL is only used for non-IP packets such as ARP. It will not be supported on a Layer 3 port or SVI.
- MAC filter will not capture IP packets even if it matches the MAC address. This applies to all interfaces (L2 Switchport, L3 Routed Port)
- MAC filter cannot capture L2 packets (ARP) on L3 interfaces.
- IPv6-based ACLs are not supported in VACL.
- Layer 2 EtherChannels are not supported.
- Starting from Cisco IOS release 16.1, Layer 3 PortChannel Support is available.
- It is not possible to modify a capture point parameter when a capture is already active or has started.
- ACL logging and Wireshark are incompatible. Once Wireshark is activated, it takes priority. All traffic, including that being captured by ACL logging on any ports, will be redirected to Wireshark. We recommend that you deactivate ACL logging before starting Wireshark. Otherwise, Wireshark traffic will be contaminated by ACL logging traffic.
- Wireshark does not capture packets dropped by floodblock.
- If you capture both PACL and RACL on the same port, only one copy is sent to the CPU. If you capture a DTLS-encrypted CAPWAP interface, two copies are sent to Wireshark, one encrypted and the other

decrypted. The same behavior will occur if we capture a Layer 2 interface carrying DTLS-encrypted CAPWAP traffic. The core filter is based on the outer CAPWAP header.

- Starting from Cisco IOS release 16.1:
  - L3 port channel support is added.
  - Minor changes have been made in the display format.
  - Ability to display the number of packets in a cap file
  - Clearing the captured buffer deletes the buffer along with its contents. It cannot be run when the packet capture is active.
  - Additional warning message is displayed for control plane capturing.
  - In buffer mode, the packet display is allowed only after stop.
  - Packet statistics displayed at stop, in IP Services and IP Base.
  - Ability to query the number of packets captured in a pcap file.
  - When the display is from a cap file, display details of the selected packet can be viewed using packet-number.
  - Display filter can be used in file mode.
  - Statistics of packet capture (packets and bytes received, dropped) can be displayed either during the capture or after capture stop.
  - The system can query statistics on a pcap cap file's contents, as supported by Wireshark.
  - The packet capture session is always in streaming mode irrespective of the size of the buffer. There is no lock-step mode anymore.
  - Clearing buffer on an active capture point is supported only on Lan Base as this only clears the content. On all other licenses, it deletes the buffer itself, hence cannot be run during active capture.

---

**Warning** Control plane packets are not rate limited and performance impacting. Please use filters to limit control plane packet capture.

---

- If the user changes interface from Switch port to routed port (L2 -> L3) or vice versa, they must delete the capture point and create a new one, once the interface comes back up. Stop/start the capture point will not work.
- If the user deletes the file used by an active capture session, the capture session cannot create a new file, and all further packets captured are lost. The user will then need to restart the capture point.

# Introduction to Packet Capture

## Overview of Packet Capture Tool

The Packet Capture feature is an onboard packet capture facility that allows network administrators to capture packets flowing to, through, and from the device and to analyze them locally or save and export them for offline analysis by using tools such as Wireshark and Embedded Packet Capture (EPC). This feature simplifies network operations by allowing devices to become active participants in the management and operation of the network. This feature facilitates troubleshooting by gathering information about the packet format. This feature also facilitates application analysis and security.

The Embedded Packet Capture is supported on Lan Base. Embedded Packet Capture with Wireshark is supported on IP Base and IP Services.

## Information about Wireshark

### Wireshark Overview

Wireshark is a packet analyzer program, formerly known as Ethereal, that supports multiple protocols and presents information in a text-based user interface.

The ability to capture and analyze traffic provides data on network activity. Prior to Cisco IOS Release XE 3.3.0(SE), only two features addressed this need: SPAN and debug platform packet. Both have limitations. SPAN is ideal for capturing packets, but can only deliver them by forwarding them to some specified local or remote destination; it provides no local display or analysis support.

So the need exists for a traffic capture and analysis mechanism that is applicable to both hardware and software forwarded traffic and that provides strong packet capture, display, and analysis support, preferably using a well known interface.

Wireshark dumps packets to a file using a well known format called .pcap, and is applied or enabled on individual interfaces. You specify an interface in EXEC mode along with the filter and other parameters. The Wireshark application is applied only when you enter a **start** command, and is removed only when Wireshark stops capturing packets either automatically or manually.

---

**Note** The current version of Wireshark installed on the switch is 1.10.8.

---

### Capture Points

A capture point is the central policy definition of the Wireshark feature. The capture point describes all of the characteristics associated with a given instance of Wireshark: which packets to capture, where to capture them from, what to do with the captured packets, and when to stop. Capture points can be modified after creation, and do not become active until explicitly activated with a **start** command. This process is termed activating the capture point or starting the capture point. Capture points are identified by name and can also be manually or automatically deactivated or stopped.

Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.

In case of stacked systems, the capture point is activated on the active member. A switchover will terminate any active packet capture session and it will have to be restarted.

## Attachment Points

An attachment point is a point in the logical packet process path associated with a capture point. An attachment point is an attribute of the capture point. Packets that impact an attachment point are tested against capture point filters; packets that match are copied and sent to the associated Wireshark instance of the capture point. A specific capture point can be associated with multiple attachment points, with limits on mixing attachment points of different types. Some restrictions apply when you specify attachment points of different types. Attachment points are directional (input or output or both) with the exception of the Layer 2 VLAN attachment point, which is always bidirectional.

In case of stacked systems, the attachment points on all stack members are valid. EPC captures the packets from all the defined attachment points. However these packets are processed only on the active member.

## Filters

Filters are attributes of a capture point that identify and limit the subset of traffic traveling through the attachment point of a capture point, which is copied and passed to Wireshark. To be displayed by Wireshark, a packet must pass through an attachment point, as well as all of the filters associated with the capture point.

A capture point has the following types of filters:

- Core system filter—The core system filter is applied by hardware, and its match criteria is limited by hardware. This filter determines whether hardware-forwarded traffic is copied to software for Wireshark purposes.

- Display filter—The display filter is applied by Wireshark. Packets that fail the display filter are not displayed.

### Core System Filter

You can specify core system filter match criteria by using the class map or ACL, or explicitly by using the CLI.

**Note** When specifying CAPWAP as an attachment point, the core system filter is not used.

In some installations, you need to obtain authorization to modify the configuration, which can lead to extended delays if the approval process is lengthy. This can limit the ability of network administrators to monitor and analyze traffic. To address this situation, Wireshark supports explicit specification of core system filter match criteria from the EXEC mode CLI. The disadvantage is that the match criteria that you can specify is a limited subset of what class map supports, such as MAC, IP source and destination addresses, ether-type, IP protocol, and TCP/UDP source and destination ports.

If you prefer to use configuration mode, you can define ACLs or have class maps refer capture points to them. Explicit and ACL-based match criteria are used internally to construct class maps and policy maps.

Note The ACL and class map configuration are part of the system and not aspects of the Wireshark feature.

### Display Filter

With the display filter, you can direct Wireshark to further narrow the set of packets to display when decoding and displaying from a .pcap file.

### Related Topics

[Additional References](#)

## Actions

Wireshark can be invoked on live traffic or on a previously existing .pcap file. When invoked on live traffic, it can perform four types of actions on packets that pass its display filters:

- Captures to buffer in memory to decode and analyze and store
- Stores to a .pcap file
- Decodes and displays
- Stores and displays

When invoked on a .pcap file only, only the decode and display action is applicable.

## Storage of Captured Packets to Buffer in Memory

Packets can be stored in the capture buffer in memory for subsequent decode, analysis, or storage to a .pcap file.

The capture buffer can be in linear or circular mode. In linear mode, new packets are discarded when the buffer is full. In circular mode, if the buffer is full, the oldest packets are discarded to accommodate the new packets. Although the buffer can also be cleared when needed, this mode is mainly used for debugging network

traffic. However, it is not possible to only clear the contents of the buffer alone without deleting it. Stop the current captures and restart the capture again for this to take effect.

---

**Note** If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

---

## Storage of Captured Packets to a .pcap File

---

**Note** When WireShark is used on switches in a stack, packet captures can be stored only on flash or USB flash devices connected to the active switch.

For example, if flash1 is connected to the active switch, and flash2 is connected to the secondary switch, only flash1 can be used to store packet captures.

Attempts to store packet captures on devices other than flash or USB flash devices connected to the active switch will probably result in errors.

---

Wireshark can store captured packets to a .pcap file. The capture file can be located on the following storage devices:

- on-board flash storage (flash:)
- USB drive (usbflash0:)

---

**Note** Attempts to store packet captures on unsupported devices or devices not connected to the active switch will probably result in errors.

---

When configuring a Wireshark capture point, you can associate a filename. When the capture point is activated, Wireshark creates a file with the specified name and writes packets to it. If the file already exists at the time of creation of the capture point, Wireshark queries you as to whether the file can be overwritten. If the file already exists at the time of activating the capture point, Wireshark will overwrite the existing file. Only one capture point may be associated with a given filename.

If the destination of the Wireshark writing process is full, Wireshark fails with partial data in the file. You must ensure that there is sufficient space in the file system before you start the capture session. With Cisco IOS Release IOS XE 3.3.0(SE), the file system full status is not detected for some storage devices.

You can reduce the required storage space by retaining only a segment, instead of the entire packet. Typically, you do not require details beyond the first 64 or 128 bytes. The default behavior is to store the entire packet.

To avoid possible packet drops when processing and writing to the file system, Wireshark can optionally use a memory buffer to temporarily hold packets as they arrive. Memory buffer size can be specified when the capture point is associated with a .pcap file.

## Packet Decoding and Display

Wireshark can decode and display packets to the console. This functionality is possible for capture points applied to live traffic and for capture points applied to a previously existing .pcap file.

---

**Note** Decoding and displaying packets may be CPU intensive.

---

Wireshark can decode and display packet details for a wide variety of packet formats. The details are displayed by entering the **monitor capture name start** command with one of the following keyword options, which place you into a display and decode mode:

- **brief**—Displays one line per packet (the default).
- **detailed**—Decodes and displays all the fields of all the packets whose protocols are supported. Detailed modes require more CPU than the other two modes.
- **(hexadecimal) dump**—Displays one line per packet as a hexadecimal dump of the packet data and the printable characters of each packet.

When you enter the **capture** command with the decode and display option, the Wireshark output is returned to Cisco IOS and displayed on the console unchanged.

### Live Traffic Display

Wireshark receives copies of packets from the core system. Wireshark applies its display filters to discard uninteresting packets, and then decodes and displays the remaining packets.

### .pcap File Display

Wireshark can decode and display packets from a previously stored .pcap file and direct the display filter to selectively displayed packets.

## Packet Storage and Display

Functionally, this mode is a combination of the previous two modes. Wireshark stores packets in the specified .pcap file and decodes and displays them to the console. Only the core filters are applicable here.

## Wireshark Capture Point Activation and Deactivation

After a Wireshark capture point has been defined with its attachment points, filters, actions, and other options, it must be activated. Until the capture point is activated, it does not actually capture packets.

Before a capture point is activated, some functional checks are performed. A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.\*

---

**Note** \*When performing a wireless capture with a CAPWAP tunneling interface, the core system filter is not required and cannot be used.

---

The display filters are specified as needed.

After Wireshark capture points are activated, they can be deactivated in multiple ways. A capture point that is storing only packets to a .pcap file can be halted manually or configured with time or packet limits, after which the capture point halts automatically.

When a Wireshark capture point is activated, a fixed rate policer is applied automatically in the hardware so that the CPU is not flooded with Wireshark-directed packets. The disadvantage of the rate policer is that you cannot capture contiguous packets beyond the established rate even if more resources are available.

The set packet capture rate is 1000 packets per sec (pps). The 1000 pps limit is applied to the sum of all attachment points. For example, if we have a capture session with 3 attachment points, the rates of all 3 attachment points added together is policed to 1000 pps.

---

**Note** Policer is not supported for control-plane packet capture. When activating control-plane capture points, you need to be extra cautious, so that it does not flood the CPU.

---

## Wireshark Features

This section describes how Wireshark features function in the environment:

- If port security and Wireshark are applied on an ingress capture, a packet that is dropped by port security will still be captured by Wireshark. If port security is applied on an ingress capture, and Wireshark is applied on an egress capture, a packet that is dropped by port security will not be captured by Wireshark.
- Packets dropped by Dynamic ARP Inspection (DAI) are not captured by Wireshark.
- If a port that is in STP blocked state is used as an attachment point and the core filter is matched, Wireshark will capture the packets that come into the port, even though the packets will be dropped by the switch.
- Classification-based security features—Packets that are dropped by input classification-based security features (such as ACLs and IPSG) are not caught by Wireshark capture points that are connected to attachment points at the same layer. In contrast, packets that are dropped by output classification-based security features are caught by Wireshark capture points that are connected to attachment points at the same layer. The logical model is that the Wireshark attachment point occurs after the security feature lookup on the input side, and symmetrically before the security feature lookup on the output side.

On ingress, a packet goes through a Layer 2 port, a VLAN, and a Layer 3 port/SVI. On egress, the packet goes through a Layer 3 port/SVI, a VLAN, and a Layer 2 port. If the attachment point is before the point where the packet is dropped, Wireshark will capture the packet. Otherwise, Wireshark will not capture the packet. For example, Wireshark capture policies connected to Layer 2 attachment points in the input direction capture packets dropped by Layer 3 classification-based security features. Symmetrically, Wireshark capture policies attached to Layer 3 attachment points in the output direction capture packets dropped by Layer 2 classification-based security features.

- Routed ports and switch virtual interfaces (SVIs)—Wireshark cannot capture the output of an SVI because the packets that go out of an SVI's output are generated by CPU. To capture these packets, include the control plane as an attachment point.
- VLANs—Starting with Cisco IOS Release 16.1, when a VLAN is used as a Wireshark attachment point, packet capture is supported on L2 and L3 in both input and output directions.
- Redirection features—In the input direction, features traffic redirected by Layer 3 (such as PBR and WCCP) are logically later than Layer 3 Wireshark attachment points. Wireshark captures these packets even though they might later be redirected out another Layer 3 interface. Symmetrically, output features redirected by Layer 3 (such as egress WCCP) are logically prior to Layer 3 Wireshark attachment points, and Wireshark will not capture them.
- SPAN—Wireshark cannot capture packets on interface configured as a SPAN destination.

- SPAN—Wireshark is able to capture packets on interfaces configured as a SPAN source in the ingress direction, and may be available for egress direction too.
- You can capture packets from a maximum of 1000 VLANs at a time, if no ACLs are applied. If ACLs are applied, the hardware will have less space for Wireshark to use. As a result, the maximum number of VLANs than can be used for packet capture at a time will be lower. Using more than 1000 VLANs tunnels at a time or extensive ACLs might have unpredictable results. For example, mobility may go down.

---

**Note** Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

---

### Wireless Packet Capture in Wireshark

- Wireless traffic is encapsulated inside CAPWAP packets. However, capturing only a particular wireless client's traffic inside a CAPWAP tunnel is not supported when using the CAPWAP tunnel as an attachment point. To capture only a particular wireless client's traffic, use the client VLAN as an attachment point and formulate the core filter accordingly.
- Limited decoding of inner wireless traffic is supported. Decoding of inner wireless packets inside encrypted CAPWAP tunnels is not supported.
- No other interface type can be used with the CAPWAP tunneling interface on the same capture point. A CAPWAP tunneling interface and a Level 2 port cannot be attachment points on the same capture point.
- You cannot specify a core filter when capturing packets for Wireshark via the CAPWAP tunnel. However, you can use the Wireshark display filters for filtering wireless client traffic against a specific wireless client.
- You can capture packets from a maximum of 135 CAPWAP tunnels at a time if no ACLs are applied. If ACLs are applied, the hardware memory will have less space for Wireshark to use. As a result, the maximum number of CAPWAP tunnels than can be used for packet capture at a time will be lower. Using more than 135 CAPWAP tunnels at a time or using extensive ACLs might have unpredictable results. For example, mobility may go down.

---

**Note** Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

---

## Guidelines for Wireshark

- During Wireshark packet capture, hardware forwarding happens concurrently.
- Before starting a Wireshark capture process, ensure that CPU usage is moderate and that sufficient memory (at least 200 MB) is available.
- If you plan to store packets to a storage file, ensure that sufficient space is available before beginning a Wireshark capture process.

- The CPU usage during Wireshark capture depends on how many packets match the specified conditions and on the intended actions for the matched packets (store, decode and display, or both).
- Where possible, keep the capture to the minimum (limit by packets, duration) to avoid high CPU usage and other undesirable conditions.
- Because packet forwarding typically occurs in hardware, packets are not copied to the CPU for software processing. For Wireshark packet capture, packets are copied and delivered to the CPU, which causes an increase in CPU usage.

To avoid high CPU usage, do the following:

- Attach only relevant ports.
  - Use a class map, and secondarily, an access list to express match conditions. If neither is viable, use an explicit, in-line filter.
  - Adhere closely to the filter rules. Restrict the traffic type (such as, IPv4 only) with a restrictive, rather than relaxed ACL, which elicits unwanted traffic.
- Always limit packet capture to either a shorter duration or a smaller packet number. The parameters of the capture command enable you to specify the following:
    - Capture duration
    - Number of packets captured
    - File size
    - Packet segment size
  - Run a capture session without limits if you know that very little traffic matches the core filter.
  - You might experience high CPU (or memory) usage if:
    - You leave a capture session enabled and unattended for a long period of time, resulting in unanticipated bursts of traffic.
    - You launch a capture session with ring files or capture buffer and leave it unattended for a long time, resulting in performance or system health issues.
  - During a capture session, watch for high CPU usage and memory consumption due to Wireshark that may impact performance or health. If these situations arise, stop the Wireshark session immediately.
  - Avoid decoding and displaying packets from a .pcap file for a large file. Instead, transfer the .pcap file to a PC and run Wireshark on the PC.
  - You can define up to eight Wireshark instances. An active **show** command that decodes and displays packets from a .pcap file or capture buffer counts as one instance. However, only one of the instances can be active.
  - Whenever an ACL that is associated with a running capture is modified, you must restart the capture for the ACL modifications to take effect. If you do not restart the capture, it will continue to use the original ACL as if it had not been modified.
  - To avoid packet loss, consider the following:

- Use store-only (when you do not specify the display option) while capturing live packets rather than decode and display, which is an CPU-intensive operation (especially in detailed mode).
- If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.
- If you use the default buffer size and see that you are losing packets, you can increase the buffer size to avoid losing packets.
- Writing to flash disk is a CPU-intensive operation, so if the capture rate is insufficient, you may want to use a buffer capture.
- The Wireshark capture session always operates in streaming mode at the rate of 1000 pps.
- The streaming capture mode rate is 1000 pps.
- If you want to decode and display live packets in the console window, ensure that the Wireshark session is bounded by a short capture duration.

---

**Warning**

A Wireshark session with either a longer duration limit or no capture duration (using a terminal with no auto-more support using the **term len 0** command) may make the console or terminal unusable.

---

- When using Wireshark to capture live traffic that leads to high CPU, usage, consider applying a QoS policy temporarily to limit the actual traffic until the capture process concludes.
- All Wireshark-related commands are in EXEC mode; no configuration commands exist for Wireshark. If you need to use access list or class-map in the Wireshark CLI, you must define an access list and class map with configuration commands.
- No specific order applies when defining a capture point; you can define capture point parameters in any order, provided that CLI allows this. The Wireshark CLI allows as many parameters as possible on a single line. This limits the number of commands required to define a capture point.
- All parameters except attachment points take a single value. Generally, you can replace the value with a new one by reentering the command. After user confirmation, the system accepts the new value and overrides the older one. A **no** form of the command is unnecessary to provide a new value, but it is necessary to remove a parameter.
- Wireshark allows you to specify one or more attachment points. To add more than one attachment point, reenter the command with the new attachment point. To remove an attachment point, use the **no** form of the command. You can specify an interface range as an attachment point. For example, enter **monitor capture mycap interface GigabitEthernet1/0/1 in** where interface GigabitEthernet1/0/1 is an attachment point.  
If you also need to attach interface GigabitEthernet1/0/2, specify it in another line as follows:  
**monitor capture mycap interface GigabitEthernet1/0/2 in**
- You cannot make changes to a capture point when the capture is active.
- The action you want to perform determines which parameters are mandatory. The Wireshark CLI allows you to specify or modify any parameter prior to entering the **start** command. When you enter the **start** command, Wireshark will start only after determining that all mandatory parameters have been provided.

- If the file already exists at the time of creation of the capture point, Wireshark queries you as to whether the file can be overwritten. If the file already exists at the time of activating the capture point, Wireshark will overwrite the existing file.
- The core filter can be an explicit filter, access list, or class map. Specifying a newer filter of these types replaces the existing one.

---

**Note** A core filter is required except when using a CAPWAP tunnel interface as a capture point attachment point.

---

- You can terminate a Wireshark session with an explicit **stop** command or by entering **q** in automore mode. The session could terminate itself automatically when a stop condition such as duration or packet capture limit is met, or if an internal error occurs, or resource is full (specifically if disk is full in file mode).
- Dropped packets will not be shown at the end of the capture. However, only the count of dropped, oversized packets will be displayed.

## Default Wireshark Configuration

The table below shows the default Wireshark configuration.

| Feature             | Default Setting        |
|---------------------|------------------------|
| Duration            | No limit               |
| Packets             | No limit               |
| Packet-length       | No limit (full packet) |
| File size           | No limit               |
| Ring file storage   | No                     |
| Buffer storage mode | Linear                 |

## Information About Embedded Packet Capture

### Embedded Packet Capture Overview

Embedded Packet Capture (EPC) provides an embedded systems management facility that helps in tracing and troubleshooting packets. This feature allows network administrators to capture data packets flowing through, to, and from a Cisco device. The network administrator may define the capture buffer size and type (circular, or linear) and the maximum number of bytes of each packet to capture. The packet capture rate can be throttled using further administrative controls. For example, options allow for filtering the packets to be captured using an Access Control List and, optionally, further defined by specifying a maximum packet capture rate or by specifying a sampling interval.

### Benefits of Embedded Packet Capture

- Ability to capture IPv4 and IPv6 packets in the device, and also capture non-IP packets with MAC filter or match any MAC address.

- Extensible infrastructure for enabling packet capture points. A capture point is a traffic transit point where a packet is captured and associated with a buffer.
- Facility to export the packet capture in packet capture file (PCAP) format suitable for analysis using any external tool.
- Methods to decode data packets captured with varying degrees of detail.

## Packet Data Capture

Packet data capture is the capture of data packets that are then stored in a buffer. You can define packet data captures by providing unique names and parameters.

You can perform the following actions on the capture:

- Activate captures at any interface.
- Apply access control lists (ACLs) or class maps to capture points.

---

**Note** Network Based Application Recognition (NBAR) and MAC-style class map is not supported.

---

- Destroy captures.
- Specify buffer storage parameters such as size and type. The size ranges from 1 MB to 100 MB. The default buffer is linear;; the other option for the buffer is circular.
- Specify match criteria that includes information about the protocol, IP address or port address.

# Configuring Packet Capture

## How to Configure Wireshark

To configure Wireshark, perform these basic steps.

1. Define a capture point.
2. (Optional) Add or modify the capture point's parameters.
3. Activate or deactivate a capture point.
4. Delete the capture point when you are no longer using it.

**Defining a Capture Point**

The example in this procedure defines a very simple capture point. If you choose, you can define a capture point and all of its parameters with one instance of the **monitor capture** command.

**Note** You must define an attachment point, direction of capture, and core filter to have a functional capture point. An exception to needing to define a core filter is when you are defining a wireless capture point using a CAPWAP tunneling interface. In this case, you do not define your core filter. It cannot be used.

Follow these steps to define a capture point.

**SUMMARY STEPS**

1. **enable**
2. **show capwap summary**
3. **monitor capture** {*capture-name*} {**interface** *interface-type interface-id* | **control-plane**} {**in** | **out** | **both**}
4. **monitor capture** {*capture-name*} [**match** {**any** | **ipv4 any any** | **ipv6**} **any any**]
5. **show monitor capture** {*capture-name*} [**parameter**]
6. **show running-config**
7. **copy running-config startup-config**

|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <p><b>monitor capture</b> {<i>capture-name</i>} [<b>match</b> {<b>any</b>   <b>ipv4</b><br/><b>any any</b>   <b>ipv6</b>} <b>any any</b>]</p> <p><b>Example:</b></p> <pre>Device# monitor capture mycap interface GigabitEthernet1/0/1 in match any</pre> | <p>Defines the core system filter.</p> <p><b>Note</b> When using the CAPWAP tunneling interface as an attachment point, do not perform this step because a core filter cannot be used.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> <li>• <i>capture-name</i>—Specifies the name of the capture point to be defined (mycap is used in the example).</li> <li>• <b>match</b>—Specifies a filter. The first filter defined is the core filter.</li> </ul> <p><b>Note</b> A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.</p> <ul style="list-style-type: none"> <li>• <b>ipv4</b>—Specifies an IP version 4 filter.</li> <li>• <b>ipv6</b>—Specifies an IP version 6 filter.</li> </ul> |
| <b>Step 5</b> | <p><b>show monitor capture</b> {<i>capture-name</i>} [<b>parameter</b>]</p> <p><b>Example:</b></p> <pre>Device# show monitor capture mycap parameter monitor capture mycap interface GigabitEthernet1/0/1 in monitor capture mycap match any</pre>        | Displays the capture point parameters that you defined in Step 2 and confirms that you defined a capture point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 6</b> | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Device# show running-config</pre>                                                                                                                                                           | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 7</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Device# copy running-config startup-config</pre>                                                                                                                             | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Example

To define a capture point with a CAPWAP attachment point:

```
Device# show capwap summary
```

```
CAPWAP Tunnels General Statistics:
Number of Capwap Data Tunnels      = 1
```

```

Number of Capwap Mobility Tunnels   = 0
Number of Capwap Multicast Tunnels = 0

```

| Name | APName           | Type | PhyPortIf | Mode    | McastIf |
|------|------------------|------|-----------|---------|---------|
| Ca0  | AP442b.03a9.6715 | data | Gi3/0/6   | unicast | -       |

| Name | SrcIP       | SrcPort | DestIP     | DstPort | DtlsEn | MTU  | Xact |
|------|-------------|---------|------------|---------|--------|------|------|
| Ca0  | 10.10.14.32 | 5247    | 10.10.14.2 | 38514   | No     | 1449 | 0    |

```

Device# monitor capture mycap interface capwap 0 both
Device# monitor capture mycap file location flash:mycap.pcap
Device# monitor capture mycap file buffer-size 1
Device# monitor capture mycap start

```

```
*Aug 20 11:02:21.983: %BUFCAP-6-ENABLE: Capture Point mycap enabled.on
```

```

Device# show monitor capture mycap parameter
  monitor capture mycap interface capwap 0 in
  monitor capture mycap interface capwap 0 out
  monitor capture mycap file location flash:mycap.pcap buffer-size 1
Device#
Device# show monitor capture mycap

```

```
Status Information for Capture mycap
```

```

Target Type:
Interface: CAPWAP,
  Ingress:
0
  Egress:
0
  Status : Active
Filter Details:
  Capture all packets
Buffer Details:
  Buffer Type: LINEAR (default)
File Details:
  Associated file name: flash:mycap.pcap
  Size of buffer(in MB): 1
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Packets per second: 0 (no limit)
  Packet sampling rate: 0 (no sampling)

```

```

Device# show monitor capture file flash:mycap.pcap

```

### What to do next

You can add additional attachment points, modify the parameters of your capture point, then activate it, or if you want to use your capture point just as it is, you can now activate it.

**Note** You cannot change a capture point's parameters using the methods presented in this topic.

If the user enters an incorrect capture name, or an invalid/non existing attachment point, the switch will show errors like "*Capture Name should be less than or equal to 8 characters. Only alphanumeric characters and underscore ( \_ ) is permitted*" and "*% Invalid input detected at '^' marker*" respectively.

## Adding or Modifying Capture Point Parameters

Although listed in sequence, the steps to specify values for the parameters can be executed in any order. You can also specify them in one, two, or several lines. Except for attachment points, which can be multiple, you can replace any value with a more recent value by redefining the same option. You will need to confirm interactively when certain parameters already specified are being modified.

Follow these steps to modify a capture point's parameters.

### Before you begin

A capture point must be defined before you can use these instructions.

### SUMMARY STEPS

1. **enable**
2. **monitor capture** {*capture-name*} **match** {**any** | **mac** *mac-match-string* | **ipv4** {**any** | **host** | **protocol**}{**any** | **host**} | **ipv6** {**any** | **host** | **protocol**}{**any** | **host**}}
3. **monitor capture** {*capture-name*} **limit** {[**duration** *seconds*] [**packet-length** *size*] [**packets** *num*] }
4. **monitor capture** {*capture-name*} **file** {**location** *filename*}
5. **monitor capture** {*capture-name*} **file** {**buffer-size** *size*}
6. **show monitor capture** {*capture-name*} [ **parameter**]
7. **end**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                                                                                                                                                                                                                      | Enables privileged EXEC mode. Enter your password if prompted.                                                                                                                                                                                                                     |
| Step 2 | <b>monitor capture</b> { <i>capture-name</i> } <b>match</b> { <b>any</b>   <b>mac</b> <i>mac-match-string</i>   <b>ipv4</b> { <b>any</b>   <b>host</b>   <b>protocol</b> }{ <b>any</b>   <b>host</b> }   <b>ipv6</b> { <b>any</b>   <b>host</b>   <b>protocol</b> }{ <b>any</b>   <b>host</b> }}<br><b>Example:</b><br>Device# <b>monitor capture mycap match ipv4 any any</b> | Defines the core system filter ( <b>ipv4 any any</b> ), defined either explicitly, through ACL or through a class map.<br><b>Note</b> If you are defining a wireless capture point using a CAPWAP tunneling interface, this command will have no effect, so it should not be used. |
| Step 3 | <b>monitor capture</b> { <i>capture-name</i> } <b>limit</b> {[ <b>duration</b> <i>seconds</i> ] [ <b>packet-length</b> <i>size</i> ] [ <b>packets</b> <i>num</i> ] }<br><b>Example:</b><br>Device# <b>monitor capture mycap limit duration 60 packet-len 400</b>                                                                                                               | Specifies the session limit in seconds (60), packets captured, or the packet segment length to be retained by Wireshark (400).                                                                                                                                                     |
| Step 4 | <b>monitor capture</b> { <i>capture-name</i> } <b>file</b> { <b>location</b> <i>filename</i> }                                                                                                                                                                                                                                                                                 | Specifies the file association, if the capture point intends to capture packets rather than only display them.                                                                                                                                                                     |

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p><b>Example:</b></p> <pre>Device# monitor capture mycap file location flash:mycap.pcap</pre>                                                                                                                                                                                                                                                                                                                              | <p><b>Note</b> If the file already exists, you have to confirm if it can be overwritten.</p> <p><b>Note</b> File option does not exist on LAN base license.</p> |
| <b>Step 5</b> | <p><b>monitor capture</b> {<i>capture-name</i>} <b>file</b> {<b>buffer-size</b> <i>size</i>}</p> <p><b>Example:</b></p> <pre>Device# monitor capture mycap file buffer-size 100</pre>                                                                                                                                                                                                                                       | Specifies the size of the memory buffer used by Wireshark to handle traffic bursts.                                                                             |
| <b>Step 6</b> | <p><b>show monitor capture</b> {<i>capture-name</i>} [<b>parameter</b>]</p> <p><b>Example:</b></p> <pre>Device# show monitor capture mycap parameter monitor capture mycap interface GigabitEthernet1/0/1 in monitor capture mycap match ipv4 any any monitor capture mycap limit duration 60 packet-len 400 monitor capture point mycap file location bootdisk:mycap.pcap monitor capture mycap file buffer-size 100</pre> | Displays the capture point parameters that you defined previously.                                                                                              |
| <b>Step 7</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config)# end</pre>                                                                                                                                                                                                                                                                                                                                                     | Returns to privileged EXEC mode.                                                                                                                                |

## Examples

### Modifying Parameters

#### Associating or Disassociating a Capture File

```
Device# monitor capture point mycap file location flash:mycap.pcap
Device# no monitor capture mycap file
```

#### Specifying a Memory Buffer Size for Packet Burst Handling

```
Device# monitor capture mycap buffer size 100
```

#### Defining an Explicit Core System Filter to Match Both IPv4 and IPv6

```
Device# monitor capture mycap match any
```

### What to do next

if your capture point contains all of the parameters you want, activate it.

## Deleting Capture Point Parameters

Although listed in sequence, the steps to delete parameters can be executed in any order. You can also delete them in one, two, or several lines. Except for attachment points, which can be multiple, you can delete any parameter.

Follow these steps to delete a capture point's parameters.

### Before you begin

A capture point parameter must be defined before you can use these instructions to delete it.

### SUMMARY STEPS

1. **enable**
2. **no monitor capture** {*capture-name*} **match**
3. **no monitor capture** {*capture-name*} **limit** [*duration*] [*packet-length*] [*packets*]
4. **no monitor capture** {*capture-name*} **file** [*location*] [*buffer-size*]
5. **show monitor capture** {*capture-name*} [ **parameter**]
6. **end**

### DETAILED STEPS

|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <b>no monitor capture</b> { <i>capture-name</i> } <b>file</b> [ <b>location</b> ]<br>[ <b>buffer-size</b> ]<br><br><b>Example:</b><br>Device# <b>no monitor capture mycap file</b><br>Device# <b>no monitor capture mycap file location</b> | Deletes the file association. The capture point will no longer capture packets. It will only display them.<br><br>Deletes the file location association. The file location will no longer be associated with the capture point. However, other defined file association will be unaffected by this action. |
| <b>Step 5</b> | <b>show monitor capture</b> { <i>capture-name</i> } [ <b>parameter</b> ]<br><br><b>Example:</b><br>Device# <b>show monitor capture mycap parameter</b><br>monitor capture mycap interface<br>GigabitEthernet1/0/1 in                        | Displays the capture point parameters that remain defined after your parameter deletion operations. This command can be run at any point in the procedure to see what parameters are associated with a capture point.                                                                                      |
| <b>Step 6</b> | <b>end</b><br><br><b>Example:</b><br><br>Device(config)# <b>end</b>                                                                                                                                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                           |

**What to do next**

If your capture point contains all of the parameters you want, activate it.

**Note** If the parameters are deleted when the capture point is active, the switch will show an error "*Capture is active*".

| <b>Step 6</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b>                                                                  | (Optional) Saves your entries in the configuration file.                                                   |

### What to do next

You can define a new capture point with the same name as the one you deleted. These instructions are usually performed when one wants to start over with defining a capture point.

## Activating and Deactivating a Capture Point

Follow these steps to activate or deactivate a capture point.

### Before you begin

A capture point can be activated even if an attachment point and a core system filter have been defined and the associated filename already exists. In such an instance, the existing file will be overwritten.

A capture point with no associated filename can only be activated to display. When the filename is not specified, the packets are captured into the buffer. Live display (display during capture) is available in both file and buffer modes.

If no display filters are specified, packets are not displayed live, and all the packets captured by the core system filter are displayed. The default display mode is brief.

**Note** When using a CAPWAP tunneling interface as an attachment point, core filters are not used, so there is no requirement to define them in this case.

### SUMMARY STEPS

1. **enable**
2. **monitor capture** {*capture-name*} **start** [**display** [**display-filter** *filter-string*]] [**brief** | **detailed** | **dump**]
3. **monitor capture** {*capture-name*} **stop**
4. **end**
5. **show running-config**
6. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                             | Purpose                                                                                            |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                                                     | Enables privileged EXEC mode. Enter your password if prompted.                                     |
| <b>Step 2</b> | <b>monitor capture</b> { <i>capture-name</i> } <b>start</b> [ <b>display</b> [ <b>display-filter</b> <i>filter-string</i> ]] [ <b>brief</b>   <b>detailed</b>   <b>dump</b> ] | Activates a capture point and filters the display, so only packets containing "stp" are displayed. |

|               | Command or Action                                                                                                             | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
|               | <b>Example:</b><br>Device# <code>monitor capture mycap start display display-filter "stp"</code>                              |                                                          |
| <b>Step 3</b> | <b>monitor capture</b> <i>{capture-name}</i> <b>stop</b><br><b>Example:</b><br>Device# <code>monitor capture name stop</code> | Deactivates a capture point.                             |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <code>end</code>                                                             | Returns to privileged EXEC mode.                         |
| <b>Step 5</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <code>show running-config</code>                                     | Verifies your entries.                                   |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config startup-config</code>       | (Optional) Saves your entries in the configuration file. |

### What to do next

While activating and deactivating a capture point, you could encounter a few errors. Here are examples of some of the possible errors.

#### Missing attachment point on activation

```
Switch#monitor capture mycap match any
Switch#monitor capture mycap start
No Target is attached to capture failed to disable provision featurefailed to remove
policyfailed to disable provision featurefailed to remove policyfailed to disable provision
featurefailed to remove policy
Capture statistics collected at software (Buffer):
  Capture duration - 0 seconds
  Packets received - 0
  Packets dropped - 0
  Packets oversized - 0

Unable to activate Capture.

## Clearing the Capture Point Buffer

Follow these steps to clear the buffer contents or save them to an external file for storage.

**Note** If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss. Do not try to clear buffer on an active capture point.

**Note** Clearing buffer on an active capture point is supported only on Lan Base as this only clears the content. On all other licenses, it deletes the buffer itself, hence cannot be run during active capture.

### SUMMARY STEPS

1. **enable**
2. **monitor capture** *{capture-name}* [**clear** | **export filename**]
3. **end**
4. **show running-config**
5. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                         | Purpose                                                        |
|--------|-----------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b> | Enables privileged EXEC mode. Enter your password if prompted. |

|               | Command or Action                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>monitor capture</b> { <i>capture-name</i> } [ <b>clear</b>   <b>export</b> <i>filename</i> ]<br><b>Example:</b><br>Device# <b>monitor capture mycap clear</b> | Clear - Completely deletes the buffer.<br><b>Note</b> When the clear command is run, <ul style="list-style-type: none"> <li>• On Lan base - the command clears the buffer contents without deleting the buffer</li> <li>• On all other licenses - the command deletes the buffer itself.</li> </ul> Export - Saves the captured packets in the buffer as well as deletes the buffer. |
| <b>Step 3</b> | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b>                                                                                                      | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 4</b> | <b>show running-config</b><br><b>Example:</b><br>Device# <b>show running-config</b>                                                                              | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 5</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b>                                                | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                             |

### Examples: Capture Point Buffer Handling

#### Exporting Capture to a File

```
Device# monitor capture mycap export flash:mycap.pcap
```

Storage configured as File for this capture

#### Clearing Capture Point Buffer

```
Device# monitor capture mycap clear
```

Capture configured with file options

#### What to do next

**Note** If you try to clear the capture point buffer on licenses other than LAN Base, the switch will show an error "*Failed to clear capture buffer : Capture Buffer BUSY*".

# How to Implement Embedded Packet Capture

## Managing Packet Data Capture

**Note** Export of an active capture point is only supported on LAN Base licence. On all other license we need to stop the capture first and only then export.

To manage Packet Data Capture in the buffer mode, perform the following steps:

### SUMMARY STEPS

1. **enable**
2. **monitor capture** *capture-name* **access-list** *access-list-name*
3. **monitor capture** *capture-name* **limit duration** *seconds*
4. **monitor capture** *capture-name* **interface** *interface-name* **both**
5. **monitor capture** *capture-name* **buffer circular size** *bytes*
6. **monitor capture** *capture-name* **start**
7. **monitor capture** *capture-name* **stop**
8. **monitor capture** *capture-name* **export** *file-location/file-name*
9. **end**

### DETAILED STEPS

3. **show monitor capture *capture-buffer-name* parameter**
4. **debug epc capture-point**
5. **debug epc provision**
6. **end**

**DETAILED STEPS**

|               | <b>Command or Action</b>                                                                                                                       | <b>Purpose</b>                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> <b>enable</b>                                                                                      | Enables privileged EXEC mode. Enter your password if prompted.                |
| <b>Step 2</b> | <b>show monitor capture <i>capture-buffer-name</i> buffer dump</b><br><b>Example:</b><br>Device# <b>show monitor capture mycap buffer dump</b> | (Optional) Displays a hexadecimal dump of captured packet and its metadata.   |
| <b>Step 3</b> | <b>show monitor capture <i>capture-buffer-name</i> parameter</b><br><b>Example:</b><br>Device# <b>show monitor capture mycap parameter</b>     | (Optional) Displays a list of commands that were used to specify the capture. |
| <b>Step 4</b> | <b>debug epc capture-point</b><br><b>Example:</b><br>Device# <b>debug epc capture-point</b>                                                    | (Optional) Enables packet capture point debugging.                            |
| <b>Step 5</b> | <b>debug epc provision</b><br><b>Example:</b><br>Device# <b>debug epc provision</b>                                                            | (Optional) Enables packet capture provisioning debugging.                     |

|        | Command or Action                                           | Purpose                          |
|--------|-------------------------------------------------------------|----------------------------------|
| Step 6 | <b>end</b><br><b>Example:</b><br>Device(config)# <b>end</b> | Returns to privileged EXEC mode. |

# Monitoring Packet Capture

## Configuration Examples for Wireshark

### Example: Displaying a Brief Output from a .pcap File

You can display the output from a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap brief
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x002e,
seq=0/0, ttl=254
  2 0.000051000  10.10.10.1 -> 10.10.10.2  ICMP 114 Echo (ping) reply   id=0x002e,
seq=0/0, ttl=255 (request in 1)
  3 0.000908000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x002e,
seq=1/256, ttl=254
  4 0.001782000  10.10.10.1 -> 10.10.10.2  ICMP 114 Echo (ping) reply   id=0x002e,
seq=1/256, ttl=255 (request in 3)
  5 0.002961000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x002e,
seq=2/512, ttl=254
  6 0.003676000  10.10.10.1 -> 10.10.10.2  ICMP 114 Echo (ping) reply   id=0x002e,

## Example: Displaying Packets from a .pcap File using a Display Filter

You can display the .pcap file packets output by entering:

```
Device# show monitor capture file flash:mycap.pcap display-filter "ip.src == 10.10.10.2"
brief
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=0/0, ttl=254
  3 0.000908000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=1/256, ttl=254
  5 0.002961000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=2/512, ttl=254
  7 0.004835000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=3/768, ttl=254
  9 0.006850000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=4/1024, ttl=254
 11 0.008768000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=5/1280, ttl=254
 13 0.010695000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=6/1536, ttl=254
 15 0.012728000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=7/1792, ttl=254
 17 0.014652000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=8/2048, ttl=254
 19 0.016682000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=9/2304, ttl=254
 21 0.018655000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=10/2560, ttl=254
 23 0.020575000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x002e,
seq=11/2816, ttl=254
```

## Example: Displaying the Number of Packets Captured in a .pcap File

You can display the number of packets captured in a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap packet-count
File name: /flash/mycap.pcap
Number of packets: 50
```

## Example: Displaying a Single Packet Dump from a .pcap File

You can display a single packet dump from a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap packet-number 10 dump
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

0000 00 e1 6d 31 f1 80 00 e1 6d 31 f1 80 08 00 45 00 ..m1....m1....E.
0010 00 64 04 be 00 00 ff 01 8e c4 0a 0a 0a 01 0a 0a .d.....
0020 0a 02 00 00 ec ce 00 2e 00 04 00 00 00 00 09 c9 .....
0030 8f 80 ab cd .....
0040 ab cd .....
0050 ab cd .....
0060 ab cd .....
0070 ab cd
```

## Example: Displaying Statistics of Packets Captured in a .pcap File

You can display the statistics of the packets captured in a .pcap file by entering:

```
Device# show monitor capture file flash:mycap.pcap statistics "h225,counter"
===== H225 Message and Reason Counter =====
RAS-Messages:
Call Signalling:
=====
```

## Example: Simple Capture and Display

This example shows how to monitor traffic in the Layer 3 interface Gigabit Ethernet 1/0/1:

**Step 1:** Define a capture point to match on the relevant traffic by entering:

```
Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 50
Device# monitor capture mycap buffer size 100
```

To avoid high CPU utilization, a low packet count and duration as limits has been set.

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```
Device# show monitor capture mycap parameter
      monitor capture mycap interface GigabitEthernet1/0/3 in
      monitor capture mycap match ipv4 any any
      monitor capture mycap buffer size 100
      monitor capture mycap limit packets 50 duration 60
```

```
Device# show monitor capture mycap
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
  Buffer Size (in MB): 100
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 50
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packet sampling rate: 0 (no sampling)
```

**Step 3:** Start the capture process and display the results.

```
Device# monitor capture mycap start display
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1  0.000000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030, seq=0/0,
  ttl=254
  2  0.003682  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
  seq=1/256, ttl=254
  3  0.006586  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0030,
```

```

seq=2/512, ttl=254
 4  0.008941  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0030,
seq=3/768, ttl=254
 5  0.011138  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0030,
seq=4/1024, ttl=254
 6  0.014099  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0030,
seq=5/1280, ttl=254
 7  0.016868  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0030,
seq=6/1536, ttl=254
 8  0.019210  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0030,
seq=7/1792, ttl=254
 9  0.024785  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0030,
seq=8/2048, ttl=254
--More--

```

**Step 4:** Delete the capture point by entering:

```
Device# no monitor capture mycap
```

**Note** A **stop** command is not required in this particular case since we have set a limit and the capture will automatically stop once that limit is reached.

For more information on syntax to be used for pcap statistics, refer the "*Additional References*" section.

## Example: Simple Capture and Store

This example shows how to capture packets to a filter:

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```

Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 50
Device# monitor capture mycap file location flash:mycap.pcap

```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```

Device# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/3 in
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location flash:mycap.pcap

```

```

monitor capture mycap limit packets 50 duration 60

Device# show monitor capture mycap

Status Information for Capture mycap

  Associated file name: flash:mycap.pcap
Limit Details:
  Number of Packets to capture: 50
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packet sampling rate: 0 (no sampling)

```

**Step 3:** Launch packet capture by entering:

```
Device# monitor capture mycap start
```

**Step 4:** Display extended capture statistics during runtime by entering:

```

Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 15 seconds
  Packets received - 40
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 40
  Bytes received - 7280
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 4560

```

**Step 5:** After sufficient time has passed, stop the capture by entering:

```

Device# monitor capture mycap stop
Capture statistics collected at software (Buffer & Wireshark):
  Capture duration - 20 seconds
  Packets received - 50
  Packets dropped - 0
  Packets oversized - 0

```

---

**Note** Alternatively, you could allow the capture operation stop automatically after the time has elapsed or the packet count has been met.

The mycap.pcap file now contains the captured packets.

---

**Step 6:** Display extended capture statistics after stop by entering:

```

Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 20 seconds
  Packets received - 50
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 50
  Bytes received - 8190
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 5130

```

### Step 7: Display the packets by entering:

```

Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=0/0, ttl=254
  2 0.002555000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=1/256, ttl=254
  3 0.006199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=2/512, ttl=254
  4 0.009199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=3/768, ttl=254
  5 0.011647000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=4/1024, ttl=254
  6 0.014168000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=5/1280, ttl=254
  7 0.016737000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=6/1536, ttl=254
  8 0.019403000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=7/1792, ttl=254
  9 0.022151000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,

 10 0.024722000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=9/2304, ttl=254
 11 0.026890000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=10/2560, ttl=254
 12 0.028862000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0031,
seq=11/2816, ttl=254
--More--

```

For more information on syntax to be used for pcap statistics, refer the "*Additional References*" section.

### Step 8: Delete the capture point by entering:

```
Device# no monitor capture mycap
```

## Example: Using Buffer Capture

This example shows how to use buffer capture:

**Step 1:** Launch a capture session with the buffer capture option by entering:

```
Device# monitor capture mycap interface GigabitEthernet1/0/3 in
Device# monitor capture mycap match ipv4 any any
Device# monitor capture mycap buffer circular size 1
Device# monitor capture mycap start
```

**Step 2:** Determine whether the capture is active by entering:

```
Device# show monitor capture mycap
Status Information for Capture mycap
  Target Type:
    Interface: GigabitEthernet1/0/3, Direction: in
    Status : Active
  Filter Details:
    IPv4
    Source IP: any
    Destination IP: any
    Protocol: any
  Buffer Details:
    Buffer Type: CIRCULAR
    Buffer Size (in MB): 1
  File Details:
    File not associated
  Limit Details:
    Number of Packets to capture: 0 (no limit)
    Packet Capture duration: 0 (no limit)
    Packet Size to capture: 0 (no limit)
    Maximum number of packets to capture per second: 1000
    Packet sampling rate: 0 (no sampling)
```

**Step 3:** Display extended capture statistics during runtime by entering:

```
Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 88 seconds
  Packets received - 1000
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 1000
  Bytes received - 182000
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 114000
```

**Step 4:** Stop the capture by entering:

```
Device# monitor capture mycap stop
Capture statistics collected at software (Buffer):
  Capture duration - 2185 seconds
  Packets received - 51500
```

```
Packets dropped - 0
Packets oversized - 0
```

**Step 5:** Display extended capture statistics after stop by entering:

```
Device# show monitor capture mycap capture-statistics
Capture statistics collected at software:
  Capture duration - 156 seconds
  Packets received - 2000
  Packets dropped - 0
  Packets oversized - 0
  Packets errored - 0
  Packets sent - 2000
  Bytes received - 364000
  Bytes dropped - 0
  Bytes oversized - 0
  Bytes errored - 0
  Bytes sent - 228000
```

**Step 6:** Determine whether the capture is active by entering:

```
Device# show monitor capture mycap
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Maximum number of packets to capture per second: 1000
  Packet sampling rate: 0 (no sampling)
```

**Step 7:** Display the packets in the buffer by entering:

```
Device# show monitor capture mycap buffer brief
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1  0.000000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40057/31132, ttl=254
  2  0.000030  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40058/31388, ttl=254
  3  0.000052  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40059/31644, ttl=254
  4  0.000073  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40060/31900, ttl=254
  5  0.000094  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40061/32156, ttl=254
  6  0.000115  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40062/32412, ttl=254
  7  0.000137  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
seq=40063/32668, ttl=254
  8  0.000158  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0038,
```

```

seq=40064/32924, ttl=254
 9  0.000179  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0038,
seq=40065/33180, ttl=254
10  0.000200  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0038,
seq=40066/33436, ttl=254
11  0.000221  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0038,
seq=40067/33692, ttl=254
12  0.000243  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request  id=0x0038,
seq=40068/33948, ttl=254
--More--

```

Notice that the packets have been buffered.

### Step 8: Display the packets in other display modes.

```
Device# show monitor capture mycap buffer detailed
```

```
Starting the packet display ..... Press Ctrl + Shift + 6 to exit
```

```

Frame 1: 114 bytes on wire (912 bits), 114 bytes captured (912 bits) on interface 0

```

**Step 9:** Clear the buffer by entering:

```
Device# monitor capture mycap clear
```

**Note** NOTE - Clearing the buffer deletes the buffer along with the contents.

**Note** If you require the buffer contents to be displayed, run the clear commands after show commands.

**Step 10:** Restart the traffic, wait for 10 seconds, then display the buffer contents by entering:

**Note** We cannot run show from buffer during an active capture. Capture should be stopped before running show from buffer. We can however run a show on a pcap file during an active capture in both file and buffer mode. In file mode, we can display the packets in the current capture session's pcap file as well when the capture is active.

```
Device# monitor capture mycap start
Switch# show monitor capture mycap

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
  Status : Active
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Maximum number of packets to capture per second: 1000
  Packet sampling rate: 0 (no sampling)
```

**Step 11:** Stop the packet capture and display the buffer contents by entering:

```
Device# monitor capture mycap stop
Capture statistics collected at software (Buffer):
Capture duration - 111 seconds
Packets received - 5000
Packets dropped - 0
Packets oversized - 0
```

**Step 12:** Determine whether the capture is active by entering:

```
Device# show monitor capture mycap
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/3, Direction: in
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1

  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
```

```
Maximum number of packets to capture per second: 1000
Packet sampling rate: 0 (no sampling)
```

**Step 13:** Display the packets in the buffer by entering:

```
Device# show monitor capture mycap buffer brief
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=0/0, ttl=254
  2 0.000030000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=1/256, ttl=254
  3 0.000051000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=2/512, ttl=254
  4 0.000072000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=3/768, ttl=254
  5 0.000093000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=4/1024, ttl=254
  6 0.000114000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=5/1280, ttl=254
  7 0.000136000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=6/1536, ttl=254
  8 0.000157000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=7/1792, ttl=254
  9 0.000178000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=8/2048, ttl=254
 10 0.000199000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=9/2304, ttl=254
 11 0.000220000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=10/2560, ttl=254
 12 0.000241000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=11/2816, ttl=254
--More<
```

**Step 14:** Store the buffer contents to the mycap.pcap file in the internal flash: storage device by entering:

```
Device# monitor capture mycap export flash:mycap.pcap
Exported Successfully
```

**Note** The current implementation of export is such that when the command is run, export is "started" but not complete when it returns the prompt to the user. So we have to wait for a message display on the console from Wireshark before it can run a display of packets in the file.

**Step 15:** Display capture packets from the file by entering:

```
Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

  1 0.000000000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=0/0, ttl=254
  2 0.000030000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=1/256, ttl=254
  3 0.000051000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=2/512, ttl=254
  4 0.000072000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=3/768, ttl=254
  5 0.000093000 10.10.10.2 -> 10.10.10.1 ICMP 114 Echo (ping) request id=0x0039,
seq=4/1024, ttl=254
```

## Example: Simple Capture and Store of Packets in Egress Direction

```

 6 0.000114000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0039,
seq=5/1280, ttl=254
 7 0.000136000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0039,
seq=6/1536, ttl=254
 8 0.000157000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0039,
seq=7/1792, ttl=254
 9 0.000178000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0039,
seq=8/2048, ttl=254
10 0.000199000  10.10.10.2 -> 10.10.10.1  ICMP 114 Echo (ping) request id=0x0039,
seq=9/2304, ttl=254

seq=11/2816, ttl=254
--More--

```

**Step 16:** Delete the capture point by entering:

```
Device# no monitor capture mycap
```

## Example: Simple Capture and Store of Packets in Egress Direction

This example shows how to capture packets to a filter:

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```

Device# monitor capture mycap interface Gigabit 1/0/1 out match ipv4 any any
Device# monitor capture mycap limit duration 60 packets 100
Device# monitor capture mycap file location flash:mycap.pcap buffer-size 90

```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```

Device# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 out
  monitor capture mycap match ipv4 any any
  monitor capture mycap file location flash:mycap.pcap buffer-size 90
  monitor capture mycap limit packets 100 duration 60

```

```
Device# show monitor capture mycap
```

```

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: out
  Status : Inactive
Filter Details:
  IPv4

```

```

Source IP: any
Destination IP: any
Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
File Details:
  Associated file name: flash:mycap.pcap
  Size of buffer(in MB): 90
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packets per second: 0 (no limit)
  Packet sampling rate: 0 (no sampling)

```

### Step 3: Launch packet capture by entering:

```

Device# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode

```

```

Device#
*Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.

```

**Note** Allow the capture operation stop automatically after the time has elapsed or the packet count has been met. When you see the following message in the output, will know that the capture operation has stopped:

```

*Oct 14 09:36:34.632: %BUFCAP-6-DISABLE_ASYNC: Capture Point mycap disabled. Reason : Wireshark Session Ended

```

The mycap.pcap file now contains the captured packets.

### Step 4: Display the packets by entering:

```

Device# show monitor capture file flash:mycap.pcap
Starting the packet display ..... Press Ctrl + Shift + 6 to exit

0.000000  10.1.1.30 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
1.000000  10.1.1.31 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
2.000000  10.1.1.32 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
3.000000  10.1.1.33 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
4.000000  10.1.1.34 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
5.000000  10.1.1.35 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
6.000000  10.1.1.36 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
7.000000  10.1.1.37 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
8.000000  10.1.1.38 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002
9.000000  10.1.1.39 -> 20.1.1.2    UDP Source port: 20001  Destination port: 20002

```

### Step 5: Delete the capture point by entering:

```

Device# no monitor capture mycap

```

## Configuration Examples for Embedded Packet Capture

### Example: Managing Packet Data Capture

The following example shows how to manage packet data capture:

```

Device> enable
Device# monitor capture mycap start
Device# monitor capture mycap access-list v4acl
Device# monitor capture mycap limit duration 1000
Device# monitor capture mycap interface GigabitEthernet 0/0/1 both
Device# monitor capture mycap buffer circular size 10
Device# monitor capture mycap start
Device# monitor capture mycap export tftp://10.1.88.9/mycap.pcap
Device# monitor capture mycap stop
Device# end
  
```

The following example shows how to display the list of commands used to configure the capture named mycap:

```
Device# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet 1/0/1 both
monitor capture mycap match any
monitor capture mycap buffer size 10
monitor capture mycap limit pps 1000
```

The following example shows how to debug the capture point:

```
Device# debug epc capture-point
EPC capture point operations debugging is on
```

```
Device# monitor capture mycap start
*Jun 4 14:17:15.463: EPC CP: Starting the capture cap1

## CHAPTER 71

# Configuring Flexible NetFlow

- [Prerequisites for Flexible NetFlow, on page 1161](#)
- [Restrictions for Flexible NetFlow, on page 1162](#)
- [Information About Flexible Netflow, on page 1164](#)
- [How to Configure Flexible NetFlow, on page 1179](#)
- [Monitoring Flexible NetFlow, on page 1196](#)
- [Configuration Examples for Flexible NetFlow, on page 1196](#)
- [Additional References, on page 1202](#)
- [Feature Information for Flexible NetFlow, on page 1203](#)

## Prerequisites for Flexible NetFlow

The following are prerequisites for your Flexible NetFlow configuration:

- You must configure a source interface. If you do not configure a source interface, the exporter will remain in a disabled state.
- You must configure a valid record name for every flow monitor.
- You must enable IPv6 routing to export the flow records to an IPv6 destination server.
- You must configure IPFIX export protocol for the flow exporter to export netflow records in IPFIX format.
- You are familiar with the Flexible NetFlow key fields as they are defined in the following commands in the Cisco IOS Flexible NetFlow Command Reference :
  - **match datalink**—Datalink (layer2) fields
  - **match flow**—Flow identifying fields
  - **match interface**—Interface fields
  - **match ipv4**—IPv4 fields
  - **match ipv6**—IPv6 fields
  - **match transport**—Transport layer fields
  - **match wireless**—Wireless fields

- **match flow cts**—CTS fields
- You are familiar with the Flexible NetFlow non key fields as they are defined in the following commands in the Cisco IOS Flexible NetFlow Command Reference :
  - **collect counter**—Counter fields
  - **collect flow**—Flow identifying fields
  - **collect interface**—Interface fields
  - **collect timestamp**—Timestamp fields
  - **collect transport**—Transport layer fields
  - **collect wireless**—Wireless fields

#### IPv4 Traffic

- The networking device must be configured for IPv4 routing.
- One of the following must be enabled on your device and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding or distributed Cisco Express Forwarding.

#### IPv6 Traffic

- The networking device must be configured for IPv6 routing.
- One of the following must be enabled on your device and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding IPv6 or distributed Cisco Express Forwarding.

## Restrictions for Flexible NetFlow

The following are restrictions for Flexible NetFlow:

- Flexible NetFlow is not supported on the L2 port-channel interface, but is supported on the L2 port-channel member ports.
- Flexible NetFlow is not supported on the L3 port-channel interface, but is supported on the L3 port-channel member ports.
- Traditional NetFlow (TNF) accounting is not supported.
- Flexible NetFlow version 9 and version 10 export formats are supported. However, if you have not configured the export protocol, version 9 export format is applied by default.
- Microflow policing feature shares the NetFlow hardware resource with FNF.
- Only one flow monitor per interface and per direction is supported .
- Layer 2, IPv4, and IPv6 traffic types are supported. Multiple flow monitors of different traffic types can be applied for a given interface and direction. Multiple flow monitors of same traffic type cannot be applied for a given interface and direction.

- Layer 2, VLAN, WLAN and Layer 3 interfaces are supported, but the device does not support SVI and tunnels.
- The following NetFlow table sizes are supported:

| Trim Level  | Ingress NetFlow Table | Egress NetFlow Table |
|-------------|-----------------------|----------------------|
| LAN Base    | Not supported         | Not supported        |
| IP Base     | 8 K                   | 16 K                 |
| IP Services | 8 K                   | 16 K                 |

- Depending on the switch type, a switch will have one or two forwarding ASICs. The capacities listed in the above table are on a per-ASIC basis.
- The switch can support either one or two ASICs. Each ASIC has 8K ingress and 16 K egress entries, whereas each TCAM can handle up to 6K ingress and 12K egress entries.
- The NetFlow tables are on separate compartments and cannot be combined. Depending on which ASIC processed the packet, the flows will be created in the table in the corresponding ASIC.
- NetFlow hardware implementation supports four hardware samplers. You can select a sampler rate from 1 out of 2 to 1 out of 1024. Only random sampling mode is supported.
- NetFlow hardware uses hash tables internally. Hash collisions can occur in the hardware. Therefore, in spite of the internal overflow Content Addressable Memory (CAM), the actual NetFlow table utilization could be about 80 percent.
- Depending on the fields that are used for the flow, a single flow could take two consecutive entries. IPv6 flows also take two entries. In these situations, the effective usage of NetFlow entries is half the table size, which is separate from the above hash collision limitation.
- The device supports up to 15 flow monitors.
- SSID-based NetFlow accounting is supported. SSID is treated in a manner similar to an interface. However, certain fields are not supported such as user ID .
- The NetFlow software implementation supports distributed NetFlow export, so the flows are exported from the same device in which the flow was created.
- Ingress flows are present in the ASIC that first received the packets for the flow. Egress flows are present in the ASIC from which the packets actually left the device set up.
- The reported value for the bytes count field (called “bytes long”) is Layer-2-packet-size—18 bytes. For classic Ethernet traffic (802.3), this will be accurate. For all other Ethernet types, this field will not be accurate. Use the "bytes layer2” field, which always reports the accurate Layer 2 packet size. For information about supported Flexible NetFlow fields, see [Supported Flexible NetFlow Fields, on page 1175](#).
- Configuration of IPFIX exporter on an AVC flow monitor is not supported.
- Flexible NetFlow export is not supported on the Ethernet management port, Gi0/0.
- When a flow record has only Source Group Tag (SGT) and Destination Group Tag (DGT) fields (or only either of the two) and if both the values are not applicable, then a flow will still be created with zero

values for SGT and DGT. The flow records are expected to include source and destination IP addresses, along with SGT and DGT fields.

- The flow monitor with flow record, that contains the CTS field, cannot be attached on the WLAN (SSID).
- When QoS marked packet is received on an interface which has NetFlow configured on the egress direction, the QoS value of the packet will be captured by the collector. However, when the packet is received on an interface which has NetFlow configured on the ingress direction, the QoS value of the packet will not be captured by the collector.

## Information About Flexible Netflow

### Flexible NetFlow Overview

Flexible NetFlow uses flows to provide statistics for accounting, network monitoring, and network planning.

A flow is a unidirectional stream of packets that arrives on a source interface and has the same values for the keys. A key is an identified value for a field within the packet. You create a flow using a flow record to define the unique keys for your flow.

The device supports the Flexible NetFlow feature that enables enhanced network anomalies and security detection. Flexible NetFlow allows you to define an optimal flow record for a particular application by selecting the keys from a large collection of predefined fields.

All key values must match for the packet to count in a given flow. A flow might gather other fields of interest, depending on the export record version that you configure. Flows are stored in the Flexible NetFlow cache.

You can export the data that Flexible NetFlow gathers for your flow by using an exporter and export this data to a remote system such as a Flexible NetFlow collector. The Flexible NetFlow collector can use an IPv4 or IPv6 address.

You define the size of the data that you want to collect for a flow using a monitor. The monitor combines the flow record and exporter with the Flexible NetFlow cache information.

### Wireless Flexible NetFlow Overview

The wireless Flexible NetFlow infrastructure supports the following:

- Flexible NetFlow Version 9.0 and 10
- User-based rate limiting
- Microflow policing
- Voice and video flow monitoring
- Reflexive access control list (ACL)

#### Microflow Policing and User-Based Rate Limiting

Microflow policing associates a 2-color 1-rate policer and related drop statistics to each flow present in the NetFlow table. When the flow mask comprises all packet fields, this functionality is known as microflow policing. When the flow mask comprises either source or destination only, this functionality is known as user-based rate limiting.

#### Voice and Video Flow Monitoring

Voice and video flows are full flow mask-based entries. The ASIC provides the flexibility to program the policer parameters, share policers across multiple flows and rewrite the IP address and Layer 4 port numbers of these flows.

**Note** For dynamic entries, the NetFlow engine will use the policer parameters that are derived for the flow based on the policy (ACL/QoS-based policies). Dynamic entries cannot share policer across multiple flows.

### Reflexive ACL

Reflexive ACLs allow IP packets to be filtered based on upper-layer session information. The ACLs allow outbound traffic and limit inbound traffic in response to the sessions that originate inside the trusted network. The reflexive ACLs are transparent to the filtering mechanism until a data packet that matches the reflexive entry activates it. At this time, a temporary ACL entry is created and added to the IP-named access lists. The information obtained from the data packet to generate the reflexive ACL entry is permit/deny bit, the source IP address and port, the destination IP address, port, and the protocol type. During reflexive ACL entry evaluation, if the protocol type is either TCP or UDP, then the port information must match exactly. For other protocols, there is no port information to match. After this ACL is installed, the firewall is then opened for the reply packets to pass through. At this time, a potential hacker could have access to the network behind the firewall. To narrow this window, an idle timeout period can be defined. However, in the case of TCP, if two FIN bits or an RST is detected, the ACL entry can be removed.

## Original NetFlow and Benefits of Flexible NetFlow

Original NetFlow uses a fixed seven tuples of IP information to identify a flow.

Flexible NetFlow allows the flow to be user defined. The benefits of Flexible NetFlow include:

- High-capacity flow recognition, including scalability and aggregation of flow information.
- Enhanced flow infrastructure for security monitoring and dDoS detection and identification.
- New information from packets to adapt flow information to a particular service or operation in the network. The flow information available will be customizable by Flexible NetFlow users.
- Extensive use of Cisco's flexible and extensible NetFlow Version 9 and version 10 export formats. With version 10 export format, support for variable length field for the wireless client's SSID is available.
- A comprehensive IP accounting feature that can be used to replace many accounting features, such as IP accounting, Border Gateway Protocol (BGP) Policy Accounting, and persistent caches.
- Support for ingress and egress NetFlow accounting.
- Support for full flow accounting and sampled NetFlow accounting.

Original NetFlow allows you to understand the activities in the network and thus to optimize network design and reduce operational costs.

Flexible NetFlow allows you to understand network behavior with more efficiency, with specific flow information tailored for various services used in the network. The following are some example applications for a Flexible NetFlow feature:

- Flexible NetFlow enhances Cisco NetFlow as a security monitoring tool. For instance, new flow keys can be defined for packet length or MAC address, allowing users to search for a specific type of attack in the network.
- Flexible NetFlow allows you to quickly identify how much application traffic is being sent between hosts by specifically tracking TCP or UDP applications by the class of service (CoS) in the packets.
- The accounting of traffic entering a Multiprotocol Label Switching (MPLS) or IP core network and its destination for each next hop per class of service. This capability allows the building of an edge-to-edge traffic matrix.

The figure below is an example of how Flexible NetFlow might be deployed in a network.

**Figure 79: Typical Deployment for Flexible NetFlow**

## Flexible NetFlow Components

Flexible NetFlow consists of components that can be used together in several variations to perform traffic analysis and data export. The user-defined flow records and the component structure of Flexible NetFlow facilitates the creation of various configurations for traffic analysis and data export on a networking device with a minimum number of configuration commands. Each flow monitor can have a unique combination of flow record, flow exporter, and cache type. If you change a parameter such as the destination IP address for a flow exporter, it is automatically changed for all the flow monitors that use the flow exporter. The same flow monitor can be used in conjunction with different flow samplers to sample the same type of network traffic at different rates on different interfaces. The following sections provide more information on Flexible NetFlow components:

## Flow Records

In Flexible NetFlow a combination of key and nonkey fields is called a record. Flexible NetFlow records are assigned to Flexible NetFlow flow monitors to define the cache that is used for storing flow data. Flexible NetFlow includes several predefined records that can help you get started using Flexible NetFlow.

A flow record defines the keys that Flexible NetFlow uses to identify packets in the flow, as well as other fields of interest that Flexible NetFlow gathers for the flow. You can define a flow record with any combination of keys and fields of interest. The device supports a rich set of keys. A flow record also defines the types of counters gathered per flow. You can configure 64-bit packet or byte counters. The device enables the following match fields as the defaults when you create a flow record:

- match datalink—Layer 2 attributes
- match flow direction — Specifies a match to the fields identifying the direction of flow.
- match interface—Interface attributes
- match ipv4—IPv4 attributes
- match ipv6—IPv6 attributes
- match transport—Transport layer fields
- match wireless—Wireless fields
- match flow cts—CTS fields

### NetFlow Predefined Records

Flexible NetFlow includes several predefined records that you can use to start monitoring traffic in your network. The predefined records are available to help you quickly deploy Flexible NetFlow and are easier to use than user-defined flow records. You can choose from a list of already defined records that may meet the needs for network monitoring. As Flexible NetFlow evolves, popular user-defined flow records will be made available as predefined records to make them easier to implement.

The predefined records ensure backward compatibility with your existing NetFlow collector configurations for the data that is exported. Each of the predefined records has a unique combination of key and nonkey fields that offer you the built-in ability to monitor various types of traffic in your network without customizing Flexible NetFlow on your router.

Two of the predefined records (NetFlow original and NetFlow IPv4/IPv6 original output), which are functionally equivalent, emulate original (ingress) NetFlow and the Egress NetFlow Accounting feature in original NetFlow, respectively. Some of the other Flexible NetFlow predefined records are based on the aggregation cache schemes available in original NetFlow. The Flexible NetFlow predefined records that are based on the aggregation cache schemes available in original NetFlow do not perform aggregation. Instead each flow is tracked separately by the predefined records.

### User-Defined Records

Flexible NetFlow enables you to define your own records for a Flexible NetFlow flow monitor cache by specifying the key and nonkey fields to customize the data collection to your specific requirements. When you define your own records for a Flexible NetFlow flow monitor cache, they are referred to as *user-defined records*. The values in nonkey fields are added to flows to provide additional information about the traffic in

the flows. A change in the value of a nonkey field does not create a new flow. In most cases the values for nonkey fields are taken from only the first packet in the flow. Flexible NetFlow enables you to capture counter values such as the number of bytes and packets in a flow as nonkey fields.

You can create user-defined records for applications such as QoS and bandwidth monitoring, application and end user traffic profiling, and security monitoring for dDoS attacks. Flexible NetFlow also includes several predefined records that emulate original NetFlow. Flexible NetFlow user-defined records provide the capability to monitor a contiguous section of a packet of a user-configurable size, and use it in a flow record as a key or a nonkey field along with other fields and attributes of the packet. The section may include any Layer 3 data from the packet. The packet section fields allow the user to monitor any packet fields that are not covered by the Flexible NetFlow predefined keys. The ability to analyze packet fields that are not collected with the predefined keys enables more detailed traffic monitoring, facilitates the investigation of dDoS attacks, and enables implementation of other security applications such as URL monitoring.

Flexible NetFlow provides predefined types of packet sections of a user-configurable size. The following Flexible NetFlow commands (used in Flexible NetFlow flow record configuration mode) can be used to configure the predefined types of packet sections:

- **collect ipv4 section header size** *bytes* --Starts capturing the number of bytes specified by the *bytes* argument from the beginning of the IPv4 header of each packet.
- **collect ipv4 section payload size** *bytes* --Starts capturing bytes immediately after the IPv4 header from each packet. The number of bytes captured is specified by the *bytes* argument.
- **collect ipv6 section header size** *bytes* --Starts capturing the number of bytes specified by the *bytes* argument from the beginning of the IPv6 header of each packet.
- **collect ipv6 section payload size** *bytes* --Starts capturing bytes immediately after the IPv6 header from each packet. The number of bytes captured is specified by the *bytes* argument.

The *bytes* values are the sizes in bytes of these fields in the flow record. If the corresponding fragment of the packet is smaller than the requested section size, Flexible NetFlow will fill the rest of the section field in the flow record with zeros. If the packet type does not match the requested section type, Flexible NetFlow will fill the entire section field in the flow record with zeros.

Flexible NetFlow adds a new Version 9 export format field type for the header and packet section types. Flexible NetFlow will communicate to the NetFlow collector the configured section sizes in the corresponding Version 9 export template fields. The payload sections will have a corresponding length field that can be used to collect the actual size of the collected section.

## Flexible NetFlow Match Parameters

The following table describes Flexible NetFlow match parameters. You must configure at least one of the following match parameters for the flow records.

Table 84: Match Parameters

| Command                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>match flow cts</b> { <b>source</b>   <b>destination</b> } <b>group-tag</b>                                                         | Specifies a match to the CTS fields support in FNF record. The following command options are available: <ul style="list-style-type: none"> <li>• <b>source</b> —Matches to the source of CTS entering the domain.</li> <li>• <b>destination</b> —Matches to the destination of the CTS leaving the domain.</li> </ul>                                                                                                                                                                                                                                                            |

## Flexible NetFlow Collect Parameters

The following table describes the Flexible NetFlow collect parameters.

*Table 85: Collect Parameters*

| Command                                                                                                                  | Purpose                                                    |
|--------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <b>collect counter</b> { <b>bytes</b> { <b>layer2</b> { <b>long</b> }   <b>long</b> }   <b>packets</b> { <b>long</b> } } | Collects the counter fields total bytes and total packets. |
| <b>collect interface</b> { <b>input</b>   <b>output</b> }                                                                | Collects the fields from the input or output interface.    |

| Command                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>collect timestamp absolute {first   last}</code> | Collects the fields for the absolute time the first packet was seen or the absolute time the most recent packet was last seen (in milliseconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>collect transport tcp flags</code>               | <p>Collects the following transport TCP flags:</p> <ul style="list-style-type: none"> <li>• <b>ack</b>—TCP acknowledgement flag</li> <li>• <b>cwr</b>—TCP congestion window reduced flag</li> <li>• <b>ece</b>—TCP ECN echo flag</li> <li>• <b>fin</b>—TCP finish flag</li> <li>• <b>psh</b>—TCP push flag</li> <li>• <b>rst</b>—TCP reset flag</li> <li>• <b>syn</b>—TCP synchronize flag</li> <li>• <b>urg</b>—TCP urgent flag</li> </ul> <p><b>Note</b> On the device, you cannot specify which TCP flag to collect. You can only specify to collect transport TCP flags. All TCP flags will be collected with this command.</p> |

## Flow Exporters

Flow exporters export the data in the flow monitor cache to a remote system, such as a server running NetFlow collector, for analysis and storage. Flow exporters are created as separate entities in the configuration. Flow exporters are assigned to flow monitors to provide data export capability for the flow monitors. You can create several flow exporters and assign them to one or more flow monitors to provide several export destinations. You can create one flow exporter and apply it to several flow monitors.

### NetFlow Data Export Format Version 10 (IPFIX)

Internet Protocol Flow Information Export (IPFIX) or version 10 is an Export Protocol that collects and exports predefined or user defined flow records. IPFIX is an IETF standard based on NetFlow version 9. The IPFIX format maintains the same principles of separate templates and records as NetFlow version 9. It supports variable length field for SSID of the wireless clients. For IPFIX exporting protocol, the default destination port is 4739, DSCP value is 0, and TTL is 255.

### NetFlow Data Export Format Version 9

The basic output of NetFlow is a flow record. Several different formats for flow records have evolved as NetFlow has matured. The most recent evolution of the NetFlow export format is known as Version 9. The distinguishing feature of the NetFlow Version 9 export format is that it is template-based. Templates provide an extensible design to the record format, a feature that should allow future enhancements to NetFlow services without requiring concurrent changes to the basic flow-record format. Using templates provides several key benefits:

- Third-party business partners who produce applications that provide collector or display services for NetFlow do not have to recompile their applications each time a new NetFlow feature is added. Instead, they should be able to use an external data file that documents the known template formats.
- New features can be added to NetFlow quickly without breaking current implementations.
- NetFlow is “future-proofed” against new or developing protocols because the Version 9 format can be adapted to provide support for them.

The Version 9 export format consists of a packet header followed by one or more template flow or data flow sets. A template flow set provides a description of the fields that will be present in future data flow sets. These data flow sets may occur later within the same export packet or in subsequent export packets. Template flow and data flow sets can be intermingled within a single export packet, as illustrated in the figure below.

Figure 80: Version 9 Export Packet

NetFlow Version 9 will periodically export the template data so the NetFlow collector will understand what data is to be sent and also export the data flow set for the template. The key advantage to Flexible NetFlow is that the user configures a flow record, which is effectively converted to a Version 9 template and then forwarded to the collector. The figure below is a detailed example of the NetFlow Version 9 export format, including the header, template flow, and data flow sets.

Figure 81: Detailed Example of the NetFlow Version 9 Export Format

For more information on the Version 9 export format, refer to the white paper titled [Cisco IOS NetFlow Version 9 Flow-Record Format](http://www.cisco.com/en/US/tech/tk648/tk362/technologies_white_paper09186a00800a3db9.shtml), available at this URL: [http://www.cisco.com/en/US/tech/tk648/tk362/technologies\\_white\\_paper09186a00800a3db9.shtml](http://www.cisco.com/en/US/tech/tk648/tk362/technologies_white_paper09186a00800a3db9.shtml).

## Flow Monitors

Flow monitors are the Flexible NetFlow component that is applied to interfaces to perform network traffic monitoring.

Flow monitors consist of a user-defined record, an optional flow exporter, and a cache that is automatically created at the time the flow monitor is applied to the first interface.

Flow data is collected from the network traffic and added to the flow monitor cache during the monitoring process based on the key and nonkey fields in the flow record.

Flexible NetFlow can be used to perform different types of analysis on the same traffic. In the figure below, packet 1 is analyzed using a record designed for standard traffic analysis on the input interface and a record designed for security analysis on the output interface.

**Figure 82: Example of Using Two Flow Monitors to Analyze the Same Traffic**

The figure below shows a more complex example of how you can apply different types of flow monitors with custom records.

Figure 83: Complex Example of Using Multiple Types of Flow Monitors with Custom Records

There are three types of flow monitor caches. You change the type of cache used by the flow monitor after you create the flow monitor. The three types of flow monitor caches are described in the following sections:

### Normal

The default cache type is “normal”. In this mode, the entries in the cache are aged out according to the timeout active and timeout inactive settings. When a cache entry is aged out, it is removed from the cache and exported via any exporters configured.

### Immediate

A cache of type "immediate" ages out every record as soon as it is created. As a result, every flow contains just one packet. The commands that display the cache contents will provide a history of the packets seen.

This mode is desirable when you expect only very small flows and you want a minimum amount of latency between seeing a packet and exporting a report.

#### Caution

This mode may result in a large amount of export data that can overload low-speed links and overwhelm any systems that you are exporting to. We recommended that you configure sampling to reduce the number of packets that are processed.

#### Note

The cache timeout settings have no effect in this mode.

### Permanent

A cache of type "permanent" never ages out any flows. A permanent cache is useful when the number of flows you expect to see is low and there is a need to keep long-term statistics on the router. For example, if the only key field in the flow record is the 8-bit IP ToS field, only 256 flows can be monitored. To monitor

the long-term usage of the IP ToS field in the network traffic, you can use a permanent cache. Permanent caches are useful for billing applications and for an edge-to-edge traffic matrix for a fixed set of flows that are being tracked. Update messages will be sent periodically to any flow exporters configured according to the "timeout update" setting.

**Note** When a cache becomes full in permanent mode, new flows will not be monitored. If this occurs, a "Flows not added" message will appear in the cache statistics.

**Note** A permanent cache uses update counters rather than delta counters. This means that when a flow is exported, the counters represent the totals seen for the full lifetime of the flow and not the additional packets and bytes seen since the last export was sent.

## Flow Samplers

Flow samplers are created as separate components in a router's configuration. Flow samplers are used to reduce the load on the device that is running Flexible NetFlow by limiting the number of packets that are selected for analysis.

Samplers use random sampling techniques (modes); that is, a randomly selected sampling position is used each time a sample is taken.

Flow sampling exchanges monitoring accuracy for router performance. When you apply a sampler to a flow monitor, the overhead load on the router of running the flow monitor is reduced because the number of packets that the flow monitor must analyze is reduced. The reduction in the number of packets that are analyzed by the flow monitor causes a corresponding reduction in the accuracy of the information stored in the flow monitor's cache.

Samplers are combined with flow monitors when they are applied to an interface with the **ip flow monitor** command.

## Supported Flexible NetFlow Fields

The following tables provide a consolidated list of supported fields in Flexible NetFlow (FNF) for various traffic types and traffic direction.

**Note** If the packet has a VLAN field, then that length is not accounted for.

| Field                 | Layer 2 In | Layer 2 Out | IPv4 In | IP v4 Out | IPv6 In | IPv6 Out | Notes |
|-----------------------|------------|-------------|---------|-----------|---------|----------|-------|
| Key or Collect Fields |            |             |         |           |         |          |       |

| Field            | Layer 2 In | Layer 2 Out | IPv4 In | IP v4 Out | IPv6 In | IPv6 Out | Notes                                                                                                                                                                                                                                                                                                                                                     |
|------------------|------------|-------------|---------|-----------|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface input  | Yes        | —           | Yes     | —         | Yes     | —        | <p>If you apply a flow monitor in the input direction:</p> <ul style="list-style-type: none"> <li>Use the <b>match</b> keyword and use the input interface as a key field.</li> <li>Use the <b>collect</b> keyword and use the output interface as a collect field. This field will be present in the exported records but with a value of 0.</li> </ul>  |
| Interface output | —          | Yes         | —       | Yes       | —       | Yes      | <p>If you apply a flow monitor in the output direction:</p> <ul style="list-style-type: none"> <li>Use the <b>match</b> keyword and use the output interface as a key field.</li> <li>Use the <b>collect</b> keyword and use the input interface as a collect field. ## Default Settings

The following table lists the Flexible NetFlow default settings for the device.

*Table 86: Default Flexible NetFlow Settings*

| Setting               | Default      |
|-----------------------|--------------|
| Flow active timeout   | 1800 seconds |
| Flow timeout inactive | 15 seconds   |

## How to Configure Flexible NetFlow

To configure Flexible NetFlow, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.

2. Create an optional flow exporter by specifying the protocol and transport destination port, destination, and other parameters.
3. Create a flow monitor based on the flow record and flow exporter.
4. Create an optional sampler.
5. Apply the flow monitor to a Layer 2 port, Layer 3 port, or VLAN.
6. If applicable to your configuration, configure a WLAN to apply a flow monitor to.

## Configuring a Customized Flow Record

Perform this task to configure a customized flow record.

Customized flow records are used to analyze traffic data for a specific purpose. A customized flow record must have at least one **match** criterion for use as the key field and typically has at least one **collect** criterion for use as a nonkey field.

There are hundreds of possible permutations of customized flow records. This task shows the steps that are used to create one of the possible permutations. Modify the steps in this task as appropriate to create a customized flow record for your requirements.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **flow record** *record-name*
4. **description** *description*
5. **match** {ipv4 | ipv6} {destination | source} **address**
6. Repeat Step 5 as required to configure additional key fields for the record.
7. **match flow cts** {source | destination} **group-tag**
8. **collect interface** {input | output}
9. Repeat the above step as required to configure additional nonkey fields for the record.
10. **end**
11. **show flow record** *record-name*
12. **show running-config flow record** *record-name*

### DETAILED STEPS

|        | Command or Action                                                          | Purpose                                                                                                            |
|--------|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><b>Example:</b><br>Device> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal | Enters global configuration mode.                                                                                  |

|               | Command or Action                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>flow record</b> <i>record-name</i></p> <p><b>Example:</b></p> <pre>Device(config)# flow record FLOW-RECORD-1</pre>                                                                                                                | <p>Creates a flow record and enters Flexible NetFlow flow record configuration mode.</p> <ul style="list-style-type: none"> <li>This command also allows you to modify an existing flow record.</li> </ul>                                                                                                                                                                                           |
| <b>Step 4</b> | <p><b>description</b> <i>description</i></p> <p><b>Example:</b></p> <pre>Device(config-flow-record)# description Used for basic traffic analysis</pre>                                                                                  | (Optional) Creates a description for the flow record.                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 5</b> | <p><b>match</b> {ipv4   ipv6} {destination   source} address</p> <p><b>Example:</b></p> <pre>Device(config-flow-record)# match ipv4 destination address</pre>                                                                           | <p>Configures a key field for the flow record.</p> <p><b>Note</b> This example configures the IPv4 destination address as a key field for the record. For information about the other key fields available for the <b>match ipv4</b> command, and the other <b>match</b> commands that are available to configure key fields, refer to the <i>Cisco IOS Flexible NetFlow Command Reference</i> .</p> |
| <b>Step 6</b> | Repeat Step 5 as required to configure additional key fields for the record.                                                                                                                                                            | —                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 7</b> | <p><b>match flow cts</b> {source   destination} group-tag</p> <p><b>Example:</b></p> <pre>Device(config-flow-record)# match flow cts source group-tag</pre> <pre>Device(config-flow-record)# match flow cts destination group-tag</pre> | <p><b>Note</b> This example configures the CTS source group tag and destination group tag as a key field for the record. For information about the other key fields available for the <b>match ipv4</b> command, and the other <b>match</b> commands that are available to configure key fields, refer to the <i>Cisco IOS Flexible NetFlow Command Reference</i> .</p>                              |

|                | Command or Action                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                                        | <p><b>Note</b></p> <ul style="list-style-type: none"> <li>• Ingress: <ul style="list-style-type: none"> <li>• In an incoming packet, if a header is present, SGT will reflect the same value as the header. If no value is present, it will show zero.</li> <li>• The DGT value will not depend on the ingress port SGACL configuration.</li> </ul> </li> <li>• Egress: <ul style="list-style-type: none"> <li>• If either propagate SGT or CTS is disabled on the egress interface, then SGT will be zero.</li> <li>• In an outgoing packet, if SGACL configuration that corresponds to the (SGT, DGT) exists, DGT will be non-zero.</li> <li>• If SGACL is disabled on the egress port/VLAN or if global SGACL enforcement is disabled, then DGT will be zero</li> </ul> </li> </ul> |
| <b>Step 8</b>  | <p><b>collect interface</b> {input   output}</p> <p><b>Example:</b></p> <pre>Device(config-flow-record)# collect interface input</pre> | <p>Configures the input interface as a nonkey field for the record.</p> <p><b>Note</b> This example configures the input interface as a nonkey field for the record. For information on the other <b>collect</b> commands that are available to configure nonkey fields, refer to the <i>Cisco IOS Flexible NetFlow Command Reference</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 9</b>  | Repeat the above step as required to configure additional nonkey fields for the record.                                                | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 10</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Device(config-flow-record)# end</pre>                                                    | Exits Flexible NetFlow flow record configuration mode and returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 11</b> | <p><b>show flow record</b> <i>record-name</i></p> <p><b>Example:</b></p> <pre>Device# show flow record FLOW_RECORD-1</pre>             | (Optional) Displays the current status of the specified flow record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|         | Command or Action                                                                                                                                | Purpose                                                             |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Step 12 | <b>show running-config flow record</b> <i>record-name</i><br><b>Example:</b><br><pre>Device# show running-config flow record FLOW_RECORD-1</pre> | (Optional) Displays the configuration of the specified flow record. |

## Creating a Flow Exporter

You can create a flow export to define the export parameters for a flow.

**Note** Each flow exporter supports only one destination. If you want to export the data to multiple destinations, you must configure multiple flow exporters and assign them to the flow monitor.

You can export to a destination using IPv4 or IPv6 address.

### SUMMARY STEPS

1. **configure terminal**
2. **flow exporter** *name*
3. **description** *string*
4. **destination** {*ipv4-address*|*ipv6-address*}
5. **dscp** *value*
6. **source** { *source type* }
7. **transport udp** *number*
8. **ttl** *seconds*
9. **export-protocol** {*netflow-v9* | *ipfix*}
10. **end**
11. **show flow exporter** [**name** *record-name*]
12. **copy running-config startup-config**

### DETAILED STEPS

|        | Command or Action                                                                                          | Purpose                                                                                                                                 |
|--------|------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><b>Example:</b><br><pre>Device# configure terminal</pre>                      | Enters the global configuration mode.                                                                                                   |
| Step 2 | <b>flow exporter</b> <i>name</i><br><b>Example:</b><br><pre>Device(config)# flow exporter ExportTest</pre> | Creates a flow exporter and enters flow exporter configuration mode. You can also use this command to modify an existing flow exporter. |

|               | Command or Action                                                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>description</b> <i>string</i></p> <p><b>Example:</b></p> <pre>Device(config-flow-exporter)# <b>description</b> ExportV9</pre>                                                                                                                               | (Optional) Describes this flow record as a maximum 63-character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 4</b> | <p><b>destination</b> {<i>ipv4-address ipv6-address</i>}</p> <p><b>Example:</b></p> <pre>Device(config-flow-exporter)# <b>destination</b> 192.0.2.1 (IPv4 destination)  Device(config-flow-exporter)# <b>destination</b> 2001:0:0:24::10 (IPv6 destination)</pre> | Sets the IPv4/IPv6 destination address or hostname for this exporter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 5</b> | <p><b>dscp</b> <i>value</i></p> <p><b>Example:</b></p> <pre>Device(config-flow-exporter)# <b>dscp</b> 0</pre>                                                                                                                                                     | (Optional) Specifies the differentiated services codepoint value. The range is from 0 to 63. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 6</b> | <p><b>source</b> { <i>source type</i> }</p> <p><b>Example:</b></p> <pre>Device(config-flow-exporter)# <b>source</b> gigabitEthernet1/0/1</pre>                                                                                                                    | <p>(Optional) Specifies the interface to use to reach the NetFlow collector at the configured destination. The following interfaces can be configured as source:</p> <ul style="list-style-type: none"> <li>• <b>Auto Template</b>—Auto-Template interface</li> <li>• <b>Capwap</b>—CAPWAP tunnel interface</li> <li>• <b>GigabitEthernet</b>—Gigabit Ethernet IEEE 802</li> <li>• <b>GroupVI</b>—Group virtual interface</li> <li>• <b>Internal Interface</b>—Internal interface</li> <li>• <b>Loopback</b>—Loopback interface</li> <li>• <b>Null</b>—Null interface</li> <li>• <b>Port-channel</b>—Ethernet Channel of interface</li> <li>• <b>TenGigabitEthernet</b>—10-Gigabit Ethernet</li> <li>• <b>Tunnel</b>—Tunnel interface</li> <li>• <b>Vlan</b>—Catalyst VLANs</li> </ul> |
| <b>Step 7</b> | <p><b>transport udp</b> <i>number</i></p> <p><b>Example:</b></p> <pre>Device(config-flow-exporter)# <b>transport udp</b> 200</pre>                                                                                                                                | (Optional) Specifies the UDP port to use to reach the NetFlow collector. The range is from 0 to 65535. For IPFIX exporting protocol, the default destination port is 4739.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|         | Command or Action                                                                                                                                 | Purpose                                                                                                                                                    |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 8  | <b>ttl</b> <i>seconds</i><br><b>Example:</b><br>Device(config-flow-exporter)# <b>ttl 210</b>                                                      | (Optional) Configures the time-to-live (TTL) value for datagrams sent by the exporter. The range is from 1 to 255 seconds. The default is 255.             |
| Step 9  | <b>export-protocol</b> { <i>netflow-v9</i>   <i>ipfix</i> }<br><b>Example:</b><br>Device(config-flow-exporter)# <b>export-protocol netflow-v9</b> | Specifies the version of the NetFlow export protocol used by the exporter. <ul style="list-style-type: none"> <li>• Default: <b>netflow-v9</b>.</li> </ul> |
| Step 10 | <b>end</b><br><b>Example:</b><br>Device(config-flow-record)# <b>end</b>                                                                           | Returns to privileged EXEC mode.                                                                                                                           |
| Step 11 | <b>show flow exporter</b> [ <i>name record-name</i> ]<br><b>Example:</b><br>Device <b>show flow exporter ExportTest</b>                           | (Optional) Displays information about NetFlow flow exporters.                                                                                              |
| Step 12 | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config startup-config</b>                                 | (Optional) Saves your entries in the configuration file.                                                                                                   |

### What to do next

Define a flow monitor based on the flow record and flow exporter.

## Creating a Customized Flow Monitor

Perform this required task to create a customized flow monitor.

Each flow monitor has a separate cache assigned to it. Each flow monitor requires a record to define the contents and layout of its cache entries. These record formats can be one of the predefined formats or a user-defined format. An advanced user can create a customized format using the **flow record** command.

**Before you begin**

If you want to use a customized record instead of using one of the Flexible NetFlow predefined records, you must create the customized record before you can perform this task. If you want to add a flow exporter to the flow monitor for data export, you must create the exporter before you can complete this task.

**Note** You must use the **no ip flow monitor** command to remove a flow monitor from all of the interfaces to which you have applied it before you can modify the parameters for the **record** command on the flow monitor. For information about the **ip flow monitor** command, refer to the *Cisco IOS Flexible NetFlow Command Reference*.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **flow monitor** *monitor-name*
4. **description** *description*
5. **record** {*record-name* | **netflow-original** | **netflow** {**ipv4** | **ipv6**} *record* [**peer**]}
6. **cache** {*entries number* | **timeout** {**active** | **inactive** | **update**} *seconds* | **type** {**immediate** | **normal** | **permanent**}}
7. Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.
8. **statistics packet protocol**
9. **statistics packet size**
10. **exporter** *exporter-name*
11. **end**
12. **show flow monitor** [[**name**] *monitor-name* [**cache** [**format** {**csv** | **record** | **table**}]]] [**statistics**]]
13. **show running-config flow monitor** *monitor-name*
14. **copy running-config startup-config**

**DETAILED STEPS**

|               | Command or Action                                                                                         | Purpose                                                                                                                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><b>Example:</b><br>Device> enable                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                       |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                | Enters global configuration mode.                                                                                                                                                                        |
| <b>Step 3</b> | <b>flow monitor</b> <i>monitor-name</i><br><b>Example:</b><br>Device(config)# flow monitor FLOW-MONITOR-1 | Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode. <ul style="list-style-type: none"> <li>• This command also allows you to modify an existing flow monitor.</li> </ul> |

|                | Command or Action                                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b>  | <b>description</b> <i>description</i><br><b>Example:</b><br><pre>Device(config-flow-monitor)# description Used for basic ipv4 traffic analysis</pre>                                                                                                                                   | (Optional) Creates a description for the flow monitor.                                                                                                                                                       |
| <b>Step 5</b>  | <b>record</b> { <i>record-name</i>   <b>netflow-original</b>   <b>netflow</b> { <b>ipv4</b>   <b>ipv6</b> } <i>record</i> [ <b>peer</b> ]}<br><b>Example:</b><br><pre>Device(config-flow-monitor)# record FLOW-RECORD-1</pre>                                                          | Specifies the record for the flow monitor.                                                                                                                                                                   |
| <b>Step 6</b>  | <b>cache</b> { <b>entries</b> <i>number</i>   <b>timeout</b> { <b>active</b>   <b>inactive</b>   <b>update</b> } <i>seconds</i>   <b>type</b> { <b>immediate</b>   <b>normal</b>   <b>permanent</b> }}<br><b>Example:</b><br><pre>Device(config-flow-monitor)# cache type normal</pre> | <p>The values for the keywords associated with the <b>timeout</b> keyword have no effect when the cache type is set to <b>immediate</b>.</p> <p>Associates a flow cache with the specified flow monitor.</p> |
| <b>Step 7</b>  | Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.                                                                                                                                                                                              | —                                                                                                                                                                                                            |
| <b>Step 8</b>  | <b>statistics packet</b> <b>protocol</b><br><b>Example:</b><br><pre>Device(config-flow-monitor)# statistics packet protocol</pre>                                                                                                                                                      | (Optional) Enables the collection of protocol distribution statistics for Flexible NetFlow monitors.                                                                                                         |
| <b>Step 9</b>  | <b>statistics packet</b> <b>size</b><br><b>Example:</b><br><pre>Device(config-flow-monitor)# statistics packet size</pre>                                                                                                                                                              | (Optional) Enables the collection of size distribution statistics for Flexible NetFlow monitors.                                                                                                             |
| <b>Step 10</b> | <b>exporter</b> <i>exporter-name</i><br><b>Example:</b><br><pre>Device(config-flow-monitor)# exporter EXPORTER-1</pre>                                                                                                                                                                 | (Optional) Specifies the name of an exporter that was created previously.                                                                                                                                    |
| <b>Step 11</b> | <b>end</b><br><b>Example:</b><br><pre>Device(config-flow-monitor)# end</pre>                                                                                                                                                                                                           | Exits Flexible NetFlow flow monitor configuration mode and returns to privileged EXEC mode.                                                                                                                  |
| <b>Step 12</b> | <b>show flow monitor</b> [[ <b>name</b> ] <i>monitor-name</i> [ <b>cache</b> [ <b>format</b> { <b>csv</b>   <b>record</b>   <b>table</b> }]]] [ <b>statistics</b> ]]<br><b>Example:</b>                                                                                                | (Optional) Displays the status and statistics for a Flexible NetFlow flow monitor.                                                                                                                           |

|                | Command or Action                                                                                                                            | Purpose                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
|                | Device# show flow monitor FLOW-MONITOR-2 cache                                                                                               |                                                                      |
| <b>Step 13</b> | <b>show running-config flow monitor</b> <i>monitor-name</i><br><b>Example:</b><br>Device# show running-config flow monitor<br>FLOW_MONITOR-1 | (Optional) Displays the configuration of the specified flow monitor. |
| <b>Step 14</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# copy running-config<br>startup-config                                | (Optional) Saves your entries in the configuration file.             |

## Configuring and Enabling Flow Sampling Creating a Flow Sampler

Perform this required task to configure and enable a flow sampler.

### Note

When you specify the "NetFlow original," or the "NetFlow IPv4 original input," or the "NetFlow IPv6 original input" predefined record for the flow monitor to emulate original NetFlow, the flow monitor can be used only for analyzing input (ingress) traffic.

When you specify the "NetFlow IPv4 original output" or the "NetFlow IPv6 original output" predefined record for the flow monitor to emulate the Egress NetFlow Accounting feature, the flow monitor can be used only for analyzing output (egress) traffic.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **sampler** *sampler-name*
4. **description** *description*
5. **mode** {random} 1 out-of *window-size*
6. **exit**
7. **interface** *type number*
8. **{ip | ipv6} flow monitor** *monitor-name* [[**sampler**] *sampler-name*] {**input** | **output**}
9. **end**
10. **show sampler** *sampler-name*

### DETAILED STEPS

|               | Command or Action | Purpose                       |
|---------------|-------------------|-------------------------------|
| <b>Step 1</b> | <b>enable</b>     | Enables privileged EXEC mode. |

|               | Command or Action                                                                                                                                                                                    | Purpose                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <b>Example:</b><br>Device> enable                                                                                                                                                                    | <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                         |
| <b>Step 2</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# configure terminal                                                                                                                           | Enters global configuration mode.                                                                                                                                                          |
| <b>Step 3</b> | <b>sampler <i>sampler-name</i></b><br><b>Example:</b><br>Device(config)# sampler SAMPLER-1                                                                                                           | Creates a sampler and enters sampler configuration mode. <ul style="list-style-type: none"> <li>This command also allows you to modify an existing sampler.</li> </ul>                     |
| <b>Step 4</b> | <b>description <i>description</i></b><br><b>Example:</b><br>Device(config-sampler)# description Sample at 50%                                                                                        | (Optional) Creates a description for the flow sampler.                                                                                                                                     |
| <b>Step 5</b> | <b>mode {random} 1 out-of <i>window-size</i></b><br><b>Example:</b><br>Device(config-sampler)# mode random 1 out-of 2                                                                                | Specifies the sampler mode and the flow sampler window size. <ul style="list-style-type: none"> <li>The range for the <i>window-size</i> argument is from 0 to 1024 2 to 32768.</li> </ul> |
| <b>Step 6</b> | <b>exit</b><br><b>Example:</b><br>Device(config-sampler)# exit                                                                                                                                       | Exits sampler configuration mode and returns to global configuration mode.                                                                                                                 |
| <b>Step 7</b> | <b>interface <i>type number</i></b><br><b>Example:</b><br>Device(config)# interface GigabitEthernet 0/0/0                                                                                            | Specifies an interface and enters interface configuration mode.                                                                                                                            |
| <b>Step 8</b> | <b>{ip   ipv6} flow monitor <i>monitor-name</i> [[sampler] <i>sampler-name</i>] {input   output}</b><br><b>Example:</b><br>Device(config-if)# ip flow monitor FLOW-MONITOR-1 sampler SAMPLER-1 input | Assigns the flow monitor and the flow sampler that you created to the interface to enable sampling.                                                                                        |
| <b>Step 9</b> | <b>end</b><br><b>Example:</b><br>Device(config-if)# end                                                                                                                                              | Exits interface configuration mode and returns to privileged EXEC mode.                                                                                                                    |

|                | Command or Action                                                                     | Purpose                                                                                 |
|----------------|---------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| <b>Step 10</b> | <b>show sampler sampler-name</b><br><b>Example:</b><br>Device# show sampler SAMPLER-1 | Displays the status and statistics of the flow sampler that you configured and enabled. |

## Applying a Flow to an Interface

You can apply a flow monitor and an optional sampler to an interface.

### SUMMARY STEPS

1. **configure terminal**
2. **interface type**
3. **{ip flow monitor | ipv6 flow monitor}name [[sampler name] {input}**
4. **end**
5. **show flow interface [interface-type number]**
6. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <b>configure terminal</b>                 | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 2</b> | <b>interface type</b><br><b>Example:</b><br>Device(config)# <b>interface GigabitEthernet1/0/1</b> | Enters interface configuration mode and configures an interface.<br><br>Flexible NetFlow is not supported on the L2 port-channel interface, but is supported on the L2 port-channel member ports.<br><br>Flexible NetFlow is not supported on the L3 port-channel member ports, but is supported on the L3 port-channel interface.<br><br>Command parameters for the interface configuration include: <ul style="list-style-type: none"> <li>• <b>GigabitEthernet</b>—GigabitEthernet IEEE 802</li> <li>• <b>Loopback</b>—Loopback interface</li> <li>• <b>TenGigabitEthernet</b>—10- Gigabit Ethernet</li> <li>• <b>Vlan</b>—Catalyst VLANs</li> <li>• <b>Range</b>—Interface range</li> </ul> |

|               | Command or Action                                                                                                                                  | Purpose                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                                    | <ul style="list-style-type: none"> <li>• <b>WLAN</b>—WLAN interface</li> </ul>                                   |
| <b>Step 3</b> | <pre>{ip flow monitor   ipv6 flow monitor}name [[sampler name] { input} <b>Example:</b> Device(config-if)# ip flow monitor MonitorTest input</pre> | Associate an IPv4 or an IPv6 flow monitor, and an optional sampler to the interface for input or output packets. |
| <b>Step 4</b> | <pre>end <b>Example:</b> Device(config-flow-monitor)# end</pre>                                                                                    | Returns to privileged EXEC mode.                                                                                 |
| <b>Step 5</b> | <pre>show flow interface [interface-type number] <b>Example:</b> Device# show flow interface</pre>                                                 | (Optional) Displays information about NetFlow on an interface.                                                   |
| <b>Step 6</b> | <pre>copy running-config startup-config <b>Example:</b> Device# copy running-config startup-config</pre>                                           | (Optional) Saves your entries in the configuration file.                                                         |

## Configuring a Bridged NetFlow on a VLAN

You can apply a flow monitor and an optional sampler to a VLAN.

### SUMMARY STEPS

1. **configure terminal**
2. **vlan [configuration] vlan-id**
3. **ip flow monitor monitor name [sampler sampler name] {input |output}**
4. **copy running-config startup-config**

### DETAILED STEPS

|               | Command or Action                             | Purpose                               |
|---------------|-----------------------------------------------|---------------------------------------|
| <b>Step 1</b> | <pre>configure terminal <b>Example:</b></pre> | Enters the global configuration mode. |

|               | Command or Action                                                                                                                                                                                                   | Purpose                                                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
|               | Device# <code>configure terminal</code>                                                                                                                                                                             |                                                                                            |
| <b>Step 2</b> | <b>vlan [configuration] <i>vlan-id</i></b><br><b>Example:</b><br>Device(config)# <code>vlan configuration 30</code><br>Device(config-vlan-config)#                                                                  | Enters VLAN or VLAN configuration mode.                                                    |
| <b>Step 3</b> | <b>ip flow monitor <i>monitor name</i> [sampler <i>sampler name</i>]</b><br><b>{input  output}</b><br><b>Example:</b><br>Device(config-vlan-config)# <code>ip flow monitor</code><br><code>MonitorTest input</code> | Associates a flow monitor and an optional sampler to the VLAN for input or output packets. |
| <b>Step 4</b> | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <code>copy running-config</code><br><code>startup-config</code>                                                                             | (Optional) Saves your entries in the configuration file.                                   |

## Configuring Layer 2 NetFlow

You can define Layer 2 keys in Flexible NetFlow records that you can use to capture flows in Layer 2 interfaces.

### SUMMARY STEPS

1. `configure terminal`
2. `flow record name`
3. `match datalink {dot1q |ethertype | mac | vlan}`
4. `end`
5. `show flow record [name ]`
6. `copy running-config startup-config`

### DETAILED STEPS

|               | Command or Action                                                                       | Purpose                               |
|---------------|-----------------------------------------------------------------------------------------|---------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code> | Enters the global configuration mode. |

|        | Command or Action                                                                                                                                  | Purpose                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Step 2 | <b>flow record</b> <i>name</i><br><b>Example:</b><br>Device(config)# <b>flow record</b> L2_record<br>Device(config-flow-record)#                   | Enters flow record configuration mode.                         |
| Step 3 | <b>match datalink</b> {dot1q   ethertype   mac   vlan}<br><b>Example:</b><br>Device(config-flow-record)# <b>match datalink</b><br><b>ethertype</b> | Specifies the Layer 2 attribute as a key.                      |
| Step 4 | <b>end</b><br><b>Example:</b><br>Device(config-flow-record)# <b>end</b>                                                                            | Returns to privileged EXEC mode.                               |
| Step 5 | <b>show flow record</b> [ <i>name</i> ]<br><b>Example:</b><br>Device# <b>show flow record</b>                                                      | (Optional) Displays information about NetFlow on an interface. |
| Step 6 | <b>copy running-config startup-config</b><br><b>Example:</b><br>Device# <b>copy running-config</b><br><b>startup-config</b>                        | (Optional) Saves your entries in the configuration file.       |

## Configuring WLAN to Apply Flow Monitor in Data Link Input/Output Direction

### SUMMARY STEPS

1. **configure terminal**
2. **wlan** [wlan-name { wlan-id SSID\_NetworkName | wlan\_id} | wlan-name | shutdown]
3. **datalink flow monitor monitor-name** {input | output}
4. **end**
5. **show run wlan** *wlan-name*

### DETAILED STEPS

|        | Command or Action                            | Purpose                           |
|--------|----------------------------------------------|-----------------------------------|
| Step 1 | <b>configure terminal</b><br><b>Example:</b> | Enters global configuration mode. |

|               | Command or Action                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                              |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Device# <code>configure terminal</code>                                                                                                                                                           |                                                                                                                                                                                                                                                                                                      |
| <b>Step 2</b> | <b>wlan</b> [ <b>wlan-name</b> { <b>wlan-id</b> <b>SSID_NetworkName</b>   <b>wlan_id</b> }   <b>wlan-name</b>   <b>shutdown</b> ]<br><b>Example:</b><br>Device (config) # <code>wlan wlan1</code> | Enters WLAN configuration submode.<br><i>wlan-id</i> is the wireless LAN identifier. The range is 1 to 64.<br>SSID_NetworkName is the SSID which can contain 32 alphanumeric characters.<br><b>Note</b> If you have already configured this command, enter the <b>wlan</b> <i>wlan-name</i> command. |
| <b>Step 3</b> | <b>datalink flow monitor monitor-name</b> { <b>input</b>   <b>output</b> }<br><b>Example:</b><br>Device (config-wlan) # <code>datalink flow monitor flow-monitor-1 {input   output}</code>        | Applies flow monitor to Layer 2 traffic in the direction of interest.                                                                                                                                                                                                                                |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device (config) # <code>end</code>                                                                                                                               | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                     |
| <b>Step 5</b> | <b>show run wlan</b> <i>wlan-name</i><br><b>Example:</b><br>Device # <code>show wlan mywlan</code>                                                                                                | (Optional) Verifies your configuration.                                                                                                                                                                                                                                                              |

### Example

## Configuring WLAN to Apply Flow Monitor in IPV4 and IPv6 Input/Output Direction

### SUMMARY STEPS

1. `configure terminal`
2. `wlan {wlan-name { wlan-id SSID_NetworkName | wlan_id} | wlan-name | shutdown}`
3. `{ip | ipv6} flow monitor monitor-name {input | output}`
4. `end`
5. `show run wlan wlan-name`

## DETAILED STEPS

|               | Command or Action                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><b>Example:</b><br>Device# <code>configure terminal</code>                                                                      | Enters global configuration mode                                                                                                                                                                                                                                                              |
| <b>Step 2</b> | <b>wlan {wlan-name { wlan-id SSID_NetworkName   wlan_id}   wlan-name   shutdown}</b><br><b>Example:</b><br>Device (config) # <code>wlan wlan1</code>         | Enters WLAN configuration submode.<br><i>wlan-id</i> is the wireless LAN identifier. The range is 1 to 64.<br>SSID_NetworkName is the SSID which can contain 32 alphanumeric characters.<br><b>Note</b> If you have already configured this command, enter the <b>wlan wlan-name</b> command. |
| <b>Step 3</b> | <b>{ip   ipv6} flow monitor monitor-name {input   output}</b><br><b>Example:</b><br>Device (config-wlan) # <code>ip flow monitor flow-monitor-1 input</code> | Associates a flow monitor to the WLAN for input or output packets.                                                                                                                                                                                                                            |
| <b>Step 4</b> | <b>end</b><br><b>Example:</b><br>Device (config) # <code>end</code>                                                                                          | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                              |
| <b>Step 5</b> | <b>show run wlan wlan-name</b><br><b>Example:</b><br>Device # <code>show wlan mywlan</code>                                                                  | (Optional) Verifies your configuration.                                                                                                                                                                                                                                                       |

# Monitoring Flexible NetFlow

The commands in the following table can be used to monitor Flexible NetFlow.

**Table 87: Flexible NetFlow Monitoring Commands**

| Command                                                                                      | Purpose                                                                           |
|----------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <code>show flow exporter [broker   export-ids   name   name   statistics   templates]</code> | Displays information about NetFlow flow exporters and statistics.                 |
| <code>show flow exporter [ name exporter-name]</code>                                        | Displays information about NetFlow flow exporters and statistics.                 |
| <code>show flow interface</code>                                                             | Displays information about NetFlow interfaces.                                    |
| <code>show flow monitor [ name exporter-name]</code>                                         | Displays information about NetFlow flow monitors and statistics.                  |
| <code>show flow monitor statistics</code>                                                    | Displays the statistics for the flow monitor                                      |
| <code>show flow monitor cache format {table   record   csv}</code>                           | Displays the contents of the cache for the flow monitor, in the format specified. |
| <code>show flow record [ name record-name]</code>                                            | Displays information about NetFlow flow records.                                  |
| <code>show flow ssid</code>                                                                  | Displays NetFlow monitor installation status for a WLAN.                          |
| <code>show sampler [broker   name   name]</code>                                             | Displays information about NetFlow samplers.                                      |
| <code>show wlan wlan-name</code>                                                             | Displays the WLAN configured on the device.                                       |

## Configuration Examples for Flexible NetFlow

### Example: Configuring a Flow

This example shows how to create a flow and apply it to an interface:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Device(config)# flow export export1
Device(config-flow-exporter)# destination 10.0.101.254
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# exit

## Example: Monitoring IPv4 ingress traffic

This example shows how to monitor IPv4 ingress traffic (int g1/0/11 sends traffic to int g1/0/36 and int g3/0/11).

```

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config) # flow record fr-1
Device(config-flow-record) # match ipv4 source address
Device(config-flow-record) # match ipv4 destination address
Device(config-flow-record) # match interface input
Device(config-flow-record) # collect counter bytes long
Device(config-flow-record) # collect counter packets long
Device(config-flow-record) # collect timestamp absolute first
Device(config-flow-record) # collect timestamp absolute last
Device(config-flow-record) # collect counter bytes layer2 long
Device(config-flow-record) # exit

Device(config) # flow exporter fe-ipfix6
Device(config-flow-exporter) # destination 2001:0:0:24::10
Device(config-flow-exporter) # source Vlan106
Device(config-flow-exporter) # transport udp 4739
Device(config-flow-exporter) # export-protocol ipfix
Device(config-flow-exporter) # template data timeout 240
Device(config-flow-exporter) # exit

Device(config) # flow exporter fe-ipfix
Device(config-flow-exporter) # description IPFIX format collector 100.0.0.80
Device(config-flow-exporter) # destination 100.0.0.80
Device(config-flow-exporter) # dscp 30
Device(config-flow-exporter) # ttl 210
Device(config-flow-exporter) # transport udp 4739
Device(config-flow-exporter) # export-protocol ipfix

```

```

Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow exporter fe-1
Device(config-flow-exporter)# destination 10.5.120.16
Device(config-flow-exporter)# source Vlan105
Device(config-flow-exporter)# dscp 32
Device(config-flow-exporter)# ttl 200
Device(config-flow-exporter)# transport udp 2055

Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for QoS

Before configuring standard QoS, you must have a thorough understanding of these items:

- Standard QoS concepts.
- Wireless concepts and network topologies.
- Classic Cisco IOS QoS.

- Modular QoS CLI (MQC).
- Understanding of QoS implementation.
- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?
- Bandwidth requirements and speed of the network.
- Location of congestion points in the network.

#### Related Topics

## QoS Components

QoS consists of the following key components:

- **Classification**— Classification is the process of distinguishing one type of traffic from another based upon ACLs, Differentiated Services Code Point (DSCP), Class of Service (CoS), and other factors.
- **Marking and mutation**— Marking is used on traffic to convey specific information to a downstream device in the network, or to carry information from one interface in a to another. When traffic is marked, QoS operations on that traffic can be applied. This can be accomplished directly using the **set** command or through a table map, which takes input values and translates them directly to values on output.
- **Shaping and policing**— Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that downstream devices are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface. Policing is used to impose a maximum rate on a traffic class. If the rate is exceeded, then a specific action is taken as soon as the event occurs.
- **Queuing** — Queuing is used to prevent traffic congestion. Traffic is sent to specific queues for servicing and scheduling based upon bandwidth allocation. Traffic is then scheduled or sent out through the port.
- **Bandwidth**—Bandwidth allocation determines the available capacity for traffic that is subject to QoS policies.
- **Trust**— Trust enables traffic to pass through the , and the DSCP, precedence, or CoS values coming in from the end points are retained in the absence of any explicit policy configuration.

## QoS Terminology

The following terms are used interchangeably in this QoS configuration guide:

- Upstream (direction towards the ) is the same as ingress.
- Downstream (direction from the ) is the same as egress.

**Note** Upstream is wireless to wired. Downstream is wired to wireless. Wireless to wireless has no specific term.

## Information About QoS

### QoS Overview

By configuring the quality of service (QoS), you can provide preferential treatment to specific types of traffic at the expense of other traffic types. Without QoS, the device offers best-effort service to each packet, regardless of the packet contents or size. The device sends the packets without any assurance of reliability, delay bounds, or throughput.

The following are specific features provided by QoS:

- Low latency
- Bandwidth guarantee
- Buffering capabilities and dropping disciplines
- Traffic policing
- Enables the changing of the attribute of the frame or packet header
- Relative services

#### Related Topics

[Restrictions for QoS on Wireless Targets](#), on page 1246

### Modular QoS Command-Line Interface

With the device, QoS features are enabled through the Modular QoS command-line interface (MQC). The MQC is a command-line interface (CLI) structure that allows you to create traffic policies and attach these policies to interfaces. A traffic policy contains a traffic class and one or more QoS features. A traffic class is used to classify traffic, while the QoS features in the traffic policy determine how to treat the classified traffic. One of the main goals of MQC is to provide a platform-independent interface for configuring QoS across Cisco platforms.

### Wireless QoS Overview

Wireless QoS can be configured on the following wireless targets:

- Wireless ports, including all physical ports to which an access point can be associated.
- Radio
- SSID (applicable on a per-radio, per-AP, and per-SSID)
- Client

From Cisco IOS XE Release 3E, marking and policing actions for ingress SSID and client policies are applied at the access point. The SSID and client ingress policies that you configure in the are moved to the access point. The access point performs policing and marking actions for each packet. However, the selects the QoS policies. Marking and policing of egress SSID and client policies are applied at the .

The following table displays how policies are supported for the wireless targets.

**Table 88: Wireless Targets Policies Support**

| Wireless Target | Policies on Wireless Targets Supported | Policies Supported Egress Direction | Policies Supported Ingress Direction |
|-----------------|----------------------------------------|-------------------------------------|--------------------------------------|
| Wireless port   | Yes                                    | Yes - user configurable             | No                                   |
| Radio           | Yes                                    | Yes - but not configurable by user  | No                                   |
| SSID            | Yes                                    | Yes - user configurable             | Yes - user configurable              |
| Client          | Yes                                    | Yes - user configurable             | Yes - user configurable              |

**Note** Additional polices that are user configured include multidestination policers and VLANs.

Wireless QoS supports the following features:

- Queuing in the egress direction.
- Policing of wireless traffic
- Marking of wireless traffic.
- Shaping of wireless traffic in the egress direction.
- Approximate Fair Drop (AFD) in the egress direction.
- Mobility support for QoS.
- Compatibility with precious metal QoS policies available on Cisco Unified Wireless Controllers.
- Combination of CLI/Traffic Class (TCLAS) and CLI/snooping.
- Application control (can drop or mark the data traffic) by configuring an AVC QoS client policy.
- Drop action for ingress policies.
- QoS statistics for client and SSID targets in the ingress direction.
- QoS attribute for local profiling policy.
- Hierarchical policies.

## QoS and IPv6 for Wireless

The supports QoS for both IPv4 and IPv6 traffic, and client policies can now have IPv4 and IPv6 filters.

## Wired and Wireless Access Supported Features

The following table describes the supported features for both wired and wireless access.

**Table 89: Supported QoS Features for Wired and Wireless Access**

| Feature                                  | Wired                                                                                                               | Wireless                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Targets                                  | <ul style="list-style-type: none"> <li>• Gigabit Ethernet</li> <li>• 10 Gigabit Ethernet</li> <li>• VLAN</li> </ul> | <ul style="list-style-type: none"> <li>• Wireless port (CAPWAP tunnel)</li> <li>• SSID</li> <li>• Client</li> <li>• Radio</li> <li>• CAPWAP multicast tunnel</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Configuration Sequence                   | QoS policy installed using the <b>service-policy</b> command.                                                       | <ul style="list-style-type: none"> <li>• When an access point joins the switch, the switch installs a policy on the port. The port policy has a child policy called <code>port_child_policy</code>.</li> <li>• A policy is installed on the radio which has a shaper configured to the radio rate. The default radio policy (which cannot be modified) is attached to the radio.</li> <li>• The default client policies take effect when a WMM client associates, and if admission control is enabled on the radio.</li> <li>• User can modify the <code>port_child_policy</code> to add more classes.</li> <li>• User can attach a user-defined policy at the SSID level.</li> <li>• User can attach a user-defined policy at the client level.</li> </ul> |
| Number of queues permitted at port level | Up to 8 queues supported on a port.                                                                                 | Only four queues supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Feature                  | Wired                                                                                                                                                                                                                                                              | Wireless                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

[Client Policies](#), on page 1216

## Port Policies

The device supports port-based policies. The port policies includes port shaper and a child policy (port\_child\_policy).

**Note** Port child policies only apply to wireless ports and not to wired ports on the switch. A wireless port is defined as a port to which APs join. A default port child policy is applied on the switch to the wireless ports at start up. The port shaper rate is limited to 1G

Port shaper specifies the traffic policy applicable between the device and the AP. This is the sum of the radio rates supported on the access point.

The child policy determines the mapping between packets and queues defined by the port-child policy. The child policy can be configured to include voice, video, class-default, and non-client-nrt classes where voice and video are based on DSCP value (which is the outer CAPWAP header DSCP value). The definition of class-default is known to the system as any value other than voice and video DSCP.

The DSCP value is assigned when the packet reaches the port. Before the packet arrives at the port, the SSID policies are applied on the packet. Port child policy also includes multicast percentage for a given port traffic. By default, the port child policy allocates up to 10 percent of the available rate.

## Port Policy Format

This section describes the behavior of the port policies on a switch. The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suit the QoS configuration. The switch is pre configured with a default class map and a policy map.

Default class map:

```
Class Map match-any non-client-nrt-class
  Match non-client-nrt
```

The above port policy processes all network traffic to the Q3 queue. You can view the class map by executing the **show class-map** command.

Default policy map:

```
Policy Map port_child_policy
  Class non-client-nrt-class
    bandwidth remaining ratio 10
```

**Note** The class map and policy map listed are system-defined policies and cannot be changed.

The following is the system-defined policy map available on the ports on which wireless devices are associated. The format consists of a parent policy and a service child policy (**port\_child\_policy**). To customize the policies to suite your network needs, you must configure the port child policy.

```

Policy-map policy_map_name
  Class class-default
    Shape average average_rate
    Service-policy port_child_policy

```

**Note** The parent policy is system generated and cannot be changed. You must configure the *port\_child\_policy* to suit the QoS requirements on your network.

Depending on the type of traffic in your network, you can configure the port child policy. For example, in a typical wireless network deployment, you can assign specific priorities to voice and video traffic. Here is an example:

```

Policy-map port_child_policy
  Class voice-policy-name (match dscp ef)
    Priority level 1
    Police (multicast-policer-name-voice) Multicast Policer
  Class video-policy-name (match dscp af41)
    Priority level 2
    Police (multicast-policer-name-video) Multicast Policer
  Class non-client-nrt-class traffic (match non-client-nrt)
    Bandwidth remaining ratio (brr-value-nrt-q2)
  Class class-default (NRT Data)
    Bandwidth remaining ratio (brr-value-q3)

```

In the above port child policy:

- *voice-policy-name*— Refers to the name of the class that specifies rules for the traffic for voice packets. Here the DSCP value is mapped to a value of 46 (represented by the keyword **ef**). The voice traffic is assigned the highest priority of 1.
- *video-policy-name*— Refers to the name of the class that specifies rules for the traffic for video packets. The DSCP value is mapped to a value of 34 (represented by the keyword **af41**).
- *multicast-policer-name-voice*— If you need to configure multicast voice traffic, you can configure policing for the voice class map.
- *multicast-policer-name-video*— If you need to configure multicast video traffic, you can configure policing for the video class map.

In the above sample configuration, all voice and video traffic is directed to the Q0 and Q1 queues, respectively. These queues maintain a strict priority. The packets in Q0 and Q1 are processed in that order. The bandwidth remaining ratios *brr-value-nrt-q2* and *brr-value-q3* are directed to the Q2 and Q3 respectively specified by the class maps and *class-default* and *non-client-nrt*. The processing of packets on Q2 and Q3 are based on a weighted round-robin approach. For example, if the *brr-value-nrtq2* has a value of 90 and *brr-value-nrtq3* is 10, the packets in queue 2 and queue 3 are processed in the ratio of 9:1.

## Radio Policies

The radio policies are system defined and are not user configurable. Radio wireless targets are only applicable in the egress direction.

Radio policies are applicable on a per-radio, per-access point basis. The rate limit on the radios is the practical limit of the AP radio rate. This value is equivalent to the sum of the radios supported by the access point.

The following radios are supported:

- 802.11 a/n
- 802.11 b/n
- 802.11 ac

### Related Topics

[Restrictions for QoS on Wireless Targets](#), on page 1246

[Supported QoS Features on Wireless Targets](#), on page 1212

## SSID Policies

You can create QoS policies on SSID BSSID (Basic Service Set Identification) in both the ingress and egress directions. By default, there is no SSID policy. All traffic is transmitted as best effort because the wireless traffic is untrusted. You can configure an SSID policy based on the SSID name. The policy is applicable on a per BSSID.

The types of policies you can create on SSID include marking by using table maps (table-maps), shape rate, and RT1 (Real Time 1) and RT2 (Real Time 2) policies. If traffic is ingress, you usually configure a marking and policing policy on the SSID. If traffic is downstream, you can configure marking and queuing.

There should be a one-to-one mapping between the policies configured on a port and an SSID. For example, if you configure class voice and class video on the port, you can have a similar policy on the SSID.

SSID priorities can be specified by configuring bandwidth remaining ratio. Queuing SSID policies are applied in the egress direction.

[Supported QoS Features on Wireless Targets](#), on page 1212

[Examples: SSID Policy](#)

[Examples: Configuring Downstream SSID Policy](#), on page 1304

## Client Policies

Client policies are applicable in the ingress and egress direction. The wireless control module of the device applies the default client policies when admission control is enabled for WMM clients. When admission control is disabled, there is no default client policy. You can configure policing and marking policies on clients.

---

**Note** A client policy can have both IPv4 and IPv6 filters.

---

You can configure client policies in the following ways:

- Using AAA
- Using the Cisco IOS MQC CLI
  - You can use **service policy client** command in the WLAN configuration.
- Using the default configuration
- Using local policies (native profiling)

Use the **show wireless client mac address *mac\_address* service-policy** command to display the source of the client policy (for example, local profiling policy, AAA, or CLI). The precedence order of client policies is AAA > local policy > WLAN service client policy CLI > default configuration.

---

**Note** If you configured AAA by configuring the unified wireless controller procedure, and using the MQC QoS commands, the policy configuration performed through the MQC QoS commands takes precedence.

---

---

**Note** When applying client policies on a WLAN, you must disable the WLAN before modifying the client policy. SSID policies can be modified even if the WLAN is enabled.

---

The default client policy is enabled only on Wi-Fi Multimedia (WMM) clients that are admission control (ACM)-enabled.

### Policy Chaining

Every packet has a maximum of two applicable policies, first at the client target and second at the SSID target. The client policing action is applied to the packet before the marking action that is specified in the client policy. After the client policing and marking actions are applied to the packet, the SSID policy action is applied to the updated packet. If no custom policies are specified, the system trust configuration is applied to the packet. Egress trust is based on DSCP, and ingress trust is based on WLAN user priority.

### Related Topics

[Configuring Client Policies \(CLI\)](#)

[Supported QoS Features on Wireless Targets](#), on page 1212

[Examples: Client Policies](#), on page 1306

## Hierarchical QoS

The supports hierarchical QoS (HQoS). HQoS allows you to perform:

- Hierarchical classification— Traffic classification is based upon other classes.
- Hierarchical policing—The process of having the policing configuration at multiple levels in a hierarchical policy.
- Hierarchical shaping—Shaping can also be configured at multiple levels in the hierarchy.

**Note** Hierarchical shaping is only supported for the port shaper, where for the parent you only have a configuration for the class default, and the only action for the class default is shaping.

### Related Topics

Examples: [Hierarchical Classification](#), on page 1301

Examples: [Hierarchical Policy Configuration](#), on page 1301

## Hierarchical Wireless QoS

The device supports hierarchical QoS for wireless targets. Hierarchical QoS policies are applicable on port, radio, SSID, and client. QoS policies configured on the device (including marking, shaping, policing) can be applied across the targets. If the network contains non-realtime traffic, the non-realtime traffic is subject to approximate fair drop. Hierarchy refers to the process of application of the various QoS policies on the packets arriving to the device. You can configure policing in both the parent and child policies.

**Note** For hierarchical client and SSID policies, you only configure marking either in the parent or child policy.

## Wireless Packet Format

*Figure 84: Wireless Packet Path in the Egress Direction during First Pass*

This figure displays the wireless packet flow and encapsulation used in hierarchical wireless QoS. The incoming packet enters the device. The device encapsulates this incoming packet and adds the 802.11e and CAPWAP headers.

## Hierarchical AFD

Approximate Fair Dropping (AFD) is a feature provided by the QoS infrastructure in Cisco IOS. For wireless targets, AFD can be configured on SSID (via shaping) and clients (via policing). AFD shaping rate is only applicable for downstream direction. Unicast real-time traffic is not subjected to AFD drops.

## QoS Implementation

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (*class*) information. Classification can also be carried in the Layer 2 frame.

**Figure 85: QoS Classification Layers in Frames and Packets**

The special bits in the Layer 2 frame or a Layer 3 packet are shown in the following

Encapsulated Packet

Layer 2 ISL Frame

3 bits used for CoS

Layer 2 802.1Q and 802.1p Frame

3 bits used for CoS (user priority)

Layer 3 IPv4 Packet

IP precedence or DSCP

Layer 3 IPv6 Packet

IP precedence or DSCP

figure:

### Related Topics

[Restrictions for QoS on Wired Targets](#), on page 1243

[Restrictions for QoS on Wireless Targets](#), on page 1246

## Layer 2 Frame Prioritization Bits

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

## Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.

## End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

## Packet Classification

Packet classification is the process of identifying a packet as belonging to one of several classes in a defined policy, based on certain criteria. The Modular QoS CLI (MQC) is a policy-class based language. The policy class language is used to define the following:

- Class-map template with one or several match criteria
- Policy-map template with one or several classes associated to the policy map

The policy map template is then associated to one or several interfaces on the .

Packet classification is the process of identifying a packet as belonging to one of the classes defined in the policy map. The process of classification will exit when the packet being processed matches a specific filter in a class. This is referred to as first-match exit. If a packet matches multiple classes in a policy, irrespective of the order of classes in the policy map, it would still exit the classification process after matching the first class.

If a packet does not match any of the classes in the policy, it would be classified into the default class in the policy. Every policy map has a default class, which is a system-defined class to match packets that do not match any of the user-defined classes.

Packet classification can be categorized into the following types:

- Classification based on information that is propagated with the packet
- Classification based on information that is specific
- Hierarchical classification

## Classification Based on Information That is Propagated with the Packet

Classification that is based on information that is part of the packet and propagated either end-to-end or between hops, typically includes the following:

- Classification based on Layer 3 or 4 headers
- Classification based on Layer 2 information

### Classification Based on Layer 3 or Layer 4 Header

This is the most common deployment scenario. Numerous fields in the Layer 3 and Layer 4 headers can be used for packet classification.

At the most granular level, this classification methodology can be used to match an entire flow. For this deployment type, an access control list (ACLs) can be used. ACLs can also be used to match based on various subsets of the flow (for example, source IP address only, or destination IP address only, or a combination of both).

Classification can also be done based on the precedence or DSCP values in the IP header. The IP precedence field is used to indicate the relative priority with which a particular packet needs to be handled. It is made up of three bits in the IP header's type of service (ToS) byte.

The following table shows the different IP precedence bit values and their names.

**Note** IP precedence is not supported for wireless QoS.

**Table 91: IP Precedence Values and Names**

| IP Precedence Value | IP Precedence Bits | IP Precedence Names  |
|---------------------|--------------------|----------------------|
| 0                   | 000                | Routine              |
| 1                   | 001                | Priority             |
| 2                   | 010                | Immediate            |
| 3                   | 011                | Flash                |
| 4                   | 100                | Flash Override       |
| 5                   | 101                | Critical             |
| 6                   | 110                | Internetwork control |
| 7                   | 111                | Network control      |

**Note** All routing control traffic in the network uses IP precedence value 6 by default. IP precedence value 7 also is reserved for network control traffic. Therefore, the use of IP precedence values 6 and 7 is not recommended for user traffic.

The DSCP field is made up of 6 bits in the IP header and is being standardized by the Internet Engineering Task Force (IETF) Differentiated Services Working Group. The original ToS byte contained the DSCP bits has been renamed the DSCP byte. The DSCP field is part of the IP header, similar to IP precedence. The

DSCP field is a super set of the IP precedence field. Therefore, the DSCP field is used and is set in ways similar to what was described with respect to IP precedence.

---

**Note** The DSCP field definition is backward-compatible with the IP precedence values.

---

### Classification Based on Layer 2 Header

A variety of methods can be used to perform classification based on the Layer 2 header information. The most common methods include the following:

- MAC address-based classification (only for access groups)—Classification is based upon the source MAC address (for policies in the input direction) and destination MAC address (for policies in the output direction).
- Class-of-Service—Classification is based on the 3 bits in the Layer 2 header based on the IEEE 802.1p standard. This usually maps to the ToS byte in the IP header.
- VLAN ID—Classification is based on the VLAN ID of the packet.

---

**Note** Some of these fields in the Layer 2 header can also be set using a policy.

---

### Classification Based on Information that is Device Specific (QoS Groups)

The also provides classification mechanisms that are available where classification is not based on information in the packet header or payload.

At times you might be required to aggregate traffic coming from multiple input interfaces into a specific class in the output interface. For example, multiple customer edge routers might be going into the same access on different interfaces. The service provider might want to police all the aggregate voice traffic going into the core to a specific rate. However, the voice traffic coming in from the different customers could have a different ToS settings. QoS group-based classification is a feature that is useful in these scenarios.

Policies configured on the input interfaces set the QoS group to a specific value, which can then be used to classify packets in the policy enabled on output interface.

The QoS group is a field in the packet data structure internal to the . It is important to note that a QoS group is an internal label to the and is not part of the packet header.

### Hierarchical Classification

The permits you to perform a classification based on other classes. Typically, this action may be required when there is a need to combine the classification mechanisms (that is, filters) from two or more classes into a single class map.

## QoS Wired Model

To implement QoS, the must perform the following tasks:

- Traffic classification—Distinguishes packets or flows from one another.

- Traffic marking and policing—Assigns a label to indicate the given quality of service as the packets move through the , and then make the packets comply with the configured resource usage limits.
- Queuing and scheduling—Provides different treatment in all situations where resource contention exists.
- Shaping—Ensures that traffic sent from the meets a specific traffic profile.

## Ingress Port Activity

The following activities occur at the ingress port of the :

- Classification—Classifying a distinct path for a packet by associating it with a QoS label. For example, the maps the CoS or DSCP in the packet to a QoS label to distinguish one type of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.
- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).

---

**Note** Applying polices on the wireless ingress port is not supported on the .

---

## Egress Port Activity

The following activities occur at the egress port of the :

- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).
- Queueing—Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, Weighted Tail Drop (WTD) differentiates traffic classes and subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.

## Classification

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is enabled on the . By default, QoS is enabled on the .

During classification, the performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.

## Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:

- If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.
- If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.
- If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the offers best-effort service to the packet.
- If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

---

**Note** When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

---

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate-limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the **access-list** global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the **mac access-list extended** global configuration command.

## Class Maps

A class map is a mechanism that you use to name a specific traffic flow (or class) and isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

You create a class map by using the **class-map** global configuration command or the **class** policy-map configuration command. You should use the **class-map** command when the map is shared among many ports. When you enter the **class-map** command, the enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the **match** class-map configuration command.

You can create a default class by using the **class class-default** policy-map configuration command. The default class is system-defined and cannot be configured. Unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as default traffic.

### Related Topics

[Creating a Traffic Class \(CLI\)](#), on page 1249

[Examples: Classification by Access Control Lists](#), on page 1299

## Policy Maps

A policy map specifies which traffic class to act on. Actions can include the following:

- Setting a specific DSCP or IP precedence value in the traffic class
- Setting a CoS value in the traffic class
- Setting a QoS group
- Setting a wireless LAN (WLAN) value in the traffic class
- Specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile

Before a policy map can be effective, you must attach it to a port.

You create and name a policy map using the **policy-map** global configuration command. When you enter this command, the router enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the **class** or **set** policy-map configuration and policy-map class configuration commands.

The policy map can also be configured using the **police** and **bandwidth** policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded. In addition, the policy-map can further be configured using the **priority** policy-map class configuration command, to schedule priority for the class or the queueing policy-map class configuration commands, **queue-buffers** and **queue-limit**.

To enable the policy map, you attach it to a port by using the **service-policy** interface configuration command.

### Note

You cannot configure both **priority** and **set** for a policy map. If both these commands are configured for a policy map, and when the policy map is applied to an interface, error messages are displayed. The following example shows this restriction:

```
Switch# configure terminal
Switch(config)# class-map cmap
Switch(config-cmap)# exit
Switch(config)# class-map classmap1
Switch(config-cmap)# exit
Switch(config)# policy-map pmap
Switch(config-pmap)# class cmap
Switch(config-pmap-c)# priority
Switch(config-pmap-c)# exit
Switch(config-pmap)# class classmap1
Switch(config-pmap-c)# set
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet 0/1/1
Switch(config-if)# service-policy output pmap

Non-queueing action only is unsupported in a queueing policy!!!
%QOS-6-POLICY_INST_FAILED:
Service policy installation failed
```

[Port Policy Format](#), on page 1214

## Policy Map on Physical Port

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions can include setting a specific DSCP or IP precedence value in the traffic class, specifying the traffic bandwidth limitations for each matched traffic class (policer), and taking action when the traffic is out of profile (marking).

A policy map also has these characteristics:

- A policy map can contain multiple class statements, each with different match criteria and policers.
- A policy map can contain a predefined default traffic class explicitly placed at the end of the map.

When you configure a default traffic class by using the **class class-default** policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (**class-default**).

- A separate policy-map class can exist for each type of traffic received through a port.

### Related Topics

[Attaching a Traffic Policy to an Interface \(CLI\)](#), on page 1263

## Policy Map on VLANs

The supports a VLAN QoS feature that allows the user to perform QoS treatment at the VLAN level (classification and QoS actions) using the incoming frame's VLAN information. In VLAN-based QoS, a service policy is applied to an SVI interface. All physical interfaces belonging to a VLAN policy map then need to be programmed to refer to the VLAN-based policy maps instead of the port-based policy map.

Although the policy map is applied to the VLAN SVI, any policing (rate-limiting) action can only be performed on a per-port basis. You cannot configure the policer to take account of the sum of traffic from a number of physical ports. Each port needs to have a separate policer governing the traffic coming into that port.

# Policing

After a packet is classified and has a DSCP-based, CoS-based, or QoS-group label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP or CoS value of the packet and allowing the packet to pass through.

To avoid out-of-order packets, both conform and nonconforming traffic typically exit the same queue.

**Note** All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can only configure policing on a physical port.

After you configure the policy map and policing actions, attach the policy to an ingress port or SVI by using the **service-policy** interface configuration command.

## Token-Bucket Algorithm

Policing uses a token-bucket algorithm. As each frame is received by the , a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).
